- Treatment of underlying etiology of the insomnia and consistent sleep hygiene are key.
- Most medications are indicated for short-term use only.
- Sedative hypnotics are not recommended in the elderly because risks may outweigh benefits.
- Patients with chronic insomnia benefit from sleep hygiene education and cognitive-behavioral therapy.

INTELLECTUAL DISABILITY (INTELLECTUAL DEVELOPMENTAL DISORDER)

Jennifer L. Ayres, PhD

BASICS

- Intellectual disability (ID) is a global deficit in cognitive functioning evidenced by a significant difference between one's mental and chronologic ages (also known as *intelligence quotient* [IQ]) and significantly impaired adaptive functioning (1).
- Although these cognitive issues typically have a pervasive impact, patients with ID will display highly variable levels of functioning and subsequent service needs.
- Patients must be evaluated individually. Treatment plans must be tailored to specific needs.
- The term *mental retardation* was deleted from the *DSM-5* and replaced with "intellectual disability" or "intellectual developmental disorder." The rationale was that the term mental retardation is considered pejorative and culturally insensitive.

DESCRIPTION

- ID is defined as an IQ ≤70 + 5 and a significant impairment in intellectual functioning, including verbal and nonverbal reasoning, planning, academic learning, problem solving, and experiential learning. The intellectual functioning is confirmed by both IQ testing and clinical assessment (1).
- A diagnosis of ID also requires deficits in adaptive functioning, such as communication, socialization, and independent living (1).
- By definition, ID is a neurodevelopmental disorder that is typically present from birth or determined during early childhood (1).
- Currently, ID is subgrouped according to the patient's level of adaptive functioning and level of support needed. Severity levels: *mild* (typical development in some domains, mild impairment in others), *moderate* (skills are markedly behind same-age peers), *severe* (skills are quite limited,

compared to peers), profound (very limited awareness of concepts, language, dependent on others for all aspects of adaptive functioning) (1).
- The three most common causes of ID are Down syndrome, fragile X syndrome, and fetal alcohol syndrome (FAS).
- If the ID reflects a loss of previously acquired intellectual skills, comorbid diagnoses of ID and neurocognitive disorder may be appropriate.

ALERT
For some causes of ID, prenatal testing is available.

EPIDEMIOLOGY

Incidence

- 1 of 6 children (2)
- Predominant sex: male > female: 1.6:1 for mild ID, 1.2:1 for severe ID (1)

Prevalence

In the United States, 1% of the general population. The prevalence for severe ID is 6/1,000 (1).

ETIOLOGY AND PATHOPHYSIOLOGY

- Causes:
  - Maternal substance abuse (e.g., alcohol); FAS is a leading environmental cause of ID.
  - Maternal infections: TORCH viruses (toxoplasma, other infections, rubella, cytomegalovirus, and herpes simplex)
  - Down syndrome
  - Sex chromosome abnormalities: fragile X, Turner syndrome, Klinefelter syndrome
  - Autosomal dominant conditions: neurocutaneous syndromes (e.g., neurofibromatosis, tuberous sclerosis)
  - Autosomal recessive conditions:
    - Amino acid metabolism (e.g., phenylketonuria, maple syrup urine disease)
    - Carbohydrate metabolism (e.g., galactosemia, fructosuria)
    - Lipid metabolism
    - Tay-Sachs disease

    - Gaucher disease
    - Niemann-Pick disease (e.g., mucopolysaccharidosis)
    - Purine metabolism (e.g., Lesch-Nyhan disease)
    - Other (e.g., Wilson disease)
- Maternal use of prescription medications (e.g., Accutane, dilantin)
- Perinatal factors:
  – Prematurity
  – Birth injuries
  – Perinatal anoxia
- Postnatal factors:
  – Childhood diseases (e.g., meningitis, encephalitis, hypothyroidism, seizure disorders)
  – Trauma (e.g., accidents, physical abuse, hypoxia)
  – Severe deprivation
  – Poisoning (e.g., lead, carbon monoxide, household products)

Genetics

A number of genetic and epigenetic causes are known, and more are under investigation (3).

RISK FACTORS

- Maternal substance abuse during pregnancy
- Maternal infection during pregnancy
- For some causes, family history

GENERAL PREVENTION

- Public health efforts to reduce alcohol and drug use by pregnant women
- Prenatal folic acid supplementation

COMMONLY ASSOCIATED CONDITIONS

- Seizures
- Mood disorders
- Behavioral disorders
- Constipation

DIAGNOSIS

A diagnosis of ID should be made only through a psychodiagnostic assessment conducted by a mental health provider who is trained and licensed to conduct formal psychological testing.

HISTORY

- Children with profound/severe ID are typically diagnosed at birth or during the newborn period and may have dysmorphic features.
- Children with ID are often identified because they fail to meet motor/language milestones.

PHYSICAL EXAM

Careful examination by a physician trained in the assessment of morphologic features suggestive of a specific etiology for ID (e.g., microcephaly) (4)

DIFFERENTIAL DIAGNOSIS

- Brain tumors
- Auditory, visual, and/or speech/language impairment
- Autism spectrum disorder (language and social skills are more affected than other cognitive abilities); however, 75% of individuals with an autistic disorder may meet criteria for a comorbid diagnosis of ID.
- Expressive/receptive language disorders
- Cerebral palsy
- Emotional/behavioral disturbance
- Learning disorders (reading, math, written expression)
- Auditory/sensory processing difficulties
- Lack of environmental opportunities for appropriate development

DIAGNOSTIC TESTS & INTERPRETATION

- Visual and hearing tests to rule out these etiologies as a cause of impairment and provide an assessment of visual and auditory functioning, which are often impaired in children and adults with ID.
- Formal testing of intellectual and adaptive functioning:
  - A child's communication skills must be considered in test selection. For example, a patient with auditory processing issues/limited

expressive/receptive language skills may need to be assessed using a nonverbal IQ test, such as the Leiter-R, Test of Nonverbal Intelligence, or other nonverbal measures.
  - Commonly used intelligence tests (e.g., Bayley Scales of Infant Development, Stanford-Binet Intelligence Scale, Wechsler Intelligence Scales) are determined by age/developmental level of the child.
  - Common tests of adaptive functioning include the Vineland Adaptive Behavior Scales, 2nd ed., and Adaptive Behavior Assessment System, 2nd ed. These tests assess areas of functioning such as age-appropriate communication, social skills, activities of daily living, and motor skills.
- Metabolic screening is not routine unless history and physical suggest or no newborn screening done (5).

Initial Tests (lab, imaging)

- Lead (5)[B]
- Thyroid-stimulating hormone if systemic features present/no newborn screening (5)[B]
- Routine cytogenetic testing (karyotype) (5)[B]:
  - Fragile X screening (FMR1 gene), particularly with a family history of ID
  - Rett syndrome (MECP2 gene) in women with unexplained moderate to severe ID (5)
- Molecular screening, such as array comparative genomic hybridization, is used increasingly and may yield a diagnosis in 10% of undiagnosed cases (4) [B].
- Neuroimaging (MRI more sensitive than CT) is routinely recommended. The presence of physical findings (microcephaly, focal motor deficit) will increase the yield of a specific diagnosis (5)[B].
- MRI may show mild cerebral abnormalities but is unlikely to establish etiology of ID (4).

Follow-Up Tests & Special Considerations

- Electroencephalogram is not routine unless epilepsy or a specific epileptiform syndrome is present (5)[C].
- Assessment of quality of life provides salient information about a patient's general sense of well-being and life satisfaction; however, quality of life may

be difficult to assess when significant behavioral issues confound an individual's self-report and socialization.

TREATMENT

- Early intervention services tailored to the individual's specific needs
- Caregiver support, including:
  - Training caregiver(s) to address behavioral issues, discipline, and support socialization development
  - Encouraging caregivers to create a structured home environment that is based on the child's developmental level and specific needs rather than age-appropriate expectations.
  - Providing caregiver(s) with an opportunity to address their reactions to the diagnosis and their child's special needs
  - Informing caregivers about advocacy groups and available community, state, and national resources (6–8)
  - Encouraging caregiver(s) to seek social support to increase overall sense of well-being
  - Encouraging caregivers to seek respite care as needed to ensure that they have an opportunity to engage in health self-care.
- Individualized education plans and, depending on the level of impairment, social skills and behavioral plans/training
- Refer to job training programs and independent living opportunities, if appropriate.
- Notice all changes in behavior, which may be indicative of pain/illness, particularly in individuals with limited communication skills.
- Assess for abuse and neglect.

MEDICATION

Medication may be appropriate for comorbid conditions (e.g., anxiety, ADHD, depression).

ONGOING CARE

The physician should match his or her communication of exam procedures, test results, and treatment recommendations to the patient's level of cognitive functioning and receptive language skills.

- Most patients with ID will fall within the mild range and are fully capable of understanding information if it is provided at the appropriate level.
- Provide oral and written explanations directly to the patient instead of solely to his or her caregivers. The dignity of the patient must be respected at all times. This includes providing honest information, responding to patient's questions with respect, and not infantilizing the patient due to his or her ID.

FOLLOW-UP RECOMMENDATIONS

- Many adults and children with ID exhibit poor physical fitness. Preliminary studies suggest structured exercise programs are effective to engage this population in healthy activities (9)[A].
- Linkage to community-based resources for job training, independent living, caregiver support, school-based services

Patient Monitoring

- Primary care with attention to associated medical conditions
- Vision testing at least once before age 40 years (age 30 years in Down syndrome) and every 2 years thereafter (10)[B]
- Hearing evaluations every 5 years after age 45 years (every 3 years throughout life in Down syndrome) (10)[B]
- Screen for sexual activity and offer contraception and testing for STIs (10)[B].
- Abuse and neglect of people with ID are common. Screen at least annually and if behavior change is noted. Report abuse/neglect to appropriate protective agencies (10)[B].
- Dysphagia and aspiration are common; consider speech pathology evaluation and swallowing study (11)[B].
- Monitor for and treat constipation (11)[B].
- Osteoporosis: common; low threshold to order imaging studies after traumatic injury (11)[B]

DIET

No restrictions, except in cases of metabolic and storage disorders (e.g.,

phenylketonuria)

PATIENT EDUCATION

- The Arc of the United States (The Arc): www.thearc.org
- American Association of Intellectual and Developmental Disabilities: www.aaidd.org
- Family support groups (Parent to Parent, local Down Syndrome, or Autism Association)
- Special Olympics: www.specialolympics.org

PROGNOSIS

Although ID is a lifelong diagnosis, individuals with ID are capable of living a fulfilling, purposeful life that includes having a career, living independently, marrying/participating in a committed relationship, and becoming a parent. Also, the level of severity and support needed may vary over the course of the individual's life.

COMPLICATIONS

- Constipation is a commonly overlooked problem and can lead to significant morbidity.
- Polypharmacy, often associated with psychotropic medication use to control behaviors, should be addressed to minimize adverse side effects.

CODES

ICD10

- F79 Unspecified intellectual disabilities
- F70 Mild intellectual disabilities
- F71 Moderate intellectual disabilities

CLINICAL PEARLS

- The term mental retardation may be interpreted as culturally insensitive and disrespectful to patients and their caregivers. ID or intellectual developmental

disorder is the correct diagnosis.

- Overall functioning with ID is highly variable and influenced by multiple factors, including appropriateness of school placement/special education services, exposure to early intervention, behavioral therapy, parent training, self-esteem, and social skills.
- Previous stereotypes of people with ID (e.g., always happy, poor prognosis, unable to function independently) have been refuted. People with ID are showing a level of functioning variability that parallels what is found in the non-ID population.
- Be aware of the unique parenting needs that caregivers may face. Link families to community and national resources that can provide practical and emotional support when appropriate.
- Because children with developmental disabilities are at higher risk of being abused than their peers without developmental disabilities, discuss with caregivers how to educate children about safety precautions in a developmentally appropriate manner.

INTERSTITIAL CYSTITIS

Rebecca R. Yeager, MD • Montiel T. Rosenthal, MD

BASICS

DESCRIPTION

- A condition of pain or discomfort in the bladder associated with a need to urinate frequently and urgently
- A disease of unknown cause, probably representing a final common pathway from several etiologies
- Likely, pathogenesis is disruption of urothelium, impaired lower urinary tract defenses, and loss of bladder muscular wall elasticity. The symptoms in many patients are insidious, and the disease progresses for years before diagnosis is established.
- Newer research implicates urine and serum inflammatory proteins antiproliferative factor, epidermal growth factor, heparin-binding epidermal growth factor, glycosaminoglycans, and bladder nitric oxide as contributing factors.
- Mild: normal bladder capacity under anesthesia; ulceration, cracking, or glomerulation of mucosa (or not) with bladder distention under anesthesia; no incontinence symptoms wax and wane and may not progress. Interstitial cystitis is a bladder sensory problem.
- Severe: progressive bladder fibrosis; small true bladder capacity under anesthesia; poor bladder wall compliance. In 5–10% of cases, Hunner ulcers present at cystoscopy; may have overflow incontinence and/or chronic bacteriuria unresponsive to antibiotics
- System(s) affected: renal/urologic
- Synonym(s): urgency frequency syndrome; IC/bladder pain syndrome (BPS)

Pregnancy Considerations

Unpredictable symptom improvement or exacerbation during pregnancy; no known fetal effects from interstitial cystitis; usual problems of unknown effect on fetus with medications taken during pregnancy

EPIDEMIOLOGY

- Occurs predominantly among whites
- Predominant sex: female > male (10:1)
- Patients <30 years have predominant symptoms: dysuria, frequency, urinary urgency, pain in external genitals, and dyspareunia; and those >60 years more commonly have nocturia, urinary incontinence, or Hunner ulcer disease.
- Predominant age
  - Mild: 20 to 40 years
  - Severe: 20 to 70 years
- Pediatric considerations
  - <10 years old and again at 13 to 17 years
  - Daytime enuresis, dysuria without infection

Prevalence

In the United States:

- Up to 1 million affected, but many cases likely are unreported
- 0.052% but may be higher up to 10%

ETIOLOGY AND PATHOPHYSIOLOGY

- Unknown but is not primarily psychosomatic
- Possible causes
  - Subclinical urinary infection
  - Damage to glycosaminoglycan mucus layer increasing bladder wall permeability to irritants such as urea
  - Autoimmune
  - Mast cell histamine release
- Neurologic upregulation/stimulation

RISK FACTORS

Unknown

COMMONLY ASSOCIATED CONDITIONS

- Fibromyalgia
- Allergies
- Chronic fatigue syndrome
- Depression

- Vulvodynia
- Sexual dysfunction
- Sleep disturbance
- Migraines
- Syncope
- Dyspepsia
- Chronic prostatitis
- Chronic pelvic pain
- Irritable bowel syndrome
- Anal/rectal disease

DIAGNOSIS

- Frequent, urgent, relentless urination day and night; >8 voids in 24 hours
- Pain with full bladder that resolves with bladder emptying (except if bacteriuria is present)
- Urge urinary incontinence if bladder capacity is small.
- Sleep disturbance
- Dyspareunia, especially with full bladder
- Secondary symptoms from chronic pain and sleeplessness, especially depression

HISTORY

- Pelvic Pain and Urgency/Frequency Patient Symptom Scale: self-reporting questionnaire for screening potential interstitial cystitis patients (1)[B] (http://www.wgcaobgyn.com/files/urgency_frequency_pt_symptom_scale.pdf)
- Frequent UTIs, vaginitis, or symptoms during the week before menses
- O'Leary/Sant Voiding and Pain Indices (http://www.ichelp.org/wp-content/uploads/2015/06/OLeary_Sant.pdf)

PHYSICAL EXAM

- Perineal/prostatic pain in men
- Anterior vaginal wall pain in women

DIFFERENTIAL DIAGNOSIS

- Uninhibited bladder (urgency, frequency, urge incontinence, less pain, symptoms usually decrease when asleep)
- Urinary infection: cystitis, prostatitis
- Bladder neoplasm
- Bladder stone
- Neurologic bladder disease
- Nonurinary pelvic disease (STIs, endometriosis, pelvic relaxation)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Urinalysis: normal except with chronic bacteriuria (rare)
- Urine culture from catheterized specimen: normal except with chronic bacteriuria (rare) or partial antibiotic treatment
- Urine cytology
  - Normal: reserve for men >40 years old and women with hematuria

Diagnostic Procedures/Other

- Cystoscopy (especially in men >40 years old or women with hematuria)
  - Bladder wall visualization
  - *Hydraulic distention: no improved diagnostic certainty over history and physical alone*
  - No role for urodynamic testing
- Intravesical lidocaine can help to pinpoint the bladder as the source of pain in patients with pelvic pain; this can be both diagnostic and therapeutic.
- Potassium sensitivity test
  - *Insert catheter, empty bladder, instill 40 mL H_2O over 2 to 3 minutes, rank urgency on scale of 0 to 5 in intensity, rank pain on scale of 0 to 5 in intensity, drain bladder, instill 40 mL potassium chloride (KCl) 0.4 mol/L solution:*
  - If immediate pain, flush bladder with 60 mL H_2O and treat with bladder instillations.
    - If no immediate pain, wait for 5 minutes and rate the urgency and pain.
- If urgency or pain >2, treat as above.
- Pain or urgency >2 is considered a positive test and strongly correlates with interstitial cystitis if no radiation cystitis or acute bacterial cystitis is present.

Test Interpretation

- Nonspecific chronic inflammation on bladder biopsies
- Urine cytology negative for dysplasia and neoplasia
- Possible mast cell proliferation in mucosa

TREATMENT

GENERAL MEASURES

- Appropriate health care: outpatient
- Self-care (eliminate foods and liquids that exacerbate symptoms on individual basis, fluid management) (2)[C]
- Biofeedback bladder retraining (2)[C]

MEDICATION

- Randomized controlled trials of most medications for interstitial cystitis demonstrate limited benefit over placebo; there are no clear predictors of what will benefit an individual. Prepare the patient that treatment may involve trial and error.
- Behavioral therapy combined with oral agents found improved outcomes compared to medications alone.
- Intravesical injections of botulinum toxin are not effective in the treatment of ulcer-type interstitial cystitis.

First Line

- Note: AUA consensus states medicines should be considered second-line therapy after patient education, stress reduction, behavior modification, and self-care (2)[C].
- Pentosan polysulfate (Elmiron) 100 mg TID on empty stomach; may take several months (3 to 6) to become effective; rated as modestly beneficial in systematic drug review (only FDA-approved treatment for interstitial cystitis)
- Amitriptyline: most effective at higher doses (≥50 mg/day); however, initiate with lower doses to minimize side effects (3)[B].
- Hydroxyzine 25 to 50 mg HS
- Sildenafil 25 mg/day (4)[B]

- Cimetidine 400 mg BID (2)[C]
- Triple-drug therapy: 6 months of pentosan, hydroxyzine, doxepin
- Antibacterials for bacteriuria
- Oxybutynin, hyoscyamine, tolterodine, and other anticholinergic medications decrease frequency.
- Prednisone (only for ulcerative lesions)
- Montelukast has shown some benefit.
- NSAIDs for pain and any inflammatory component
- Bladder instillations
  - Lidocaine, sodium bicarbonate, *and* heparin *or* pentosan polysulfate sodium
  - *Dimethyl sulfoxide (DMSO) every 1 to 2 weeks for 3 to 6 weeks, then PRN*
  - Heparin *sometimes added to DMSO*
  - *Intravesical liposomes*
  - *Other agents: steroids,* silver nitrate, *oxychlorosene (Clorpactin)*
  - Contraindication
  - *No anticholinergics for patients with close-angle glaucoma*
  - Significant possible interaction
  - *Refer to manufacturer's profile of each drug.*

Second Line

- Phenazopyridine, a local bladder mucosal anesthetic, usually is not very effective.
- Intravesicular injection of botulinum type A for nonulcer interstitial cystitis
- Cyclosporin A (2)[C]
- Hyaluronic acid instillations (5)[C]
- Chondroitin sulfate instillations (single or in combination with hyaluronic acid) have shown mixed results (5)[C].

ISSUES FOR REFERRAL

- Need for clarity with respect to diagnosis
- Surgical intervention

ADDITIONAL THERAPIES

Myofascial physical therapy (targeted pelvic, hip girdle, abdominal trigger point massage) (6)[B]

SURGERY/OTHER PROCEDURES

- Hydraulic distention of bladder under anesthesia: symptomatic but transient relief
- Cauterization of bladder ulcer
- Augmentation cystoplasty to increase bladder capacity and decrease pressure with or without partial cystectomy. Expected results in severe cases: much improved, 75%; with residual discomfort, 20%; unchanged, 5%
- Urinary diversion with total cystectomy only if disease is completely refractory to medical therapy
- Sacral neuromodulation
- Transurethral electro- or laser fulguration (effective for Hunner lesions). Pain relief may persist from several months to 2 years (5)[C].

COMPLEMENTARY & ALTERNATIVE THERAPIES

Guided imagery

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Not specifically needed unless symptoms are unresponsive to treatment

DIET

- Variable effects from person to person
- Common irritants include caffeine, chocolate, citrus, tomatoes, carbonated beverages, potassium-rich foods, spicy foods, acidic foods, and alcohol.

PATIENT EDUCATION

Interstitial Cystitis Association, 110 Washington St. Suite 340, Rockville, MD 20850; 1-800-HELPICA: http://www.ichelp.org/

PROGNOSIS

- Mild: exacerbations and remissions of symptoms; may not be progressive; does not predispose to other diseases
- Severe: progressive problems that usually require surgery to control symptoms

COMPLICATIONS

Severe, with long-term, continuous high bladder pressure could be associated with renal damage.

SEE ALSO

- Urinary Tract Infection (UTI) in Females
- Algorithm: Pelvic Girdle Pain (Pregnancy or Postpartum Pelvic Pain)

CODES

ICD10

- N30.10 Interstitial cystitis (chronic) without hematuria
- N30.11 Interstitial cystitis (chronic) with hematuria

CLINICAL PEARLS

- The potassium sensitivity test has been the most useful in confirming an initial diagnosis of interstitial cystitis.
- At present, there is no definitive treatment for interstitial cystitis.
- Most patients with severe disease receive multiple treatment approaches. Regular multidisciplinary follow-up, pharmacologic therapy, avoidance of symptom triggers, and psychological and supportive therapy are all important because this disease tends to wax and wane. Monitor patients for comorbid depression.
- Empowering patients to manage their symptoms, communicate regularly with their physicians, and learn as much as they can about this disease which may help them to optimize their outcome

INTERSTITIAL NEPHRITIS

Roger P. Holland, MD, PhD

BASICS

DESCRIPTION

- Acute and chronic tubulointerstitial diseases result from the interplay of renal cells and inflammatory cells and their products. Lethal or sublethal injury to renal cells leads to expression of new local antigens, inflammatory cell infiltration, and activation of proinflammatory and chemoattractant cytokines. These cytokines are produced by macrophages and lymphocytes and also by the renal cells (i.e., proximal tubule, vascular endothelial cells, interstitial cells, fibroblasts). The outcome can be acute interstitial nephritis (AIN) or chronic interstitial nephritis (CIN).
- AIN presents as acute kidney injury (AKI) after the use of offending drugs or agents (OFA) and is associated with typical findings of proteinuria, hematuria, and white cell casts. Less frequently, AIN is secondary to infection or systemic diseases (e.g., sarcoidosis, mixed connective tissue disease [MCTD], SLE, Sjögren syndrome).
- System(s) affected: renal/urologic, endocrine/metabolic, immunologic
- Synonym(s): acute interstitial allergic nephritis

EPIDEMIOLOGY

Pediatric Considerations

- Children with history of lead poisoning are more likely to develop CIN as young adults.
- Tubulointerstitial nephritis with uveitis (TINU) presents in adolescent females.

Incidence

- AIN and CIN account for 10–15% of kidney disease.
- Peak incidence in women 60 to 70 years of age

Geriatric Considerations

The elderly (≥65 years) have more severe disease and increased risk of permanent damage due to their increased use of OFA, specifically more drug-induced AIN (87% vs. 64%), proton-pump inhibitor-induced AIN (18% vs. 6%), but less AIN due to autoimmune or systemic causes (7% vs. 27%) than younger adults (1)[B].

ETIOLOGY AND PATHOPHYSIOLOGY

- AIN
  - Delayed drug hypersensitivity reactions
  - Causes AKI
  - Renal dysfunction generally is usually partially or completely reversible, possibly reflecting the regenerative capacity of tubules with a preserved basement membrane.
  - Hypersensitivity to drugs (75%): not dose dependent. The three top drug causes were omeprazole (12%), amoxicillin (8%), and ciprofloxacin (8%) in a recent case series (2)[C].
    - Antibiotics (e.g., penicillins, cephalosporins, sulfonamides, tetracycline, vancomycin, fluoroquinolones, macrolides, TB meds)
    - Proton pump inhibitors
    - Antivirals (Indinavir)
    - NSAIDs (all, including Cox-2 inhibitors)
    - Diuretics (thiazide, loop, and triamterene)
    - Miscellaneous (allopurinol, H_2 blockers, diphenylhydantoin, and 5-aminosaliclates such as Azulfidine and mesalamine)
  - Infections: *Legionella*, *Leptospira*, streptococci, CMV, *Mycobacterium* tuberculosis (5–10%)
  - Autoimmune disorders (e.g., SLE, Sjögren syndrome, sarcoidosis, Wegener granulomatosis, cryoglobulinemia) (10–15%)
  - Toxins (e.g., snake bite venom)
- CIN
  - Follows long-term exposure to OFA (e.g., heavy metals, especially lead)
  - Often found on routine labs or evaluation for hypertension (HTN)
  - Characterized by interstitial scarring, fibrosis, and tubular atrophy, resulting in progressive chronic kidney disease (CKD)

GENERAL PREVENTION

- Early recognition and prompt discontinuation of OFA
- Avoid further nephrotoxic substances.

COMMONLY ASSOCIATED CONDITIONS

CIN

- Chronic pyelonephritis
- Abuse of analgesics
- Lithium use
- Gout and gout therapy
- Immune disorders
- Malignancy (lymphoma, multiple myeloma)
- Amyloidosis
- Exposure to heavy metals (e.g., lead, cadmium)
- Renal papillary necrosis

DIAGNOSIS

- AIN: suspected in a patient who presents with nonspecific signs and symptoms of AKI (e.g., malaise, fever, nausea, vomiting) with an elevated serum creatinine and an abnormal urinalysis
  - AKI
    - Elevated creatinine, BUN, and electrolyte abnormalities (e.g., hyperkalemia, low serum bicarbonate)
    - Decreased urine output (oliguria in 51%)
    - Signs of fluid overload or depletion
  - Signs of systemic allergy (e.g., fever [27%], maculopapular rash [15%], peripheral eosinophilia [23%], arthralgias [45%] but less commonly found when NSAIDs are the OFA)
  - White cells, red cells, and white cell casts
- CIN
  - HTN
  - Decreased urine output or polyuria
  - Inability to concentrate urine

- Polydipsia
- Metabolic acidosis
- Anemia
- Fanconi syndrome

HISTORY

- Medications: Onset of AIN following drug exposure ranges from 3 to 5 days (as occurs with a second exposure to an OFA) to as long as several weeks to many months (the latter with NSAIDs, especially) (2)[B].
- Infections: may have symptoms related to an associated infection or systemic condition
- TINU patients present with interstitial nephritis and uveitis and occasionally systemic findings.
- Exposure to heavy metals
- Post organ transplant

PHYSICAL EXAM

- Increased BP
- Fluid retention/extremity swelling/weight gain
- Rash accompanying renal findings in acute AIN
- Lung crackles if fluid is overloaded
- Pericardial rub if uremic pericarditis

DIFFERENTIAL DIAGNOSIS

- AKI secondary to other causes:
  - Prerenal (e.g., hypovolemia, shock, sepsis, renal artery emboli)
  - Intrarenal (e.g., acute tubular necrosis, hypertensive nephropathy, DM nephropathy)
  - Postrenal (e.g., obstructive uropathy)
  - Some OFA that cause AIN can produce other forms of AKI as well:
    - NSAIDs can exacerbate prerenal disease.
    - Aminoglycosides can cause acute tubular necrosis.
- CKD secondary to long-standing HTN, diabetes, and chronic pyelonephritis

DIAGNOSTIC TESTS & INTERPRETATION

- Chemistry

  - Elevated plasma creatinine: seen in all patients, with 40% requiring dialysis
  - Hyperkalemia and acidosis
- CBC
  - Eosinophilia (80%): NSAID-induced AIN is only associated with eosinophilia in ~15% of cases.
  - Anemia
- Urinalysis with urine electrolytes
  - Hematuria (95%)
  - Mild and variable proteinuria: usually <1 g/24 hr, except in AIN associated with NSAIDs where it is significantly higher (3)[B]
  - Urine sediment: white cells, red cells, white cell casts. Red blood cell casts are rare.
  - Eosinophiluria but has no clinical utility specific for AIN (4)[C]
  - Fractional excretion of sodium (FENa >1%) indicative of tubular damage
  - Normal urinalysis does not rule out AIN.
- CXR to evaluate for pulmonary tuberculosis, sarcoidosis, and other infections
- Serologic testing for immunologic disease (e.g., sarcoidosis, Sjögren syndrome, Wegener granulomatosis, Behçet syndrome) or infectious causes (e.g., histoplasmosis, coccidiomycosis, toxoplasmosis, EBV)
  - Serum levels of angiotensin-converting enzyme and serum Ca^{++} for sarcoidosis
  - Antinuclear antibody (ANA) and dsDNA to exclude SLE
  - Urinary antigen to exclude *Legionella* infection
  - Anti-Ro/SSA, anti-La/SSB antibodies, CRP, and rheumatoid factor to exclude Sjögren syndrome
- Liver function tests: elevated serum transaminase levels in patients with associated drug-induced liver injury
- Renal US may demonstrate kidneys that are normal to enlarged in size with increased cortical echogenicity, but no US findings will reliably confirm or exclude AIN versus other causes of AKI.
- IV pyelography (IVP) and CT scans with contrast are relatively contraindicated because of the associated nephrotoxicity and limited diagnostic yield.

Initial Tests (lab, imaging)

Follow-Up Tests & Special Considerations

Patients who do not recover renal function and those with CIN should receive long-term follow-up care to protect kidneys from further potentially nephrotoxic therapies.

Diagnostic Procedures/Other

- Renal biopsy is the definitive method of establishing the diagnosis of AIN. Ideally, it should be performed to:
  - Patients treated with an OFA known to cause AIN but have normal urinalysis
  - Patients who are being considered for steroid therapy
  - Patients who are not on glucocorticosteroid therapy initially and do not have spontaneous recovery following cessation of the OFA
  - Patients with advanced renal failure of recent onset (<3 months)
  - Patients with any features (e.g., high-grade proteinuria) that makes the diagnosis of AIN uncertain
- Contraindications: Renal biopsy is contraindicated in bleeding diathesis, solitary kidney, end-stage renal disease (ESRD) with small kidneys, uncontrolled HTN and sepsis, or renal parenchymal infection.

Test Interpretation

- Acute
  - Marked interstitial infiltrate consisting of T lymphocytes and monocytes. Eosinophils, plasma cells, and neutrophils also may be found.
  - In general, the urinary findings will distinguish AIN from other causes (e.g., acute tubular necrosis, glomerulonephritis).
- Chronic: CIN is characterized by tubular atrophy, fibrosis, and cellular infiltration with mononuclear cells.

TREATMENT

For AIN, data on corticosteroids' efficacy have been limited (5,6)[B].

GENERAL MEASURES

- Discontinue offending agent. If topical NSAIDs are in use, discontinue these as well.
- Reduce exposure to other nephrotoxic agents (e.g., furosemide, aminoglycosides).
- Supportive measures:
  - Maintain adequate hydration.
  - Symptomatic relief for fever, rash, and so forth
  - Control of BP and anemia
  - Correct acidosis and electrolyte imbalances.
  - Possible short-term dialysis until recovery of renal function (5)[B]

MEDICATION

- Mainstay of treatment is supportive therapy.
- If patient is taking multiple offending agents, a reasonable clinical approach should include substitution of the suspected drug with another medication.
- If AKI persists after removing the offending agent, attempt medication therapy.

First Line

- Optimal therapy of AIN is unknown because there are no randomized controlled trials (RCTs) or large observational studies.
- Immunosuppressive therapy employed if no subsequent improvement within 3 to 7 days after discontinuation of OFA.
- A renal biopsy is preferred to confirm AIN and to exclude other possible diseases or CIN, where immunosuppressive Rx not indicated.
- Prednisone 1 mg/kg/day PO or equivalent IV dose to a max of 40 to 60 mg/day for 1 to 2 weeks, beginning a gradual taper after serum creatinine has returned to near baseline for a duration of 2 to 3 months, followed by a gradual taper over 3 to 4 weeks (6)[B]. Complete recovery is noted in 49% and partial in 39% (1)[C].
  - Steroids started within 7 days of withdrawal of offending agent more likely to recover function than those who started later (odds ratio [OR] 6.6).

Second Line

- There is limited experience with treating AIN in patients who are steroid

dependent (i.e., relapse during prednisone taper), steroid resistant (as with NSAID-induced disease), or cannot tolerate steroids.

- Mycophenolate mofetil may be considered in these patients who have biopsy-proven AIN. Rx may need to be continued for 1 to 3 years.
- Lead toxicity: Chelation may improve function.
  - Succimer 10 mg/kg (max 500 mg) PO q8h for 5 days, then q12h for 14 days, or
  - EDTA 2 g IV/IM; if IM, use with 2% lidocaine.
- SLE nephritis: steroids + cyclophosphamide or azathioprine
- Urate nephropathy: urate-lowering agents
  - Allopurinol starting at 100 mg/day, increasing to 300 mg/day to achieve serum urate level <6 mg/dL
  - Dose may need to be adjusted down depending on level of renal impairment.
  - Allopurinol itself can be a cause of AIN.
  - Discontinue thiazide.
- Lithium-induced nephritis: Use amiloride as adjunct.
- Indinavir-induced nephritis: Use probenecid as adjunct.

ISSUES FOR REFERRAL

Most patients presenting with AKI, proteinuria, and acid–base and/or electrolyte disorders require consultation with a nephrologist.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Patients with AKI and/or with serious electrolyte or acid–base disorders may require inpatient care until stabilization or resolution.

- Admission criteria/initial stabilization
  - Persistent oliguria or anuria
  - Severe acidosis and/or electrolyte abnormalities
  - ECG changes
- Discharge criteria
  - Stable vitals; correction of all electrolyte imbalances, including magnesium; and resolution of acute ECG changes
  - Normal urine production

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

If patients must remain on nephrotoxic agents, measure renal function, electrolytes, and phosphorus frequently.

DIET

- Low potassium (<2 g/day)
- Low sodium
- Low protein

PATIENT EDUCATION

Printed materials for patients are available at the National Kidney Disease Education Program, (866) 4-KIDNEY, http://www.niddk.nih.gov/health-information/health-communication-programs/nkdep/Pages/default.aspx.

PROGNOSIS

- If the associated AIN is detected early (within 1 week of the rise in serum creatinine) and the offending agent is discontinued promptly, the long-term outcome is favorable for a return to baseline or near baseline serum creatinine levels, except in the instance of NSAID-induced AIN.
- Renal biopsy reveals extent of damage.
- AIN
  - Recovery within weeks to months
  - Acute dialysis is needed for 1/3 of patients before resolution.
  - Rarely progresses to ESRD
- CIN: can progress to ESRD
  - Renal disease may remit in 1 year if untreated.
  - TINU has relapsing course, requiring systemic corticosteroids.
- Untreated severe AKI has 45–70% mortality.

COMPLICATIONS

- Chronic tubulointerstitial disease may progress to ESRD, requiring dialysis or transplantation.

- Analgesics increase the risk of transitional cell cancers of the uroepithelium.

CODES

ICD10

- N12 Tubulo-interstitial nephritis, not spcf as acute or chronic
- N10 Acute tubulo-interstitial nephritis
- N11.9 Chronic tubulo-interstitial nephritis, unspecified

CLINICAL PEARLS

- First step in treatment is to remove OFA.
- Most common OFA in elderly is PPIs and antibiotics.
- A renal biopsy is preferred to confirm AIN.
- Immunosuppressive therapy is employed if no subsequent improvement within 3 to 7 days after discontinuation of OFA.

IRRITABLE BOWEL SYNDROME

Mohamed Abdalaziz, MD • Naureen Rafiq, MD

BASICS

DESCRIPTION

- A gastrointestinal disorder characterized by
  - Chronic and/or recurrent abdominal pain or discomfort and alteration in bowel habits
- May be characterized as diarrhea-predominant or constipation-predominant and may alternate between the two
- Synonym(s): spastic colon; irritable colon

EPIDEMIOLOGY

Irritable bowel syndrome (IBS) accounts for up to 50% of visits to gastroenterologists:

- Second only to upper respiratory infection as cause of lost workdays

Prevalence

Pooled estimate of 11% IBS prevalence internationally; ranges from South Asia (7%) to South America (21%) (1)

- Predominant age: 20 to 39 years
- If age >50 years, consider other diagnoses.
- Predominant sex: in the United States, female > male (2:1)
- More common in low socioeconomic communities

ETIOLOGY AND PATHOPHYSIOLOGY

- The etiology is unknown, associated with intestinal motility abnormalities and enhanced sensitivity to visceral stimuli.
- The trigger may be luminal or environmental.
- Evidence for the role of small intestine bacterial overgrowth (SIBO) in IBS and association with antibiotic therapy is controversial; older age and female gender are predictors of SIBO in IBS patients.

Genetics

Unknown but more common in families of IBS patients

RISK FACTORS

- Other family members with similar GI disorder
- History of childhood sexual abuse
- Sexual/domestic abuse (primarily in women)
- Depression
- Gastrointestinal infection

Pregnancy Considerations

No risk to mother or fetus

GENERAL PREVENTION

See "Diet."

COMMONLY ASSOCIATED CONDITIONS

- Chronic migraine
- Fibromyalgia
- Chronic fatigue syndrome
- Sleep disorders
- Psychiatric disorders: major depression, anxiety, somatoform disorders and posttraumatic stress
- Chronic pelvic pain
- Temporomandibular joint dysfunction

DIAGNOSIS

HISTORY

- Rome III criteria: recurrent pain or discomfort in the abdomen at least 3 days per month over the past 3 months associated with at least two other criteria:
  - Symptoms improve with defecation.
  - Onset is associated with a change in stool frequency.
  - Onset is associated with a change in the form or appearance of the stool.
- Symptoms can also include:
  - Mucus in stools
  - Constipation, bloating, diarrhea, abdominal distension

  - Upper abdominal discomfort after eating
  - Straining for normal consistency stools
  - Urgency of defecation
  - Feelings of incomplete evacuation
  - Abnormal stool form
  - Nausea, vomiting (rarely)
- May have history of abuse or depression
- Patient may note worsening of symptoms with stress or around menses.
- IBS is unlikely in patients with a history of:
  - Weight loss
  - Bleeding
  - Nocturnal diarrhea
  - Fever
  - Anemia

PHYSICAL EXAM

- Important to conduct a complete exam to exclude other causes.
- Vital signs and general exam are typically normal.
- There is typically an absence of jaundice and organomegaly, but there may be tenderness to palpation.

DIFFERENTIAL DIAGNOSIS

- Inflammatory bowel disease
- Lactose intolerance; fructose malabsorption
- Infections (*Giardia lamblia*, *Entamoeba histolytica*, *Salmonella*, *Campylobacter*, *Yersinia*, *Clostridium difficile*)
- Celiac sprue
- Microscopic colitis
- Laxative abuse
- Magnesium-containing antacids
- Hypo-/hyperthyroidism
- Pancreatic insufficiency
- Depression
- Small bowel bacterial overgrowth
- Somatization

- Villous adenoma
- Endocrine tumors
- Diabetes mellitus
- Radiation damage to colon or small bowel

DIAGNOSTIC TESTS & INTERPRETATION

- With a typical history and no warning signs (anemia or weight loss), obtain baseline labs to rule out other causes and begin treatment.
- In patients who do not respond to treatment, further evaluation with imaging and/or endoscopy is warranted to exclude organic pathology.

Initial Tests (lab, imaging)

Rule out pathology specific to the patient's symptoms:

- Diarrhea-predominant: ESR, CBC, tissue transglutaminase, thyroid-stimulating hormone (TSH), and stool for ova and parasites (2)
- Constipation-predominant: CBC, TSH, electrolytes, calcium (2)
- Abdominal pain: LFTs and amylase
- When obtained, abdominal CT scan and ultrasound are generally normal.
- Consider small bowel series or video capsule endoscopy to rule out Crohn disease (typically normal).
- Sitz Marker study may be used to evaluate colonic transit in patients with constipation.

Follow-Up Tests & Special Considerations

Consider lactulose breath test to assess for small bowel bacterial overgrowth associated with IBS (2)[C].

Diagnostic Procedures/Other

Sigmoidoscopy/colonoscopy may be used to rule out inflammatory bowel disease or microscopic colitis.

ALERT

Screen all persons >50 for colorectal cancer.

Test Interpretation

None

TREATMENT

- Goals: Relieve symptoms and improve quality of life (3).
  - Determine if diarrhea predominant, constipation predominant, or mixed type.
- Lifestyle modification
  - Exercising 3 to 5 times per week decreases severity (3).
  - Food diary to determine triggers (3)
- Medications
  - Fiber supplementation (psyllium) increases stool bulk; does not typically relieve abdominal pain; may be used for all types (3)[B]
- Medications that improve abdominal pain, global symptoms, and symptom severity in all types:
  - Antispasmodics such as hyoscyamine 0.125 to 0.25 mg PO/SL q4h PRN and dicyclomine 20 to 40 mg PO BID can be used for all types but have adverse effects such as dry mouth, dizziness, and blurred vision (3).
  - Probiotics such as *Lactobacillus*, *Bifidobacterium*, and *Streptococcus* (4)[C]
- Diarrhea predominant
  - Antidiarrheal such as loperamide 4 to 8 mg/day orally divided into once a day to 3 times a day as needed to decrease stool frequency and increase stool consistency; does not help with abdominal pain; may also use diphenoxylate/atropine (3)
  - Antibiotics such as 2-week course of rifaximin improve bloating, pain, and stool consistency (5).
  - Alosetron (Lotronex 0.5 mg orally twice a day), for women with severe symptoms. Associated with ischemic colitis, constipation, and death in a small number of patients.
- Constipation-predominant
  - Laxatives such as polyethylene glycol (MiraLAX) may improve stool frequency but not pain.
  - Antibiotics such as neomycin and selective chloride channel activators such as lubiprostone (Amitiza) 8 mg twice a day can improve global symptoms and severity (3)[B].
  - Linaclotide (guanylate cyclase-C agonist) has been shown to improve

bowel function and reduces abdominal pain and overall severity in adults only (6).

- Mixed
  - Use medications to match symptoms (3).
- Treat underlying behavioral issues:
  - Tricyclic antidepressants can help control IBS symptoms in moderate to severe cases.
  - Behavioral therapy helps reduce symptoms (5).

ISSUES FOR REFERRAL

- Behavioral health referral may help with management of affective or personality disorders.
- Gastroenterology referral for difficult to control cases

ADDITIONAL TREATMENT

Probiotics use may result in reducing IBS symptoms and decreasing pain and flatulence. There is no difference among *Lactobacillus*, *Streptococcus*, *Bifidobacterium*, and combinations of probiotics.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

The IBS Severity Score is a validated measure to assess the severity of IBS symptoms and can help monitor response to treatment.

IBS Severity Score:

- How severe has your abdominal pain been over the last 10 days?
- On how many of the last 10 days did you get pain?
- How severe has your abdominal distension (bloating, swollen, or tight) been over the last 10 days?
- How satisfied have you been with your bowel habit (frequency, ease, etc.) over the last 10 days?
- How much has your IBS been affecting/interfering with your life in general over the last 10 days?

DIET

- **Low FODMAPs diet:** This diet contains fermentable oligosaccharides, disaccharides, and monosaccharides, and polyols that are carbohydrates (sugars) found in foods. FODMAPs are osmotic, so they may not be digested or absorbed well and could be fermented upon by bacteria in the intestinal tract when *eaten in excess*.
- A low FODMAP diet may help reduce symptoms, which will limit foods high in fructose, lactose, fructans, galactans, and polyols.
  - Increase fiber slowly to avoid excess intestinal gas production.
  - During initial evaluation, consider 2 weeks of lactose-free diet to rule out lactose intolerance.
  - Avoid large meals, fatty foods, and caffeine, which can exacerbate symptoms.
  - A gluten-free diet resolves symptoms for some patients (especially diarrhea predominant IBS) despite negative testing for celiac disease.

PATIENT EDUCATION

IBS is not a psychiatric illness.

PROGNOSIS

- IBS is a disorder that reduces quality of life. Many patients have behavioral health issues. IBS does not increase mortality (1).
- Expect recurrences, especially when under stress.
- Evidence suggests that “symptom shifting” occurs in some patients, whereby resolution of functional bowel symptoms is followed by the development of functional symptoms in another system (1).

SEE ALSO

Algorithm: Diarrhea, Chronic

CODES

ICD10

- K58.9 Irritable bowel syndrome without diarrhea
- K58.0 Irritable bowel syndrome with diarrhea

CLINICAL PEARLS

- Use Rome III criteria to establish the diagnosis of IBS.
- Goals of treatment are to relieve symptoms and improve quality of life.
- If patient does not respond to initial treatment, consider further evaluation (including imaging and/or referral for endoscopy) to exclude organic pathology.

KAWASAKI SYNDROME

Zachariah Clark, MD • Scott P. Grogan, DO, MBA, FAAFP

BASICS

DESCRIPTION

- Kawasaki syndrome (KS) is a self-limited acute, febrile, systemic vasculitis of small- and medium-sized arteries that predominantly affects patients age 6 months to 5 years and is the most prominent cause of acquired coronary artery disease in pediatric populations.
  - Vasculitis of coronary arteries resulting in aneurysms/ectasia, further leading to myocardial infarction (MI)/ischemia or sudden death
- System(s) affected: cardiovascular, gastrointestinal, hematologic/lymphatic/immunologic, musculoskeletal, nervous, pulmonary, renal/urologic, skin/exocrine
- Synonym(s): mucocutaneous lymph node syndrome (MCLS), infantile polyarteritis, Kawasaki disease

ALERT

KS should be considered in any child with extended high fever unresponsive to antibiotics or antipyretics, rash, and nonexudative conjunctivitis.

EPIDEMIOLOGY

Incidence

- Worldwide: affects all races but most prevalent in Asia; Japan annual incidence rate 265/100,000 in children <5 years of age
- In the United States, the annual incidence in children <5 years is 19/100,000. In comparison to Caucasians, African Americans have a 1.5 times risk, and Asian Americans have a 2.5 times increased risk. Highest state incidence is in Hawaii.
- Leading cause of acquired heart disease in children in developed countries
  - Predominant age: 1 to 5 years
  - 85% of cases are children <5 years of age and 50% <2 years of age.

– Male-to-female ratio = 1.5:1

Prevalence

- Highest to lowest prevalence: Asians > African Americans > Hispanics > Caucasians
- Seasonal variation: increased in winter and early spring in temperate places, summer in Asia, and outbreaks at 2- to 3-year intervals

ETIOLOGY AND PATHOPHYSIOLOGY

- Acute KS causes inflammation in the smooth muscle layer of medium extraparenchymal arteries, especially the coronary arteries.
- Inflammatory cells in the media secrete cytokines (TNF-α), interleukins, and matrix metalloproteases that cause fragmentation of the internal elastic lamina.
- A prominence of IgA plasma cells and IgA deposits are characteristic features and may be found in the lungs.
- As the process resolves, active inflammatory cells are replaced by fibroblasts and monocytes; tissue repair/remodeling may cause vascular fibrosis and stenosis.
- Unknown; believed to be an exaggerated immune response to infectious agent due to the acute, self-limited nature; community-wide outbreaks; age distribution; seasonality; and laboratory features indicating respiratory route of entry

Genetics

- Siblings of patients in Japan have a 10- to 30-fold increased risk, and >50% develop KS within 10 days of first case. Increased occurrence of KS in children whose parents also had illness in childhood.
- Populations at higher risk and family link suggest a genetic predisposition.

GENERAL PREVENTION

No preventive measures available

DIAGNOSIS

≥5 days of fever and ≥4 of the following 5 principal clinical features; or <4

features and presence of coronary artery disease on 2D echocardiography:

- Bilateral conjunctival injection with limbic sparing
- Erythematous mouth and pharynx, tongue, and lips
- A polymorphous, generalized, erythematous rash
- Changes in the skin of the peripheral extremities
- Cervical lymphadenopathy

Pediatric Considerations

- Prolonged fever without rash and treated with antibiotics may cause clinicians to believe that later rash development is due to a drug reaction.
- Can be diagnosed on day 4 of illness if ≥4 principal features are present
- Incomplete KS
  - ≥5 days of fever, 2 to 3 principal clinical features, labs indicating systemic inflammation, and exclusion of other diseases
  - Incomplete cases that exhibit <4 clinical criteria often occur in infants ≤6 months of age or older children/adolescents. The frequency of coronary artery aneurysms (CAAs) is often higher in patients with missed diagnosis/delayed treatment. Therefore, in infants with prolonged fever and few or no clinical features, consider echocardiography and inflammatory labs.

HISTORY

- Fever is the first sign during the acute phase.
- Symptoms may not occur all at once, but usually occur in close proximity.

PHYSICAL EXAM

- High-spiking and remittent fever for ≥5 days
  - Fever is high (102–105°F [39.4–40.5°C]) and unresponsive to antibiotics.
  - May be prolonged up to 3 to 4 weeks
  - Extreme irritability is a very common feature.
- Bilateral, painless, nonpurulent, conjunctival injection without corneal ulceration or edema. Limbic sparing is usually seen.
- Changes in lips and oral cavity
  - Redness and swelling of lips in the acute stage; cracking, fissuring, bleeding in subacute phase

  - Strawberry/erythematous tongue
- Extensive erythematous polymorphous rash: within 5 days of fever
  - Morbilliform is most common. May be maculopapular, scarlatiniform; can resemble erythema multiforme, erythroderma, urticarial exanthem; rarely micropustular
  - Perineal desquamation, especially in skin folds
- Extremity changes
  - Reddened palms and soles on days 3 to 5
  - Edema of hands and feet on days 4 to 7; painful induration
  - Desquamation of fingers and toes that begins in periungual area at 2 to 3 weeks
- Acute, unilateral cervical lymphadenopathy (least common symptom)
  - ≥1 lymph nodes >1.5 cm, firm, nonfluctuant, and usually with no to slight tenderness
- Cardiac exam: tachycardia, gallop rhythms, hyperdynamic precordium, innocent flow murmurs, depressed contractility
- Other organ system involvement
  - Cardiovascular: myocarditis; pericarditis (often subclinical), CAAs, and other medium-sized arterial aneurysms
  - Gastrointestinal: anorexia, abdominal pain, vomiting/diarrhea, acute gallbladder hydrops, hepatic enlargement, jaundice
  - Renal: proteinuria, sterile pyuria
  - Joints: polyarthritis of small joints in acute phase; weight-bearing joints affected after 10th day from onset of fever
  - Neurologic: irritability, aseptic meningitis, peripheral neuropathy (unilateral facial palsy), transient high-frequency hearing loss

DIFFERENTIAL DIAGNOSIS

- Bacterial: staphylococcal scalded-skin syndrome, toxic shock syndrome, scarlet fever, bacterial cervical lymphadenitis, *Mycoplasma* infection, leptospirosis, Lyme disease, Rocky Mountain spotted fever
- Viral: measles, adenovirus, Epstein-Barr virus
- Toxoplasmosis
- Reiter syndrome
- Hypersensitivity drug reactions (erythema multiforme minor, Stevens-Johnson

syndrome)
- Juvenile rheumatoid arthritis
- Acrodynia (mercury poisoning)

DIAGNOSTIC TESTS & INTERPRETATION

- Initial workup: CBC with differential, urinalysis (UA)/culture, blood culture; lumbar puncture if signs of meningitis or if <90 days old
  - Leukocytosis (12,000 to 40,000 cells/mm^3) with immature and mature granulocytes
  - Anemia: normochromic, normocytic
  - Thrombocytosis (500,000 to >1,000,000/mm^3) in second and third week. Thrombocytopenia during acute phase is associated with CAA and MI.
- Elevated C-reactive protein (CRP) (>35 mg/L in 80% cases), erythrocyte sedimentation rate (ESR) (>60 mm/hr in 60% cases), and α_1-antitrypsin

ALERT

ESR can be artificially high after intravenous immunoglobulin (IVIG) therapy.

- Hyponatremia
- Moderately elevated AST, ALT, GGT, and bilirubin
- Decreased albumin and protein
- CSF pleocytosis may be seen (lymphocytic with normal protein and glucose).
- *N*-terminal brain natriuretic peptide might be elevated in acute phase.
- Sterile pyuria but not seen in suprapubic collection
- Nasal swab to rule out adenovirus

Initial Tests (lab, imaging)

- If KS is suspected, obtain ECG and echocardiogram.
  - ECG may show arrhythmias, prolonged PR interval, and ST/T wave changes.
  - Echocardiography has a high sensitivity and specificity for detection of abnormalities of proximal left main coronary artery, and right coronary artery may show perivascular brightening, ectasia, decreased left ventricular contractility, pericardial effusion, or aneurysms.
  - Cardiac stress test if CAA seen on echocardiogram
- Baseline chest x-ray (CXR): may show pleural effusion, atelectasis, and

congestive heart failure (CHF)
- Hydrops of the gallbladder may be associated with abdominal pain or may be asymptomatic.

Diagnostic Procedures/Other
- No laboratory study is diagnostic; diagnosis rests on constellation of clinical features and exclusion of other illnesses.
- Magnetic resonance coronary angiography is noninvasive modality to visualize coronary arteries for stenosis, thrombi, and intimal thickening (1).
- Patients with complex coronary artery lesions may benefit from coronary angiography after the acute inflammatory process has resolved; generally recommended in 6 to 12 months

TREATMENT

GENERAL MEASURES
Use antibiotics until bacterial etiologies are excluded (e.g., sepsis or meningitis).

MEDICATION
- Optimal therapy is IVIG 2 g/kg IV over 10 to 12 hours with high-dose aspirin preferably within 7 to 10 days of fever, followed by low-dose aspirin until follow-up echocardiograms indicate a lack of coronary abnormalities.
  - IVIG lowers the risk of CAA and may shorten fever duration.
  - The extreme irritability often resolves very quickly after IVIG is given.
- Retreatment with IVIG if clinical response is incomplete or fever persists/returns >36 hours after start of IVIG treatment.
  - ≥10% of patients do not respond to initial IVIG treatment. 2/3 of nonresponders respond to the second dose of IVIG.
  - Nonresponders tend to have ↑ bands, ↓ albumin, and an abnormal echo.
- Aspirin, 80 to 100 mg/kg/day in 4 doses beginning with IVIG administration. Switch to low-dose aspirin (3 to 5 mg/kg/day) when afebrile for 48 to 72 hours, or continue until day 14 of illness. Maintain low dose for 6 to 8 weeks until follow-up echocardiogram is normal and CRP and/or ESR are normal. Continue salicylate regimen in children with coronary abnormalities long term or until documented regression of aneurysm (2)[C].

- Aspirin does not appear to reduce CAA (3)[B].
- Contraindications
  - IVIG: documented hypersensitivity, IgA deficiency, anti-IgE/IgG antibodies, severe thrombocytopenia, coagulation disorders
  - Aspirin: vitamin K deficiency, bleeding disorders, liver damage, documented hypersensitivity, hypoprothrombinemia
- Precautions
  - No statistically significant difference is noted between different preparations of IVIG.
  - High-dose aspirin therapy can result in tinnitus, decrease of renal function, and increased transaminases.
  - Do not use ibuprofen in children with CAAs who are taking aspirin for antiplatelet effects.
  - Significant possible interactions: Aspirin therapy has been associated with Reye syndrome in children who develop viral infections, especially influenza B and varicella. Yearly influenza vaccination thus is recommended for children requiring long-term treatment with aspirin. Delay any live vaccines for 11 months after IVIG treatment.

Second Line

- Corticosteroids should be used only if ≥2 IVIG treatments have failed. The addition of corticosteroids to IVIG and aspirin during initial treatment might improve CAA outcomes but lacks consistent evidence (4)[C].
- In patients refractory to IVIG and steroids, consider infliximab or cyclosporine (5)[B].
- Plasma exchange may decrease likelihood of CAA in IVIG nonresponders (6)[B].

ISSUES FOR REFERRAL

Pediatric cardiologist if abnormalities on echo or if extensive stenosis

ADDITIONAL THERAPIES

- Treatment and prevention of thrombosis are crucial.
- Antiplatelet agents (clopidogrel, dipyridamole), heparin, low-molecular-weight heparin, or warfarin are sometimes added to the low-dose aspirin

regimen, depending on severity of coronary involvement.

SURGERY/OTHER PROCEDURES

- Rarely needed; coronary artery bypass grafting for severe obstruction/recurrent MI. Younger patients have a higher mortality rate.
- Coronary revascularization via percutaneous coronary intervention for patients with evidence of ischemia on stress testing

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Normal saline (NS) for rehydration and 1/2 NS for maintenance
- Discharge if afebrile after IVIG treatment for 24 hours.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

With aneurysms, contact and high-risk sports should be avoided.

Patient Monitoring

- Repeat ECG and echocardiogram at 6 to 8 weeks. If abnormal, repeat at 6 to 12 months.
- Patients with complex coronary artery lesions may benefit from coronary angiography at 6 to 12 months.

PROGNOSIS

- Usually self-limited
- Moderate-sized aneurysms usually regress in 1 to 2 years, resolving in 50–66% of cases.
- Recurrence (3% in Japan, <1% in the United States)
- Sudden death in early adulthood (rare)

COMPLICATIONS

- 15–25% of untreated patients develop CAAs in convalescent phase.
- 2–7% of treated patients develop aneurysms. 1% develop giant aneurysms.
- Risk factors for aneurysm
  - Male, <1 year of age, ↑ ESR >4 weeks, fever >2 weeks, fever >48 hours

after IVIG treatment

- Mortality of 0.08–0.17% is due to cardiac disease.

CODES

ICD10

M30.3 Mucocutaneous lymph node syndrome [Kawasaki]

CLINICAL PEARLS

- The diagnosis of KS rests on a constellation of clinical features.
- Once KS is suspected, all patients need an inpatient cardiac evaluation, including ECG and echocardiogram.
- Expert recommendation for optimal therapy is IVIG 2 g/kg IV over 10 hours, with high-dose aspirin 80 to 100 mg/kg/day in 4 doses.

KERATOACANTHOMA

Carl Bryce, MD • Matthew J. Snyder, DO

BASICS

DESCRIPTION

- Rapidly proliferating, solitary, dome-shaped, erythematous or flesh-colored papule or nodule with a central keratinous plug, typically reaching 1 to 2 cm in diameter
- Highly debated as to whether keratoacanthoma (KA) is a benign or malignant variant of squamous cell carcinoma (SCC). Majority are benign and resolve spontaneously, but lesions do have the potential for invasion and metastasis; therefore require treatment.
- Three clinical stages of KAs (1):
  - Proliferative: rapid growth of the lesion over weeks to several months
  - Maturation/stabilization: Lesion stabilizes and growth subsides.
  - Involution: spontaneous resolution of the lesion, leaving a hypopigmented, depressed scar; most but not all lesions will enter this stage.
- System(s) affected: integumentary

EPIDEMIOLOGY

- Greatest incidence over the age of 50 years but may occur at any age
- Presentation increased during summer and early fall seasons
- Most frequently on sun-exposed, hair-bearing skin but may occur anywhere
- Predominant sex: male > female (2:1)
- Most commonly in fair-skinned individuals; highest rates in Fitzpatrick I–III
- 104 cases per 100,000 individuals

ETIOLOGY AND PATHOPHYSIOLOGY

- Derived from an abnormality causing hyperkeratosis within the follicular infundibulum
- Squamous epithelial cells proliferate to extend upward around the keratin plug and proceed downward into the dermis; followed by invasion of elastic and collagen fibers

- Cellular mechanism responsible for the hyperkeratosis is currently unknown; role of human papillomavirus has been discussed but has no established causality (2).
- Regression may be due to immune cytotoxicity or terminal differentiation of keratinocytes.
- Multiple etiologies have been suggested:
  - UV radiation
  - May be provoked by surgery, cryotherapy, chemical peels or laser therapy
  - Viral infections: human papillomavirus (HPV) or Merkel cell polyomavirus
  - Genetic predisposition: Muir-Torre syndrome, xeroderma pigmentosum, Ferguson-Smith syndrome
  - Immunosuppression
  - Chemical carcinogen exposure

Genetics

- Mutation of *p53* or H-*ras*
- Ferguson-Smith (AD)
- Witten-Zak (AD)
- Muir-Torre (AD)
- Xeroderma pigmentosum (AR)
- Gzybowski (sporadic)
- Incontinentia pigmenti (XLD)

RISK FACTORS

- UV exposure/damage: outdoor and/or indoor tanning
- Fitzpatrick skin type I–III
- Trauma (typically appears within 1 month of injury): laser resurfacing, surgery, cryotherapy, tattoos
- Chemical carcinogens: tar, pitch, and smoking
- Immunocompromised state
- Discoid lupus erythematosus

GENERAL PREVENTION

Sun protection

COMMONLY ASSOCIATED CONDITIONS

- Frequently, the patient has concurrent sun-damaged skin: solar elastosis, solar lentigines, actinic keratosis, nonmelanoma skin cancers (basal cell carcinoma, SCC)
- In Muir-Torre syndrome, KAs are found with coexisting sebaceous neoplasms and malignancy of the GI and GU tracts.

DIAGNOSIS

HISTORY

- Lesion begins as a small, solitary, pink macule that undergoes a rapid growth phase; classically reaching a diameter of 1 to 2 cm; size may vary.
- Once the proliferative stage has subsided, lesion size remains stable.
- May decrease in size, indicating regression
- Asymptomatic, occasionally tender
- If multiple lesions present, important to elicit a family history and recent therapies or treatments.
- If sebaceous neoplasms present, must review history for signs/symptoms of GI or GU malignancies

PHYSICAL EXAM

- Firm, solitary, erythematous or flesh-colored, dome-shaped papule or nodule with a central keratin plug, giving a crateriform appearance
- Surrounding skin and borders of lesion may show telangiectasia, atrophy, or dyspigmentation.
- Solitary; although multiple lesions can occur.
- Most commonly seen on sun-exposed areas: face, neck, scalp, dorsum of upper extremities, and posterior legs
- May also be seen on areas without sun exposure: buttocks, anus, subungual, mucosal surfaces
- Subungual KAs are very painful and seen on the first 3 digits of the hands.
- Examine for regional lymphadenopathy due to chance of lesion invasion and metastasis.
- Dermoscopy (3)[B]
  - Central keratin

  - White circles, blood spots
  - Cannot reliably distinguish between AK and SCC

DIFFERENTIAL DIAGNOSIS

- SCC
- Nodular or ulcerative basal cell carcinoma
- Cutaneous horn
- Hypertrophic actinic keratosis
- Amelanotic melanoma
- Merkel cell carcinoma
- Metastasis to the skin
- Molluscum contagiosum
- Prurigo nodularis
- Verruca vulgaris
- Verrucous carcinoma
- Sebaceous adenoma
- Hypertrophic lichen planus
- Hypertrophic lupus erythematosus
- Deep fungal infection
- Atypical mycobacterial infection
- Nodular Kaposi sarcoma

DIAGNOSTIC TESTS & INTERPRETATION

- Excisional biopsy including the center of the lesion as well as the margin is the best diagnostic test (2)[C].
- A shave biopsy may be insufficiently deep to distinguish KA from an SCC.
- If unable to perform an excisional biopsy, a deep shave (saucerization) of the entire lesion, extending into the subcutaneous fat, can be done.
- Punch biopsies should be avoided because they give an insufficient amount of tissue to represent the entire lesion.

Initial Tests (lab, imaging)

- Subungual KA: radiograph of the digit to monitor for osteolysis (cup-shaped radiolucent defect)
- Aggressive tumors may need CT with contrast for evaluation of lymph nodes

and MRI if there is concern of perineural invasion.
- Most lesions do not need any form of imaging.

Test Interpretation

- Pathology of biopsy: a well-demarcated central core of keratin surrounded by well-differentiated, mildly pleomorphic, atypical squamous epithelial cells with a characteristic glassy eosinophilic cytoplasm
- May see elastic and collagen fibers invading into the squamous epithelium
- Histologic differentiation of a KA from an SCC may be difficult and unreliable, although immunochemical staining for cellular protein Ki-67 may help do this (4).
- KAs have a greater tendency than SCC to display fibrosis and intraepidermal abscesses of neutrophils and eosinophils.
- Regressing KA shows flattening and fibrosis at base of lesion.

TREATMENT

- Treatment of choice is an excisional procedure plus electrodessication and curettage; however, there are many treatment options available (2)[C].
- Aggressive tumors (>2 cm) or lesions in cosmetically sensitive areas (face, digits, genitalia) that require tissue sparing, consider Mohs micrographic surgery
  - Mohs is the treatment of choice in cases with perineural or perivascular invasion.
- Small lesions (<2 cm) of the extremities may undergo electrodessication and curettage.
- Immunocompromised patients should receive immediate surgical treatment.

MEDICATION

- Nonsurgical management is a viable and relatively cost-effective option in these select cases not amenable to surgery due to lesion number, size, or location; also for patients with multiple comorbidities who are unwilling or unable to withstand surgery
- Evidence for the following treatments based on case reports and retrospective reviews:

- Intralesional methotrexate 12.5 to 25 mg in 0.5 mL normal saline every 2 to 3 weeks for one to four treatment sessions (5)[B]
  - Monitor for pancytopenia with complete blood count (5)[C].
- 5% Imiquimod cream 3 times per week for 11 to 13 weeks (5)[B]
- Topical 5% 5-fluorouracil cream daily, 61–92% cure rate (5)[B]
- Intralesional 5-fluorouracil of 50 mg/mL on a weekly basis for three to eight treatment sessions—98% cure rate (5)[B]
- Intralesional IFN a-2a or a-2b (83%, 100% cure rate, respectively) (5)[B]
- Intralesional bleomycin—100% cure rate (5)[B]
- Isotretinoin oral 0.5 to 1 mg/kg/day

ISSUES FOR REFERRAL

Dermatology referral if lesions are >2 cm, numerous, mucosal, or subungual

ADDITIONAL THERAPIES

- Photodynamic therapy with methyl aminolevulinic acid and red light, successful case reports (6)[B] but also reported aggravation following treatment
- Cryotherapy
- Argon or YAG lasers
- Radiotherapy, primary or adjuvant: KAs may regress with low doses of radiation but may require doses up to 25 to 50 Gy in low-dose (5 to 10 Gy) fractions for possible SCC (7)[B].
- Erlotinib (EGFR inhibitor) 150 mg daily for 21 days, single case report (8)[B]

SURGERY/OTHER PROCEDURES

Excisional and office-based procedures as discussed above.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

After the surgical site has healed or lesion has resolved, patient should be seen every 6 months due to increased risk of developing new lesions or skin cancers, annually at minimum (3)[C].

Patient Monitoring

- Skin self-exams should be routinely performed with detailed instructions (see "Additional Reading").
- If multiple KAs are present in patient or family members, evaluate for Muir-Torre syndrome and obtain a colonoscopy beginning at age 25 years, as well as testing for genitourinary cancer (3)[C].

PATIENT EDUCATION

- Sun protection measures: sun block with SPF >30, wide-brimmed hats, long sleeves, dark clothing, avoiding indoor tanning
- Arc welding may produce harmful UV radiation and skin should not be exposed.
- Tar, pitch, and smoking should be avoided.

PROGNOSIS

- Atrophic scarring and hypopigmentation can occur with self-resolution but may be significantly reduced by intervention.
- 52 of 445 cases (12%) spontaneously regressed without treatment and none of these recurred (2).
- 393 (88%) regressed following medical or excisional treatment (2).
- 445 cases reported with no metastases or deaths attributable to the KA (2).
- 4–8% recurrence
- Mucosal and subungual lesions do not regress, must undergo treatment

SEE ALSO

Squamous Cell Carcinoma, Cutaneous

CODES

ICD10

- D23.9 Other benign neoplasm of skin, unspecified
- D48.5 Neoplasm of uncertain behavior of skin
- L85.8 Other specified epidermal thickening

CLINICAL PEARLS

- Suspect KA with a solitary, dome-shaped, erythematous or flesh-colored papule or nodule with a central keratinous plug.
- If KA is in the differential diagnosis, elicit time frame of onset during patient encounter; rapid onset supports diagnosis.

- Due to the broad differential diagnosis of a suspected KA and unreliable clinical differentiation between these, strongly consider surgical excision as first-line diagnostic test and therapy.
- Medical and radiation therapies are reasonable and effective options available for patients who are not surgical candidates or for lesions that are not amenable for surgery.

KERATOSIS, ACTINIC

Zoltan Trizna, MD, PhD

BASICS

DESCRIPTION

- Common, usually multiple, premalignant lesions of sun-exposed areas of the skin. Many resolve spontaneously, and a small proportion progress to squamous cell carcinoma
- Common consequence of excessive cumulative ultraviolet (UV) light exposure
- Synonym(s): solar keratosis

Geriatric Considerations

Frequent problem

Pediatric Considerations

Rare (if child, look for freckling and other stigmata of xeroderma pigmentosum)

EPIDEMIOLOGY

Incidence

- Rates vary with age group and exposure to sun.
- Predominant age: ≥40 years; progressively increases with age
- Predominant sex: male > female
- Common in those with blonde and red hair; rare in darker skin types

Prevalence

- Age-adjusted prevalence rate for actinic keratoses (AKs) in U.S. Caucasians is 6.5%.
- For 65- to 74-year-old males with high sun exposure: ~55%; low sun exposure, ~18%

ETIOLOGY AND PATHOPHYSIOLOGY

- The epidermal lesions are characterized by atypical keratinocytes at the basal layer with occasional extension upward. Mitoses are present. The

histopathologic features resemble those of squamous cell carcinoma (SCC) in situ or SCC, and the distinction depends on the extent of epidermal involvement.
- Cumulative UV exposure

Genetics

The *p53* chromosomal mutation has been shown consistently in both AKs and SCCs. Many new genes have been shown recently to have similar expression profiles in AKs and SCCs.

RISK FACTORS

- Exposure to UV light (especially long-term and/or repeated exposure due to outdoor occupation or recreational activities, indoor or outdoor tanning)
- Skin type: burns easily, does not tan
- Immunosuppression, especially organ transplantation

GENERAL PREVENTION

Sun avoidance and protective techniques are helpful.

COMMONLY ASSOCIATED CONDITIONS

- SCC
- Other features of chronic solar damage: lentigines, elastosis, and telangiectasias

DIAGNOSIS

HISTORY

- The lesions are frequently asymptomatic; symptoms may include pruritus, burning, and mild hyperesthesia.
- Lesions may enlarge, thicken, or become more scaly. They also may regress or remain unchanged.
- Most lesions occur on the sun-exposed areas (head and neck, hands, forearms).

PHYSICAL EXAM

- Usually small (<1 cm), often multiple red, pink, or brown macules, papules, or

plaques that are rough to palpation
- Yellow or brown adherent scale is often present on top of the lesion.
- Several clinical variants exist.
  - Atrophic: dry, scaly macules with indistinct borders and an erythematous base
  - Hypertrophic: Overlying hyperkeratosis (in an extreme form, cutaneous horn) may be impossible to differentiate from SCC clinically.
  - Pigmented: smooth tan/brown plaque, spreading centrifugally
  - Bowenoid: red scaly plaques with distinct borders
  - Actinic cheilitis: inflammatory lesion involving usually the lower lip

DIFFERENTIAL DIAGNOSIS

- SCC (hypertrophic type)
- Keratoacanthoma
- Bowen disease
- Basal cell carcinoma
- Verruca vulgaris
- Less likely: verrucous nevi, warty dyskeratoma, lichenoid keratoses, seborrheic keratoses, porokeratoses, seborrheic dermatitis or psoriasis (near hairline), lentigo maligna, solar lentigo, discoid lupus erythematosus

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other

- The diagnosis is usually made clinically, except where there is a suspicion of carcinoma.
- Skin biopsy is especially recommended if large, ulcerated, indurated, or bleeding; or if the lesions are nonresponsive to treatment.

Test Interpretation

- Dysplastic keratinocytes in lower levels of epidermis with a dermal lymphocytic infiltrate
- Neoplastic cells, mostly found in the lower epidermal layers, are cytologically identical to those of SCCs.
- If neoplastic cells extend throughout entire epidermis or into the dermis, the lesions will qualify as an SCC in situ or invasive SCC, respectively.

- Malignant cells are sparse except of the bowenoid variety.
- Hypertrophic, atrophic, bowenoid, acantholytic, and pigmented varieties show the corresponding epidermal findings.

TREATMENT

First-line treatment is cryotherapy (technically, this is considered surgery, especially by insurance companies) (1,2)[A]. Medical therapy is usually reserved for extensive AKs (“field therapy”).

GENERAL MEASURES

- Sun-protective techniques
- Sunscreens and physical sun protection recommended.

MEDICATION

First Line

- Topical treatments target both visible and subclinical lesions.
- With the exception of generic 5-fluorouracil, medication cost is high ($600 to $1,200 per course).
- Topical fluorouracil (Efudex, Carac, Fluoroplex cream, Fluoroplex solution)
  - Every day—BID for 3 to 6 weeks, depending on the brand, concentration, and formulation
  - Can be very irritating
  - May be most effective of the topical treatments (3)[A] listed in this section.
- Topical imiquimod (Aldara) 5% cream
  - Apply 2 days per week at HS for up to 16 weeks to an area not larger than the forehead or one cheek.
  - Can be irritating
- Topical imiquimod (Zyclara) 3.75% cream
  - Apply once a day for 2 weeks, followed by no treatment for the next 2 weeks; then apply once a day for another 2 weeks.
  - Can be irritating
- Topical ingenol mebutate (Picato) 0.015% and 0.05% gel
  - Apply to the face and scalp once a day for 3 consecutive days.

  - Apply to the trunk and extremities once a day for 2 consecutive days.
    - It should only be used on one contiguous skin area of not more than 25 cm^2.
    - Cases of severe allergic reactions (including anaphylaxis) and herpes zoster reactivation unrelated to application errors have been reported.
- Diclofenac (Solaraze) 3% gel
  - Apply BID for 60 to 90 days.

Second Line

- Topical tretinoin (Retin-A) or tazarotene (Tazorac): may be used to enhance the efficacy of topical fluorouracil
- Systemic retinoids: used infrequently

ADDITIONAL THERAPIES

Close monitoring with no treatment is an appropriate option for mild lesions.

SURGERY/OTHER PROCEDURES

- Cryosurgery ("freezing," liquid nitrogen)
  - Most common method for treating AK
  - Cure rate: 75–98.8%
  - May leave scars
  - May be superior to photodynamic therapy for thicker lesions
- Photodynamic therapy with a photosensitizer (e.g., aminolevulinic acid) and "blue light"
  - May clear >90% of AKs
  - Less scarring than cryotherapy
  - May be superior to cryotherapy, especially in the case of more extensive skin involvement
- Curettage and electrocautery (electrodesiccation and curettage [ED&C]; "scraping and burning")
- Medium-depth peels, especially for the treatment of extensive areas
- CO_2 laser therapy
- Dermabrasion
- Surgical excision (excisional biopsy)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Depends on associated malignancy and frequency with which new AKs appear

PATIENT EDUCATION

- Teach sun-protective techniques.
  - Limit outdoor activities between 10 AM and 4 PM.
  - Wear protective clothing and wide-brimmed hat.
  - Proper use (including reapplication) of sunscreens with SPF >30, preferably a preparation with broad-spectrum (UV-A and UV-B) protection
- Teach self-examination of skin (melanoma, squamous cell, basal cell).
- Patient education materials
  - http://dermnetnz.org/lesions/solar-keratoses.html
  - www.skincarephysicians.com/actinickeratosesnet/index.html
  - www.skincancer.org/Actinic-Keratosis-and-Other-Precancers.htm

PROGNOSIS

Very good. A significant proportion of the lesions may resolve spontaneously (4), with regression rates of 20–30% per lesion per year.

COMPLICATIONS

- AKs are premalignant lesions that may progress to SCCs. The rate of malignant transformation is unclear; the reported percentages vary (4) but range from 0.1% to a few percent per year per lesion.
- Patients with AKs are at increased risk for other cutaneous malignancies.
- Approximately 60% of SCCs arise from an AK precursor.

CODES

ICD10

L57.0 Actinic keratosis

CLINICAL PEARLS

- AKs are premalignant lesions.
- Often more easily felt than seen
- Therapy-resistant lesions should be biopsied, especially on the face.

KERATOSIS, SEBORRHEIC

Jelaun Newsome, DO

BASICS

DESCRIPTION

- One of the most common benign tumors of the epidermis
- Formed from keratinocytes
- Frequently appears in multiples on the head, neck, and trunk of older individuals but may occur on any hair-bearing area of the body. Lesions spare the palms and soles.
- Typically are light brown to black, sharply demarcated, round, or elongated lesions with a velvety, verrucous-like, "stuck-on" appearance; lesions may also appear waxy yellow or pink.
- Clinical variants include the following:
  - Common seborrheic keratosis
  - Dermatosis papulosa nigra
  - Stucco keratosis
  - Flat seborrheic keratosis
  - Pedunculated seborrheic keratosis
- System(s) affected: integumentary
- Synonym(s): verruca seborrhoica; seborrheic wart; senile wart; basal cell papilloma; verruca senilis; basal cell acanthoma; benign acanthokeratoma

EPIDEMIOLOGY

Incidence

- Predominant age
  - Usually appear after the 3rd decade
  - Most commonly seen during middle and older age
  - Can occasionally arise as early as adolescence
- Predominant sex: male = female
- Most common among Caucasians, except for the dermatosis papulosa nigra variant, which usually presents in darker skinned individuals

Prevalence

- 69–100% in patients >50 years of age
- The prevalence rate increases with advancing age.

ETIOLOGY AND PATHOPHYSIOLOGY

- Seborrheic keratoses are monoclonal tumors.
- Etiology still is largely unclear.
- Ultraviolet (UV) light and genetics are thought to be involved.
- The role of human papillomavirus is uncertain.

Genetics

An autosomal dominant inheritance pattern is suggested.

RISK FACTORS

- Advanced age
- Exposure to UV light and genetic predisposition are possible factors (1).

GENERAL PREVENTION

Sun protection methods may help prevent seborrheic keratoses from developing.

COMMONLY ASSOCIATED CONDITIONS

- Sign of Leser-Trélat: A paraneoplastic syndrome characterized by a sudden eruption of multiple seborrheic keratoses in association with an internal malignancy, most commonly stomach or colon adenocarcinoma. Usually represents a poor prognosis. The validity of this syndrome as a marker for internal malignancy is controversial (2)[B].
- Documentation of other cutaneous lesions, such as basal cell carcinoma, malignant melanoma, Bowen disease, or squamous cell carcinoma, growing adjacent to or within a seborrheic keratosis, has been reported. The exact relationship between lesions is unclear.

DIAGNOSIS

HISTORY

- Usually asymptomatic
- Trauma or irritation of the lesion may result in pruritus, erythema, bleeding,

pain, and/or crusting.

PHYSICAL EXAM

- Typically begin as oval- or round-shaped, flat, dull, sharply demarcated patches
- As they mature, may develop into thicker, elevated, uneven, verrucous-like papules, plaques, or peduncles with a waxy or velvety surface, and appear "stuck on" to the skin (3)
- Commonly appear on sun-exposed areas of the body, predominately the head, neck, or trunk but may appear on any hair-bearing skin
- Vary in color from black, brown, tan, gray to white, or skin-colored, and range in size, from 1 mm to 4 cm
- Usually occur as multiples, with patients having >100 is not uncommon.
- May grow along folds on truncal skin, forming a "Christmas tree" pattern
- If irritated, may be bleeding, inflamed, painful, pruritic, or crusted
- Common clinical variants include the following (4):
  - Common seborrheic keratoses: on hair-bearing skin, usually on the face, neck, and trunk; verrucous-like, waxy, or velvety lesions that appear "stuck on" to the skin
  - Dermatosis papulosa nigra: Small black papules that usually appear on the face, neck, chest, and upper back; most common in darker skinned individuals, more common in females; most have a positive family history.
  - Stucco keratoses: small gray-white, rough, verrucous papules; usually occur in large numbers on the lower extremities or forearms; more common in men
  - Flat seborrheic keratoses: oval-shaped, brown patches or macules on face, chest, and upper extremities; increases with age
  - Pedunculated seborrheic keratoses: Hyperpigmented peduncles appear on areas of friction (neck, axilla).

DIFFERENTIAL DIAGNOSIS

Consider the following diagnoses if the seborrheic keratosis is:

- Pigmented
  - Malignant melanoma
  - Melanocytic nevus

  - Angiokeratoma
  - Pigmented basal cell carcinoma
- Lightly pigmented
  - Basal cell carcinoma
  - Bowen disease
  - Condyloma acuminatum
  - Fibroma
  - Verruca vulgaris
  - Eccrine poroma
  - Invasive squamous cell carcinoma
  - Acrochordon
  - Acrokeratosis verruciformis of Hopf
  - Follicular infundibulum tumor
- Flat
  - Solar lentigo
  - Verrucae planae juveniles
- Hyperkeratotic
  - Actinic keratosis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

Not needed unless internal malignancy is suspected

Diagnostic Procedures/Other

- The diagnosis can usually be made based on clinical appearance.
- Dermoscopy
  - Can aid in diagnosis
  - Common findings are comedo-like openings, fissures, ridges, sharply demarcated borders, milia-like cysts, pseudofollicular openings, hairpin vessels, and horn pseudocysts (5,6).
- Biopsy and histologic exam should be performed if the seborrheic keratosis
  - Is atypical
  - Has inflammation
  - Recently changed in appearance
  - Diagnosis remains unclear.

Test Interpretation

- Histologic findings include the following:
  - Acanthosis and papillomatosis due to basaloid cell proliferation
  - "Squamous eddies" or squamous epithelial cell clusters
  - Hyperpigmentation
  - Hyperkeratosis
  - Horn cysts
  - Pseudocysts
- Several histologic variants exist.

TREATMENT

- Treatment is not usually necessary due to the benign nature of the lesions.
- Removal of seborrheic keratoses may be indicated if
  - Symptomatic
  - Aesthetically displeasing or undesirable (common)
  - There is a question of malignancy.

MEDICATION

Current topical treatments of seborrheic keratoses are less effective than a surgical approach.

ISSUES FOR REFERRAL

- New seborrheic keratoses appear abruptly.
- A seborrheic keratosis becomes inflamed or changes in appearance.

SURGERY/OTHER PROCEDURES

- A surgical approach to treatment is preferred.
- Choice depends on physician preference and availability of the treatment.
- The following procedures are used:
  - Cryotherapy (liquid nitrogen)
    - Spray flat lesions for 5 to 10 seconds; may require more time or additional treatments if the seborrheic keratosis is thicker
    - Possible complications include scarring, hypopigmentation, recurrence.
  - Curettage

  - Electrodessication
  - Shave excision
  - Excisional biopsy
  - Chemical peel
- Use of following laser treatments have been reported:
  - Ablative CO_2
  - Ablative erbium-YAG
  - Argon
  - 492 nm
  - 510 nm
  - Alexandrite lasers
- No statistically significant differences were found in patient's ratings of cosmetic appearance between cryotherapy and curettage. The majority of patients preferred cryotherapy over curettage due to decreased postoperative wound care, despite the increased discomfort experienced and increased frequency of seborrheic keratosis remaining after cryotherapy when compared to curettage (7)[B].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

After initial diagnosis, follow-up is not usually required unless

- Inflammation or irritation develops.
- There is a change in appearance.
- New seborrheic keratoses suddenly appear.

PATIENT EDUCATION

- Sun-protective methods may help reduce seborrheic keratosis development.
- Patient education materials
  - http://www.aad.org/dermatology-a-to-z/diseases-and-treatments/q–t/seborrheic-keratoses
  - www.cdc.gov/cancer/skin/basic_info/prevention.htm

PROGNOSIS

- Seborrheic keratoses generally do not become malignant.
- Sign of Leser-Trélat usually represents a poor prognosis.

COMPLICATIONS

- Irritation and inflammation due to mechanical irritation (i.e., from clothing, jewelry)
- Possible complications of surgical treatment include hypopigmentation, hyperpigmentation, scarring, incomplete removal, and recurrence.
- Misdiagnosis (rare)

CODES

ICD10

- L82.1 Other seborrheic keratosis
- L82.0 Inflamed seborrheic keratosis

CLINICAL PEARLS

- Seborrheic keratoses are one of the most common benign tumors of the epidermis.

- Prevalence increases with age.
- Underlying internal malignancy should be considered if large numbers of seborrheic keratoses appear suddenly.

KNEE PAIN

Kimberly Sikule, MD • J. Herbert Stevenson, MD

BASICS

DESCRIPTION

A common outpatient complaint with a broad differential

- Knee pain may be acute, chronic, or an acute exacerbation of a chronic condition.
- Trauma, overuse, and degenerative change are frequent causes.
- A detailed history, including patient age, pain onset and location, mechanism of injury, and associated symptoms can help narrow the differential diagnosis.
- A thorough and focused examination of the knee (as well as the back, hips, and ankles) helps to establish the correct diagnosis and appropriate treatment.

EPIDEMIOLOGY

Incidence

- Knee pain accounts for 1.9 million primary care visits annually.
- The incidence of knee osteoarthritis is 240 cases/100,000 person/year.

Prevalence

- The knee is a common site of lower extremity injury.
  - Patellar tendinopathy and patellofemoral syndrome are the most common causes of knee pain in runners (1).
- Osteoarthritis (OA) of the hip/knee is 11th cause of global disability and 38th most common cause of disability-adjusted life years (DALYS)

ETIOLOGY AND PATHOPHYSIOLOGY

- Trauma (ligament or meniscal injury, fracture, dislocation)
- Overuse (tendinopathy, patellofemoral syndrome, bursitis, apophysitis)
- Age (arthritis, degenerative conditions in older patients; apophysitis in younger patients)
- Rheumatologic (rheumatoid arthritis [RA], gout, pseudogout)
- Infectious (bacterial, postviral, Lyme disease)

- Referred pain (hip, back)
- Vascular: popliteal artery aneurysm, deep vein thrombosis
- Others: tumor, cyst, plica

RISK FACTORS

- Obesity
- Malalignment
- Poor flexibility, muscle imbalance, or weakness
- Rapid increases in training frequency and intensity
- Improper footwear, training surfaces, technique
- Activities that involve cutting, jumping, pivoting, deceleration, kneeling
- Previous injuries

GENERAL PREVENTION

- Maintain normal body mass index.
- Proper exercise technique, volume, and equipment; avoid overtraining.
- Correct postural strength and flexibility imbalances.

COMMONLY ASSOCIATED CONDITIONS

- Fracture, contusion
- Effusion, hemarthrosis
- Patellar dislocation/subluxation
- Meniscal or ligamentous injury
- Tendinopathy, bursitis
- Osteochondral injury
- OA, septic arthritis
- Muscle strain

DIAGNOSIS

HISTORY

- Pain location, quality and mechanism of injury guide diagnostic reasoning (also see Differential Diagnosis):
  - Diffuse pain: OA, patellofemoral pain syndrome, chondromalacia
  - Pain ascending/descending stairs: meniscal injury, patellofemoral pain

syndrome
  - Pain with prolonged sitting, standing from sitting: patellofemoral pain syndrome
  - Mechanical symptoms (locking): meniscal injury
- Mechanism of injury:
  - Hyperextension, deceleration, cutting: anterior cruciate ligament (ACL) injury
  - Hyperflexion, fall on flexed knee, “dashboard injury”: posterior cruciate ligament (PCL) injury
  - Lateral force (valgus load): medial collateral injury
  - Twisting on planted foot: meniscal injury
- Effusion:
  - Rapid onset (2 hours): ACL tear, patellar subluxation, tibial plateau fracture. Hemarthrosis is common.
  - Slower onset (24 to 36 hours), smaller: meniscal injury, ligament sprain
  - Swelling behind the knee: popliteal cyst. Prepatellar: bursitis.

PHYSICAL EXAM

- Observe gait (antalgia), patellar tracking.
- Inspect for malalignment, atrophy, swelling, ecchymosis, or erythema.
- Palpate for effusion, warmth, and tenderness.
- Evaluate active and passive range of motion (ROM) and flexibility of quadriceps and hamstrings.
- Evaluate strength and muscle tone.
- Note joint instability, locking, and catching.
- Evaluate hip ROM, strength, and stability.
- Special tests:
  - Patellar apprehension test: patellar instability. Patellar grind test: patellofemoral pain or OA (1)
  - Lachman test (more sensitive and specific), pivot shift, anterior drawer: ACL integrity
  - Posterior drawer, posterior sag sign: PCL integrity
  - Valgus/varus stress test: medial/lateral collateral ligament (MCL/LCL) integrity
  - McMurray test, Apley grind, Thessaly test: meniscal injury

- Ober test: iliotibial band (ITB) tightness
- Dial test: positive with posterolateral corner laxity
- Patellar tilt test and squatting may help suggest patellofemoral pain syndrome, but there is not yet one definitive test.
- Patella facet tenderness suggests OA or patellofemoral pain syndrome (1) [A].

DIFFERENTIAL DIAGNOSIS

- Acute onset: fracture, contusion, cruciate or collateral ligament tear, meniscal tear, patellar dislocation/subluxation. If systemic symptoms: septic arthritis, gout, pseudogout, Lyme disease, osteomyelitis.
- Insidious onset: patellofemoral pain syndrome/chondromalacia, ITB syndrome, OA, RA, bursitis, tumor, tendinopathy, loose body, bipartite patella, degenerative meniscal tear
- Anterior pain: patellofemoral pain syndrome, patellar injury, patellar tendinopathy, pre- or suprapatellar bursitis, tibial apophysitis, fat pad impingement, quadriceps tendinopathy, OA (1)
- Posterior pain: PCL injury, posterior horn meniscal injury, popliteal cyst or aneurysm, hamstring or gastrocnemius injury, deep venous thrombosis (DVT)
- Medial pain: MCL injury, medial meniscal injury, pes anserine bursitis, medial plica syndrome, OA
- Lateral pain: LCL injury, lateral meniscal injury, ITB syndrome, OA

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Suspected septic joint, gout, pseudogout:
  - Arthrocentesis with cell count, Gram stain, culture, protein/glucose, synovial fluid analysis
- Suspected RA:
  - CBC, erythrocyte sedimentation rate (ESR), rheumatoid factor
- Consider Lyme titer.
- Radiographs to rule out fracture in patients with acute knee trauma (Ottawa rules):
  - Age >55 years *or*
  - Tenderness at the patella or fibular head *or*

  - Inability to bear weight 4 steps *or*
  - Inability to flex knee to 90 degrees
- Radiographs help diagnose OA, osteochondral lesions, patellofemoral pain syndrome:
  - Weight bearing, upright anteroposterior, lateral, merchant/sunrise, notch/tunnel views

Follow-Up Tests & Special Considerations

- MRI is a "gold standard" for soft tissue imaging.
- Ultrasound may help diagnose tendinopathy (2)[B].
- CT can further elucidate fracture.

Diagnostic Procedures/Other

Arthroscopy may be beneficial in the diagnosis of certain conditions, including meniscus and ligament injuries.

Geriatric Considerations

OA, degenerative meniscal tears, and gout are more common in middle-aged and elderly populations.

Pediatric Considerations

- 3 million pediatric sports injuries occur annually.
- Look for physeal/apophyseal and joint surface injuries in skeletally immature:
  - Acute: patellar subluxation, avulsion fractures, ACL tear
  - Overuse: patellofemoral pain syndrome, apophysitis, osteochondritis dissecans, patellar tendonitis, stress fracture
  - Others: neoplasm, juvenile RA, infection, referred pain from slipped capital femoral epiphysis

TREATMENT

GENERAL MEASURES

Acute injury: PRICEMM therapy (**p**rotection, **r**elative rest, **i**ce, **c**ompression, **e**levation, **m**edications, **m**odalities)

MEDICATION

First Line

- Oral medications:
  - Acetaminophen: up to 3 g/day. Safe and effective in OA.
  - Nonsteroidal anti-inflammatory drugs (NSAIDs):
    - Ibuprofen: 200 to 800 mg TID
    - Naproxen: 250 to 500 mg BID:
      - Useful for acute sprains, strains
      - Useful for short-term pain reduction in OA. Long-term use is not recommended due to side effects.
      - Not recommended for fracture, stress fracture, chronic muscle injury; may be associated with delayed healing; low dose and brief course only if necessary
  - Tramadol/opioids: not recommended as first-line treatment; can be used with acute injuries for severe pain
  - Celecoxib: 200 mg QD may be effective in OA with less GI side effects than NSAIDs (3)[A].
- Topical medications:
  - Topical NSAIDs may provide pain relief in OA and are more tolerable than oral medications.
  - Topical capsaicin may be an adjuvant for pain management in OA.
- Injections:
  - Intra-articular corticosteroid injection may provide short-term benefit in knee OA stage 2 or 3 (2)[A].
  - Viscosupplementation may reduce pain and improve function in patients with OA (2)[A]. Peak effectiveness is 5 to 13 weeks.
  - Equivocal evidence for platelet-rich plasma (PRP) compared to viscosupplementation
  - Stem cell therapy with insufficient data

ISSUES FOR REFERRAL

- Acute trauma, young athletic patient
- Joint instability
- Lack of improvement with conservative measures
- Salter-Harris physeal fractures (pediatrics)

ADDITIONAL THERAPIES

- Physical therapy is recommended as initial treatment for patellofemoral pain (4) and tendinopathies (2)[A].
- Muscle strengthening improves outcome in OA.
- Foot orthoses, taping, acupuncture
- May need bracing for stability (4)
- Botulinum toxin A for patellofemoral pain syndrome (5)[B]

SURGERY/OTHER PROCEDURES

- Surgery may be indicated for certain injuries (e.g., ACL tear in competitive athletes or Grade IV OA).
- Chronic conditions refractory to conservative therapy may require surgical intervention.

COMPLEMENTARY & ALTERNATIVE MEDICINE

May reduce pain and improve function in early OA:

- Glucosamine sulfate (500 mg TID)
- Chondroitin (400 mg TID)
- Turmeric or curcumin 1,000 mg/day (6)
- Collagen hydrolysates 10 g daily
- S-adenosylmethionine (SAMe), ginger extract, methylsulfonylmethane: less reliable improvement with inconsistent supporting evidence
- Acupuncture: need to do 4 weeks or 10 sessions

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Activity modification in overuse conditions
- Rehabilitative exercise in OA:
  - Low-impact exercise: walking, swimming, cycling
  - Strength, ROM, and proprioception training

Patient Monitoring

- Rehabilitation after initial treatment of acute injury
- In chronic and overuse conditions, assess functional status, rehabilitation

adherence, and pain control at follow-up visit.

DIET

Weight reduction by 10% improved function by 28%.

PATIENT EDUCATION

- Review activity modifications.
- Encourage active role in the rehabilitation process.
- Review medication risks and benefits.

PROGNOSIS

Varies with diagnosis, injury severity, chronicity of condition, patient motivation to participate in rehabilitation, and whether surgery is required

COMPLICATIONS

- Disability
- Arthritis
- Chronic joint instability
- Deconditioning

SEE ALSO

Algorithms: Knee Pain; Popliteal Mass

CODES

ICD10

- M25.569 Pain in unspecified knee
- M17.9 Osteoarthritis of knee, unspecified
- M76.50 Patellar tendinitis, unspecified knee

CLINICAL PEARLS

- A careful history (location/quality of pain and mechanism of injury) targets diagnosis for most causes of knee pain.
- Consider ligamentous injury, meniscal tear, and fracture for patients presenting with acute knee pain.
- Consider OA, patellofemoral pain syndrome, tendinopathy, bursitis, and stress

fracture in patients presenting with more chronic symptoms.

- Consider physeal, apophyseal, or articular cartilage injury in young patients presenting with knee pain.
- The presence of an effusion in a patient <30 years of age indicates a significant injury.
- Referred pain from the hip (slipped capital femoral epiphysis, Legg-Calvé-Perthes disease) can present as knee pain.

LABYRINTHITIS

Mary S. Lindholm, MD

BASICS

DESCRIPTION

- The sudden and persistent onset of vertigo, often accompanied by hearing loss, caused by acute inflammation or infection of the labyrinth
- Labyrinthitis is a clinical diagnosis in absence of neurologic deficits.
- Typically presents with false sense of motion or room-spinning vertigo lasting for hours or days and often sudden unilateral hearing loss
- Often associated with vestibular hypofunction of the involved ear. Peripheral vertigo improves over time with central compensation.
- System(s) affected: nervous, special sensory (auditory and vestibular)
- Synonym(s): acute peripheral vestibulopathy; vestibular neuronitis (vertigo/dizziness only); vestibular neuritis (vertigo/dizziness only)

ALERT

- "Vertigo" and "dizziness" are commonly used terms. Clarify symptoms by giving options of alternative descriptions such as light-headedness, disequilibrium, room-spinning vertigo, or imbalance.
- Hearing loss and duration of symptoms can help narrow the differential diagnosis in patients with vertigo.
- Benign paroxysmal positional vertigo (BPPV) is the most common cause of vertigo. Unlike labyrinthitis, BPPV is episodic, with severe symptoms lasting <1 minute. BPPV is diagnosed using the Dix-Hallpike maneuver. Unlike labyrinthitis, it is not associated with hearing loss.
- Ménière disease presents with the classic triad of episodic vertigo, tinnitus, and sensorineural hearing loss that is often fluctuant (1)[C].

Geriatric Considerations

- Elderly are less likely to compensate fully and may report symptoms of disequilibrium lasting weeks to months after resolution of the acute vertigo.
- Avoid excessive use of scopolamine, meclizine, and other vestibular

suppressants following the initial event, as this will delay central compensation.
- Benzodiazepines are preferred vestibular suppressant treatment but do increase the risk of falls in older persons.

Pediatric Considerations

Less common in children, incidence of vestibular vertigo in 10-year-olds estimated to be 5.7% (2)[C].

EPIDEMIOLOGY

- 10% of all patients seen for dizziness
- Most common in 30 to 50 years of age (3)
- Predominant sex: female = male

Incidence

- Viral labyrinthitis is the most common etiology.
- Suppurative or serous labyrinthitis secondary to otitis media is increasingly rare.

Prevalence

In the United States, second most common cause of dizziness due to persistent peripheral vestibular hypofunction (9%); benign positional vertigo (40%) is most common. More than 1/3 of adults see a health care provider for vertigo in their lifetimes (4).

ETIOLOGY AND PATHOPHYSIOLOGY

- Acute inflammation or damage to the inner ear, involving both branches of the vestibulocochlear nerve
- Viruses pass via hematogenous spread into the labyrinth or directly from the middle ear to labyrinth via the round/oval window.
- Bacterial toxins and host inflammatory mediators from a middle ear infection may reach the inner ear.
- Ischemia: Ischemic or thromboembolic events involving the labyrinthine artery can cause symptoms that mimic acute labyrinthitis; often presents with associated neurologic symptoms
- Autoimmune: Local or systemic inflammatory processes may affect the inner

ear via autoantibodies vasculitis of the labyrinthine artery.
  - Wegener granulomatosis, Cogan syndrome, systemic lupus erythematosus, polyarteritis nodosa, Behçet disease
- Infections
  - Common viral: cytomegalovirus, mumps, varicella zoster, rubeola, influenza, parainfluenza, herpes simplex, adenovirus, coxsackievirus, respiratory syncytial virus, HIV
  - Common bacterial: *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Moraxella catarrhalis*, *Neisseria meningitidis*, *Streptococcus* spp., *Staphylococcus* spp., *Borrelia burgdorferi*
  - Treponemal: *Treponema pallidum*
- Ototoxic drugs (e.g., aspirin, aminoglycosides, loop diuretics, cisplatin)

Genetics

No known genetic link

RISK FACTORS

- Viral upper respiratory infection
- Otitis media
- Vestibulotoxic/ototoxic medications
- Head trauma
- History of allergies
- Meningitis
- Cerebrovascular disease
- Other risk factors include autoimmune disease, herpes zoster infection, excessive alcohol consumption, and smoking.

GENERAL PREVENTION

- Scheduled immunizations (to prevent common viral pathogens)
- Prevent maternal transmission of pathogens, including syphilis and HIV.

COMMONLY ASSOCIATED CONDITIONS

- Viral upper respiratory infection
- Allergies
- Otitis media
- Cholesteatoma

- Head injury

DIAGNOSIS

HISTORY

- Vertigo *AND* (often) hearing loss in one ear
- Vertigo is acute in onset and lasts days to weeks.
- Nausea and vomiting are common.
- Fullness of affected ear
- Tinnitus of affected ear (roaring, ringing)
- Upper respiratory tract infection symptoms
- Otorrhea or otalgia (not common with viral causes)
- Severe headache, fever, and nuchal rigidity in the setting of meningitis
- Recurrent symptoms should raise suspicion for autoimmune causes.
- Profound imbalance or associated focal neurologic signs are not typical and should prompt imaging.

PHYSICAL EXAM

- Nystagmus
  - Fast-beating nystagmus toward affected ear (acutely)
  - Fast-beating nystagmus away from affected ear (chronically)
- Symptoms abate in supine position and with eyes closed or with visual fixation.
- Otologic exam may be unremarkable in the setting of viral labyrinthitis.
- Serous/purulent effusion may be present in the middle ear.
- Retraction of the tympanic membrane and keratinaceous debris may be present with cholesteatoma.

DIFFERENTIAL DIAGNOSIS

- Vestibular neuritis/neuronitis (vertigo without hearing loss)
- BPPV: episodic, vertigo lasting seconds/minutes, worse when lying down or looking up
- Ménière disease: episodic vertigo lasting minutes to hours, associated with the triad of episodic vertigo, tinnitus, and hearing loss

- Vestibular migraine
- Autoimmune inner ear disease
- Postconcussive syndrome
- Acute otitis media
- Ototoxicity
- Cardiovascular accident (CVA)/brainstem infarct
- Cerebellopontine-angle tumors (e.g., vestibular schwannoma)
- Less common etiologies: parainfectious encephalomyelitis or cranial polyneuritis, Ramsay Hunt syndrome, HIV infection, syphilis, temporal lobe epilepsy, perilymphatic fistula, superior canal dehiscence, idiopathic sudden single-sided deafness, multiple sclerosis, vasculitis (cerebral or systemic)

DIAGNOSTIC TESTS & INTERPRETATION

- Routine lab studies are not helpful in making the diagnosis unless an autoimmune cause is highly suspected.
- Consider culture of otorrhea or middle ear fluid to direct antibiotic choice.
- Consider lumbar puncture only if meningitis is suspected.
- Consider screening for syphilis or HIV when clinically indicated by risk factors or clinical history.
- Imaging is not required for the diagnosis of acute labyrinthitis.
- If associated neurologic symptoms or sensorineural hearing loss are present, an MRI and MR angiography of brain and brainstem are recommended.
- Vertigo usually spontaneously resolves, and there is a low risk of developing Ménière disease or migraines.

Follow-Up Tests & Special Considerations

Labyrinthitis ossificans is fibrosis of the internal auditory canal following bacterial meningitis and is thought to occur due to a suppurative labyrinthitis. This can occur rapidly, especially after *S. pneumoniae* meningitis.

Diagnostic Procedures/Other

- Audiogram should be obtained.
- Vestibular tests are not typically indicated in the acute setting. If vertigo and dizziness persist after expected resolution of symptoms, electronystagmography should be used.

Test Interpretation

- Audiogram may show varying degrees of both hearing loss and discrimination.
- Caloric testing may show relative weakness of the horizontal semicircular canal of the affected side. Sensitivity and specificity of this test are variable within literature.

TREATMENT

- Symptom management and reassurance
- Vestibular rehabilitation is the mainstay of treatment and has been shown to be safe and effective management for unilateral peripheral vestibular dysfunction (5)[A].
- Patients should begin exercises as soon as the acute phase resolves and movement is tolerable, generally within 2 to 3 days of onset.
- Vestibular suppressants as needed (see "Medication") for severe acute attacks of vertigo only. Patients should be advised *NOT* to use these medications as scheduled medications or for prophylaxis without symptoms.
- Sudden single-sided hearing loss (onset within 2 weeks) should be managed with high-dose oral steroids as soon as possible.
- Auricular acupuncture and Ginkgo biloba may be emerging adjunctive therapies to reduce vertiginous symptoms, although research is limited.
- For suppurative labyrinthitis, appropriate antibiotics to eradicate infection

GENERAL MEASURES

Vestibular exercises for prolonged symptoms and unilateral vestibular loss have been shown to alleviate postural control.

MEDICATION

Use of the following drugs should be on a PRN basis. Benzodiazepines can also assist with the anxiety associated with vertigo. No patient should take vestibular suppressants as a chronic medication, as they can block central compensation.

- Vestibular suppressants
  - Lorazepam (Ativan): 0.5 to 2 mg sublingual (SL)/PO BID PRN or diazepam (Valium) 2 to 5 mg QID PO PRN

  - Meclizine (Antivert, Bonine, Zentrip [dissolvable]) 12.5 to 25 mg PO BID–TID PRN
  - Dimenhydrinate (Dramamine) 25 to 50 mg PO q4–6h PRN
- Antiemetics
  - Ondansetron (Zofran) 4 to 8 mg PO TID PRN or granisetron (Kytril) 1 mg PO TID PRN
  - Meclizine (Antivert, Bonine) 12.5 to 25 mg PO q4h PRN
  - Promethazine (Phenergan) 12.5 to 25 mg PO/PR QID PRN or prochlorperazine (Compazine) 25 mg PR BID PRN
  - Metoclopramide (Reglan) 10 mg PO TID PRN
- Antivirals
  - Acyclovir 800 mg PO 5 times per day for 7 days can be used in cases associated with herpes.
- Steroids
  - Adults: methylprednisolone initially 100 mg PO daily and then tapered to 10 mg PO daily over 3 weeks
  - Pediatrics: prednisone 1 mg/kg PO daily 3 times per week and then taper over 3 weeks
  - Given early in the setting of bacterial meningitis, may decrease the otologic sequelae, specifically labyrinthitis ossificans
  - Used in treatment of labyrinthitis for associated sudden sensorineural hearing loss

Pregnancy Considerations

Dimenhydrinate, diphenhydramine, ondansetron, granisetron, and metoclopramide are pregnancy Category B.

First Line

- Benzodiazepines, which are better vestibular suppressants, are preferred over antihistamine/anticholinergics such as meclizine. Sublingual benzodiazepines are very effective for vertigo and should be considered first-line therapy.
- Urgent steroid treatment in acute setting

ISSUES FOR REFERRAL

- Consider neuro-otology referral for other peripheral causes of vertigo or

unremitting vertigo.
- Consider neurology referral for suspected central causes of vertigo or dizziness.
- Consider otolaryngology referral for progressive bilateral hearing loss and vertigo after preliminary laboratory workup excluding rheumatologic causes.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Patients with systemic infection, young age, or intractable vertigo with nausea and vomiting may need to be hospitalized for intravenous fluids and medications.
- Usually outpatient management

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Follow hearing loss weekly with audiograms until hearing stabilizes. Acute vertiginous symptoms may last up to 6 weeks. Residual symptoms have been documented to last months or years.

DIET

Avoid alcohol, as this may exacerbate symptoms.

PATIENT EDUCATION

Lie still with eyes closed in a darkened room during acute attacks. Otherwise, encourage activity as tolerated. Minimize rapid head movement until symptoms resolve.

PROGNOSIS

Prognosis depends on cause of labyrinthitis.

COMPLICATIONS

Permanent hearing loss, more common with bacterial causes, and chronic impairment of balance

SEE ALSO

Ménière Disease; Postconcussion Syndrome (Mild Traumatic Brain Injury); Tinnitus

CODES

ICD10

- H83.09 Labyrinthitis, unspecified ear
- H83.01 Labyrinthitis, right ear
- H83.02 Labyrinthitis, left ear

CLINICAL PEARLS

- Ask patients to describe symptoms in their own words; alternative symptoms include light-headedness, vertigo, disequilibrium, or imbalance.
- Benzodiazepines are better vestibular suppressants and are preferred over antihistamine/anticholinergics such as meclizine.
- Episodic vertigo tends to be caused by BPPV or Ménière disease, whereas persistent vertigo is more consistent with labyrinthitis.

LACTOSE INTOLERANCE

Nihal K. Patel, MD

BASICS

DESCRIPTION

- Inability to digest lactose into constituent components (glucose and galactose) due to low levels of lactase in the brush border of the small intestinal mucosa, causing bloating, borborygmi (audible stomach "rumblings"), abdominal pain, and diarrhea
  - Congenital lactose intolerance: very rare
  - Primary lactose intolerance: common in adults who develop low lactase levels after childhood
  - Secondary lactose intolerance: inability to digest lactose caused by any condition injuring the intestinal mucosa (e.g., infectious enteritis, celiac disease, eosinophilic gastroenteritis, or inflammatory bowel disease) or a reduction of available mucosal surface (e.g., resection)
- Lactase activity peaks at birth then decreases after the first few months of life, declining continuously during lifetime. 75% of adults' worldwide exhibit decline in lactase activity. *However, only 50% of lactase activity is needed to digest lactose without causing symptoms of lactose intolerance*.
- Lactose malabsorption also results from reduction of lactase activity. It is asymptomatic, and is as common in healthy patients as in those with functional bowel disorders.
- System(s) affected: endocrine/metabolic, gastrointestinal

Pediatric Considerations

- Primary lactose intolerance usually begins in late childhood.
- No consensus exists on whether young children (<5 years of age) should avoid lactose following diarrheal illness.
- Lactose-free formulas are available.
- Exclude milk protein allergy.

EPIDEMIOLOGY

Incidence

- ≥50% of infants with acute or chronic diarrheal disease have lactose intolerance. Particularly common with rotavirus infection.
- Lactose intolerance is common with giardiasis, ascariasis, irritable bowel syndrome (IBS), tropical and nontropical sprue, and the AIDS malabsorptive syndrome.

Prevalence

- In South America, Africa, and Asia, rates of lactose intolerance are >50%.
- In the United States, the prevalence is 15% among whites, 53% among Hispanic Americans, and 80% among African Americans.
- In Europe, lactose intolerance varies from 15% in Scandinavian countries to 70% in Italy.
- Predominant age:
  - Primary: teenage and adult
  - Secondary: depends on underlying condition
- Predominant sex: male = female

ETIOLOGY AND PATHOPHYSIOLOGY

- Primary lactose intolerance: Normal decline in the lactase activity in the intestinal mucosa is genetically controlled and permanent after weaning from breastmilk.
- Secondary lactose intolerance: associated with gastroenteritis in children and with nontropical and tropical sprue, regional enteritis, abetalipoproteinemia, cystic fibrosis, inflammatory bowel disease, celiac disease, and immunoglobulin deficiencies in both adults and children

Genetics

- In Caucasians, lactase deficiency has been associated with a single nucleotide polymorphism (SNP) consisting of a nucleotide switch of T for C 13.910.bp on chromosome 2. This results in variants of CC-13910 (lactase nonpersistence) *OR* CT-13910/TT-13910 (lactase persistence) (1).
- SNP (C/T-13910) is associated with lactase persistence in northern Europeans.
- Other SNPs (G/C-14010, T/G-13915, and C/G-13907) have been linked to lactase persistence in Africans.

RISK FACTORS

- Adult-onset lactase deficiency has wide geographic variation.
- Age:
  - Signs and symptoms usually do not become apparent until after age 6 to 7 years.
  - Symptoms may not be apparent until adulthood, depending on dietary lactose intake and rate of decline of intestinal lactase activity.
  - Lactase activity correlates with age, regardless of symptoms.

GENERAL PREVENTION

Lactose avoidance relieves symptoms. Patients can learn what level of lactose is tolerable in their diet.

COMMONLY ASSOCIATED CONDITIONS

- Tropical or nontropical sprue
- Giardiasis
- Inflammatory bowel disease
- Immunoglobulin deficiencies
- Celiac disease
- Cystic fibrosis

DIAGNOSIS

- Lactose intolerance is defined by a positive lactose hydrogen breath test result plus accompanying clinical symptoms.
- Lactose intolerance can mimic symptoms of functional gastrointestinal disorders. Lactose intolerance can also be a coexisting condition.

HISTORY

- Assess patient's daily lactose consumption. A single dose of lactose (12 g, equivalent to 1 cup of milk) consumed alone produces no or minor symptoms in persons with lactose intolerance or maldigestion.
- Lactose doses of 15 to 18 g are well tolerated with other nutrients. Doses >18 g cause progressively more symptoms, and quantities >50 g elicit symptoms in most individuals.

- Symptoms may arise 30 minutes to 2 hours after consumption of lactose-containing products.
- Symptoms include bloating, cramping, abdominal discomfort, vomiting diarrhea or loose stools, and flatulence.
- Symptoms tend to appear 30 minutes to 2 hours after eating.
- Abdominal pain may be crampy in nature and often is localized to the periumbilical area or lower quadrant.
- Stools usually are bulky, frothy, and watery
- Only 1/3 to 1/5 of individuals with lactose malabsorption develop symptoms.

PHYSICAL EXAM

Borborygmi may be audible on physical examination and to the patient. The exam is otherwise typically nonspecific.

DIFFERENTIAL DIAGNOSIS

- Sucrase deficiency
- Cow's milk protein allergy
- IBS
- Bacterial overgrowth
- Celiac disease
- Inflammatory bowel disease

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- The lactose breath hydrogen test (LBT) is the best diagnostic test for lactose intolerance. It is noninvasive, easy to perform, and cost effective. It is limited by suboptimal sensitivity (2)[B]. Intestinal bacteria digest carbohydrates and produce hydrogen and methane that are measurable in expired air:
  - Oral lactose is administered in the fasting state, (2 g/kg; max dose 25 g). Breath hydrogen is sampled at baseline and at 30-minute intervals for 3 hours. The postlactose and baseline values are compared. A breath hydrogen value of 10 ppm is normal. Values between 10 and 20 ppm may be indeterminate unless accompanied by symptoms; values >20 ppm are considered diagnostic of lactose malabsorption.
- The biochemical assay of lactase activity on duodenal sampling is as sensitive

as LBT in detecting lactase deficiency. It is more accurate than LBT in predicting the clinical response to a lactose-free diet. Cost and invasiveness limit clinical utility

- For patients with symptoms of lactose intolerance who are undergoing endoscopy for other reasons, a biochemical assay on duodenal biopsies can rule out lactose malabsorption.
- A positive LBT confirms lactose malabsorption but does not define the etiology.

Diagnostic Procedures/Other

Lactose absorption test is an alternative to LBT in adults (more invasive and equivalent in sensitivity and specificity to breath test). Following oral administration of a 50-g test dose in adults (2 g/kg in children), blood glucose levels are monitored at 0, 60, and 120 minutes. An increase in blood glucose of <20 mg/dL (1.1 mmol/L) with the concurrent development of symptoms is diagnostic. False-negative results may occur in patients with diabetes or bacterial overgrowth.

Test Interpretation

Lactase deficiency in intestinal mucosa may be patchy or focal.

TREATMENT

There is insufficient evidence on treatments (including probiotics, colonic adaptation, and other supplements) to recommend any as definitive first-line.

- Treatment of lactose malabsorption in the absence of a correctable underlying disease includes four general principles (3)[B].
  - Patients should avoid milk and dairy products in order to improve symptoms.
  - Up to 12 to 15 g of lactose can be tolerated in patients with lactose intolerance without significant symptoms (1 cup of milk).
  - Lactose should be gradually reintroduced along with other nutrients until the patient’s threshold for symptoms is reached. Spreading lactose servings throughout the day instead of a single dose has been shown to improve tolerance.

  - If symptoms persist, patients can substitute fermented and matured milk products for lactose.
- Certain strains, concentrations, and preparations of probiotics may alleviate symptoms.
- Incrementally increasing doses of lactose to induce colonic adaptation have met with limited success.
- To date, insufficient scientific evidence exists to strongly recommend lactose-reduced or hydrolyzed milk, lactase supplements taken with milk, probiotics, or colonic adaptation to treat lactose intolerance. Use of these supplements should be considered on a case-by-case fashion.
- Maintain calcium and vitamin D intake.

MEDICATION

First Line

Lactase (Lactaid, Lactrase):

- Commercially available “lactase” preparations are bacterial or yeast β-galactosidases.
- Take 1 to 2 capsules or tablets prior to ingesting milk products.
- Vary in effectiveness at preventing symptoms
- Can add tablets or contents of capsules to milk (1 to 2 caps/tabs per quart of milk) before drinking; also available in milk in some areas
- Not effective for all people with lactose intolerance
- High-quality, large, randomized controlled trials showing efficacy and safety are lacking.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Certain probiotic formulations taken with meals may alleviate some symptoms of lactose intolerance (4)[B].

ONGOING CARE

DIET

- Reduce or restrict dietary lactose to control symptoms. This is patient-specific and done as “trial-and-error.”

- Yogurt and fermented products such as hard cheese are often better tolerated than milk.
- Supplement calcium (e.g., calcium carbonate)
- Prehydrolyzed milk (Lactaid) is available.

PATIENT EDUCATION

- Patients must learn to read labels on commercial products because milk sugar is used in many products and may cause symptoms.
- Lactose-intolerant patients may tolerate whole milk or chocolate milk better than skim milk due to slower rate of gastric emptying.
- Lactose consumed with other food products is better tolerated than when consumed with milk alone.
- Primary lactase deficiency is permanent; secondary lactose intolerance usually is temporary, although it may persist for months after the inciting event.
- 20% of prescription drugs and 6% of over-the-counter (OTC) medicines use lactose as a base.
- Most patients can tolerate 12 to 15 g of lactose, despite lactose intolerance or malabsorption.

PROGNOSIS

- Normal life expectancy
- Symptoms can be controlled through diet alone if lactase tablets are ineffective.

COMPLICATIONS

Calcium deficiency: Avoidance of milk and other dairy products can lead to reduced calcium intake, which may increase the risk for osteoporosis and fracture.

CODES

ICD10

- E73.9 Lactose intolerance, unspecified
- E73.8 Other lactose intolerance
- E73.1 Secondary lactase deficiency

CLINICAL PEARLS

- The diagnosis of lactose intolerance is based on clinical history and typically confirmed by hydrogen breath testing.
- Most lactose intolerant patients can tolerate 12 to 15 g of lactose per day.

- Lactose-intolerant patients may tolerate yogurt and fermented products better than milk and cheese.
- A food diary helps identify problematic foods.
- Patients should read ingredient labels to look for milk, lactose, whey, and curd.
- Lactose-intolerant patients may tolerate whole milk or chocolate milk better than skim milk due to a slower rate of gastric emptying.
- Many patients with lactose intolerance unnecessarily avoid all dairy products, causing inadequate intake of calcium and vitamin D, which may predispose them to osteoporosis.

LARYNGITIS

Sheila O. Stille, DMD • Hugh Silk, MD, MPH, FAAFP

BASICS

DESCRIPTION

- Laryngitis is inflammation, erythema, and edema of the mucosa of the larynx and/or vocal cords characterized by hoarseness, loss of voice, throat pain, coughing, and often a negative impact on a person's quality of life and daily activities.
- There is a range of severity, but most cases are acute and are associated with viral upper respiratory infection, irritation, or acute vocal strain.
- System(s) affected: pulmonary; ears, nose, throat (ENT)
- Synonym(s): acute laryngitis; chronic laryngitis; croup or laryngotracheitis (in children)

EPIDEMIOLOGY

- Predominant age: affects all ages
- Children more susceptible than adults due to increased risk of symptomatic inflammation from smaller airways
- Predominant sex: male = female

Incidence

Common

Prevalence

Common

ETIOLOGY AND PATHOPHYSIOLOGY

- Misuse or abuse of voice
- Infectious
  - Viral: influenza A, B; parainfluenza; adenovirus; coronavirus; rhinovirus; human papillomavirus; cytomegalovirus; varicella-zoster virus; herpes simplex virus; respiratory syncytial virus; coxsackievirus
  - Fungal: uncommon but thought to be underdiagnosed, potentially

accounting for up to 10% of presentations in both immunocompromised and immunocompetent patients; risk factors include recent antibiotic or inhaled corticosteroid use (1): histoplasmosis, blastomycosis, *Coccidioides*, *Cryptococcus*, and *Candida*.
  - Bacterial: (uncommon): *β*-hemolytic streptococcus, *Streptococcus pneumoniae*, *Haemophilus influenzae*, tuberculosis (TB), leprosy, *Moraxella catarrhalis*, *Mycoplasma pneumoniae*, *Chlamydophila pneumoniae*
  - Secondary syphilis if left untreated
  - Leprosy (in 30–55% of those with leprosy, larynx is affected; tropical and warm countries)
- Irritants
  - Inhalation of irritating substances (e.g., air pollution, cigarette smoke)
  - Aspiration of caustic chemicals
  - Gastroesophageal reflux disease (GERD)/laryngopharyngeal reflux disease (LPRD)
  - Excessively dry environment
  - Allergy exposures (including pollens)
- Anatomic
  - Aging changes: muscle atrophy, loss of moisture in larynx, and bowing of vocal cords
  - Vocal cord nodules/polyps (“singer’s nodes”)
  - Local cancer
- Iatrogenic: inhaled steroids such as those used to treat asthma, surgical injury, endotracheal intubation injury
- Idiopathic
- Neuromuscular disorder (e.g., myasthenia gravis); stroke
- Rheumatoid arthritis
- Trauma (e.g., blunt or penetrating trauma to neck)

RISK FACTORS

- Acute:
  - Infection or trauma
  - Upper respiratory tract viral infection (e.g., influenza, rhinovirus, adenovirus, parainfluenza)

  - Voice overuse—excess talking, singing, or shouting
  - Pneumonia—viral or bacterial
  - Coughing
  - Lack of immunization for pertussis or diphtheria
  - Immunocompromised
  - Recent endotracheal intubation or local surgery
- Chronic (persists beyond 3 weeks):
  - Allergic laryngitis (2)
  - Chronic rhinitis/sinusitis
  - Voice abuse
  - GERD/LPRD (1)
  - Smoking: primary or secondhand
  - Excessive alcohol use
  - Autoimmune disorders (e.g., rheumatoid arthritis) (1,3)
  - Granulomatous diseases (e.g., sarcoidosis) (1)
  - Stroke
  - Environmental pollution; constant exposure to dust or other irritants such as chemicals at workplace
  - Medications: inhaled steroids, anticholinergics, antihistamines, anabolic steroids

Geriatric Considerations

May be more ill, slower to heal

Pediatric Considerations

- Common in this age group
- Consider congenital/anatomic causes.

GENERAL PREVENTION

- Avoid overuse of voice (voice training is helpful for vocal musicians/public speakers).
- Influenza virus vaccine is suggested.
- Quit smoking, and avoid secondhand smoke.
- Limit or avoid alcohol/caffeine/acidic foods.
- Control GERD/LPRD.

- Maintain proper hydration status.
- Avoid allergens.
- Wear mask around chemical/environmental irritants.
- Good hand washing (infection prevention)

COMMONLY ASSOCIATED CONDITIONS

- Viral pharyngitis
- Diphtheria (rare): Membrane can descend into the larynx.
- Pertussis: larynx involved as part of the respiratory system
- Bronchitis
- Pneumonitis
- Croup, epiglottitis, in children

DIAGNOSIS

HISTORY

- Hoarseness, throat “tickle,” dry cough, and rawness (4)
- Dysphonia (abnormal-sounding voice)
- Constant urge to clear the throat
- Possible fever
- Malaise
- Dysphagia/odynophagia
- Regional cervical lymphadenopathy
- Stridor or possible airway obstruction in children (1)
- Cough may be worse at night in children.
- Hemoptysis
- Laryngospasm or sense of choking
- Allergic rhinitis/rhinorrhea/postnasal drip (PND) (4)
- Occupation or other reasons for voice overuse
- Smoking history
- Blunt or penetrating trauma to neck
- GERD/LPRD

PHYSICAL EXAM

- Head and neck exam, including airway patency, cervical nodes; cranial nerve

exam
- Visualization of the larynx: preferably with a flexible or rigid endoscope or with an indirect mirror examination as a screening technique to dictate further appropriate testing (4)
- Note quality of voice (i.e., hoarse, breathy, wet, “hot potato like,” asthenic [weak], strained) (2).

DIFFERENTIAL DIAGNOSIS

- Diphtheria
- Vocal nodules or polyps
- Laryngeal malignancy
- Thyroid malignancy
- Upper airway malignancy (2,4)[A]
- Epiglottitis
- Pertussis
- Laryngeal nerve trauma/injury
- Foreign body (in children)
- Autoimmune (rheumatoid arthritis) (3)[A]

DIAGNOSTIC TESTS & INTERPRETATION

- Rarely needed
- WBCs elevated in bacterial laryngitis
- Viral culture (seldom necessary)

Follow-Up Tests & Special Considerations

- Barium swallow, only if needed for differential diagnosis
- CT scan if foreign body suspected

Diagnostic Procedures/Other

- Fiber-optic or indirect laryngoscopy: looking for red, inflamed, and occasionally hemorrhagic vocal cords; rounded edges and exudate (Reinke edema)
- Consider otolaryngologic evaluation and biopsy: laryngitis lasting >2 weeks in adults with history of smoking or alcohol abuse to rule out malignancy
- pH probe (24-hour): no difference in incidence of pharyngeal reflux as measured by pH probe between patients with chronic reflux laryngitis and

healthy adults (2)[A]
- Strobovideo laryngoscopy for diagnosis of subtle lesions (e.g., vocal cord nodules or polyps)(4)[A]

TREATMENT

- Limited but good evidence that treatment beyond supportive care is ineffective (4)[A]
- Supportive care consists of hydration, voice rest, humidification, and limitation of caffeine (1)[A].
- Antibiotics appear to have no benefit, as etiologies are predominantly viral (1,5)[A].
- Corticosteroids in severe cases of laryngitis to reduce inflammation such as croup
- May need voice training, if voice overuse
- Nebulized epinephrine reduces croup symptoms 30 minutes posttreatment; evidence does not favor racemic epinephrine or L-epinephrine or IPPB over simple nebulization. Racemic epinephrine reduces croup symptoms at 30 minutes, but effect lasts only 2 hours (5)[A].

GENERAL MEASURES

- Acute:
  - Usually a self-limited illness lasting <3 weeks and not severe
  - Antibiotics of no value (5)[A]
  - Avoid excessive voice use, including whispering.
  - Steam inhalations or cool-mist humidifier
  - Increase fluid intake, especially in cases associated with excessive dryness.
  - Avoid smoking (or secondhand exposure).
  - Warm saltwater gargles
- Chronic:
  - Symptomatic treatment as above
  - Voice therapy (for patients with intermittent dysphagia and vocal abuse)
  - Smoking cessation
  - Reduction or cessation of alcohol intake

  - Occupational change or modification, if exposure driven
  - Allergen avoidance
  - Consider discontinuing offending medication (e.g., inhaled steroids) (5)[A].
- Reflux laryngitis: Elevate head of bed, diet changes, other antireflux lifestyle change management; proton pump inhibitors (1)[A]

MEDICATION

Usually none

First Line

- Analgesics
- Antipyretics (rare)
- Cough suppressants
- Throat lozenges
- Plenty of fluids

Second Line

- Inhaled corticosteroids (consider only if allergy induced) (2)
- Oral corticosteroids: only if urgent need in adults (presenter, singer, actor)
- Oral corticosteroids: Evidence of benefit has been studied with single-dose dexamethasone in children ages 6 months to 5 years for moderate-severity croup; reduces symptoms within 6 hours; reduces hospitalizations, hospital length of stay, and revisits to office (5)[A]
- Standard of care is to prescribe proton pump inhibitors for chronic laryngitis if GERD or LPRD is suspected; however, evidence suggests only a modest benefit, if any (1)[A].
- Treat nonviral infectious underlying causes.
- Candidal laryngitis:
  - Mild cases: oral antifungal (fluconazole)
  - Amphotericin B or echinocandin can be given in life-threatening cases (1)[A].

ISSUES FOR REFERRAL

- Immediate emergency ENT referral for patients with stridor or respiratory distress (1)[A].
- ENT referral for persistent symptoms (>2 to 3 weeks) or concern for foreign

body

- Consider otolaryngologic evaluation and biopsy for laryngitis lasting >3 weeks in adults, especially in those with history of smoking or alcohol abuse to rule out malignancy.
- Consider GI consult to rule out GERD/LPRD.

SURGERY/OTHER PROCEDURES

- Vocal cord biopsy of hyperplastic mucosa and areas of leukoplakia if cancer or TB is suspected
- Removal of nodules or polyps if voice therapy fails

COMPLEMENTARY & ALTERNATIVE MEDICINE

The following, although not well studied, have been recommended by some experts:

- Barberry, black currant, *Echinacea*, *Eucalyptus*, German chamomile, goldenrod, goldenseal, warmed lemon and honey, licorice, marshmallow, peppermint, saw palmetto, slippery elm, vitamin C, zinc

ONGOING CARE

PATIENT EDUCATION

- Educate on the importance of voice rest, including whispering.
- Provide assistance with smoking cessation.
- Help the patient with modification of other predisposing habits or occupational hazards.

PROGNOSIS

Complete clearing of the inflammation without sequelae

COMPLICATIONS

Chronic hoarseness

CODES

ICD10

- J04.0 Acute laryngitis
- J37.0 Chronic laryngitis
- J04.2 Acute laryngotracheitis

CLINICAL PEARLS

- Laryngitis is usually self-limited and needs only comfort care. Standard treatment is voice rest, hydration, humidification, and limit caffeine intake.
- Refer to ENT for direct visualization of vocal cords for prolonged laryngitis.
- Corticosteroids have some benefits for children with moderately severe croup.
- Voice training useful for chronic laryngitis

LAXATIVE ABUSE

Matthew E. Bryant, MD

BASICS

DESCRIPTION

- A chronic watery diarrhea caused by intentional or unintentional misuse of laxatives due to self-medication or provider error
- System(s) affected: gastrointestinal, nervous, psychiatric, skin, and renal
- Synonym(s): factitious diarrhea; cathartic colon; as part of Münchausen syndrome (self or by proxy)—most dramatic form

EPIDEMIOLOGY

- Predominant age: 18 to 40 years associated with bulimia or anorexia nervosa
- Common in the elderly as a result of treatment for constipation, either by health care professional or self-directed (*unintentional*)
- Associated with athletes in sports with weight limits (wrestling)
- Predominant sex (*intentional abuse*): female (90%) > male
- More common in upper socioeconomic classes

Prevalence

Laxative abuse in different groups

- 0.7–5.5% in the general population
- As many as 15% undergoing evaluation for chronic diarrhea
- Unexplained chronic diarrhea after routine investigations: 4–7%
- Up to 70% of patients with binging/purging anorexia and bulimia nervosa abuse laxatives but rarely as the sole method of purging.
- Chronic use of constipating medications (opioids)

Pediatric Considerations

Children may be given excess laxatives by caregivers (Münchausen syndrome by proxy).

Geriatric Considerations

Elderly in nursing homes are at increased risk for laxative overuse (usually

inadvertent).

ETIOLOGY AND PATHOPHYSIOLOGY

- Four types of chronic diarrhea: secretory, osmotic, inflammatory, and fatty. Rule out other causes, laxative abuse is a diagnosis of exclusion (1).
- Chronic ingestion of any laxative agent
  - Stimulant (most common, rapid onset of action)
    - Diphenylmethane (Bisacodyl)
    - Anthraquinones (Senna, Cascara, Castor oil)
  - Saline and osmotic products (sodium phosphate, magnesium sulfate/citrate and hydroxide, lactulose, polyethylene glycol)
  - Bulking agents (psyllium)
  - Surfactants (docusate)
- Psychologic factors
  - Bulimia or anorexia nervosa (associated with behavioral pathology)
  - Secondary gain (attention-seeking): disability claims or need for concern, caring from others
  - Inappropriate perceptions of “normal” bowel habits

RISK FACTORS

In patients with eating disorders

- Longer duration of illness
- Comorbid psychiatric diagnoses (e.g., major depression, obsessive-compulsive disorder, posttraumatic stress disorder, anxiety, borderline personality disorder)
- Early age of eating disorder symptoms

GENERAL PREVENTION

- Educate patients about proper nutrition, normal bowel function, potential adverse effects of excessive laxative use, and medications (e.g., magnesium-containing antacids) that can cause diarrhea.
- Ask patients specifically about laxative use; inadvertent overuse is common.

COMMONLY ASSOCIATED CONDITIONS

- Anorexia nervosa, bulimia nervosa
- Use of constipating medications (opioids, iron supplements).

- Any chronic disorder associated with constipation
- Depression and anxiety
- Borderline personality
- Self-injurious behaviors/suicidal ideation
- Impulsive behavior
- Münchausen syndrome/Münchausen syndrome by proxy (children) may have associated factitious symptoms involving diverse organ systems.
- Fictitious disorders
- Patient is dependent on a caregiver.

DIAGNOSIS

HISTORY

- Suspect in patients with undiagnosed, refractory chronic diarrhea.
- Assess over-the-counter medication use, and take thorough dietary history (2).
- Signs and symptoms: increasing frequency of bowel movements; large volume, watery diarrhea; nocturnal bowel movements (typically absent in osmotic diarrhea or in irritable bowel syndrome) (2,3).
- Additional symptoms: abdominal pain, rectal pain, nausea, vomiting, weight loss, malaise, muscle weakness, or chronic constipation.
- Assess “doctor shopping” and potential factitious symptoms.

PHYSICAL EXAM

- No specific findings but may include cachexia, evidence of dehydration, abdominal pain or distension, and edema; fever may be due to self-infected wounds or thermometer manipulation (2).
- Bulimics or anorexics who purge may have Russell sign (excoriation of fingers from repeated self-induced retching) (4); clubbing, cyclic edema, skin pigmentation changes, parotid hypertrophy
- Rarely, severe cases may be associated with renal failure, cardiac arrhythmias, skeletal muscle paralysis, anemia from blood-letting or self-induced skin wounds.

DIFFERENTIAL DIAGNOSIS

Any etiology of chronic diarrhea, especially in high-risk groups

DIAGNOSTIC TESTS & INTERPRETATION

If patient has not had an initial workup for chronic diarrhea, rule out infectious, inflammatory, and malignant causes based on patient demographics and risk factors.

Initial Tests (lab, imaging)

- Serum electrolytes hypokalemia, hypernatremia, hyperphosphatemia
  - Acute diarrhea: metabolic acidosis (hypovolemia)
  - Chronic diarrhea: metabolic alkalosis secondary to hypokalemia-induced inhibition of chloride uptake with inhibited bicarbonate secretion
- CBC, stool cultures, *Clostridium difficile* polymerase chain reaction (PCR) to rule out infectious cause if history is suspicious (fecal leukocytes, ova and parasites (O&P)—check for giardia, isospora, and cryptosporidia specifically) (2,3).
- Colonoscopy, small-bowel endoscopy, or imaging studies are not usually necessary but help to evaluate other causes of chronic diarrhea (2).
- *Melanosis coli* on sigmoidoscopy or colonoscopy indicate overuse of anthracene laxatives.

Follow-Up Tests & Special Considerations

The following algorithm can be used to confirm diagnosis and determine what laxative is being used (1,5)[B].

- Collect 24-hour stool: If stool is solid, workup is over.
- Obtain stool osmolality, stool electrolytes, and calculate osmolal gap [$-290 - 2(Na^+ + K^+)$], Na^+ and K^+ are stool concentrations.
  - If osmolality >400 mOsm/kg, rule out urine contamination of stool. Measure urea and creatinine of sample.
  - If osmolality <250 to 400 mOsm/kg, rule out water added to stool (colon cannot dilute stool to osmolality of plasma).
  - If osmolality = 250 to 400 mOsm/kg, measure osmolal gap.
    - Gap >50: unmeasured solute; check fecal fat and stool magnesium levels.
    - Gap <50: Rule out use of secretory laxative; urinalysis and stool analysis for laxative titers. Do not obtain serum laxative titers, as they peak 1 to 2 hours after ingestion. Urine titers can be 10 times as high as plasma titers.
- Confirm diagnosis with multiple stool analyses before addressing patient with

concern for intentional abuse.

TREATMENT

GENERAL MEASURES

- Behavioral support is essential in intentional use.
- Wean patient off laxatives and supplements; substitute high-fiber diet and bulk preparations or short-term saline enemas
- Treat secondary constipation (3)[C].
- Treat metabolic abnormalities.

MEDICATION

Replace needed fluid, vitamins, electrolytes, and minerals.

First Line

- Patient education on normal bowel habits
- Nonstimulant laxatives (if needed) to treat constipation (3)[C]
  - Polyethylene glycol (3)[C]
  - Lactulose (3)[C]
  - High-fiber diet
- Precautions: Patients may be manipulative to deny problem; may hide laxatives in hospital rooms.
- Significant possible interactions
  - Increased rate of intestinal motility may affect rate of absorption of medications (e.g., antibiotics, hormones).
  - Docusate sodium may potentiate hepatotoxicity of other drugs.
  - Consider loperamide to improve anal tone and promote rectal inhibitory reflex (6)[C].

ISSUES FOR REFERRAL

In cases of Münchausen syndrome by proxy, legal proceedings must be considered, because most victims are children. Behavioral health support for patients with significant psychological comorbidities

SURGERY/OTHER PROCEDURES

Avoid exploratory surgery and repetitive evaluations or invasive procedures.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Admission criteria/initial stabilization
  - Persistent diarrhea with hemodynamic instability
  - Electrolyte/metabolic complications, including lactic acidosis
  - Cardiac arrhythmias
- Resuscitate based on clinical presentation. If patient is hemodynamically stable and without significant abnormalities in serum sodium, give normal saline boluses or oral replacement to correct metabolic alkalosis (chronic) or acidosis (acute) as needed. If patient is hemodynamically unstable, treat volume status as in hypovolemic shock, while monitoring serum electrolytes closely (especially sodium, potassium, and bicarbonate (6,7)[C].
- If stable, patient does not need continuous telemetry. Depending on psychiatric history, patient may need one-on-one or line-of-sight observation. Special care must be taken to ensure adequate nutrition and control access to laxatives. If surreptitious laxative ingestion is suspected, do not perform unauthorized room searches due to legal constraints.
- Discharge criteria
  - Psychological evaluation, support, and follow-up
  - Diet and bowel programs
  - Resolution of electrolyte abnormalities/dehydration

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Ongoing behavioral counseling
- Careful medical support; frequent visits as needed
- Assess serum electrolytes.

DIET

Ensure good nutritional habits.

- Increase fiber intake.
- Avoid constipating substances.

- Adequate calories, especially with bulimia

PROGNOSIS

- Natural history is unclear and varied depending on underlying cause.
- Prognosis is related to underlying behavioral disorders in intentional abuse or underlying organic disease (if present).
- Prognosis is poor with anorexia nervosa; very poor in Münchausen syndrome.
- Cathartic colon is commonly refractory to treatment (7)[C].

COMPLICATIONS

- Risk of multiple tests, procedures, and surgeries (intentional use)
- Malnutrition
- Electrolyte imbalances (hypokalemia, hypermagnesemia, phosphate nephropathy) (3)
- Renal failure
- Cardiac arrhythmias/sudden death (3)
- Renal calculi
- Cathartic colon with constipation as a consequence of prolonged irritant laxative use (7)
- Fecal impaction in elderly
- Recurrences are common for factitious abuse, even after confrontation.
- Rebound edema (7)

Algorithm: Diarrhea, Chronic

CODES

ICD10

F55.2 Abuse of laxatives

CLINICAL PEARLS

- Laxative abuse may be intentional or unintentional.
- When associated with eating disorders, laxative abuse is associated with more

severe disease.

- Consider laxative abuse in patients with watery diarrhea, especially if unexplained or refractory.
- As many as 15% of patients referred to tertiary care centers for unexplained chronic diarrhea abuse laxatives.
- Presentation is diverse and nonspecific including weight loss, weakness, and hypotension.
- Patients often won’t acknowledge diarrhea if laxative abuse is intentional.

LEAD POISONING

Jason Chao, MD, MS

BASICS

DESCRIPTION

- Consequence of a high body burden of lead (Pb), an element with no known physiologic value
- Synonym(s): lead poisoning, inorganic

EPIDEMIOLOGY

- Predominant age: 1 to 5 years, adult workers
- Predominant sex: male > female (1:1 in childhood)

Prevalence

- Centers for Disease Control and Prevention (CDC) estimates half a million U.S. children aged 1 to 5 years have blood Pb levels >5 μg/dL, but levels are variable among communities and populations.
- Case prevalence rate blood Pb level ≥10 μg/dL is 22.5 per 100,000 employed adults, CDC 2012 data

ETIOLOGY AND PATHOPHYSIOLOGY

- Inhalation of Pb dust or fumes, or ingestion of Pb
- Pb replaces calcium in bones. Pb interferes with heme synthesis, causes interstitial nephritis, and interferes with neurotransmitters, especially glutamine; high levels affect blood–brain barrier and lead to encephalopathy, seizures, and coma.
- Early life Pb exposure causes methylation changes leading to epigenetic alterations that may lead to brain dysfunction.

RISK FACTORS

- Children with pica or with iron-deficiency anemia
- Residence in or frequent visitor to deteriorating pre-1960 housing with Pb-painted surfaces or recent renovation
- Soil/dust exposure near older homes, Pb industries, or urban roads

- Sibling or playmate with current or past Pb poisoning
- Dust from clothing of Pb worker or hobbyist
- Pb dissolved in water from Pb or Pb-soldered plumbing (Example: Flint Michigan 2014 to 2015)
- Pb-glazed ceramics especially with acidic food or drink
- Recent refugee
- Folk remedies and cosmetics
  - Mexico: Azarcon, Greta
  - Dominican Republic: Litargirio, a topical agent
  - Asia and Middle East: Chuifong tokuwan, pay-loo-ah, ghasard, bali goli, kandu, ayurvedic herbal medicine from South Asia, kohl (alkohl, ceruse), surma, saoott, cebagin
- Hobbies: glazed pottery making, target shooting, Pb soldering, preparing Pb shot or fishing sinkers, stained-glass making, car or boat repair, home remodeling
- Occupational exposure: plumbers, pipe fitters, Pb miners, auto repairers, glass manufacturers, shipbuilders, printer operators, plastic manufacturers, Pb smelters and refiners, steel welders or cutters, construction workers, rubber product manufacturers, battery manufacturers, bridge reconstruction workers
- Dietary: zinc or calcium deficiency
- Imported toys with Pb

Pediatric Considerations

- Children are at increased risk because of incomplete development of the blood–brain barrier at <3 years of age, allowing more Pb into the CNS; ingested Pb has 40% bioavailability in children compared with 10% in adults.
- Common childhood behaviors such as frequent hand-to-mouth activity and pica (repeated ingestion of nonfood products) greatly increase the risk of ingesting Pb.

GENERAL PREVENTION

- Family should receive counseling on potential sources of Pb and methods to decrease Pb exposure. Children at high risk should receive blood Pb screening (1)[C].
- Warn parents about the dangers posed by unsafe renovation methods.

- Wet mopping and dusting with a high-phosphate solution (e.g., powdered automatic dishwasher detergent with 1/4 cup/gallon of water) will help to control Pb-bearing dust. But high-phosphate detergent is no longer available in some states.
- If tap water is potentially Pb contaminated: use cold water, not hot; and run for 30 to 60 seconds first to flush pipes; or use Pb-free water source.
- Pregnant women with community-specific or any individual risk factor for Pb poisoning should be screened for Pb toxicity (2)[C].

COMMONLY ASSOCIATED CONDITIONS

Iron-deficiency anemia

DIAGNOSIS

HISTORY

- Often asymptomatic
- Mild-to-moderate toxicity
  - May cause myalgia or paresthesia, fatigue, irritability, lethargy
  - Abdominal discomfort, arthralgia, difficulty concentrating, headache, tremor, vomiting, weight loss, muscular exhaustibility
- Severe toxicity: three major clinical syndromes:
  - Alimentary type: anorexia, metallic taste, constipation, severe abdominal cramps due to intestinal spasm and sometimes associated with abdominal wall rigidity
  - Neuromuscular type (characteristic of adult plumbism): peripheral neuritis, usually painless and limited to extensor muscles
  - Cerebral type or Pb encephalopathy (more common in children): seizure, coma, and long-term sequelae, including neurologic defects, delayed mental development, and chronic hyperactivity
- Chronic exposure may cause renal failure.

PHYSICAL EXAM

Often normal, but abdominal tenderness may be severe. Neurologic exam may reveal neuropathy or encephalopathy.

DIFFERENTIAL DIAGNOSIS

- Alimentary type may be confused with acute abdomen.
- Neuromuscular type may be confused with other polyneuropathies.
- Cerebral type may be confused with ADD, mental retardation, autism, dementia, and other causes of seizures.
- Elevated erythrocyte protoporphyrin may be caused by iron-deficiency anemia or, less commonly, hemolytic anemia.
- Erythropoietic protoporphyria produces a very high erythrocyte protoporphyrin level.

DIAGNOSTIC TESTS & INTERPRETATION

- Venous blood Pb >5 μg/dL (0.24 μmol/L) collected with Pb-free container
- Use a laboratory that can achieve routine performance within 2 μg/dL.
- In 2012, CDC recommended using a reference value as the basis for management, currently >5 μg/dL
- Screening capillary Pb levels >5 μg/dL (0.24 μmol/L) should be confirmed with a venous sample.
- Hemoglobin and hematocrit slightly low; eosinophilia or basophilic stippling on peripheral smear may be seen but is not diagnostic of Pb toxicity.
- Renal function is decreased in late stages.
- Abdominal radiograph for Pb particles in gut if recent ingestion is suspected
- Radiograph of long bones may show lines of increased density in the metaphyseal plate resulting from growth arrest but does not usually alter management and is not routinely recommended.
- X-ray fluorescence for the total body burden of Pb is experimental.

TREATMENT

Blood level (μg/dL)	Time to confirmation testing
≥ref value–9	1–3 months
10–44	1 week–1 month
45–59	48 hours
60–69	24 hours
≥70	Urgently as emergency test

ALERT

- For any blood Pb levels persistently >15 μg/dL, contact local public health department for home inspection.
- If Pb level is between 5 and 45 μg/dL, the higher the Pb level, the more urgent the need for confirmation testing.
- For all elevated levels: Educate family on sources of Pb.
- Pb level > ref level to <45: Complete history and physical exam, follow-up Pb monitoring; complete inspection of home or workplace to determine source of Pb and Pb-hazard reduction; neurodevelopmental monitoring: iron status, Hgb, or Hct (3)[C]
- Pb level 45 to 69: Actions for lower level plus free erythrocyte protoporphyrin, oral chelation therapy, or hospitalization if Pb-safe environment cannot be ensured (3)[C].
- Pb >70: Hospitalize for chelation therapy (4)[C].

MEDICATION

- Consider oral chelation for asymptomatic and Pb >45 and <70; chelation (preferably parenteral) for Pb >70 or symptomatic Pb <70 (4)[C].
- Do not begin chelation until Pb particles present in gut are cleared (5)[C].

First Line

- Oral chelation: Succimer (Chemet), dimercaptosuccinic acid (DMSA) 350 mg/m^2 or 10 mg/kg q8h for 5 days; then q12h for 2 weeks. This may be repeated after 2 weeks off if Pb levels are not stabilized at <15 μg/dL (<0.72 μmol/L) (4)[C].
- Parenteral chelation (begin after establishment of adequate urine output):
  - Dimercaprol (British anti-Lewisite [BAL]) 75 mg/m^2 given deep IM; then BAL 450 mg/m^2/day divided q4h for 5 days plus Ca edetate calcium disodium (EDTA) 1,500 mg/m^2/day continuous IV infusion for 5 days. If rebound Pb level ≥45 μg/dL (≥2.17 μmol/L), chelation may be repeated after 2-day interval if symptomatic or after 5-day interval if asymptomatic.
  - Ca EDTA 1,000 mg/m^2/day for 5 days; may be repeated after 5 to 7 days
- Diazepam for initial control of seizures; further control maintained with paraldehyde
- Contraindications: BAL should not be given to patients allergic to peanuts (the

drug solution contains peanut oil).

- Precautions
  - Succimer: GI upset, rash, nasal congestion, muscle pains, elevated liver function tests
  - BAL: nausea, vomiting, fever, headache, transient hypertension, hepatocellular damage
  - Ca EDTA: renal failure, increased excretion of zinc, copper, and iron
- Significant possible interactions
  - Vitamins should not be given concurrently with oral chelation.
  - BAL may precipitate hemolytic crisis in a patient with glucose-6-phosphate dehydrogenase deficiency.

Second Line

Oral chelation with penicillamine (D-penicillamine, Depen, Cuprimine) (5)[C]

- Penicillin-allergic patient should not receive penicillamine (cross-sensitivity is common).
- 10 to 15 mg/kg/day given BID mixed in apple juice/sauce on empty stomach (*not* FDA approved)
- Penicillamine may cause GI upset, renal failure, granulocytopenia, liver dysfunction, iron deficiency, and drug-induced lupus-like syndrome.

ISSUES FOR REFERRAL

Consider consultation if parenteral chelation is required.

ADDITIONAL THERAPIES

Remove patient from potential source of Pb if Pb level >45 until complete home inspection is performed.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Garlic has been used to treat mild to moderate Pb poisoning in adults (6)[B],

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Blood Pb level >70 μg/dL
- If symptomatic, blood Pb level >35 μg/dL
- Outpatient care unless parenteral chelation or immediate removal from

contaminated environment is required.
- If Pb source is in the home, the patient must reside elsewhere until the abatement process is completed.
- Avoid visit to any site of potential contamination.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- After chelation, check for rebound Pb level in 7 to 10 days. Follow with regular monitoring, initially biweekly or monthly.
- Correct iron deficiency or any other nutritional deficiencies present.
- Once Pb <35 μg/dL, repeat testing every 1 to 3 months until level <25 μg/dL is achieved. Then, monitor every 3 to 6 months until level <10 μg/dL. Once <9 μg/dL, test every 6 to 9 months (3)[C].

DIET

- If symptomatic, avoid excessive fluids.
- Avoid pica.
- Adequate calcium, iron, zinc, and vitamin C to reduce absorption and retention of Pb (7)[B]

PATIENT EDUCATION

- Needleman HL, Landrigan PJ. *Raising Children Toxic Free: How to Keep Your Child Safe From Lead, Asbestos, Pesticides, and Other Environmental Hazards*. New York, NY: Farrar, Straus and Giroux; 1995.
- National Lead Information Center, 422 South Clinton Avenue, Rochester, NY 14620; 800-424-5323; www.epa.gov/lead/

PROGNOSIS

- Symptomatic Pb poisoning without encephalopathy generally improves with chelation, but subtle CNS toxicity may be long lasting or permanent.

- If encephalopathy occurs, permanent sequelae (e.g., mental retardation, seizure disorder, blindness, and hemiparesis) occurs in 25–50%.

COMPLICATIONS

- CNS toxicity may be long lasting or permanent.
- Long-term Pb exposure may cause chronic renal failure (Fanconi-like syndrome), gout, or Pb line (blue–black) on gingival tissue.
- Pb exposure in pregnancy is associated with reduced birth weight and premature birth.
- Pb is an animal teratogen.

SEE ALSO

Anemia, Iron Deficiency

CODES

ICD10

- T56.0X4A Toxic effect of lead and its compounds, undetermined, init
- T56.0X1A Toxic effect of lead and its compounds, accidental, init

CLINICAL PEARLS

- The following children should have Pb screening:
  - 6 to 11 months of age with ≥1 risk factors:
    - Live in or visit a house built before 1960 with peeling paint or recent renovation
    - Sibling/playmate with elevated Pb
    - Live with adult with job or hobby involving Pb
    - Live near industry likely to release Pb
  - Children living in high-risk communities (>12% elevated Pb) should be tested yearly from ages 1 to 5 years.
  - Newly arrived refugees
  - Children in low-risk areas should be screened by a questionnaire containing the above risk factors.
- There is no clear safe Pb level. Many experts consider Pb levels >4 μg/dL as elevated.
- There are no studies that show benefit of chelation for asymptomatic children

with Pb <45. Removal of sources of Pb is paramount.

LEGIONNAIRES' DISEASE

Andrew G. Alexander, MD • Kenneth A. Ballou, MD

BASICS

DESCRIPTION

- *Legionnaires' disease* was named for an epidemic of lower respiratory tract disease at an American Legion convention in Philadelphia in 1976. The causative bacterium was previously unrecognized. It was isolated, identified, and named *Legionella pneumophila*. The organism primarily causes pneumonia and flulike illness. *Legionella* preferentially colonizes man-made water systems (e.g., hotels, hospitals, air conditioning cooling towers).
  - Among the three most common clinical pneumonias
  - Most common atypical pneumonia
- System(s) affected: pulmonary, gastrointestinal
- Synonym(s): Legionella pneumonia; legionellosis

EPIDEMIOLOGY

- Predominant age: 15 months to 84 years; 74–91% of patients are >50 years old.
- Predominant gender: male > female

Incidence

- The number of cases reported in the United States increased from 3.9 to 11.5 cases per million from 2000 to 2009.
- Outbreaks are most common in late summer and early fall.
- Represents 2–9% of all cases of pneumonia in the United States

ETIOLOGY AND PATHOPHYSIOLOGY

- *L. pneumophila* is a weak gram-negative aerobic saprophytic freshwater bacterium. It is widely distributed in soil and water. Bipolar flagella provide motility; grows optimally at 40–45°C
- Exists in nature as protozoan parasite and within fresh water biofilms
- Serogroups 1 to 6 account for clinical disease.

- Serogroup 1 represents 70–92% of all clinical cases of *Legionella* in the United States.
- In the lung, *Legionella* infects alveolar macrophages.
- The organism is transmitted by breathing in contaminated water droplets or by aspiration of contaminated water (e.g., contaminated shower water—felt responsible for the inaugural Philadelphia outbreak).
- Recently, community outbreaks associated with whirlpools, spas, fountains, and aboard cruise ships

RISK FACTORS

- Impaired cellular immunity (*Legionella* are intracellular pathogens)
- Male gender
- Smoking
- Alcohol abuse
- Immunosuppression/HIV
- Chronic cardiopulmonary disease
- Advanced age
- Transplant recipients
- Diabetes mellitus
- Use of antimicrobials within the past 3 months
- Corticosteroid use

GENERAL PREVENTION

- *Not transmitted person to person* (respiratory isolation is unnecessary)
- Superheat and flush water systems: Heat water to 70°C and flush outlets with hot water for 30 minutes (1)[C].
- Ultraviolet light or copper–silver ionization are bactericidal.
- Monochloramine disinfection of municipal water supplies decreases risk for *Legionella* infection.
- Point of use 0.2 micron water filters, changed regularly
- Keep water heaters >60°C, cold water <20°C

COMMONLY ASSOCIATED CONDITIONS

Pontiac fever: self-limited flulike illness without pneumonia caused by *Legionella* species

DIAGNOSIS

- Illness ranges from asymptomatic seroconversion and mild febrile illness to severe pneumonia.
- Wound infections with *Legionella* also reported
- Incubation period is 2 to 14 days.

HISTORY

- Signs and symptoms (with associated percentage):
  - Dry cough: 92% (occasionally productive)
  - Fever/chills: 90%
  - Dyspnea: 62%
  - Pleuritic chest pain: 35%
  - Headache: 48%
  - Myalgia/arthralgia: 40%
  - Watery diarrhea: 50%
  - Nausea and vomiting: 49%
  - Neuropsychiatric symptoms include encephalopathy, confusion, disorientation, obtundation, depression, hallucinations, insomnia, seizure: 53%.
- History of immunosuppression increases risk.

PHYSICAL EXAM

- Fever
- Relative bradycardia (key sign)
  - Defined as a temperature ≥102°F with an inappropriately low pulse pressure <100 beats/min (normal compensatory reaction to fever is tachycardia >110 beats/min)
- Rales and signs of consolidation (egophony; tactile fremitus)

DIFFERENTIAL DIAGNOSIS

- Other bacterial pneumonias, especially atypical pneumonias: *Mycoplasma pneumoniae*, Q fever (*Coxiella burnetii*), *Chlamydophila pneumoniae*, *Chlamydophila psittaci*, *Francisella tularensis*
- Viral pneumonias, such as adenovirus, influenza (human, avian, swine),

cytomegalovirus (CMV)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Diagnosis:
  - Culture for *Legionella* requires a good sputum sample and special media (BCYE agar). Culture has variable sensitivity (10–80%), and time delays up to 7 days for results.
  - Urinary antigen test (UAT) detects serogroup 1 (which causes most human disease). UATs are highly specific (95–100%) but variably sensitive. *Legionella* antigenuria can be detected 1 to 2 days after onset of disease and persists for up to 10 months. Limited by only detecting serogroup 1 (may miss 40% of cases) (2)[C]
  - *Legionella* PCR detects nearly 100% of all legionella species from respiratory secretions (3)[C].
- Other lab abnormalities (seen less commonly with other forms of pneumonia):
  - Hyponatremia
  - Hypophosphatemia (transient)
  - Lymphopenia
  - Mildly elevated serum transaminases; elevated LDH; elevated creatinine kinase
  - Microscopic hematuria
  - Highly elevated C-reactive protein (CRP) (>30)
  - Highly elevated ferritin (≥2 times normal)
- Chest radiograph
  - Not specific for *Legionella*
  - Commonly shows unilateral lower lobe patchy alveolar infiltrate with consolidation
  - Cavitation and abscess formation is more common in immunocompromised patients.
  - Pleural effusion occurs in up to 50%.
  - May take 1 to 4 months for radiographic findings to resolve. Progression of infiltrate on x-ray can be seen despite antibiotic therapy.

Diagnostic Procedures/Other

Transtracheal aspiration/bronchoscopy occasionally necessary for sputum/lung samples

Test Interpretation

- Multifocal pneumonia with alveolitis and bronchiolitis and fibrinous pleuritis; may have serous or serosanguineous pleural effusion
- Abscess formation occurs in up to 20% of patients.
- Progression of infiltrates on x-ray (despite appropriate therapy) suggests Legionnaires'. Radiographic improvement may not correlate with clinical findings (longer lag times).

TREATMENT

GENERAL MEASURES

- Severity of illness and available resources dictate the appropriate site for care.
- Supportive care:
  - Oxygenation, hydration, and electrolyte balance with antibiotic therapy
- Extrapulmonary complications and higher mortality in patients with AIDS
- In severe pneumonia, guidelines recommend obtaining a UAT and starting empiric antibiotics to include coverage for *Legionella* (4)[C].

MEDICATION

First Line

- Antibiotics that achieve high intracellular concentrations (e.g., macrolides, tetracyclines, fluoroquinolones) are most effective; first-line treatment is levofloxacin; however, no prospective randomized controlled trials have compared fluoroquinolones to macrolides for the treatment of *Legionella*. Levofloxacin was associated with more rapid defervescence, fewer complications, decreased hospital stay by 3 days, and decreased mortality (4% vs. 10.9%) compared with macrolide antibiotics (4)[A].
- Start antibiotics parenterally if sufficiently ill due to the GI symptoms associated with *Legionella*:
  - Levofloxacin is the preferred agent:
    - Levofloxacin 750 mg/day IV (switch to PO when patient is

afebrile/tolerating PO) for 5 days or 750 mg/day for 7 to 10 days
  - Azithromycin may also be used first line. It requires a shorter duration of treatment than levofloxacin due to a longer half-life:
    - Azithromycin 500 mg/day IV (switch to PO when afebrile/tolerating PO) for 7 to 10 days
- Contraindications: hypersensitivity reactions
- Precautions: liver disease
- Significant drug interactions:
  - Can increase theophylline, carbamazepine, and digoxin levels; can increase activity of oral anticoagulants
  - May decrease the effectiveness of digoxin, quinidine, oral contraceptives, and hypoglycemic agents
- Longer courses of treatment (up to 21 days) may be needed in immunocompromised patients or if treating valvular heart disease.

Second Line

- Doxycycline 100 mg IV/PO q12h for total 14 days; for severe infections, initial dose is 200 mg IV/PO q12h.
- Doxycycline cannot be used in pregnant patients and is not approved for children <8 years of age.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Inability to tolerate oral antibiotics
- Hypoxemia
- Criteria for direct admission to the ICU:
  - Any of the major criteria for severe CAP:
    - Septic shock requiring vasopressor support
    - Acute respiratory failure requiring intubation and/or mechanical ventilation
  - Three or more of the minor criteria for severe CAP:
    - RR ≥30 breaths/min; PaO_2:FiO_2 ratio ≤250; multilobular infiltrates; confusion/disorientation; uremia (BUN ≥20 mg/dL); leukopenia (WBC <4,000 cells/mm^3); thrombocytopenia (PLT <100,000 cells/mm^3); hypothermia (temperature <36°C); hypotension requiring aggressive fluid

resuscitation

- Discharge criteria
  - Afebrile
  - Able to tolerate oral antibiotics
  - Normal room air oxygen saturation

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Monitor respiratory status, hydration, and electrolyte status closely.
- Chest radiography lags behind the clinical status and may not help with monitoring clinical response.

PATIENT EDUCATION

- Disease prevention: Eliminate pathogens from water supplies, low-emission cleaning procedures of cooling towers with control measurements of water and air samples.
- *Legionella* is not spread person to person.

PROGNOSIS

- Improved prognosis when appropriate antibiotics are started early in the disease course
- Recovery is variable:
  - Patients may clinically worsen despite appropriate initial treatment (first 1 to 2 days of therapy).
  - Improvement with defervescence in 3 to 5 days and complete recovery in 6 to 10 days is typical. Some have a more protracted course.
- Mortality in nosocomial infections ranges from 15% to 34%.

COMPLICATIONS

- Dehydration
- Hyponatremia
- Respiratory insufficiency requiring ventilator support
- Bacteremia/lung abscess formation in up to 20%

- Extrapulmonary diseases:
  - Endocarditis (most common extrapulmonary site
  - Cellulitis
  - Sinusitis
  - Pancreatitis
  - Pyelonephritis
  - Encephalitis
  - Pericarditis
  - Perirectal abscess
- Renal failure
- Disseminated intravascular coagulation
- Multiple organ dysfunction syndrome (MODS)
- Coma
- Death occurs in 8–12% of treated immunocompetent patients and in up to 80% of untreated immunocompromised patients.

SEE ALSO

Pneumonia, Bacterial

CODES

ICD10

- A48.1 Legionnaires' disease
- A48.2 Nonpneumonic Legionnaires' disease [Pontiac fever]

CLINICAL PEARLS

- *Legionella* is an intracellular organism that can only be grown on buffered charcoal yeast extract agar.
- Because an increase in *Legionella* antibody titers cannot be detected >3 to 4 weeks, serology is not useful in early stages of the disease.
- Urine antigen testing (UAT) and *Legionella* sputum PCR are the most sensitive and practical initial tests. Sputum culture is definitive but can take 7 days with a sensitivity of 10–80%.
- Consider Legionnaires' disease in cases of nosocomial pneumonia.
- Consider Legionnaires' disease in patients with pneumonia, extrapulmonary findings (atypical CAP), and relative bradycardia, with any three of the

following: relative lymphopenia, mildly elevated serum transaminases (aspartate aminotransferase/alanine aminotransferase), highly increased ferritin levels, or hypophosphatemia.

LEUKEMIA, ACUTE LYMPHOBLASTIC IN ADULTS (ALL)

Richard A. Larson, MD

BASICS

DESCRIPTION

- ALL in adults is a malignant proliferation and accumulation of immature lymphocytes.
- ALL is the most common malignancy in children (see “Acute Lymphoblastic Leukemia, Pediatric”)
- System(s) affected: hemic/lymphatic/immunologic
- Synonym(s): acute lymphocytic leukemia

Pregnancy Considerations

Many chemotherapy drugs are teratogenic.

EPIDEMIOLOGY

- Predominant age in adults: median age, 35 to 40 years; incidence increases with age
- Predominant sex: male > female (slightly)

Incidence

In the United States: 3,000 adult cases per year

ETIOLOGY AND PATHOPHYSIOLOGY

- Unknown
- Epstein-Barr virus is implicated in Burkitt leukemia/lymphoma.

Genetics

- Increased incidence in children with Down syndrome or in rare familial diseases such as ataxia-telangiectasia, Bloom syndrome, Fanconi anemia, Klinefelter syndrome, and neurofibromatosis (1)
- With P53 mutation in Li-Fraumeni syndrome
- Can rarely occur in adult identical twins

RISK FACTORS

- Age >60 years
- Incidence seems to increase after exposure to chemical agents such as benzene or to radiation, but acute myeloid leukemia (AML) is more common.
- May follow aplastic anemia

DIAGNOSIS

HISTORY

- Anemia: fatigue, shortness of breath, light-headedness, angina, headache
- Thrombocytopenia: easy bruising
- Neutropenia: fever, infection
- Lymphocytosis: bone pain
- CNS: confusion

PHYSICAL EXAM

- Thrombocytopenia: petechiae, ecchymoses, epistaxis, retinal hemorrhages
- Anemia: pallor
- Neutropenia: fever, infection
- Lymphocytosis: lymphadenopathy, splenomegaly; less often, hepatomegaly
- CNS: cranial nerve palsies, confusion

DIFFERENTIAL DIAGNOSIS

- Malignant disorders: other leukemias, especially AML; chronic myeloid leukemia in lymphoid blast phase; prolymphocytic leukemia; malignant lymphomas; multiple myeloma; bone marrow metastases from solid tumors (breast, prostate, lung, renal); myelodysplastic syndromes
- Nonmalignant disorders: aplastic anemia, myelofibrosis, autoimmune diseases (Felty syndrome, lupus), infectious mononucleosis, pertussis, autoimmune thrombocytopenic purpura, leukemoid reaction to infection

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

CBC with differential, liver function tests, uric acid anemia: normochromic, normocytic

- Thrombocytopenia
- Peripheral blood lymphoblasts (B-cells or T-cells)
- Elevated lactate dehydrogenase
- Elevated uric acid

Follow-Up Tests & Special Considerations

Special tests

- Immunophenotyping of marrow/blood lymphoblasts: B lineage (CD19, CD20, CD22, CD24); T lineage (CD2, cCD3, CD5, CD7); common ALL antigen (CD10); human leukocyte antigen (HLA)-DR; terminal deoxynucleotidyl transferase (TdT); aberrant myeloid antigens (CD13, CD33); stem cell antigen (CD34)
- Cytochemical stains: myeloperoxidase negative; Sudan black B usually negative; TdT positive; periodic acid–Schiff ± is variable, depending on subtype.
- Cytogenetics: Specific recurring chromosomal abnormalities have independent diagnostic and prognostic significance (hyperdiploidy >50 chromosomes or t[14q11q13] are favorable; the Philadelphia (Ph) chromosome, t[9;22], t[4;11], −7 and +8 are unfavorable). A translocation t(8;14) or t(2;8) or t(8;22) identifies Burkitt-type mature B-cell leukemia that requires specific therapy.
- Reverse transcription polymerase chain reaction for rapid diagnosis of BCR/ABL1+ ALL
- Genomic analysis by next-generation sequencing: detection of mutations associated with Ph-like ALL
- HLA typing of patient and siblings for hematopoietic cell transplantation
- Chest CT scan and/or chest radiograph to evaluate for mediastinal mass or hilar adenopathy and for pulmonary infiltrates suggestive of infection
- US exam to assess splenomegaly or renal enlargement suggestive of leukemic infiltration

Diagnostic Procedures/Other

- Bone marrow examination with aspiration, biopsy, immunophenotyping, cytochemistry, cytogenetics, and molecular diagnostics
- Lymph node biopsy is rarely necessary but can be diagnostic.

- Lumbar puncture is mandatory and typically done both for diagnosis of CNS involvement and for intrathecal IT chemotherapy. It should be done at diagnosis and immediately if neurologic symptoms or signs are present. Repeat lumbar puncture after bone marrow remission is achieved to evaluate occult CNS involvement and continue prophylactic CNS treatment.

Test Interpretation

Diffuse replacement of marrow and lymph node architecture by sheets of malignant lymphoblasts

TREATMENT

GENERAL MEASURES

- Appropriate health care
  - Inpatient care during remission induction chemotherapy
  - Postremission therapy is usually outpatient.
- Protective isolation from infection
- Adequate calcium and vitamin D supplementation may reduce bone injury from corticosteroids and avascular necrosis of large joints.

MEDICATION

First Line

Optimal therapy is not yet known (2)[B]. ALL should be treated at a comprehensive oncology center. All treatment regimens are still investigational but clearly effective for some fraction of patients. Enrollment on a clinical trial is recommended. Younger adults (<40 years old) benefit from pediatric-inspired regimens (3,4)[B]. The modified Cancer and Leukemia Group B protocol 9111 is an example of therapy for older adults (5)[B]:

- Remission induction
  - Cyclophosphamide: 1,200 mg/m^2 IV on day 1 (800 mg/m^2 if ≥60 years old)
  - Daunorubicin: 45 mg/m^2 IV on days 1, 2, and 3 (30 mg/m^2 if ≥60 years old)
  - Vincristine: 2 mg IV on days 1, 8, 15, and 22
  - Pegylated asparaginase 2,000 U/m^2 (max 3,750 U) given on day 5. 1,000 U/m^2 may be better tolerated.

  - Dexamethasone 10 mg/m^2 on days 1 to 7 and 15 to 21
  - Filgrastim, G-CSF: 5 μg/kg/day SC starting on day 4 has been shown to shorten the duration of neutropenia and improve the complete remission rate, especially in older patients.
  - Imatinib mesylate: 600 to 800 mg/day (or dasatinib 70 mg BID) are effective alone and in combination with chemotherapy for Philadelphia chromosome-positive ALL (6)[B].
- Consolidation (repeat twice in 8 weeks)
  - Cyclophosphamide: 1,000 mg/m^2 IV day 1
  - IT methotrexate: 15 mg with hydrocortisone 50 mg on day 1
  - Mercaptopurine (6-mercaptopurine): 60 mg/m^2/day on days 1 to 14
  - Cytarabine: 75 mg/m^2/day SC on days 1 to 4 and 8 to 11
  - Vincristine: 2 mg IV on days 15 and 22
  - Pegylated asparaginase 2,000 U/m^2 (maximum 3,750 U) on day 15
- CNS prophylaxis and interim maintenance: 24 Gy cranial irradiation on days 1 to 12
  - IT-methotrexate: 15 mg with hydrocortisone 50 mg on days 1, 8, 15, 22, and 29
  - Mercaptopurine: 60 mg/m^2/day on days 1 to 70, taken in the evening
  - Oral methotrexate: 20 mg/m^2 on days 36, 43, 50, 57, and 64
- Late intensification (one 8-week course)
  - Doxorubicin: 30 mg/m^2 IV on days 1, 8, and 15
  - Vincristine: 2 mg IV on days 1, 8, and 15
  - Dexamethasone: 10 mg/m^2 on days 1 to 14
  - Cyclophosphamide: 1,000 mg/m^2 IV on day 29
  - Thioguanine (6-thioguanine): 60 mg/m^2 on days 29 to 42
  - Cytarabine: 75 mg/m^2 SC on days 29 to 32 and 36 to 39
- Prolonged maintenance (4-week cycles)
  - Vincristine: 2 mg/m^2 IV on day 1 for 16 months
  - Prednisone: 60 mg/m^2 for 5 days with the vincristine or dexamethasone 10 mg/m^2 on days 1 to 5
  - Mercaptopurine: 60 mg/m^2/day for 16 months, taken in the evening
  - Oral methotrexate: 20 mg/m^2/week for 16 months

- Special: Philadelphia chromosome–positive ALL (6)[B]
  - Imatinib mesylate (400 to 800 mg/day) is effective alone and in combination with chemotherapy.
  - Dasatinib (70 mg BID) is effective in combination with dexamethasone or with chemotherapy (7)[B].
- Contraindications: Doses and schedule may need to be altered for older patients and for concurrent infection and organ toxicity.
- Precautions
  - Tumor lysis syndrome (elevated uric acid, potassium, and phosphate with decreased calcium, leading to renal failure, disseminated intravascular coagulation, and cardiac arrhythmias) may be prevented by administering allopurinol 300 mg/day. Begin 2 days before chemotherapy begins. Reduce doses if used with mercaptopurine or azathioprine. Give increased fluids; IV urate oxidase (rasburicase) can be used to treat hyperuricemia rapidly (if not G6PD deficient).
  - Oral sulfamethoxazole-trimethoprim or aerosolized pentamidine is given for *Pneumocystis jiroveci* prophylaxis.
  - Profound immunosuppression: Take appropriate precautions when patient is neutropenic.
  - High-dose cyclophosphamide causes severe nausea and vomiting. Use appropriate antiemetic regimen to prevent.
  - Neurotoxicity, ileus with vincristine
  - Asparaginase may cause severe allergic reactions as well as impaired pancreatic and liver function. Monitor serum glucose concentrations frequently and carefully. Pancreatitis or thrombosis may occur. Peg-asparaginase is preferred now and can be used IV, SC, or IM in place of native *Escherichia coli* asparaginase.
  - Avascular (osteo) necrosis (AVN) of bone may occur in adolescents and young adults after alkylating agents and corticosteroids.
  - Rituximab (anti-CD20 monoclonal antibody) appears to improve the outcome of patients with ALL if CD20 is expressed on >20% of their blast cells.
  - Also note: Burkitt leukemia/lymphoma (mature B-cell ALL-L3)
    - The outcome is clearly better if high-dose methotrexate and alkylating

agents are used as part of initial therapy.
  - Only 18 weeks of treatment are required.
  - Rituximab (anti-CD20 monoclonal antibody) improves the outcome of patients with Burkitt leukemia when added to chemotherapy.

Second Line

- Clofarabine has been approved for relapsed childhood ALL. Nelarabine has been approved as a single agent for relapsed T-cell ALL. Pegylated asparaginase (IV or IM) is now used in place of *E. coli*–derived L-asparaginase. Liposomal vincristine has been approved for single-agent use for the treatment of relapsed ALL in adults.
- Immunoconjugates such as inotuzumab ozogamicin are under investigation.
- The bifunctional anti-CD19/anti-CD3 antibody blinatumomab is approved for relapsed/refractory ALL.
- Allogeneic hematopoietic stem cell transplantation is recommended for any patient with relapsed ALL or during first remission if high-risk genetic features are present.

ISSUES FOR REFERRAL

ALERT

ALL can become a fatal disorder quickly. As soon as the diagnosis is suspected, patients should be referred immediately to an appropriate oncology center

SURGERY/OTHER PROCEDURES

Surgical placement of a percutaneous, silastic, double-lumen central venous catheter or a percutaneous intravenous central catheter (PICC)

COMPLEMENTARY & ALTERNATIVE MEDICINE

Unproven; may result in adverse drug interactions with chemotherapy

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Ambulatory as tolerated

Patient Monitoring

- Daily during induction chemotherapy for metabolic and infectious complications
- Weekly during remission consolidation chemotherapy
- Monthly during maintenance therapy
- Every 3 months thereafter

DIET

- Nutritional support; if needed IV hyperalimentation
- Avoid alcohol.
- Calcium and vitamin D

PATIENT EDUCATION

- Risks of infection, transfusion, chemotherapy
- Stop smoking.

PROGNOSIS

- ~80–95% of adults <60 years will achieve a complete remission, and 35–60% will remain free of disease at 5 years.
- Older patients (>60 years) do less well, but 80% may achieve a complete remission.
- Patients with unfavorable cytogenetic subtypes (e.g., t[9;22] and t[4:11]) should undergo allogeneic stem cell transplantation in first remission if an HLA-identical donor is available. Autologous stem cell transplantation should be considered for Ph+ ALL patients who become reverse transcriptase polymerase chain reaction negative for BCR/ABL1 and lack an allogeneic donor.

COMPLICATIONS

- Infections (*Pneumocystis carinii* pneumonia, bacterial pneumonia or sepsis, fungal pneumonia)
- Bleeding
- Coagulopathy (deep vein thrombosis) from asparaginase therapy
- Need for transfusions
- Sterility from treatment
- Arachnoiditis and CNS effects from IT chemotherapy, high-dose methotrexate

and irradiation
- Pancreatitis and liver dysfunction from chemotherapy
- Osteonecrosis of joints (avascular necrosis) related to corticosteroids
- Relapse of ALL in marrow or extramedullary sites (CNS, testis)

CODES

ICD10

- C91.00 Acute lymphoblastic leukemia not having achieved remission

- C91.01 Acute lymphoblastic leukemia, in remission
- C91.02 Acute lymphoblastic leukemia, in relapse

CLINICAL PEARLS

- ALL can become fatal quickly; as soon as diagnosis is suspected, refer the patient to an oncology center. Optimal therapy is not yet known. All treatment regimens are still investigational but clearly are effective for a large fraction of patients.
- ALL in adults is a malignant proliferation and accumulation of immature lymphocytes.
- Presenting findings include fatigue, shortness of breath, light-headedness, angina, headache (anemia), easy bruising (thrombocytopenia), fever, infection (neutropenia), bone pain (lymphocytosis), and confusion (CNS involvement).

LEUKEMIA, ACUTE MYELOID

Jan Cerny, MD, PhD

BASICS

DESCRIPTION

- Acute myeloid leukemia (AML) is characterized by proliferation and accumulation of abnormal immature myeloid progenitors (blasts) with reduced capacity to differentiate into more mature cellular elements. This leads to bone marrow failure and results in a variety of systemic symptoms.
- Previously, the French–American–British (FAB) classification system divided AML based on the cell morphology with the addition of cytogenetics (subtypes M0–M7).
- The World Health Organization (WHO) classification attempts to provide more meaningful prognostic information.
  - AML with characteristic genetic abnormalities: translocation t(8;21), t(15;17), and inversion in chromosome 16 inv(16)
  - AML with multilineage dysplasia: presence of a prior myelodysplastic syndrome (MDS) or myeloproliferative neoplasm (MPN) that transformed into AML
  - AML and MDS, therapy related
  - AML not otherwise categorized
  - Acute leukemias of ambiguous lineage (*biphenotypic acute leukemia*)

EPIDEMIOLOGY

- ~19,950 cases estimated in 2016 making it the most common type of leukemia in adults
- Predominant sex: male ≥ female

Incidence

The incidence of AML increases with age, and median age is 67 years.

ETIOLOGY AND PATHOPHYSIOLOGY

Precise causes unknown, but some risk factors have been identified (see “Risk

Factors”).

Genetics

- Unknown; some are familial.
- Cytogenetics and genetics play an important role in diagnosis and prognosis of AML and have implications for therapy.
- Three risk groups
  - Good risk: inv(16), t(8;21), t(15;17)
  - Standard risk: normal karyotype
  - Poor risk: monosomy 5 and 7 (typically secondary AML), deletion 5q, abnormalities of 11q23 or complex karyotype
- *FLT3* gene mutations, especially internal transmembrane duplications (FLT3-ITD), have been associated with poor survival in AML. These and growing list of (onco)gene (e.g., *NPM1*, *DNMT3A*, and *P53*) mutations have been studied to further risk-stratify patients (1,2)[A].

RISK FACTORS

- Genetic predisposition (e.g., Down syndrome); other familial disorders are Bloom syndrome (~25% develop AML), Fanconi anemia (52%), neurofibromatosis, Li-Fraumeni syndrome, Wiskott-Aldrich syndrome, Kostmann syndrome, and Diamond-Blackfan anemia.
- Radiation exposure
- Immunodeficiency states
- Chemical and drug exposure (nitrogen mustard and alkylating agents; benzene)
- MDS
- Cigarette smoking

GENERAL PREVENTION

None currently identified, but treatment of high-risk MDS with demethylating agents (Vidaza, 5-azacitidine) has been shown to prolong time to transformation from MDS into AML (3)[A].

COMMONLY ASSOCIATED CONDITIONS

The following are oncologic emergencies:

- Disseminated intravascular coagulopathy (DIC) especially in acute

promyelocytic leukemia (APL) but may be seen in any AML
- Leukostasis (high blast number and increased adhesive ability of blasts)
- Tumor lysis syndrome (TLS): spontaneous or in response to chemotherapy

DIAGNOSIS

HISTORY

Fatigue (anemia or tumor burden); bleeding (low platelets or DIC); difficulty clearing infections (neutropenia or immune dysregulation)

PHYSICAL EXAM

- Mostly nonspecific and related to marrow or tissue infiltration
  - Fever
  - Bleeding
  - Pallor
  - Splenomegaly
  - Hepatosplenomegaly
  - Lymphadenopathy (usually reactive)
- If CNS is involved, symptoms of increased intracranial pressure can be present.
- Occasionally, patients will present with prominent extramedullary sites of leukemia (e.g., skin infiltration or ultimately as a myeloid sarcoma).

DIFFERENTIAL DIAGNOSIS

- Virus-induced cytopenia, lymphadenopathy, and organomegaly
- Immune cytopenias (including systemic lupus erythematosus [SLE])
- Drug-induced cytopenias
- Other marrow failure and infiltrative diseases (e.g., aplastic anemia, paroxysmal nocturnal hemoglobinuria, MDSs, Gaucher disease)

DIAGNOSTIC TESTS & INTERPRETATION

- CBC shows subnormal RBCs, neutrophils, and platelets.
- Bone marrow for histology, flow cytometry, and cytogenetics to establish diagnosis and prognosis
- ESR

- Lactate dehydrogenase (LDH) and uric acid can be elevated (e.g., TLS).
- Coagulation profile can be normal or prolonged (e.g., DIC).
- Drugs that may alter lab results: chemotherapy agents, corticosteroids
- Other special tests: Spinal tap may reveal fluid with leukemic cells.
- Ultrasonography or CT scan of the abdomen may discover organomegaly.

Diagnostic Procedures/Other

Bone marrow studies are usually necessary to make the diagnosis.

- Aspirates: for cell morphology, cytochemistries, immunophenotyping (can confirm differentiation stage of AML); cytogenetics: chromosomal aberration (prognostic value; see "Genetics")
- Biopsies provide valuable information for cellularity, architecture, and so forth.

Test Interpretation

- Marrow is usually hypercellular and the normal architecture effaced; leukemic blast count is 20% or more.
- Liver and spleen may be infiltrated with leukemic cells.

TREATMENT

- Chemotherapy is the backbone of AML therapy; it consists of induction and consolidation phase ± maintenance (APL).
- Bone marrow transplantation (BMT) for high-risk AML
- Only modest improvements have been made in AML induction chemotherapy. Supportive care has improved significantly.

GENERAL MEASURES

- Ongoing assessment of bone marrow, liver, heart, and kidney functions during therapy
- Close monitoring of coagulation parameters (risk for DIC)
- Supportive therapy with
  - Good hydration
  - Transfusions of packed RBCs and platelets based on patient's needs (threshold as for platelets as low as 5,000); use leuko-reduced, irradiated

blood products, as all patients can be considered for BMT.
  - Avoid antiplatelet agents (e.g., aspirin products).
  - Follow febrile neutropenic guidelines in neutropenic patient who becomes febrile (even low-grade fever).

Geriatric Considerations

- Older patients (>60 to 65 years of age) remain a therapeutic challenge. These patients are offered so-called reduced-intensity or nonmyeloablative BMT.
- Adding growth factors (granulocyte-colony stimulating factor [G-CSF]) may reduce toxicity in older patients (but is not broadly accepted).
- Hypomethylating agent, such as 5-azacitidine, significantly prolongs survival in older adults with low marrow blast count (<30%).

Pediatric Considerations

- Tolerate intense treatments better

Pregnancy Considerations

- Chemotherapy is a viable option in the 2nd and 3rd trimesters.

MEDICATION

First Line

- APL (APL, AML with t[15;17])
  - All-trans retinoic acid (ATRA) and arsenic trioxide both promote maturation to granulocytes.
  - Idarubicin is often added to induction therapy.
- Treatment of AML in younger adults: AML (other than APL)
  - Induction (daunorubicin or idarubicin [anthracycline and cytarabine]): The generally accepted combination is 3 + 7 (anthracycline is given for 3 days and cytarabine for 7 days) or more intensive regimens with high dose of cytarabine (HiDAC) or high dose of anthracycline.
- Remission is typically consolidated in younger patients by the following:
  - In good-risk AML, 3 to 4 cycles of HiDAC and BMT is reserved for time of recurrence.
  - In poor-risk patients, 1 to 2 cycles of HiDAC (until donor is identified) are followed by allogeneic BMT.
  - Intermediate-risk AML should be treated based on individual patient’s

features, donor availability, and access to clinical trials. A meta-analysis showed that even intermediate-risk patients benefit from allogeneic BMT (4)[A].

- Treatment of AML in older adults (>65 years of age) remains a challenge. These patients have poor performance status, more likely secondary AML, higher incidence of unfavorable cytogenetics, comorbidities, shorter remissions, and shorter overall survival.
  - Intensive chemotherapy may be feasible for patients with good performance status; alternative regimens with mitoxantrone, fludarabine, and clofarabine. New drugs (hypomethylating agents as above, FLT3 inhibitors, monoclonal antibodies, etc.) are being studied in clinical trials (5)[A].
- Contraindications: comorbidities; therapy has to be individualized.
- Precautions
  - If organ failure, some drugs may be avoided or dose reduced (e.g., no anthracyclines in patients with preexisting cardiac problems).
  - Patients will be immunosuppressed during treatment. Avoid live vaccines. Administer varicella-zoster or measles immunoglobulin as soon as exposure of patient occurs.
- Significant possible interactions: Allopurinol accentuates the toxicity of 6-mercaptopurine.

Second Line

Healthy, younger patients usually are offered reinduction chemotherapy and allogeneic BMT.

ISSUES FOR REFERRAL

- AML should be managed by specialized team led by a hematologist/oncologist.
- Refer patient to a transplant center early because a search for a donor may be necessary.

SURGERY/OTHER PROCEDURES

- BMT: Decision between myeloablative and nonmyeloablative approach should be based on patient’s performance status, comorbidities, and AML risk

factors.
  - Allogeneic BMT is usually indicated in first remission in intermediate- or high-risk AML or in second remission in all other AML patients. Matched related donor used to be preferred over matched unrelated donor (lower risk of graft-versus-host disease); recent data suggest equal outcomes, as allogeneic transplant regimens and posttransplant care have improved significantly.
- Haploidentical transplants and cord blood have emerged as alternative sources of hematopoietic stem cells for adults that show comparable outcomes as well.
- Autologous BMT may be acceptable in specific situations (e.g., no donor is available).

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Induction treatment for AML requires inpatient care, usually on a specialized ward. Episodes of febrile neutropenia typically require admission and IV antibiotics.
- Appropriate hydration to prevent TLS
- IV may lead to chemical burns in the event of extravasation.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Ambulatory, as tolerated; no intense or contact sports; no aspirin due to risk of bleeding

Patient Monitoring

- Repeat bone marrow studies to document remission and also if a relapse is suspected.
- Follow CBC with differential, coagulation studies, uric acid level, and other chemistries related to TLS (creatinine, potassium, phosphate, calcium); monitor urinary function at least daily during induction phase and less frequently later.
- Physical evaluation, including weight and BP, should be done frequently

during treatment.

DIET

Ensure adequately balanced calorie/vitamin intake. Total parenteral nutrition (TPN) in case of severe mucositis

PATIENT EDUCATION

- Leukemia Society of America, 600 Third Avenue, New York, NY 10016, 212-573-8484
- National Cancer Institute, Bethesda, MD, has pamphlets and telephone education.
- Baker LS. *You and Leukemia: A Day at a Time*. Philadelphia, PA: Saunders; 1978.

PROGNOSIS

AML remission rate is 60–80%, with only 20–40% long-term survival. The wide variable prognosis is due to prognostic group (age, cytogenetics, and genetics).

COMPLICATIONS

- Acute side effects of chemotherapy, including febrile neutropenia
- TLS
- DIC
- Late-onset cardiomyopathy in patients treated with anthracyclines
- Chronic side effects of chemotherapy (secondary malignancies)
- Graft-versus-host disease in patients who have received allogeneic BMT

Disseminated Intravascular Coagulation; Leukemia, Acute Lymphoblastic in Adults (ALL); Leukemia, Chronic Myelogenous; Myelodysplastic Syndromes; Myeloproliferative Neoplasms

CODES

ICD10

- C92.00 Acute myeloblastic leukemia, not having achieved remission
- C92.01 Acute myeloblastic leukemia, in remission
- C92.02 Acute myeloblastic leukemia, in relapse

CLINICAL PEARLS

- Prognosis of leukemia depends on the cytogenetic and molecular profile of the disease.
- Allogeneic transplant remains the only therapy with curative potential for patients with intermediate- and high-risk AML.

LEUKEMIA, CHRONIC LYMPHOCYTIC

Jan Cerny, MD, PhD • Amy E. Pratt, DO

BASICS

DESCRIPTION

- Chronic lymphocytic leukemia (CLL) is a monoclonal disorder characterized by a progressive accumulation of mature but functionally incompetent lymphocytes.
- CLL should be distinguished from prolymphocytic leukemia (PLL); based on percentage of prolymphocytes, the disease may be regarded as CLL (<10% prolymphocytes), PLL (>55% prolymphocytes), or CLL/PLL (>10% and <55% prolymphocytes).
- Small lymphocytic lymphoma is a lymphoma variant of CLL.
- System(s) affected: hematologic, lymphatic, immunologic.

EPIDEMIOLOGY

Incidence

- CLL represents the most common form of leukemia in adults in the United States with an estimated 18,960 new cases to be diagnosed in 2016 (1)[A].
- In 2016, an estimated 4,660 adults in the United States will die from CLL, which makes it the second leading cause of death among adults with leukemia in the United States after acute myeloid leukemia (1)[A].
- Predominant age: CLL primarily affects elderly individuals, median age of diagnosis being 70 years. Incidence continues to rise in those age >55 years.
- Predominant sex: male > female (1.7:1)
- The incidence is higher among Caucasians than among African Americans.

ETIOLOGY AND PATHOPHYSIOLOGY

- The cell of origin in CLL is a clonal B cell arrested in the B-cell differentiation pathway, intermediate between pre–B cells and mature B cells. In the peripheral blood, these cells resemble mature lymphocytes and typically show B-cell surface antigens: CD19, CD20, CD21, and CD23. In addition, they express CD5 (usually found on T cells).

- The bcl2 proto-oncogene is overexpressed in B-CLL. Bcl2 is a known suppressor of apoptosis (programmed cell death), resulting in extremely long life of the affected lymphocytes.
  - Genetic mutations leading to disrupted function and prolonged survival of affected lymphocytes are suspected but unknown.

Genetics

CLL is an acquired disorder, and reports of truly familial cases are exceedingly rare. CLL has been shown, however, to occur at higher frequency among first-degree relatives of patients with the disease, and several somatic gene mutations have been identified at significantly higher rates among CLL patients.

RISK FACTORS

- As in the case of most malignancies, the exact cause of CLL is uncertain.
- Possible chronic immune stimulation is suspected but is still being evaluated.
- Monoclonal B-cell lymphocytosis: 1% risk progression to CLL.

GENERAL PREVENTION

Unknown

COMMONLY ASSOCIATED CONDITIONS

- Immune system dysregulation is common.
- Conditions that may accompany CLL:
  - Autoimmune hemolytic anemia (AIHA)
  - Immune thrombocytopenia purpura (ITP)
  - Pure red cell aplasia (PRCA)

DIAGNOSIS

HISTORY

- Insidious onset. It is not unusual for CLL to be discovered incidentally (up to 40% of patients are asymptomatic at the time of diagnosis).
- Others may have the following symptoms:
  - B symptoms: fevers, night sweats, >10% weight loss
  - Fatigue and/or other symptoms of anemia
  - Enlarged lymph nodes (lymphadenopathy = LAD)

- Mucocutaneous bleeding and/or petechiae
- Early satiety and/or abdominal discomfort related to an enlarged spleen
- Recurrent infection(s)

PHYSICAL EXAM

- Lymphadenopathy, localized or generalized
- Organomegaly (splenomegaly, hepatomegaly)
- Mucocutaneous bleeding (thrombocytopenia)
- Skin: petechiae (thrombocytopenia), pallor (anemia), rash (leukemia cutis)

DIFFERENTIAL DIAGNOSIS

- Infectious:
  - Bacterial (tuberculosis, pertussis)
  - Viral (mononucleosis)
- Neoplastic:
  - Leukemic phase of non-Hodgkin lymphomas
  - Hairy cell leukemia
  - PLL
  - Large granular lymphocytic leukemia
  - Waldenstrom macroglobulinemia

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (labs, imaging)

- CBC with differential: B cell absolute lymphocytosis with >5,000 B lymphocytes/μL; often also shows anemia and/or thrombocytopenia
- Blood smear: ruptured lymphocytes (“smudge” cells) and morphologically small mature-appearing lymphocytes
- Confirm diagnosis with immunophenotyping: CLL cells are positive for CD19, CD20, CD23, and CD5; low levels of surface membrane immunoglobulin (Ig)—either IgM or IgM&D; only a single Ig light chain is expressed (κ or λ) confirming monoclonality.
- Additional labs:
  - Hemolysis labs (in cases associated with high disease activity or AIHA): high LDH and indirect bilirubin, low haptoglobin, +/− elevated reticulocyte count (bone marrow infiltration)

  - High plasma β_2-microglobulin (poor prognosis)
  - Hypogammaglobulinemia
- Liver/spleen ultrasound: may demonstrate organomegaly and enlarged abdominal lymph nodes
- CT scan of chest/abdomen/pelvis: not necessary for staging but may identify compression of organs or internal structures from enlarged lymph nodes
- Positron emission tomography (PET) scan: not recommended unless Richter transformation suspected and biopsy necessary (see "Prognosis")

Follow-Up Tests & Special Considerations

Frequency and type of follow-up depend on severity of symptoms as well as risk factors (see "Prognosis").

Diagnostic Procedures/Other

- Bone marrow biopsy: has prognostic value (diffuse infiltration is a risk factor) but not performed routinely
- Lymph node biopsy: Consider if lymph node(s) begins to rapidly enlarge in a patient with known CLL to assess the possibility of transformation to a high-grade lymphoma (Richter syndrome), especially when accompanied by fever, weight loss, and painful LAD.

Test Interpretation

- Bone marrow biopsy aspirate usually shows >30% lymphocytes.
- Cytogenetics (fluorescence in situ hybridization) may show chromosomal changes, which are prognostic:
  - Unfavorable: del(17p), del(11q)
  - Neutral: normal, trisomy 12
  - Favorable: del(13q), del(6q)

TREATMENT

GENERAL MEASURES

Patients with CLL with frequent infections associated with hypogammaglobulinemia are likely to benefit from infusions of intravenous immunoglobulin (IVIG).

MEDICATION

First Line

- Standard of care for new diagnosis with no symptoms or early stage disease: observation
- Standard of care for new diagnosis with symptoms (B symptoms, symptomatic anemia and/or thrombocytopenia, AIHA and/or thrombocytopenia poorly responsive to corticosteroids, progressive organomegaly) or progressive lymphocytosis (increase >50% in 2 months or a doubling time of <6 months): Initiate treatment.
- Low-risk disease, Rai stage 0, and Binet stage A: observation with periodic follow-up
- Intermediate-risk group, Rai stages I and II, and Binet stage B: Observe until evidence of disease progression or development of symptoms.
- High-risk patients, Rai stage III and IV, and Binet stage C: Initiate treatment.
- Selection of first-line therapy depends on patient factors: age, performance status, and medical comorbidities.
- Three main groups of chemotherapeutic drugs:
  - Alkylators: cyclophosphamide (C), chlorambucil, and bendamustine (B)
  - Purine analogs: fludarabine (F) and pentostatin (P)
  - Monoclonal antibodies: rituximab (R) (chimeric anti-CD20) and alemtuzumab (anti-CD52)
- Commonly used single-agent regimens: B, C (historically, the standard of care in older patients with comorbidities), and F
- Commonly used fludarabine- and rituximab-based combination regimens: FC, FR (lower toxicity), FCR (preferred first-line regimen if tolerable to patient), and PCR
- Steroids, high dose: useful in autoimmune manifestations of CLL (AIHA, ITP)

Second Line

- Second-line therapy consists of combinations of chemotherapeutic agents that patient did not fail yet or, occasionally, retreatment with a drug used previously.
- Novel agents (listed below) have also shown promising activity in CLL:

  - Ibrutinib (Bruton tyrosine kinase inhibitor): showed favorable findings in older patients with comorbidities and previously untreated CLL (2)[A]
  - Idelalisib (PI3Kδ kinase inhibitor): Combination of this drug with rituximab compared to placebo with rituximab significantly improved the rate of progression-free survival in patients with comorbidities and relapsed CLL unable to undergo standard chemotherapy (3)[A].
  - Obinutuzumab (humanized anti-CD20 monoclonal antibody): Combination of this drug with chlorambucil improved response rates and prolonged progression-free survival in patients with comorbidities and previously untreated CLL (4)[A].
  - Ofatumumab (O) (anti-CD20 monoclonal antibody distinct from [R])
- Lenalidomide, a thalidomide derivative, is sometimes first line for elderly patients or second line when combined with (R) for relapsed/refractory disease.
- Alemtuzumab (anti-CD52) is second line when used for relapsed/refractory disease.
- Allogenic (nonmyeloablative conditioning) and autologous hematopoietic stem cell transplant (hSCT) may be considered in high-risk and younger patients, particularly those with refractory (limited data available as still considered experimental therapy).

ISSUES FOR REFERRAL

- Surgical consultation for splenectomy in patients with progressive splenomegaly +/− refractory cytopenias
- Radiation oncology consultation for large or bulky lymphadenopathy, particularly those causing compressive symptoms

ADDITIONAL THERAPIES

- Patients requiring therapy who are high risk for tumor lysis syndrome should be given allopurinol to prevent uric acid nephropathy.
- Vaccinations (avoid live vaccines):
  - Annual influenza vaccine
  - Pneumococcal vaccine every 5 years

SURGERY/OTHER PROCEDURES

See “Issues for Referral” above.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

No specific criteria but may require inpatient admission for complications of disease (AIHA) or of therapy (febrile neutropenia, tumor lysis syndrome)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Patients with low-risk CLL and/or patients in remission:

- CBC with differential (lymphocytosis), LDH, and β_2-microglobulin every 3 to 6 months
- Physical exam (lymphadenopathy, organomegaly)

DIET

- Ensure adequately balanced calorie/vitamin intake.
- Follow weights.

PATIENT EDUCATION

Leukemia and Lymphoma Society has educational pamphlets: https://www.lls.org/resource-center/download-or-order-free-publications?language=English&category=Leukemia&sortby=alpha

PROGNOSIS

- Two staging systems are used, but neither is completely satisfactory: Rai system in the United States and Binet system in Europe
- Rai staging system:
  - Stage 0: lymphocytosis only; low risk status
  - Stage I: lymphocytosis and adenopathy; intermediate risk status
  - Stage II: lymphocytosis +/− adenopathy and splenomegaly and/or hepatomegaly; intermediate risk status
  - Stage III: lymphocytosis and anemia (hemoglobin <11 g/dL); high risk status

  - Stage IV: lymphocytosis and thrombocytopenia (platelets <100 × 10^9/L); high risk status
- Binet staging system:
  - Stage A: hemoglobin ≥10 g/dL, platelets ≥100 × 10^9, and <3 lymph node areas involved (Rai stages 0, I, and II); survival >120 months
  - Stage B: hemoglobin and platelet levels as in stage A and ≥3 lymph node areas involved (Rai stages I and II); survival 61 months
  - Stage C: hemoglobin <10 g/dL, platelets <100 × 10^9, and any number of lymph nodes involved (Rai stages III and IV); survival 32 months
- Adverse risk factors:
  - Advanced Rai or Binet stage
  - Peripheral lymphocyte doubling time <12 months
  - Diffuse marrow infiltration
  - Increased number of prolymphocytes or cleaved cells
  - Poor response to chemotherapy
  - High β_2-microglobulin and thymidine kinase levels and low micro RNAs (miRNAs)
  - Abnormal karyotyping: del(17p) and del(11q)
  - Mutated immunoglobulin heavy chain variable (IgHV) genes (expression of ZAP-70 >20% or CD38 >30% evaluated by immunophenotyping are surrogate markers)
  - NOTCH1 mutation (associated with unmutated IgVH)

COMPLICATIONS

- Acute or long-term effects of chemotherapy
- Richter syndrome
- AIHA (some cases may be related to the use of fludarabine)
- Slightly increased risk of solid tumors (especially Kaposi sarcoma, malignant melanoma, laryngeal cancer, lung cancer, colon cancer)
- Infection
- Membranoproliferative glomerulonephritis (MPGN) or other glomerular pathology

CODES

ICD10

- C91.10 Chronic lymphocytic leukemia of B-cell type not achieve remission
- C91.11 Chronic lymphocytic leukemia of B-cell type in remission
- C91.12 Chronic lymphocytic leukemia of B-cell type in relapse

CLINICAL PEARLS

- CLL is the most common form of leukemia in adults in the United States.
- CLL primarily affects elderly individuals, median age of diagnosis being 70 years. Incidence continues to rise in those age >55 years.
- Clinical monitoring of asymptomatic and low-risk patients is a reasonable approach (“watch and wait”).
- High-risk patients, patients with bulky disease, and patients who fail fludarabine- and rituximab-based therapies typically have poor prognoses and

may require intensive therapies, including allogeneic hematopoietic stem cell transplantation.

- Several novel agents are being developed to improve therapeutic approaches to CLL.

LEUKEMIA, CHRONIC MYELOGENOUS

Jan Cerny, MD, PhD

BASICS

DESCRIPTION

- Chronic myelogenous leukemia (CML) is a myeloproliferative neoplasm characterized by clonal proliferation of myeloid precursors in the bone marrow with continuing differentiation into mature granulocytes.
- Hallmark of CML is Philadelphia chromosome (translocation t[9;22]).
- Natural history of the disease evolves in three clinical phases: a chronic phase, an accelerated phase, and a blast phase or crisis (transformation to acute leukemia).

EPIDEMIOLOGY

Incidence

- Per year, 1.6 cases/100,000 persons
- Predominant age: 50 to 60 years
- Predominant sex: male > female (1.3:1)

Prevalence

Accounts for 15–20% of adult leukemias

ETIOLOGY AND PATHOPHYSIOLOGY

Philadelphia chromosome is a balanced translocation between *BCR* (on chromosome 22) and *ABL* (on chromosome 9) genes t(9;22)(q34;q11). This fusion gene, *BCR-ABL*, codes for an abnormal constitutively active tyrosine kinase that affects numerous signal transduction pathways, resulting in uncontrolled cell proliferation and reduced apoptosis.

Genetics

Acquired genomic changes

RISK FACTORS

Ionizing radiation exposure (uncommon)

GENERAL PREVENTION

None currently identified

DIAGNOSIS

85–90% of patients present in the chronic phase, and the disease can be found accidentally during routine screening.

HISTORY

- Chronic phase: fatigue, weight loss, night sweats, abdominal fullness owing to enlarged spleen, early satiety, dyspnea, bleeding. Rare: bruising, left upper quadrant abdominal pain, sternal pain (owing to expanding bone marrow), and gouty arthritis; up to 30% of patients are asymptomatic.
- Accelerated phase progressive splenomegaly and left upper quadrant abdominal pain occasionally referred to the left shoulder (owing to splenic infarction or rupture), progressive weight loss and sweats, unexplained fever or bone pain, chloromas (extramedullary tumors)
- Blast phase: bleeding, bruising, infections, prominent constitutional symptoms

PHYSICAL EXAM

- Splenomegaly (50–90%), hepatomegaly (up to 50%)
- Less common: splenic friction rub, lymphadenopathy

DIFFERENTIAL DIAGNOSIS

- Chronic myelomonocytic leukemia, chronic neutrophilic leukemia, chronic eosinophilic leukemia, juvenile myelomonocytic leukemia, infectious mononucleosis, leukemoid reaction, polycythemia vera, and treatment with granulocyte-stimulating factors
- Acute myelogenous leukemia resembles blast crisis with myeloid blasts, and acute lymphoblastic leukemia resembles blast crisis with lymphoid blasts.
- Atypical CML is a chronic myeloproliferative disorder with a clinical hematologic picture similar to CML, but it lacks Philadelphia chromosome and *BCR-ABL* rearrangement.

DIAGNOSTIC TESTS & INTERPRETATION

- CBC

  - Hematocrit: may be normal, slightly increased, or decreased
  - WBC count: markedly increased (50,000 to 100,000/μL), with granulocytes in all stages of development, including occasional blasts <10% in chronic phase, basophilia, eosinophilia
  - Platelets: normal, elevated (34%), or occasionally low
  - In accelerated phase: anemia, 10–19% blood or marrow blasts, basophils plus eosinophils >20%, thrombocytopenia
  - Blast phase: blood or marrow blasts >20%
- Genetics
  - Demonstration of the Philadelphia chromosome, t(9;22), by cytogenetic techniques, fluorescence in situ hybridization (FISH), or reverse transcription-polymerase chain reaction (RT-PCR)
  - Additional cytogenetic abnormalities occur in the accelerated and blast phases (monosomy 7, t[3,21], trisomies 8 and 19, Philadelphia chromosome duplication, abnormalities of chromosome 17 such as monosomy, trisomy, and isochromosome mutations). These may contribute to resistance to tyrosine kinase inhibitors (TKIs; e.g., imatinib). Further molecular testing (mutations within *BCR-ABL*) is suggested in case of loss of response to therapy.
- Others:
  - Low or absent leukocyte alkaline phosphatase in neutrophils
  - High lactate dehydrogenase (LDH)
  - Elevated uric acid

Initial Tests (lab, imaging)

- CBC, LDH, uric acid, bone marrow biopsy and aspiration, cytogenetics on bone marrow, and FISH for *BCR-ABL*, RT-PCR, LFTs
- Abdominal ultrasound or CT scan shows splenomegaly; not mandatory.

Follow-Up Tests & Special Considerations

- Mutation analysis of tyrosine kinase domain of *ABL* kinase, as they may cause resistance to therapy with TKIs
- HLA-A*02 positive is associated with CML, and a protective effect is seen with the HLA-B*35 allele (pooled odds ratio 0.64, 95% CI 0.48–0.86).

Diagnostic Procedures/Other

Bone marrow aspiration and biopsy

Test Interpretation

Myeloid hyperplasia with elevated myeloid: erythroid ratio, normal maturation, marrow basophilia, and increased reticulin fibrosis

TREATMENT

MEDICATION

- TKIs (e.g., imatinib) provide durable, long-term control of disease.
- The response to TKIs is assessed at specific time points from the beginning of treatment and is categorized as follows:
  - Complete hematologic response (CHR): normalization of peripheral counts, no disease symptoms, no immature cells
  - Minor/partial/complete cytogenetic response (CCR): 1–34%, 35–90%, no Philadelphia-positive metaphases
  - Major molecular response (MMR): decreased level of *BCR-ABL* transcript by PCR 3-log
  - Complete molecular response (CMR): *BCR-ABL* transcript is undetectable by PCR.

First Line

- Imatinib mesylate (Gleevec), an oral TKI, 400 mg/day
- Side effects: thrombocytopenia, anemia, elevated liver enzymes, edema, GI disturbances, rash
- International Randomized Study of Interferon versus STI571 (IRIS) established imatinib as first-line therapy (1)[A].
- Imatinib dose can be increased to 600 and 800 mg/day if only suboptimal response is achieved with standard dose.
- 2nd-generation TKIs have shown higher efficacy and fewer side effects and are approved for first-line therapy of chronic phase CML: nilotinib (Tasigna) and dasatinib (Sprycel) (2,3)[A].

Second Line

- Dasatinib, 2nd-generation TKI; active against most of BRC-ABL mutants; not

active in T315I mutation
  - 100 mg/day in patients resistant or intolerant to imatinib and 70 mg BID or 140 md/day for patients in accelerated or blastic phase
  - Side effects: pleural effusions, cytopenias
- Nilotinib, also 2nd-generation TKI; highly selective and more potent BCR-ABL TKI; active against most BRC-ABL mutants; not active in T315I mutation
  - 400 mg PO BID in patients resistant or intolerant to imatinib in chronic or accelerated phase
  - Side effects: cytopenias, QTc prolongation, pancreatitis
- Bosutinib and omacetaxine are now approved for patient who failed or did not tolerate two TKIs previously. Ponatinib has now more restricted approval, but together with omacetaxine, they are the only effective agents in patients with *T315I* mutation. Agents targeting leukemic stem cells are being developed for clinical use.

ISSUES FOR REFERRAL

All patients with CML should be referred to a hematologist. Patients with inadequate response to TKIs or with *T315I* mutation should consult with a bone marrow transplant physician.

SURGERY/OTHER PROCEDURES

Allogenic bone marrow transplant (BMT)

- It is the only known cure; however, 71% of patients who achieve CCR with imatinib maintain that response beyond 7 years, and no patient progressed on the trial between years 5 and 6 of treatment.
- Most effective in patients <50 years of age who are in the chronic phase
- Initial mortality is higher (related to the use of myeloablative regimens) than medical management but provided higher rates of survival in pre-TKI era.
- Significant improvement in transplant techniques leading to better outcomes, such as alternative sources of stem cells; nonmyeloablative regimens have shown improvements in transplant-related mortality.
- Transplant option should be thoroughly discussed with young patients in chronic phase and considered an alternative to TKIs especially if the patient does not tolerate TKIs or disease is not responding.

- Can be considered in patients who fail to achieve CHR by 3 months, have no cytogenetic response or cytogenetic relapse, or have *T315I* mutation

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Acute abdominal symptoms (infarcted or ruptured spleen); tumor lysis syndrome owing to initial therapy; complications of BMT
  - Hydroxyurea might be given, with the goal of reduction of the WBC count, but it has minimal impact on patient response to TKIs.
  - Induction chemotherapy (for acute leukemia) in setting of blastic phase
  - Allopurinol to prevent tumor lysis syndrome in patients with very high counts; however, probably not necessary when TKIs are used
- Discharge criteria: abatement of acute symptoms

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Frequency depends on stage at presentation and response to first-line therapy.
- Although splenomegaly persists, avoid contact sports or trauma to abdomen.

Patient Monitoring

- CBC with differential: weekly until blood counts stable, then every 2 to 4 weeks during CHR; once in CCR and stable, patient can be followed less frequently (3-month intervals).
- Bone marrow cytogenetics (evaluation for clonal evolution) every 6 months while in CHR, every 12 to 18 months while in complete cytogenic response, MMR, CMR
- Quantitative RT-PCR every 3 months (peripheral blood)
- ECGs (concern for QT prolongation), LFTs while on TKIs. Nilotinib, bosutinib, and ponatinib can cause pancreatitis.

PROGNOSIS

- With treatment and good response, the survival is similar to the normal population.
- Without treatment: CML invariably will progress to accelerated phase within

2 to 5 years and blast phase within several months of the accelerated phase.
- Poor prognosis: patients presenting in accelerated or blastic phase or presenting with very large spleen size, platelets >700,000/μL, and patients resistant to TKIs (*T315I* mutation)

COMPLICATIONS

- Splenic infarct or rupture
- Progression to accelerated or blastic phase
- Thrombotic events owing to elevated platelets
- Bleeding owing to low or dysfunctional platelets
- Sequelae of anemia

chronic myelogenous leukemia: a meta-analysis. *Leuk Lymphoma*. 2010;51(7):1288–1292.

CODES

ICD10

- C92.10 Chronic myeloid leukemia, BCR/ABL-positive, not having achieved remission
- C92.11 Chronic myeloid leukemia, BCR/ABL-positive, in remission
- C92.12 Chronic myeloid leukemia, BCR/ABL-positive, in relapse

CLINICAL PEARLS

- CML belongs to the myeloproliferative disorders group
- The gold standard for diagnosis of CML is detection of the Philadelphia chromosome or its products, *BCR-ABL* mRNA, and fusion protein.
- TKIs provide durable, long-term control of the disease and have dramatically altered treatment.
- Atypical CML is a form of clinically typical CML but without the presence of the typical *BCR-ABL* translocation.
- Blast crisis is a form of acute leukemia that is a possible complication of CML.

LEUKOPLAKIA, ORAL

Christine K. Jacobs, MD

BASICS

DESCRIPTION

- Oral leukoplakia is a white plaque on the oral mucosa, generally precancerous.
- System(s) affected: gastrointestinal

EPIDEMIOLOGY

- Develops in middle age, increases with age
- Most common in India, where more people smoke and chew tobacco and areca nuts

Prevalence

- 0.1–0.5% of the adult population is affected.
- Usual age of onset is >40 years old with peak in the 60s.
- Males twice as often as females

Geriatric Considerations

Malignant transformation to carcinoma is more common in older patients.

ETIOLOGY AND PATHOPHYSIOLOGY

Hyperkeratosis or dyskeratosis of the oral squamous epithelium

- Tobacco use in any form
- Alcohol consumption/alcoholism
- Periodontitis
- *Candida albicans* infection may induce dysplasia and increase malignant transformation.
- Human papillomavirus, types 11 and 15
- Sunlight
- Vitamin deficiency
- Syphilis
- Dental restorations/prosthetic appliances

- Estrogen therapy
- Chronic trauma or irritation
- Epstein-Barr virus (oral hairy leukoplakia)
- Areca nut/betel (Asian populations)
- Mouthwash preparations and toothpaste containing the herbal root extract sanguinaria

Genetics

- Dyskeratosis congenital and epidermolysis bullosa increase the likelihood of oral malignancy
- P53 overexpression correlates with leukoplakia and particularly squamous cell carcinoma

RISK FACTORS

- 70–90% of oral leukoplakia is related to tobacco, particularly smokeless tobacco or areca/betel nut use.
- Alcohol increases risk 1.5-fold.
- Repeated or chronic mechanical trauma from dental appliances or cheek biting
- Chemical irritation to oral regions
- Diabetes
- Age
- Socioeconomic status
- Risk factors for malignant transformation of leukoplakia
  - Female
  - Long duration of leukoplakia
  - Nonsmoker (idiopathic leukoplakia)
  - Located on tongue or floor of mouth
  - Size >200 mm^2
  - Nonhomogenous type
  - Presence of epithelial dysplasia

GENERAL PREVENTION

- Avoid tobacco of any kind, alcohol, habitual cheek biting, tongue chewing.
- Use well-fitting dental prosthesis.
- Regular dental check-ups to avoid bad restorations

- Diet rich in fresh fruits and vegetables may help to prevent cancer.
- HPV vaccination may be preventive.

COMMONLY ASSOCIATED CONDITIONS

- HIV infection is closely associated with hairy leukoplakia.
- Erythroplakia in association with leukoplakia, “speckled leukoplakia,” or erythroleukoplakia is a marker for underlying dysplasia.

DIAGNOSIS

Leukoplakia is an asymptomatic white patch on the oral mucosa.

HISTORY

- Usually asymptomatic
- History of tobacco or alcohol use or oral exposure to irritants

PHYSICAL EXAM

- Location
  - 50% on tongue, mandibular alveolar ridge, and buccal mucosa
  - Also seen on maxillary alveolar ridge, palate, and lower lip
  - Infrequently seen on floor of the mouth and retromolar areas
  - Floor of mouth, ventrolateral tongue, and soft palate complex are more likely to have dysplastic lesions.
- Appearance
  - Varies from homogeneous, nonpalpable, faintly translucent white areas to thick, fissured, papillomatous, indurated plaques
  - May feel rough or leathery
  - Lesions can become exophytic or verruciform.
  - Color may be white, gray, yellowish white, or brownish gray.
  - Cannot be wiped or scraped off
- World Health Organization classification
  - Homogeneous refers to color
    - Flat, corrugated, wrinkled, or pumice
  - Nonhomogeneous refers to color and texture (more likely to be dysplastic or malignant).

- Erythroleukoplakia (mixture of red and white)
- Exophytic: papillary or verrucous texture

DIFFERENTIAL DIAGNOSIS

- White oral lesions that can be wiped away: acute pseudomembranous candidiasis
- White oral lesions that cannot be rubbed off:
  - Morsicatio buccarum (habitual cheek-biting), generally benign
  - Chemical injury
  - Acute pseudomembranous candidiasis
  - Traumatic or frictional keratosis (e.g., linea alba)
  - Leukoedema (benign milky opaque lesions that disappear with stretching)
  - Aspirin burn (from holding aspirin in cheek)
  - Lichen planus (bilateral fairly symmetric lesions, reticular pattern of slightly raised gray-white lines)
  - Lichenoid reaction
  - Verrucous carcinoma
  - Discoid lupus erythematosus
  - Skin graft (known history)
  - Squamous cell carcinoma
  - Oral hairy leukoplakia, commonly on the lateral border of the tongue with a bilateral distribution (in HIV patients with Epstein-Barr virus infection)
  - Smoker’s palate (leukokeratosis nicotina palati)
  - White sponge nevus (congenital benign spongy lesions)
  - Syphilitic oral lesion
  - Dyskeratosis congenita (a rare inherited multisystem disorder)

DIAGNOSTIC TESTS & INTERPRETATION

Biopsy is the gold standard.

Initial Tests (lab, imaging)

- Laboratory tests generally are not indicated.
  - Consider saliva culture if *C. albicans* infection is suspected.
- No imaging is indicated.

Follow-Up Tests & Special Considerations

- Biopsy is necessary to rule out carcinoma if lesion is persistent, changing, or unexplained.
- Consider CBC, rapid plasma reagin (RPR).

Diagnostic Procedures/Other

- Oral cytology is superior to conventional oral examination (1)[A].
- Computer-assisted cytology or liquid-based cytology is not superior to oral cytology (1)[A].
- Noninvasive brush biopsy and analysis of cells with DNA–image cytometry constitute a sensitive and specific screening method.
- Patients with dysplastic or malignant cells on brush biopsy should undergo more formal excisional biopsy.
- Excisional biopsy is definitive procedure.

Test Interpretation

- Biopsy specimens range from hyperkeratosis to invasive carcinoma.
- At initial biopsy, 6% are invasive carcinoma.
- 0.13–6% subsequently undergo malignant transformation.
- Location is important: 60% on floor of mouth or lateral border of tongue are cancerous; buccal mucosal lesions are generally not malignant but require biopsy if not resolving.

TREATMENT

- All oral leukoplakias should be treated.
- Treatment may include the following:
  - For 2 to 3 circumscribed lesions, surgical excision
  - For multiple or large lesions where surgery would cause unacceptable deformity, consider cryosurgery or laser surgery (2)[C].
  - Removal of predisposing habits (alcohol and tobacco)
- Complete excision is standard treatment for dysplasia or malignancy.
- After treatment, up to 30% of leukoplakia recurs, and some leukoplakia still transforms to squamous cell carcinoma (2)[B].
- Oral hairy leukoplakia may be treated with podophyllin with acyclovir cream.

GENERAL MEASURES

- Eliminate habitual lip biting.
- Correct ill-fitting dental appliances, bad restorations, or sharp teeth.
- Stop smoking and using alcohol.
- Some small lesions may respond to cryosurgery.
- β-Carotene, lycopene, retinoids, and cyclooxygenase 2 (COX-2) inhibitors may cause partial regression.
- For hairy tongue: tongue brushing

MEDICATION

Carotenoids; vitamins A, C, and K; bleomycin, and photodynamic therapy ineffective to prevent malignant transformation and recurrence

ISSUES FOR REFERRAL

Consider otolaryngologist or oral surgery referral for extensive disease.

SURGERY/OTHER PROCEDURES

- Scalpel excision, laser ablation, electrocautery, or cryoablation
- Cryotherapy slightly less effective than photodynamic therapy response (73% vs. 90%) and recurrence (27% vs. 24%) (3)[A]
- CO_2 laser had 20% recurrence and 10% malignant transformation within 5 years (4)[B].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Eliminate etiologic factors.
- Reevaluate in 7 to 14 days.
- Biopsy if lesion is persistent.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Regular, close follow-up, even after successful treatment
- Biopsy as needed

DIET

Regular

PATIENT EDUCATION

- If biopsy is negative, stress importance of periodic and careful follow-up.
- Initiate a dental referral to eliminate dental factors.
- Stress importance of stopping tobacco and alcohol use.
- Encourage participation in smoking cessation program.

PROGNOSIS

- Most leukoplakia is benign.
- Leukoplakia may regress, remain stable, or progress.
- 0.13–6% of initially benign lesions subsequently develop into cancer.
- Size >4 cm increases risk of malignant transformation.
- 5-year survival rate of oral cancer is 50%.

COMPLICATIONS

- New lesions may develop after treatment.
- Risk of malignant transformation to squamous cell carcinoma is approximately 5–17% (5)[B].
- Larger lesions and nonhomogeneous leukoplakia are associated with higher rates of malignant transformation.

CODES

ICD10

- K13.21 Leukoplakia of oral mucosa, including tongue
- K13.3 Hairy leukoplakia

CLINICAL PEARLS

- Excisional biopsy is indicated for any undiagnosed leukoplakia.
- After treatment, up to 30% of leukoplakia recurs, and some leukoplakia still transforms to squamous cell carcinoma; thus, long-term surveillance is essential.
- To lessen risk of malignant transformation, encourage tobacco and alcohol cessation and consider *C. albicans* eradication.

LICHEN PLANUS

Mercedes E. Gonzalez, MD, FAAD • Herbert P. Goodheart, MD

BASICS

Lichen planus (LP) is an idiopathic eruption with characteristic shiny, flat-topped (Latin: *planus*, "flat") purple (violaceous) papules and plaques on the skin, often accompanied by characteristic mucous membrane lesions. Itching may be severe.

DESCRIPTION

- Classic (typical) LP is a relatively uncommon inflammatory disorder of the skin and mucous membranes; hair and nails may also be affected.
  - Skin lesions are small, flat, angular, red-to-violaceous, shiny, pruritic papules and/or plaques with overlying fine, white lines (called Wickham striae), or gray-white puncta; most commonly seen on the flexor surfaces of the upper extremities, extensor surfaces of the lower extremities, the genitalia, and on the mucous membranes
  - On the oral mucosa, lesions typically appear as raised white lines in a lacelike pattern seen most often on the buccal mucosa.
  - Onset is abrupt or gradual. Course is unpredictable; may resolve spontaneously, recur intermittently, or persist for many years
- Drug-induced LP
  - Clinical and histopathologic findings may mimic those of classic LP. Lesions usually lack Wickham striae (see in the following text) and oral involvement is rare.
  - There is generally a latent period of months from drug introduction until lesions appear.
  - Lesions resolve when the inciting agent is discontinued, often after a prolonged period.
- LP variants
  - Follicular: also called lichen planopilaris; typically seen on the scalp, can

lead to scarring alopecia
  - Annular: Papules spread centrifugally as central area resolves; occur on glans penis, axillae, and oral mucosa
  - Linear: may be an isolated finding
  - Hypertrophic: itchy, hyperkeratotic, thick plaques on dorsal legs and feet
  - Atrophic: rare, most often the result of resolved lesions
  - Bullous LP: Intense inflammation in the dermis leads to blistering of epidermis.
  - LP pemphigoides: a combination of LP and bullous pemphigoid (IgG autoantibodies to collagen 17)
  - Nail LP: affects the nail matrix, lateral thinning, longitudinal ridging, and fissuring
- System(s) affected: skin/exocrine
- Synonym(s): lichenoid eruptions

EPIDEMIOLOGY

- Predominant age: 30 to 60 years old; rare in children and the geriatric population
- Predominant sex: female > male

Prevalence

In the United States, 450/100,000

ETIOLOGY AND PATHOPHYSIOLOGY

LP is considered to be a T-cell–mediated autoimmune response to self-antigens on damaged keratinocytes.

RISK FACTORS

Exposure to certain drugs or chemicals

- Thiazides, furosemide, β-blockers, sulfonylureas, antimalarials, penicillamine, gold salts, and angiotensin-converting enzyme inhibitors
- Rarely: photo-developing chemicals, dental materials, tattoo pigments

COMMONLY ASSOCIATED CONDITIONS

- An association has been noted between LP and hepatitis C virus infection, particularly in certain geographic regions (Asia, South America, the Middle

East, Europe) (1). Hepatitis should be considered in patients with widespread presentations of LP and those with primarily oral disease.

- In addition, chronic active hepatitis, lichen nitidus, and primary biliary cirrhosis have been noted to coexist with LP.
- Association with dyslipidemia has been reported (2)[B].
- LP has also been reported in association with other diseases of altered immunity, more often than would be expected by chance.
  - Bullous pemphigoid
  - Alopecia areata
  - Myasthenia gravis
  - Vitiligo
  - Ulcerative colitis
  - Graft-versus-host reaction
  - Lupus erythematosus (lupus erythematosus–LP overlap syndrome)
  - Morphea and lichen sclerosis et atrophicus

DIAGNOSIS

LP is most commonly diagnosed by its appearance despite its range of clinical presentations. A skin biopsy should be performed if the diagnosis is in doubt.

HISTORY

A minority of patients have a family history of LP. Affected families have an increased frequency of human leukocyte antigen B7 (HLA-B7). A thorough drug history should be performed.

PHYSICAL EXAM

- Skin (often severe pruritus)
  - Papules: 1 to 10 mm, shiny, flat-topped (planar) lesions that occur in crops; lesions may have a fine scale.
  - Evidence of scratching (i.e., crusts and excoriations) is usually absent.
  - Color: violaceous, with white lacelike pattern (Wickham striae) on surface of papules. Wickham striae are best seen after topical application of mineral oil and, if present, are virtually pathognomonic for LP.
  - Shape: polygonal or oval. Annular lesions may appear on trunk and mucous

membranes. Various shapes and sizes may be noted (polymorphic).
  - Arrangement: may be grouped, linear, or scattered individual lesions
  - Koebner phenomenon (isomorphic response): New lesions may be noted at sites of minor injuries, such as scratches or burns.
  - Distribution: ventral surface of wrists and forearms, dorsa hands, glans penis, dorsa feet, groin, sacrum, shins, and scalp. Hypertrophic (verrucous) lesions may occur on lower legs and may be generalized.
  - Postinflammatory hyperpigmentation: Lesions typically heal, leaving darkly pigmented macules in their wake.
- Mucous membranes (40–60% of patients with skin lesions; 20% have mucous membrane lesions without skin involvement)
  - Most commonly asymptomatic, nonerosive, milky-white lines with an elegant, lacy, netlike streaked pattern
  - Usually seen on buccal mucosa but may appear on tongue, gingiva, palate, or lips
  - Less commonly, LP may be erosive; rarely bullous
  - Painful, especially if ulcers present
  - Lesions may develop into squamous cell carcinoma (1–3%).
  - Glans penis, labia minora, vaginal vault, and perianal areas may be involved.
- Hair/scalp
  - LP of the hair follicle (lichen planopilaris) presents with keratotic plugs at the follicle orifice with a violaceous rim; may result in atrophy and permanent destruction of hair follicles (scarring alopecia)
- Nails (10%)
  - Involvement of nail matrix may cause proximal-to-distal linear grooves and partial or complete destruction of nail bed with pterygium formation.

DIFFERENTIAL DIAGNOSIS

- Skin
  - Lichen simplex chronicus
  - Eczematous dermatitis
  - Psoriasis
  - Discoid lupus erythematosus
  - Other lichenoid eruptions (those that resemble LP)

  - Pityriasis rosea
  - Lichen nitidus
- Oral mucous membranes
  - Leukoplakia
  - Oral hairy leukoplakia
  - Candidiasis
  - Squamous cell carcinoma (particularly in ulcerative lesions)
  - Aphthous ulcers
  - Herpetic stomatitis
  - Secondary syphilis
- Genital mucous membranes
  - Psoriasis (penis and labia)
  - Nonspecific balanitis, Zoon balanitis
  - Fixed drug eruption (penis)
  - Candidiasis (penis and labia)
  - Pemphigus vulgaris, bullous pemphigoid, and Behçet disease (all rare)
- Hair and scalp
  - Scarring alopecia (central centrifugal cicatricial alopecia)

DIAGNOSTIC TESTS & INTERPRETATION

If suggested by history

- Serology for hepatitis
- Liver function tests

Diagnostic Procedures/Other

- Skin biopsy
- Direct immunofluorescence helps to distinguish LP from discoid lupus erythematosus.

Test Interpretation

- Dense, bandlike (lichenoid) lymphocytic infiltrate of the upper dermis
- Vacuolar degeneration of the basal layer
- Hyperkeratosis and irregular acanthosis, increased granular layer
- Basement membrane thinning with “saw-toothing”
- Degenerative keratinocytes, known as colloid or Civatte bodies, are found in

the lower epidermis.
- Melanin pigment in macrophages

TREATMENT

Although LP can resolve spontaneously, treatment is usually requested by patients who may be severely symptomatic or troubled by its cosmetic appearance.

GENERAL MEASURES

- Goal is to relieve itching and resolve lesions.
- Asymptomatic oral lesions require no treatment.

MEDICATION

First Line

- Skin
- Superpotent topical steroids (e.g., 0.05% clobetasol propionate) twice daily.
  - Potent topical steroids such as triamcinolone acetonide 0.1% or fluocinonide 0.05% under occlusion
  - Intralesional corticosteroids (e.g., triamcinolone [Kenalog] 5 to 10 mg/mL) for recalcitrant and hypertrophic lesions
  - Antihistamines (e.g., hydroxyzine, 25 mg PO q6h) have limited benefit for itching but may be helpful for sedation at bedtime.
  - "Soak and smear" technique: can lead to a rapid improvement of symptoms in even 1 to 2 days and may obviate the need for systemic steroids. Soaking allows water to hydrate the stratum corneum and allows the anti-inflammatory steroid in the ointment to penetrate more deeply into the skin. Smearing of the ointment traps the water in the skin because water cannot move out through greasy materials.
    - Soaking is done in a bathtub using lukewarm plain water for 20 minutes, then, without drying the skin, the affected area is immediately smeared with a thin film of the steroid ointment containing clobetasol or another superpotent topical steroid.
    - Soak and smear may be done for 4 to 5 days or longer, if necessary. The treatments are best done at night because the greasy ointment applied to

the skin gets on pajamas (instead of on daytime clothes) and the ointment is on the skin during sleep. A topical steroid cream is applied thereafter during the daytime hours, if necessary.

- Mucous membranes
  - For oral, erosive, painful LP, a Cochrane review found at best weak evidence for the effectiveness of any intervention (3)[A].
    - Topical corticosteroids (0.1% triamcinolone [Kenalog] in Orabase) or 0.05% clobetasol propionate ointment BID
    - Intralesional corticosteroids
    - Topical 0.1% tacrolimus (Protopic ointment) BID or 1% pimecrolimus (Elidel) cream BID. A Cochrane review found no evidence that calcineurin inhibitors are better than placebo (4)[A].
    - Topical retinoids (e.g., 0.05% tretinoin [retinoic acid] in Orabase)

Pediatric Considerations

Children may absorb a proportionally larger amount of topical steroid because of larger skin surface-to-weight ratio.

Second Line

Skin and mucous membranes

- Intralesional corticosteroids
- Topical 0.1% tacrolimus (Protopic ointment) BID or topical 1% pimecrolimus (Elidel) cream BID
- Oral prednisone: used only for a short course (e.g., 30 to 60 mg/day for 2 to 4 weeks) or IM triamcinolone (Kenalog) 40 to 80 mg every 6 to 8 weeks
  - Precautions with systemic steroids
    - Systemic absorption of steroids may result in hypothalamic-pituitary-adrenal axis suppression, Cushing syndrome, hyperglycemia, or glucosuria.
    - Increased risk with high-potency topical steroids (i.e., use over large surface area, prolonged use, occlusive dressings)
    - In pregnancy: usually safe, but benefits must outweigh the risks
- Oral retinoids: Isotretinoin in doses of 10 mg PO daily for 2 months, acitretin 30 mg, or alitretinoin 30 mg PO daily have resulted in improvement in some refractory cases. Observe carefully for resultant dyslipidemia.

- Oral metronidazole 500 mg BID for 20 to 60 days can be given as a safer alternative to systemic corticosteroids.
- Cyclosporine may be used in severe cases, but cost and potential toxicity limit its use; topical use for severe oral involvement refractory to other treatments
- Thalidomide
- Psoralen ultraviolet-A (PUVA), broad- or narrow-band ultraviolet B (UVB) (5)[A]
- Griseofulvin (5)[A]
- Azathioprine
- Mycophenolate mofetil
- Metronidazole

ALERT

Avoid oral and topical retinoids during pregnancy.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Outpatient care

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Serial oral examinations for erosive/ulcerative lesions

PATIENT EDUCATION

- Oral, erosive, or ulcerative LP: annual follow-up to screen for malignancy (6) [A]
- Avoid spicy foods, cigarettes, and excessive alcohol.
- Avoid dry crispy foods such as corn chips, pretzels, and toast.

PROGNOSIS

- Spontaneous resolution in weeks is possible, but disease may persist for years, especially oral lesions and hypertrophic lesions on the shins.
- There is a tendency toward relapse.

- Recurrence in 12–20%, especially in those with generalized involvement

COMPLICATIONS

- Alopecia
- Nail destruction
- Squamous cell carcinoma of the mouth or genitals

CODES

ICD10

- L43.9 Lichen planus, unspecified
- L43.0 Hypertrophic lichen planus
- L43.1 Bullous lichen planus

CLINICAL PEARLS

- Remember the 7 P's of LP: **p**urple, **p**lanar, **p**olygonal, **p**olymorphic, **p**ruritic (not always), **p**apules that heal with **p**ostinflammatory hyperpigmentation.
- Serial oral or genital exams are indicated for erosive/ulcerative LP lesions to monitor for the development of squamous cell carcinoma.
- An association has been noted between LP and hepatitis C virus infection, chronic active hepatitis, and primary biliary cirrhosis.
- The "soak and smear" technique can lead to a rapid improvement of symptoms in 1 to 2 days and may obviate the need for systemic steroids.

LICHEN SIMPLEX CHRONICUS

Geoffrey Strider Farnsworth, MD

BASICS

DESCRIPTION

- Lichen simplex chronicus (LSC) is a chronic dermatitis resulting from chronic, repeated rubbing or scratching of the skin. Skin becomes thickened with accentuated lines ("lichenification").
- System(s) affected: skin
- Synonym(s): LSC; lichen simplex; localized neurodermatitis; neurodermatitis circumscripta

EPIDEMIOLOGY

Geriatric Considerations

Most common in middle aged and elderly

Pediatric Considerations

Rare in preadolescents

Incidence

- Common
- Peak incidence 35 to 50 years
- Predominant sex: females > males (2:1)

Prevalence

Common

ETIOLOGY AND PATHOPHYSIOLOGY

- Itch–scratch cycle leads to a chronic dermatosis. Repeated scratching or rubbing causes inflammation and pruritus, which leads to continued scratching.
- Primary LSC: Scratching secondary to nonorganic pruritus, habit or a conditioned response to stress/anxiety
- Common triggers are excess dryness of skin, heat, sweat, and psychological

stress.

- Secondary LSC: begins as a pruritic skin disease that evolves into neurodermatitis, which persists after resolution of the primary condition. Precursor dermatoses include atopic dermatitis, contact dermatitis, lichen planus, stasis dermatitis, psoriasis, tinea, and insect bites.
- There is a possible relation between disease development and underlying neuropathy, particularly radiculopathy or nerve root compression.
- Pruritus-specific C neurons are temperature sensitive, which may explain itching that occurs in warm environments.

RISK FACTORS

- Anxiety disorders
- Dry skin
- Insect bites
- Pruritic dermatosis

GENERAL PREVENTION

Avoid common triggers such as psychological distress, environmental factors such as heat and excessive dryness, skin irritation, and the development of pruritic dermatoses.

COMMONLY ASSOCIATED CONDITIONS

- Prurigo nodularis is a nodular variety of the same disease process.
- Atopic dermatitis
- Anxiety, depression, and obsessive-compulsive disorders

DIAGNOSIS

HISTORY

- Gradual onset
- Begins as a localized area of pruritus
- Most patients acknowledge that they respond with vigorous rubbing, itching, or scratching, which brings temporary satisfaction.
- Pruritus is typically paroxysmal, worse at night, and may lead to scratching during sleep.

- Can be asymptomatic with patient scratching at night while asleep

PHYSICAL EXAM

- Well-circumscribed lichenified plaques with varying amounts of overlying excoriation or scaling
- Lichenification: accentuation of normal skin lines
- Hyperpigmentation or hypopigmentation can be seen.
- Scarring is uncommon with typical LSC; can be seen following ulcer formation or secondary infection.
- Most commonly involves easily accessible areas
  - Lateral portions of lower legs/ankles
  - Nape of neck (lichen simplex nuchae)
  - Vulva/scrotum/anus
  - Extensor surfaces of forearms
  - Palmar wrist
  - Scalp

DIFFERENTIAL DIAGNOSIS

- Lichen sclerosis
- Psoriasis
- Atopic dermatitis
- Contact, irritant, or stasis dermatitis
- Extramammary Paget disease
- Lichen planus
- Mycosis fungoides
- Lichen amyloidosis
- Tinea
- Nummular eczema

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- No specific diagnostic test
- Microscopy (i.e., KOH prep) and culture preparation may be helpful in identifying possible bacterial or fungal infection.

Diagnostic Procedures/Other

- Skin biopsy if diagnosis is in question.
- Patch testing may be used to rule out a contact dermatitis.

Test Interpretation

- Hyperkeratosis
- Acanthosis
- Lengthening of rete ridges
- Hyperplasia of all components of epidermis
- Mild to moderate lymphohistiocytic inflammatory infiltrate with prominent lichenification

TREATMENT

GENERAL MEASURES

- Patient education is critical.
- Low likelihood of resolution if patient unable to avoid scratching.
- Treatment aimed at reducing inflammation and pruritus.

MEDICATION

First Line

- Reducing inflammation
  - Topical steroids are first-line agents (1,2)[C].
  - High-potency steroids alone, such as 0.05% betamethasone dipropionate cream or 0.05% clobetasol propionate cream, can be used initially but should be avoided on the face, anogenital region, or intertriginous areas. They should be used on small areas only, for no longer than 2 weeks except under the close supervision of a physician.
  - Switch to intermediate- or low-potency steroids as response allows.
  - An intermediate-potency steroid, such as 0.1% triamcinolone cream, may be used for initial, brief treatment of the face and intertriginous areas, and for maintenance treatment of other areas.
  - A low-potency steroid, such as 1% hydrocortisone cream, should be used for maintenance treatment of the face and intertriginous areas.
  - Steroid tape, flurandrenolide, has optimized penetration and provides a

barrier to continued scratching. Change tape once daily.
  - Intralesional steroids, such as triamcinolone acetate, are also safe and effective for severe cases.
- Preventing scratching
  - Topical antipruritic agents
  - 1st-generation oral antihistamines such as diphenhydramine and hydroxyzine for antipruritic and sedative effects
  - Sedating tricyclics, such as doxepin and amitriptyline, for nighttime itching
  - Itching may occur at night while the patient is asleep; occlusive dressings may be helpful in these cases.

ALERT

High-dose and prolonged treatment with topical steroids can cause dermal/epidermal atrophy as well as pigmentary changes and should not be used on the face, intertriginous areas, or anogenital region. Duration of treatment on other parts of the body should not exceed 3 weeks without close physician supervision.

Second Line

All recommendations

- Topical aspirin has been shown to be helpful in treating neurodermatitis (3) [C].
- Topical 5% doxepin cream has significant antipruritic activity (3)[C].
- Topical capsaicin cream can be helpful for treatment of early disease manifestations (3)[C].
- 0.1% tacrolimus applied twice daily over 6 weeks for as an effective alternative treatment (4)[C]
- Gabapentin was found to decrease symptoms in patients who are nonresponsive to steroids.
- Topical lidocaine can be effective in decreasing neuropathic pruritus (3)[C].
- Intradermal botulinum toxin injections has been reported to improve symptoms in patients with recalcitrant pruritus.
- Transcutaneous electrical nerve stimulation may relieve pruritus in patients for whom topical steroids were not effective (5)[C].
- A case report showed NB-UVB as a possible off-label treatment of refractory

LSC (6)[C].

- SSRIs may be effective in controlling compulsive scratching secondary to psychiatric diagnosis.

ISSUES FOR REFERRAL

- No response to treatment
- Presence of signs and symptoms suggestive of a systemic cause of pruritus
- Consultation with a psychiatrist for patients with severe stress, anxiety, or compulsive scratching
- Consultation with an allergist for patients with multisystem atopic symptoms

ADDITIONAL THERAPIES

- Cooling of the skin with ice or cold compresses
- Soaks and lubricants to improve barrier layer function
- Occlusion of lesion with bandages or Unna boots.
- Nail trimming
- Silk underwear to decrease friction in genital LSC.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Acupuncture has been shown as an effective treatment for pruritus (7)[C].
- Cognitive-behavioral therapy may improve awareness and help to identify coping strategies.
- Hypnosis may be beneficial in decreasing pruritus and preventing scratching.
- Homeopathic remedies (i.e., thuja and graphite) have been used.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Patients should be followed for response to therapy, complications from therapy (especially topical steroids), and secondary infections.

DIET

Regular balanced diet

PATIENT EDUCATION

- Patients should understand the cause of this disease and the critical role they play in its resolution:
  - Emphasize that scratching and rubbing must stop for lesions to heal. Medications ineffective if scratching continues
- Stress reduction techniques can be useful for patients for whom stress plays a role.
- Avoid exposure to known triggers.

PROGNOSIS

- Often chronic and recurrent
- Good prognosis if the itch–scratch cycle can be broken
- After healing, the skin should return to normal appearance but may also retain accentuated skin markings or post inflammatory pigmentary changes that may be slow to resolve.

COMPLICATIONS

- Secondary infection
- Scarring is rare without ulceration or secondary infection.
- Complications related to therapy, as mentioned in medication precautions
- Squamous cell carcinoma within affected regions is rare.

CODES

ICD10

L28.0 Lichen simplex chronicus

CLINICAL PEARLS

- LSC is a chronic inflammatory condition that results from repeated scratching and rubbing.
- Primary LSC originates de novo, whereas secondary LSC occurs in the setting of a preexisting pruritic dermatologic condition.
- LSC is a clinical diagnosis based on history and skin examination with biopsy only indicated in difficult or unclear cases.
- Stopping the itch–scratch cycle through patient education, skin lubrication, and topical medications is key.
- Treatment aimed at decreasing both inflammation and pruritus utilizing topical steroids and antipruritics.

LONG QT INTERVAL

Carl Bryce, MD • Matthew J. Snyder, DO

BASICS

DESCRIPTION

- QT interval: electrocardiogram (ECG) measurement that measures the duration of repolarization of myocardial cells. Measured from the onset of the QRS complex to the end of the T wave
- Corrected QT interval (QTc): QT interval corrected for heart rate (interval shortens with increased rate). See formulas.
- Prolonged QTc is generally defined as >470 ms for adult males and >480 ms for adult females (1):
  - 440 to 460 ms considered borderline in men
  - 440 to 470 ms considered borderline in women
  - 440 to 460 ms considered borderline in children aged 1 to 15 years old (2)
- Most cases of prolonged QT are acquired, but genetic mutations can also cause hereditary long QT syndromes (LQTS).
- Prolonged QTc from any cause can precipitate polymorphic ventricular tachycardia (VT) called torsade de pointes (TdP), leading to dizziness, syncope, and sudden cardiac death from ventricular fibrillation (VF).

EPIDEMIOLOGY

Incidence

Incidence of medication-induced QTc prolongation and TdP varies with medication and a host of other factors. Exact incidences are difficult to estimate but may be 1:2,000 to 1:2,500. (1).

Prevalence

- Hereditary LQTS is estimated to occur in 1/2,500 to 1/7,000 births.
- Five thousand people across the United States may die yearly due to LQTS-related cardiac arrhythmia (2).

ETIOLOGY AND PATHOPHYSIOLOGY

- Acquired
  - Electrolyte abnormalities such as hypokalemia, hypomagnesemia
  - Hypothyroidism
  - Underlying heart disease
  - Medications (3)[A]
    - Antiarrhythmic medications (quinidine, procainamide, dofetilide, sotalol, disopyramide, and amiodarone)
    - Antipsychotic medications, especially if given IV (haloperidol*, chlorpromazine*, thioridazine*, pimozide*)
    - Many antidepressants (SSRIs, SNRIs, trazodone, TCAs)
    - Antibiotics/antivirals/antifungals (clarithromycin*, erythromycin* which are also CYP3A4 inhibitors)
    - Antiemetics (metoclopramide, ondansetron, promethazine)
    - Opioids (methadone*, buprenorphine)
    - Antihistamines (cetirizine, hydroxyzine, diphenhydramine)
    - Decongestants (pseudoephedrine, phenylephrine
    - Stimulants (albuterol, phentermine)
    - Misc: chloroquine*, pentamidine*
    - *Denote “high-risk” medication for TdP.
- Congenital
  - Defective membrane proteins that work as channels for sodium and potassium in myocytes
- Pathophysiology
  - Depolarization of the myocardium results from the rapid influx of sodium through sodium channels and causes myocyte contraction, with resulting cardiac muscle contraction and systole (seen on ECG as the QRS complex).
  - During repolarization, there is an efflux of potassium from the cell through both rapid (I_{Kr}) and slow (I_{Ks}) potassium channels. The T wave on an ECG represents myocyte repolarization.
  - Drug-induced QT prolongation due to blockade of I_{Kr} leading to delayed repolarization (2).
  - Medications, medical conditions, electrolyte disturbances, and genetic mutations that affect functioning of these membrane channels can cause delayed repolarization.

  - Delayed repolarization can lead to a propensity for reentry and initiate TdP.
  - TdP type rhythm may be self-limited but symptomatic (syncope or near syncope). It can also degrade into VF.

Genetics

- 12 different genes have been linked to LQTS (3).
- Incomplete penetrance makes both diagnosis and management of asymptomatic disease challenging.
- LQTS 1 (42–54%) is the most common. Mutation causes a defect in the I_{Ks} transport protein. Arrhythmias can be triggered by tachycardia due to exercise (swimming seems to be especially problematic) and other high catecholamine states.
- LQTS 2 (35–45%) is a defect in the I_{Kr} transport protein that is sensitive to catecholamine surges. Sudden loud noises or emotional arousal can provoke arrhythmias.
- LQTS 3 (8%) is a defect in the sodium channel that allows an excess of sodium into the cell, increasing repolarization time. Arrhythmias tend to manifest more during rest or sleep.
- Jervell and Lange-Nielsen syndrome: Autosomal recessive form of LQTS that features homozygous mutations affect the I_{Ks} channel and presents with severe form of LQTS 1. Features also include deafness.
- Romano-Ward syndrome: autosomal dominant form of LQTS with variable penetrance. Hearing is normal.

RISK FACTORS

For the feared complication, TdP, risk factors include the following (3):

- Female (∼2 times increased risk)
- QTc >500 ms (2 to 3 times increased risk)
- QTc >60 ms over previous baseline
- History of syncope or presyncope
- History of TdP
- Bradycardia
- Liver or kidney disease (by increasing blood levels of QT prolonging medications)
- Medications that cause QTc prolongation

  - High doses
  - Fast infusions
  - Combination of medications
- Electrolyte abnormalities
  - Hypokalemia
  - Hypomagnesemia
  - Hypocalcemia
- For hereditary LQTS
  - Catecholamine surges from exercise (especially swimming), emotional stress, loud noises

GENERAL PREVENTION

- Avoid (or use with caution) causative medications, including combinations with potentially additive effects. Replete electrolytes (goal Mg >2, K 4.5 to 5.0) (4)[C]
- Treat underlying medical disease (hypothyroidism, cardiac disease).
- Avoid strenuous sports in LQTS.
- Avoid sudden loud noises in LQTS (alarm clocks, doorbells, telephones).
- 36th Bethesda Conference recommends restriction of athletes from participation to class 1A activities (e.g., bowling, golf, riflery) although evidence regarding safe participation is emerging (1)[C].

DIAGNOSIS

HISTORY

- Evaluate for syncope, near syncope, and associated precipitating events (such as emotional triggers, swimming, diving).
- Evaluate for history of seizures in patient or in family (tonic–clonic movement may due to cerebral hypoperfusion during episodes of ventricular arrhythmia or due to seizure-like activity during a syncopal episode.).
- Detailed medication history
- Evaluate for family history of sudden death and syncope.
- Congenital deafness

PHYSICAL EXAM

- Usually normal physical exam
- If underlying cardiac disease present, may have findings specific to cardiac condition
- Evaluate for signs of hypothyroidism.
- Congenital deafness may be present in some forms of LQTS.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- ECG
- Metabolic panel
- Calcium level
- Magnesium level
- TSH

Follow-Up Tests & Special Considerations

- Echocardiogram to evaluate for cardiomyopathy
- Outpatient cardiac rhythm monitoring
- Consider provocative testing (epinephrine infusion, exercise stress testing) to evaluate for QTc interval changes and/or to evaluate for coronary artery disease (2)[C].
  - Genetic testing for LQTS mutations

Test Interpretation

- QTc calculation using ECG is best done by measuring the QT interval in lead II and measuring the RR interval immediately preceding this QT interval. The Bazett formula is commonly used, although it overcorrects for tachycardia and undercorrects for bradycardia (2).
- Bazett formula: QTc = QT/√(RR) (all measurements in seconds, and RR obtained by direct measurement or 60/heart rate)
- Fridericia formula is similar to Bazett but uses a cube root instead of a square root of the RR interval. QTc = $QT/(RR)^{1/3}$

TREATMENT

GENERAL MEASURES

- VT, TdP, and VF should be treated emergently as per ACLS guidelines.
- Cardiac pacing may be needed emergently for drug-induced TdP to prevent bradycardia.
- Withdraw offending agents, correct electrolytes (2)[C].

MEDICATION

First Line

- For Tdp: magnesium sulfate 2 g infused over 2 to 15 minutes, followed by continuous infusion of 2 to 4 mg/min if needed. Monitor for magnesium toxicity in those with renal insufficiency (2)[C].
- For hereditary LQTS, to prevent life-threatening arrhythmias: Propranolol or nadolol are generally regarded as the best β-blockers for management of LQTS, though rigorous studies are lacking (4)[B].
- β-Blockers are effective in decreasing but not eliminating the risk of fatal arrhythmias.
- For high-risk patients or those who remain symptomatic on a β-blocker, implantable cardiac defibrillators (ICDs) with or without pacemaker is an important consideration (2)[B].

Second Line

- Atenolol or metoprolol may be used, although switching from other β-blockers may precipitate lethal or near-lethal events (4)[B].

ISSUES FOR REFERRAL

- Refer to cardiologist for establishing diagnosis, especially for hereditary LQTS.
- Symptomatic prolonged QT

SURGERY/OTHER PROCEDURES

- ICD for those with a history of major cardiac events
- Left cervical-thoracic sympathetic denervation was used for symptomatic LQTS prior to the advent of β-blockers. It is still an option for those patients with LQTS who are refractory to β-blocker therapy (3)[B].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Patients with TdP, VT, and VF should be promptly treated as per ACLS guidelines. Correct electrolytes on an emergent basis. Evaluate for acquired QT prolongation. If no cause is found, consider hereditary LQTS.
- Patients with prolonged QTc and syncope/near syncope should be monitored on telemetry during evaluation.
- Monitor ECG if initiating medications or combining medications that may prolong QT, suggest at baseline, within 30 days, and then annually (3)[C].
- Monitor electrolytes and urgently treat hypomagnesemia and hypokalemia in those with significantly prolonged QT, and discontinue or change offending medications (5)[C].
- Avoid sudden loud noises or emotional stress for those who have LQTS.
- Review adherence to β-blocker therapy.
- Notify others if telemetry monitoring reveals prolonged QT interval in hospitalized patients—they are at risk for poor outcomes (6).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

On routine visits, ask about syncope, presyncope, and palpitations in those who have QTc prolongation.

- Patient monitoring: Consider ECG and/or outpatient cardiac rhythm monitoring with any medication additions or dosage changes that may cause further prolongation of the QTc.
- For those who may have symptomatic QTc prolongation of any cause, prompt evaluation is warranted.
- Check labs for electrolyte imbalances, correct as needed.

PATIENT EDUCATION

- Educate patients with QTc prolongation about medications side effects and possibility of medication interactions.
- Patients with congenital forms of LQTS should be aware of, and avoid situations that may trigger torsade (depending on their specific gene mutation)
- Large emotional and psychological impact of diagnosis. Additional reading by Fortescue shares personal impact of LQTS.

- Information and support from groups listed (see "Additional Reading") may be helpful.

PROGNOSIS

Untreated, quite poor. Perhaps 20% of untreated patients presenting with syncope die within 1 year, 50% within 10 years (3).

SEE ALSO

Algorithms: Cardiac Arrhythmias; Arrhythmias, Torsade de Pointes Ventricular Tachycardia

CODES

ICD10

I45.81 Long QT syndrome

CLINICAL PEARLS

- Evaluate for acquired causes before making a diagnosis of hereditary LQTS.
- For accurate diagnosis, calculate QTc manually.
- The ideal management of TdP is prevention; avoid multiple “stacking” risk factors and seek alternates to high-risk medications, correct electrolytes, and monitor treatment with serial ECGs if no alternatives exist.
- Magnesium sulfate is the treatment of choice during ACLS for TdP.
- *β*-Blockers are initial treatment of choice for hereditary LQTS.

LUNG, PRIMARY MALIGNANCIES

Brian P. Bateson, DO • Nathaniel Walsh, MD • Carsten Schroeder, MD, PhD

BASICS

DESCRIPTION

- Lung cancers (primary) are the leading cause of cancer-related death in the United States (estimated 159,260 deaths in 2015, 27% of all cancer-related deaths).
- Divided into two broad categories
  - Non–small cell lung cancer (NSCLC) (>85% of all lung cancers); normally originate in periphery
    - Adenocarcinoma (~40% of NSCLC): Most common type in the United States, most common type in nonsmokers, metastasizes earlier than squamous cell, poor prognosis; lipidic growth, a subtype of adenocarcinoma has better prognosis.
    - Squamous cell carcinoma (~25% of NSCLC): dose-related effect with smoking; slower growing than adenocarcinoma
    - Large cell (~10% of NSCLC): prognosis similar to adenocarcinoma
  - Small cell lung cancer (SCLC) (16% of all lung cancers): centrally located, early metastases, aggressive
- Other: mesothelioma and carcinoid tumor
- Staging
  - Both NSCLC and SCLC: staged from I to IV based on: primary tumor (T), lymph node status (N), and presence of metastasis (M)
  - SCLC further staged by:
    - Limited disease: confined to ipsilateral hemithorax, which may include malignant pleural or pericardial effusion or hematogenous metastases (stage IV)
    - Extensive disease: beyond ipsilateral hemithorax (stages IIIB and IV)
    - Tumor locations: upper: 60%; lower: 30%; middle: 5%; overlapping and main stem: 5%

- May spread by local extension to involve chest wall, diaphragm, pulmonary vessels, vena cava, phrenic nerve, esophagus, or pericardium
- Most commonly metastasize to lymph nodes (pulmonary, mediastinal), then liver, adrenal, bone, brain

EPIDEMIOLOGY

Incidence

- Estimated 224,210 new cases in the United States in 2015
- Predominant age: >40 years; peak at 70 years
- Predominant sex: male > female

Prevalence

- Most common cancer worldwide
- Lifetime probability: men: 1 in 13; women: 1 in 16

ETIOLOGY AND PATHOPHYSIOLOGY

Multifactorial; see "Risk Factors."

Genetics

NSCLC

- Oncogenes: Ras family (H-ras, K-ras, N-ras)
- Tumor suppressor genes: retinoblastoma, *p53*

RISK FACTORS

- Smoking (relative risk [RR] 10 to 30)
- Secondhand smoke exposure
- Radon
- Environmental and occupational exposures
  - Asbestos exposure (synergistic increase in risk for smokers)
  - Air pollution
  - Ionizing radiation
  - Mutagenic gases (halogen ethers, mustard gas, aromatic hydrocarbons)
  - Metals (inorganic arsenic, chromium, nickel)
- Lung scarring from tuberculosis
- Radiation therapy to the breast or chest

GENERAL PREVENTION

- Smoking cessation and prevention programs
- Screening recommended by and NCCN and shown to reduce mortality in National Lung Screening Trial (NLST) (1)[A].
- Annual screening recommended with low-dose computed tomography in adults ages 55 to 74 years who have a 30 pack-year smoking history and currently smoke or have quit within the past 15 years.
- Screening should be discontinued once a person has not smoked for 15 years or develops a health problem that substantially limits life expectancy or the ability or willingness to have curative lung surgery.
- Prevention via aggressive smoking cessation counseling and therapy; a 20–30% risk reduction occurs within 5 years of cessation.
- Avoid hormone replacement therapy in postmenopausal smokers or former smokers (increased risk of death from NSCLC).

COMMONLY ASSOCIATED CONDITIONS

- Paraneoplastic syndromes: hypertrophic pulmonary osteoarthropathy, Lambert-Eaton syndrome, Cushing syndrome, hypercalcemia from ectopic parathyroid-releasing hormone, syndrome of inappropriate antidiuretic hormone (SIADH)
- Hypercoagulable state
- Pancoast syndrome
- Superior vena cava syndrome
- Pleural effusion
- Chronic obstructive pulmonary disease (COPD), other sequelae of cigarette smoking

DIAGNOSIS

HISTORY

- May be asymptomatic for most of course
- Respiratory
  - Cough (new or change in chronic cough)
  - Wheezing and stridor
  - Dyspnea

  - Hemoptysis
  - Pneumonitis (fever and productive cough)
- Constitutional
  - Malaise
  - Bone pain (metastatic disease)
  - Fatigue
  - Weight loss, anorexia
  - Fever
  - Anemia
  - Clubbing of digits
- Other presentations:
  - Chest pain (dull, pleuritic)
  - Shoulder/arm pain (Pancoast tumors)
  - Dysphagia
  - Plethora (redness of face or neck)
  - Hoarseness (involvement of recurrent laryngeal nerve)
  - Horner syndrome
  - Neurologic abnormalities (e.g., headaches, syncope, weakness, cognitive impairment)
  - Pericardial tamponade (pericardial invasion)

PHYSICAL EXAM

- General: fever, chills, night sweats, weight loss
- Head, eye, ear, nose, throat (HEENT): Horner syndrome, dysphonia, stridor, scleral icterus
- Neck: supraclavicular/cervical lymph nodes, mass
- Lungs: effusion, wheezing, airway obstruction, pleural effusion
- Abdomen/groin: hepatomegaly or lymphadenopathy
- Extremities: signs of hypertrophic pulmonary osteoarthropathy, deep venous thrombosis (DVT)
- Neurologic: Rule out cognitive and focal motor defects.

DIFFERENTIAL DIAGNOSIS

- COPD (may coexist)
- Granulomatous (tuberculosis, sarcoidosis)

- Cardiomyopathy
- Congestive heart failure (CHF)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Serum
  - CBC
  - Comprehensive metabolic panel (CMP)
  - Hypercalcemia (paraneoplastic syndrome)
  - Hyponatremia (SIADH)
  - Lactate dehydrogenase (LDH)
- Sputum cytology
- Chest x-ray (CXR) (compare with prior XRs)
  - Nodule or mass, especially if calcified
  - Persistent infiltrate
  - Atelectasis
  - Mediastinal widening
  - Hilar enlargement
  - Pleural effusion
- CT scan of chest (with IV contrast)
  - Nodule or mass (central or peripheral)
  - Lymphadenopathy
- Evaluation for metastatic disease
  - Positron emission tomography (PET) scan to evaluate metastasis mediastinal lymphadenopathy (replacing CT abdomen/pelvis and bone scan)
  - Brain MRI: lesions may be necrotic, bleeding.
  - CT (abdomen/pelvis and bone scan)

Follow-Up Tests & Special Considerations

CBC, BUN, serum creatinine, LFTs prior to each cycle of chemotherapy

Diagnostic Procedures/Other

- Pulmonary function tests
  - Bronchoscopy
  - Transbronchial biopsy (Wang needle)

  - Enlarged mediastinal lymph nodes necessitate staging by mediastinoscopy, video-assisted thoracoscopy, endobronchial ultrasound or fine needle aspiration
- Biopsy with pathology review
- In patients with advanced NSCLC, determination of epidermal growth factor receptor (EGFR)-activating mutations, *KRAS/NRAS* mutations, and *ALK* gene rearrangements in patients with nonsquamous or mixed squamous histology
- Cervical mediastinoscopy (biopsy of upper and lower paratracheal and subcarinal lymph nodes)
- Video-assisted thoracoscopy (associated pleural disease and suspected mediastinal nodal spread)
- Bone marrow aspirate (small cell)

Test Interpretation

Pathologic changes from smoking are progressive: basal cell proliferation, development of atypical nuclei, stratification, metaplasia of squamous cells, carcinoma in situ, and then invasive disease.

TREATMENT

GENERAL MEASURES

- NSCLC
  - Stage I, stage II, and selected stage III tumors are surgically resectable. Neoadjuvant or adjuvant therapy is recommended for many patients with high risk IB, II, and IIIA NSCLC. Patients with resectable disease who are not surgical candidates may receive radiation therapy.
  - Patients with unresectable or N2, N3 disease are treated with concurrent chemoradiation. Selected patients with T3 or N2 disease can be treated effectively with surgical resection and either pre- or postoperative chemotherapy or chemoradiation therapy.
  - Patients with distant metastases (M1B) can be treated with radiation therapy or chemotherapy for palliation or best supportive care alone.
- SCLC
  - Limited stage: concurrent chemoradiation

  - Extensive stage: combination chemotherapy
  - Consider prophylactic cranial irradiation (PCI) in patients achieving a complete or partial response (2)[A].
- Quality-of-life assessments: Karnofsky performance scale (KPS) (http://www.hospicepatients.org/karnofsky.html); Eastern Cooperative Oncology Group (ECOG)
- Discussions with patient and family about end-of-life care

MEDICATION

- Chemotherapy is the mainstay of treatment.
- Adjuvant chemotherapy following surgery improves survival in patients with fully resected stage II–III NSCLC.
- Palliative measures: analgesics
- Dyspnea: oxygen, morphine

First Line

- NSCLC
  - Stages II–III: neoadjuvant or adjuvant chemotherapy
    - Cisplatin-based doublets (combination with paclitaxel, etoposide, vinorelbine, docetaxel, gemcitabine)
    - Carboplatin alternative for patients unlikely to tolerate cisplatin
    - Cisplatin plus pemetrexed (nonsquamous cell)
  - Unresectable stage IIA, IIIB
    - Concurrent chemoradiation
      - Cisplatin plus etoposide, vinblastine, or pemetrexed (nonsquamous cell) plus concurrent radiation
      - Carboplatin plus pemetrexed (nonsquamous cell) plus concurrent radiation
- Stage IV
  - No chemotherapy regimen can be recommended for routine use.
  - Cisplatin or carboplatin-based doublets
  - +/− bevacizumab (nonsquamous cell)
  - Erlotinib or afatinib for patients with EGFR mutations
  - Crizotinib for patients with EML4-ALK translocations
    - Ceritinib for patients that fail or are intolerant to crizotinib

- Maintenance therapy after 4 to 6 cycles in patients achieving a response or stable disease
  - Continuation of bevacizumab, pemetrexed (nonsquamous cell), gemcitabine, erlotinib, or crizotinib or switch to pemetrexed (nonsquamous cell), erlotinib (EGFR mutations), docetaxel or observation
- SCLC
  - Cisplatin or carboplatin plus etoposide

Second Line

- NSCLC
  - Cisplatin-based doublets +/− bevacizumab (nonsquamous cell) if not previously used
  - Docetaxel, pemetrexed (nonsquamous cell), erlotinib, gemcitabine, ramucirumab plus docetaxel, or nivolumab (squamous cell)
- SCLC
  - Topotecan or CAV (cyclophosphamide, doxorubicin, vincristine), gemcitabine, docetaxel, paclitaxel

ADDITIONAL THERAPIES

- Immunotherapy
  - Anti PD-L1 (programmed cell death ligand) antibody therapy
- Smoking cessation counseling
- Consider IV bisphosphonates or denosumab in patients with bone metastases to reduce skeletal-related events.

SURGERY/OTHER PROCEDURES

- Resection for NSCLC, for stages I, II, and IIIA, if medically fit to undergo surgery
- Resection of isolated, distant metastases has been achieved and may improve survival.
- Resection involves lobectomy in 71%, wedge in 16%, and complete pneumonectomy in 18%.
- Resection should be accompanied by lymph node dissection for pathologic staging.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Depends on clinical history; in general, postoperative visits every 3 to 6 months in the first 2 years after surgery with physical exam and CT scan
- Follow-up usually lifelong with CT scans, following NCCN criteria

PATIENT EDUCATION

- National Cancer Institute: http://www.cancer.gov/
- Smokefree.gov:http://smokefree.gov/

PROGNOSIS

- For combined, all types and stages, 5-year survival rate is 16% (NSCLC: 17%; SCLC 6%).
- NSCLC
  - Localized disease (stages I and II): 49%
  - Regional disease: 16%
  - Distant metastatic disease: 2%
- SCLC
  - Without treatment: median survival from diagnosis of only 2 to 4 months
  - 5-year survival rate: ranges from 2% (stage IV) to 31% (stage I)
  - Extensive-stage disease: median survival of 6 to 12 months; long-term disease-free survival is rare.

COMPLICATIONS

- Development of metastatic disease, especially to brain, bones, adrenals, and liver
- Local recurrence of disease
- Postoperative complications
- Side effects of chemotherapy or radiation

CODES

ICD10

- C34.90 Malignant neoplasm of unsp part of unsp bronchus or lung
- C34.10 Malignant neoplasm of upper lobe, unsp bronchus or lung
- C34.30 Malignant neoplasm of lower lobe, unsp bronchus or lung

CLINICAL PEARLS

- 2 types: NSCLC and SCLC
  - NSCLC (>85% of all lung cancers); normally originate in periphery
    - Adenocarcinoma (~40% of NSCLC)
    - Squamous cell carcinoma (~25% of NSCLC):
    - Large cell (~10% of NSCLC):
  - SCLC centrally located, early metastases, aggressive
- Prognosis and treatment of lung cancer differs greatly between small cell- and non–small cell histologies.
- Adjuvant cisplatin-based chemotherapy improves survival in patients with completely resected stage II–III NSCLC.
- Chemotherapy, with or without radiation, can be offered to patients with advanced NSCLC or SCLC.
- There is little role for surgery in the treatment of SCLC.

LUPUS ERYTHEMATOSUS, SYSTEMIC (SLE)

Katherine M. Tromp, PharmD • Hershey S. Bell, MD, MS, FAAFP

BASICS

DESCRIPTION

- Systemic lupus erythematosus (SLE) is a multisystem autoimmune inflammatory disease characterized by a chronic relapsing/remitting course; can be mild to severe and may be life-threatening (CNS and renal forms)
- System(s) affected: mucocutaneous; musculoskeletal; renal; nervous; pulmonary; cardiac; hematologic; vascular; gastrointestinal (GI)
- Synonym(s): SLE; lupus

ALERT

Women with SLE have a 7- to 50-fold increased risk of coronary artery disease and may present with atypical/nonspecific symptoms.

EPIDEMIOLOGY

Predominant age: 15 to 45 years

Incidence

- Per year, 1.6 to 7.6/100,000 and increasing due to better diagnosis
- Most common: African American women (8.1 to 11.4/100,000/year)
- Least common: Caucasian men (0.3 to 0.9/100,000/year)

Prevalence

Occurs in 30 to 50/100,000 and increasing due to increased survival

ETIOLOGY AND PATHOPHYSIOLOGY

- Skin: photosensitivity; scaly erythematous, plaques with follicular plugging, dermal atrophy, and scarring; nonscarring erythematous psoriasiform/annular rash; alopecia; mucosal ulcers
- Musculoskeletal: nonerosive arthritis; ligament and tendon laxity, ulnar deviation, and swan neck deformities; avascular necrosis

- Renal: glomerulonephritis
- Pulmonary: pleuritis, pleural effusion, alveolar hemorrhage, pneumonitis, interstitial fibrosis, pulmonary hypertension, pulmonary embolism (PE)
- Cardiac: nonbacterial verrucous endocarditis, pericarditis, myocarditis, atherosclerosis
- CNS: thrombosis of small intracranial vessels ± perivascular inflammation resulting in micro- or macroinfarcts ± hemorrhage
- Peripheral nervous system: mononeuritis multiplex, peripheral neuropathy
- GI: pancreatitis, peritonitis, colitis
- Hematologic: hemolytic anemia, thrombocytopenia, leukopenia, lymphopenia
- Vascular: vasculitis, thromboembolism
- Most cases are idiopathic with possible environmental factors.
- Drug-induced lupus: hydralazine, D penicillamine, quinidine, procainamide, minocycline, isoniazid, etc.

Genetics

- Identical twins: 24–58% concordance
- Fraternal twins and siblings: 2–5% concordance
- 8-fold risk if first-degree relative with SLE
- Major histocompatibility complex associations: HLA-DR2, HLA-DR3
- Deficiency of early complement components, especially C1q, C1r/s, C2, and C4
- Immunoglobulin receptor polymorphisms: *FCγR2A*, *FCγR3A*, *and others*
- Polymorphism in genes associated with regulation of programmed cell death, protein tyrosine kinases, and interferon production

RISK FACTORS

- Race: African Americans, Hispanics, Asians, and Native Americans
- Predominant sex: females > males (8:1)
- Environmental: UV light, infectious agents, stress, diet, drugs, hormones, vitamin D deficiency, and tobacco

COMMONLY ASSOCIATED CONDITIONS

- Overlap syndromes: rheumatoid arthritis (RA), Sjögren syndrome, scleroderma

- Antiphospholipid syndrome; coronary artery disease; nephritis; depression

DIAGNOSIS

Consider SLE in multisystem disease including fever, fatigue, and signs of inflammation.

HISTORY

- Fever, fatigue, malaise, weight loss, headache
- Rash (butterfly/*hyperpigmented ears* or *scalp*), photosensitivity, alopecia
- Oral/nasal ulcers (usually painless)
- Arthritis, arthralgia, myalgia, weakness
- Pleuritic chest pain, cough, dyspnea, hemoptysis
- Early stroke (age <50 years), seizure, psychosis, cognitive deficits
- Proteinuria, cellular casts
- Hemolytic anemia, leukopenia, lymphopenia, thrombocytopenia
- Abdominal pain, anorexia, nausea, vomiting
- Raynaud phenomenon

PHYSICAL EXAM

- Vital signs: fever, hypertension
- Malar, discoid, psoriasiform, or annular rash, alopecia
- Oral/nasal ulcers (*often minimally symptomatic*)
- Lymphadenopathy, splenomegaly
- Acrocyanosis
- Inflammatory arthritis, tenosynovitis
- Pleural/pericardial rub, heart murmur
- Bibasilar rales
- Cranial/peripheral neuropathies

DIFFERENTIAL DIAGNOSIS

Undifferentiated connective tissue disease, Sjögren syndrome, fibromyalgia, RA, vasculitis, idiopathic thrombocytopenia purpura, antiphospholipid antibody syndrome, drug-induced lupus

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Antinuclear antibody (ANA)
  - High sensitivity (98%), low specificity
  - False-positive rate of 5–30%: elderly, autoimmune thyroid/liver disease, chronic infection, etc.
  - Low titers <1:160 of limited clinical use
- Anti–double-stranded DNA (dsDNA) and anti-Smith antibodies: high specificity for SLE; predictor of nephritis and hemolytic anemia
  - Correlates with disease activity
- RNA protein antibodies (anti-RNP, anti-Ro, anti-La): less specific for SLE
- False-positive Venereal Disease Research Laboratory (VDRL) test: high sensitivity, low specificity; surrogate marker of cardiolipin antibody presence
- Low serum complement levels: C3, C4
- Erythrocyte sediment rate (ESR): nonspecific, often high in active disease
- CBC: hemolytic anemia, thrombocytopenia, leukopenia, or lymphopenia
- Serum creatinine: elevated in lupus nephritis
- Urinalysis (UA): proteinuria, hematuria, cellular cast
- Phospholipid antibodies: cardiolipin immunoglobulin (Ig) G/IgM, lupus anticoagulant, β_2-glycoprotein IgG/IgM
- Anti-P (ribosomal autoantibodies) is associated with SLE arthritis and disease activity.
- Initial imaging is dependent on presenting symptoms.
- Radiograph of involved joints
- Chest x-ray: infiltrates, pleural effusion, low lung volumes
- Chest CT scan, ventilation/perfusion (V/Q) scan, duplex ultrasound for PE or deep vein thrombosis
- Head CT scan: ischemia, infarct, hemorrhage
- Brain MRI: focal areas of increased signal intensity
- Echocardiogram: pericardial effusion, valvular vegetations, pulmonary hypertension
- Contrast angiography for medium-size artery vasculitis: mesenteric/limb ischemia, CNS symptom

Follow-Up Tests & Special Considerations

- Hemolytic anemia: elevated reticulocyte count and indirect bilirubin, low

haptoglobin, positive direct Coombs test

- Confirm positive phospholipid antibodies results in 12 weeks.
- If phospholipid antibodies are initially negative, but symptoms arise, repeat, as they may become positive over time.
- 24-hour urine collection/spot protein/creatinine to quantify proteinuria
- Histone antibodies present in >95% of drug-induced lupus (vs. 80% of idiopathic SLE)
- Fasting lipid panel and glucose
- Follow vitamin D[25(O)H] levels and replenish PRN.

Diagnostic Procedures/Other

- Renal biopsy to diagnose lupus nephritis (if UA abnormal)
- Skin biopsy with immunofluorescence on involved and uninvolved non–sun-exposed skin (*lupus band test*) may help differentiate SLE rash from others.
- Lumbar puncture in patients with fever and CNS/meningeal symptoms
- EEG for seizures/global CNS dysfunction
- Neuropsychiatric testing for cognitive impairment
- EMG/nerve conduction study (NCS) for peripheral neuropathy and myositis
- Nerve and/or muscle biopsy
- ECG, cardiac enzymes, stress tests
- American College of Rheumatology classification (not diagnostic) criteria: any 4 of the 11 listed (95% specificity and 85% sensitivity):
  - Malar (butterfly) rash
  - Discoid rash
  - Photosensitivity: by patient history/physician observation
  - Oral/nasopharyngeal ulcers
  - Nonerosive arthritis: involving ≥2 peripheral joints
  - Pleuritis *OR* pericarditis
  - Renal disorder: proteinuria (>0.5 g/day or >3+) *OR* cellular casts (red cell, hemoglobin, granular, tubular, or mixed)
  - Neurologic disorder: psychosis/seizures
  - Hematologic disorder: hemolytic anemia, leukopenia (<4,000/mm^3 on ≥2 tests), lymphopenia (<1,500/mm^3 on ≥2 tests), thrombocytopenia (<100,000/mm^3)

  - Immunologic disorder: anti-DNA, anti-Sm, anticardiolipin IgG/IgM, lupus anticoagulant, or false–positive VDRL findings
  - Positive ANA in absence of drugs known to cause positive ANA

Test Interpretation

- Skin: vascular/perivascular inflammation, immune-complex deposition at dermal–epidermal junction, mucinosis, basal layer vacuolar changes
  - Similar findings seen in other connective tissue disorders such as dermatomyositis
- Renal: mesangial hypercellularity/matrix expansion, subendothelial/subepithelial immune deposits, glomerular sclerosis, fibrous crescents
  - Vary depending on degree of involvement
- Vascular: immune-complex deposition in vessel walls with fibrinoid necrosis and perivascular mononuclear cell infiltrates, intraluminal fibrin thrombi

TREATMENT

GENERAL MEASURES

- Education, counseling, and support
- Influenza/pneumococcal vaccines are safe; weigh risk versus benefit for live vaccines in immunocompromised patients.
- Low-estrogen oral contraceptives safe in mild SLE

MEDICATION

First Line

- *Antimalarial agents and NSAIDs are first-line therapy for patients with mild SLE* (1)[A].
  - Hydroxychloroquine for constitutional and musculoskeletal symptoms, rash, mild serositis; may reduce flares and increase long-term survival (2,3)[A]; NSAIDs for musculoskeletal manifestations, mild serositis, headache, and fever (2)[C]
- Systemic glucocorticoids (prednisone or equivalent)
  - Low dose (<0.5 mg/kg) for minor disease activity not responsive to

NSAIDs or when NSAIDs are contraindicated (2)[A]
  - High-dose (1 to 2 mg/kg/day) (2)[A] or IV pulse methylprednisolone for organ-threatening disease, particularly CNS and renal; often combined with immunosuppressive agent (2)[A]
- Topical glucocorticosteroids for skin manifestations

Second Line

- Methotrexate (2)[A], azathioprine (2)[B], mycophenolate mofetil (2)[C], or leflunomide as steroid-sparing agent for persistent active disease or to maintain remission
  - Requires laboratory monitoring for toxicity
- Belimumab as adjunct for preventing flares in patients with active lupus despite first-line therapy (4)[A]
  - 10 mg/kg IV q2wk × 3 doses, then monthly
- Treatments under investigation: rituximab, epratuzumab, abatacept, interferon-α inhibitors
- Immunosuppressive agents for severe disease
  - Cyclophosphamide (2)[A]: adequate hydration to reduce risk of hemorrhagic cystitis
  - Mycophenolate mofetil (2)[A]: more efficacious for lupus nephritis (1)[A]

SURGERY/OTHER PROCEDURES

Renal transplant for end-stage renal disease

COMPLEMENTARY & ALTERNATIVE MEDICINE

Biofeedback, visual imagery, cognitive therapy

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Difficult to differentiate SLE flare from infection; may need to treat both pending full evaluation
- IV pulse Solu-Medrol 1 g/day for 3 to 5 days for life- or organ-threatening disease (2)[A]

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Clinical evaluation for signs and symptoms
  - Weekly to monthly for active disease
  - Every 3 to 6 months for mild/inactive disease
- Measures of disease activity and damage: Systemic Lupus Erythematosus Disease Activity Index, British Isles Lupus Assessment Group Index, European Consensus Lupus Activity Measure
- Laboratory studies
  - CBC with differential
  - Serum creatinine, UA
  - Vitamin D
  - Declining C3/C4 and rising DS-DNA and ESR may correlate with disease activity
- Monitor for adverse effects of treatment.
  - NSAIDs: GI bleeding and/or ulceration
  - Glucocorticoids: glucose, lipids, bone density
  - Hydroxychloroquine: ophthalmologic exam every 6 to 12 months
  - Methotrexate: CBC, creatinine, albumin, aspartate aminotransferase (AST), alanine aminotransferase (ALT) every 2 months
  - Azathioprine and mycophenolate mofetil: CBC every 1 to 3 months
  - Cyclophosphamide
    - CBC, creatinine, UA every 2 weeks, and liver function tests monthly during treatment
    - UA every 6 to 12 months for life

DIET

- No special diet unless for complications such as renal failure, diabetes, hyperlipidemia (2)[C].
- Adequate calcium/vitamin D intake in patients on corticosteroids (2)[A]
- Low glycemic index or calorie-restricted diet in patients on corticosteroids

PATIENT EDUCATION

- Avoid UV light exposure: sunscreens (SPF ≥30), protective clothing (2)[B]
- Weight control, smoking cessation, exercise (2)[C]
- Stress avoidance/management

PROGNOSIS

- Permanent treatment-free remission is uncommon.
- 5-year survival after diagnosis is 95%.
- Poor prognostic factor: major organ involvement
- Drug-induced lupus resolves within weeks to months after discontinuation of the offending drug.

COMPLICATIONS

Infections, neoplasms, cardiac disease, nephritis, neuropsychiatric lupus; depression

Pregnancy Considerations

- Exacerbations during pregnancy are less common when in remission for 6 months prior to conception.
- Fetal loss is increased, especially in those with active lupus/antiphospholipid antibodies.
- A 2% risk of congenital heart block if anti-SS-A (Ro) or anti-SS-B (La) antibodies are present
- See "Antiphospholipid Antibody Syndrome" for recommendations regarding use of aspirin and heparin to prevent pregnancy complications.

SEE ALSO

Antiphospholipid Antibody Syndrome

CODES

ICD10

- M32.9 Systemic lupus erythematosus, unspecified
- M32.10 Systemic lupus erythematosus, organ or system involv unsp
- M32.14 Glomerular disease in systemic lupus erythematosus

CLINICAL PEARLS

- Aggressiveness of therapy should reflect intensity of disease.
- Most important diagnostic test is the UA: if abnormal, order kidney biopsy; serum and urine lab values often do not reveal extent of kidney disease.
- Atherosclerotic and atheroembolic complications are the major cause of death; address modifiable cardiovascular risk factors.

LUPUS NEPHRITIS

Neena R. Gupta, MD

BASICS

DESCRIPTION

- The renal manifestation of systemic lupus erythematosus (SLE)
- American College of Rheumatology (ACR) criteria: persistent proteinuria >500 mg/day or ≥3 on dipstick and/or presence of cellular casts. Alternatively, spot urine protein-to-creatinine ratio >0.5 and "active urinary sediment" (>5 RBC/hpf, >5 WBC/hpf in absence of infection, or cellular casts—RBC or WBC casts) (1)
- Clinical manifestations primarily due to immune complex–mediated glomerular disease. Tubulointerstitial and vascular involvement often coexist. Diagnosis is based on clinical findings, urine abnormalities, autoantibodies, and renal biopsy.
- Treatment and prognosis depend on International Society of Nephrology/Renal Pathology Society (ISN/RPS) histologic class—risk of end-stage renal disease (ESRD) highest in class IV.
- Delay in diagnosis/treatment increases risk of ESRD.

EPIDEMIOLOGY

- Peak incidence of SLE is 15 to 45 years of age.
- Predominant sex: female > male (10:1)
- Once SLE develops, lupus nephritis (LN) affects both genders equally; it is more severe in children and men and less severe in older adults.

Incidence

- SLE: 1.4 to 21.9/100,000
- Up to 60% of SLE patients develop LN over time, and 25–50% of SLE patients have nephritis as the initial presentation.

Pediatric Considerations

LN is more common and more severe in children: 60–80% have LN at or soon

after SLE onset.

Prevalence

SLE: 7.4 to 159.4/100,000

ETIOLOGY AND PATHOPHYSIOLOGY

- Immune complex–mediated inflammation injures glomeruli, tubules, interstitium, and vasculature.
- Glomeruli: Varying degrees of mesangial proliferation, crescent formation (see "Test Interpretation"), and fibrinoid necrosis cause reduced glomerular filtration rate (GFR).
- Persistent inflammation (chronicity) leads to sclerosis and glomerular loss.
- Tubulointerstitial injury (edema, inflammatory cell infiltrate acutely; tubular atrophy in chronic phase) with or without tubular basement membrane immune complex deposition leads to reduced renal function.
- Vascular lesions: immune complex deposition and noninflammatory necrosis in arterioles
- SLE is a multifactorial disease, with a multigenic inheritance; exact etiology remains unclear.
- Defective T-cell autoregulation and polyclonal B-cell hyperactivity contribute to dysregulated apoptosis. Impaired clearance of apoptotic cells inhibits self-tolerance to nuclear antigen
- Anti-DNA, anti-C1q, anti-α-actin, and other nuclear component autoantibodies develop.
- Deposition of circulating immune complexes or autoantibodies attaching to local nuclear antigens leads to complement activation, inflammation, and tissue injury.
- Interaction of genetic, hormonal, and environmental factors leads to great variability in LN severity.

Genetics

Multigenic inheritance; clustering in families, ~25% concordance in identical twins

RISK FACTORS

Younger age, African American or Hispanic race, more ACR criteria for SLE,

longer disease duration, hypertension, lower socioeconomic status, family history of SLE, anti-dsDNA antibodies

COMMONLY ASSOCIATED CONDITIONS

Skin, hematologic, cerebral, pulmonary, GI, and cardiopulmonary systems are often involved in SLE.

DIAGNOSIS

HISTORY

Assess for risk factors and other signs/symptoms of SLE: rash, photosensitivity, arthritis, neurologic complaints, fever, weight loss, alopecia.

PHYSICAL EXAM

- Hypertension, fever
- Pleural/pericardial rub
- Skin rash
- Edema
- Arthritis
- Alopecia
- Oral ulcers

DIFFERENTIAL DIAGNOSIS

- Primary glomerular disease
- Secondary renal involvement in other systemic disorders such as antineutrophil cytoplasmic autoantibody (ANCA)-associated vasculitis, Henoch-Schönlein purpura (HSP), antiglomerular basement membrane disease, and viral infections
- Mixed connective tissue disorder may have glomerulonephritis indistinguishable from LN.

DIAGNOSTIC TESTS & INTERPRETATION

- Renal biopsy is the gold standard for diagnosing and classifying LN.
- Combine clinical data with serologic and renal biopsy patterns to differentiate LN from other conditions.
- Active urine sediment suggests nephritis.

- Autoantibodies, low C3, C4, and CH50 complement levels support LN diagnosis.

Initial Tests (lab, imaging)

- Urinalysis may show hematuria, proteinuria, and active urine sediment (2)[C].
- Serum electrolytes, BUN, creatinine, albumin, routine serologic markers of SLE such as antinuclear antibody (ANA), anti-dsDNA, anti-Ro, anti-La, anti-RNP, anti-Sm, antiphospholipid antibody, C3, C4, CH50, CBC with differential, and C-reactive protein (CRP) (2)[C]
- CBC may show anemia, thrombocytopenia, and leukopenia.
- Renal ultrasound (2)[C]

Follow-Up Tests & Special Considerations

- Monitor disease activity q3mo (2)[C]: urinalysis for hematuria and proteinuria; blood for C3, C4, anti-dsDNA, serum albumin, and creatinine.
- Patients with estimated glomerular filtration rate (eGFR) of <60 mL should be managed according to the National Kidney Foundation guidelines for chronic kidney disease (CKD). http://www.kdigo.org/clinical_practice_guidelines/pdf/CKD/KDIGO_2012_CI

Pregnancy Considerations

- Pregnancy leads to worsening of renal function in LN. Risk factors include renal impairment at baseline, active disease, hypertension, and proteinuria.
- Risk factors for fetal loss include elevated serum creatinine, heavy proteinuria, hypertension, and anticardiolipin antibodies.
- Mycophenolate mofetil (MMF) is contraindicated in pregnancy; azathioprine can be safely used.

Test Interpretation

- Adequate renal biopsy (at least 10 glomeruli for light microscopy or total 20 to 25 glomeruli) is essential. Light, immunofluorescence, and electron microscopy are needed for accurate classification.
- On immunofluorescence microscopy: Immune complex deposits consisting of IGG, IGA, IGM, C1q, and C3 (“full house”) are highly suggestive of LN.
- Revised ISN/RPS histologic classification guides therapeutic decisions. http://jasn.asnjournals.org/content/15/2/241.full.pdf

- LN is classified as purely mesangial (classes I and II), focal proliferative: <50% glomeruli (class III), diffuse proliferative: ≥50% (class IV), membranous (class V), and advanced sclerosis (class VI). Subdivisions for activity (A) and chronicity (C) in class III/IV and for segmental (S) or global (G) glomerular involvement in class IV (Class III A, C, A/C and class IV S[A], G[A], S[A/C], S[C], G[C]).
- LN may change to another class over time or with therapy.
- Focal and diffuse proliferative LN (classes III and IV) are common and most likely to progress to ESRD.

TREATMENT

GENERAL MEASURES

- Monitor bone density; optimize vitamin D and calcium intake in patients on glucocorticoid therapy.
- Low-salt diet for hypertension and edema. For eGFR <60 mL: Follow National Kidney Foundation guidelines for chronic kidney disease.
- Avoid sun or ultraviolet light exposure.

MEDICATION

Note: Other than methylprednisolone and prednisone, no other medications listed below are FDA approved for LN.

First Line

- **Class I + II LN**: No specific therapy is needed, as long-term renal prognosis is good. Renin-angiotensin system blockade (ACE inhibitors or angiotensin receptor blockers) to manage BP and proteinuria. There are many drugs in this class (e.g., lisinopril 5 to 40 mg/day PO, losartan 25 to 100 mg/day PO).
- **Proliferative LN (Class III, IV, V + III/IV)**: Induce remission by steroids + IV cyclophosphamide or MMF and maintenance of remission by low-dose steroids and azathioprine (AZA) or MMF (1).
- Principles of treatment:
  - Avoid delay in treatment.
  - Induce remission quickly (3 to 6 months).
  - Maintain response and avoid iatrogenic morbidity (5 to 10 years).

- **INDUCTION**: steroids + immunosuppressive agent (for mild class III, high-dose steroids may be sufficient):
  - Glucocorticoids: methylprednisolone pulse 0.5 to 1 g/day for 3 days followed by oral prednisone 0.5 to 1 mg/kg/day PO (max 60 mg/day, taper after 4 to 8 weeks) (3)[A] *AND*
  - Cyclophosphamide (CYC): IV CYC (high dose = 0.5 to 1 g/m^2 monthly for 6 doses—NIH regimen; low dose = 0.5 g q2wk for 6 doses—Euro-Lupus regimen) *OR*
  - MMF: 1 to 3 g/day PO divided BID (target 3 g/day as tolerated) for 6 months. MMF is as effective as CYC in achieving remission with fewer side effects (3)[A].
- **MAINTENANCE**:
  - Glucocorticoids: oral prednisone tapered to low doses (generally <10 mg/day by 6 months) AND
  - MMF 1 to 2 g/day divided BID PO OR AZA (azathioprine): 1 to 2.5 mg/kg/day PO (3)[A]
  - In the ALMS (Aspreva Lupus Management Study) MMF shown to be superior than AZA for maintenance therapy in a varied population (4)[A].
  - In the MAINTAIN nephritis trial, MMF shown to be equal to AZA for maintenance therapy in mostly Caucasian population (5)[A].
  - Cyclophosphamide IV quarterly for 1 to 2 year after renal remission; not used now due to availability of less toxic regimen
  - Optimum duration of maintenance therapy is unclear, but periods ranging from 3 to 10 years have been studied in clinical trials (4,5).
- **Class V LN**: good prognosis in general, treatment not standardized
  - For subnephrotic patients, no specific treatment except renin-angiotensin system blockade.
  - Options for nephrotic patients include steroids with either calcineurin inhibitors, IV CYC, AZA, or MMF (3)[B].
  - Class V LN with presence of class III or class IV biopsy findings needs aggressive combination regimen as for class III/IV.

Second Line

Other treatments in selected patients: rituximab, plasma exchange, IVIG,

calcineurin inhibitors. Belimumab was approved by FDA in 2011, but trials excluded patients with severe active LN (3)[C].

ISSUES FOR REFERRAL

Nephrology consults for initial management and relapses.

ADDITIONAL THERAPIES

- KDIGO 2012 guidelines for LN state that all patients with LN of any class be treated with hydroxychloroquine (maximum daily dose of 6 to 6.5 mg/kg ideal body weight), unless they have a specific contraindication to this drug.
- BP control; treat dyslipidemia and other modifiable cardiovascular risk factors.
- Anticoagulation for symptomatic antiphospholipid antibody syndrome

SURGERY/OTHER PROCEDURES

- Renal transplant for ESRD when indicated
- Patient and graft survival rates are similar to non-SLE patients.
- Risk of recurrent LN in renal transplant recipients ranges between 0% and 30%; graft loss due to recurrence is rare.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Admission criteria/initial stabilization
  - Uncontrolled hypertension, acute kidney injury
  - Severe extrarenal manifestation
  - Control hypertension and proteinuria, if present.
  - Labs to help confirm SLE/LN, renal ultrasound
  - Nephrology for manage input and renal biopsy
- Patients who have nephrotic syndrome or acute kidney injury should be fluid restricted.
- Once the patient is stabilized and renal biopsy is performed, manage safely as an outpatient.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Monitor urine protein-to-creatinine ratio, urine microscopy, serum albumin and creatinine, antibody titers (especially anti-dsDNA), C3, C4, BP at least every 3 months for first 2 to 3 years (2)[C].
- Once stable on maintenance therapy with no active disease, follow-up every 6 to 12 months (2)[C].
- Cyclophosphamide: CBC, ensure adequate hydration
- MMF: CBC, LFT, SrCr
- Azathioprine: CBC

DIET

Low-salt diet. For eGFR <60 mL: Follow National Kidney Foundation guidelines for chronic kidney disease.

PATIENT EDUCATION

Medication adherence and self-monitoring for relapse

PROGNOSIS

- 10-year survival of 88% and 94% in SLE patients with and without renal involvement (1)
- Relapse rate is ~35%. 10–20% of patients progress to ESRD within 10 years.
- 5-year renal survival of class IV LN <30% before 1970 has improved to >80% in last 2 decades.
- Early and complete remission of proteinuria with treatment is the best prognostic factor. Other predictors of remission include low baseline proteinuria, normal creatinine, Caucasian race, and treatment initiated within 3 months of diagnosis.
- Indicators of poor prognosis: diffuse proliferative LN (especially crescentic), higher activity/chronicity index, African American race, lower socioeconomic status, poor response to treatment, high creatinine at baseline, uncontrolled hypertension, and relapse

COMPLICATIONS

- Risks of immunosuppressive therapy: infections, malignancy
- Treatment side effects: Cyclophosphamide causes primary amenorrhea.

- MMF may cause GI upset and nausea and is a teratogen (azathioprine recommended for women who desire pregnancy).
- Risk of vascular thromboses (hypercoagulable state from antiphospholipid antibodies)
- About 10–20% of patients develop ESRD from progressive disease refractory to treatment requiring dialysis/kidney transplantation.

CODES

ICD10

M32.14 Glomerular disease in systemic lupus erythematosus

CLINICAL PEARLS

- Early diagnosis, correct classification (requires renal biopsy), and rapid treatment improve renal survival in patients with LN.
- Treat proliferative/progressive LN with a short induction course followed by maintenance therapy using glucocorticoids and immunosuppressants.
- Survival rates for patients with LN have improved dramatically over the past several decades.

LYME DISEASE

Felix B. Chang, MD, DABMA, FAAMA

BASICS

DESCRIPTION

- A multisystem infection caused by *Borrelia* spirochetes, transmitted primarily by ixodid ticks
  - *Ixodes scapularis* (deer ticks) in the New England and Great Lakes areas
  - *Ixodes pacificus* in the West (blacklegged ticks and Western blacklegged ticks)
  - *Ixodes ricinus* in Europe
  - *Ixodes persulcatus* in Asia and Russia
- Early localized Lyme disease includes a characteristic expanding skin rash (erythema migrans [EM]) (80%) and constitutional flu-like symptoms (1).
- Early neurologic manifestations 15%: cranial nerve palsy, meningitis, acute radiculopathy, or mononeuropathy
- Disseminated Lyme disease presents with involvement of ≥1 organ systems. Most commonly neurologic, cardiac, and pauciarticular arthritis
- Lyme carditis: AV block, myopericarditis 1%
- Post-Lyme disease syndrome includes arthritis (50%) and chronic neurologic syndromes.
- System(s) affected: hemic/lymphatic/immunologic; musculoskeletal; skin/exocrine; cardiac; neurologic
- Synonym(s): Lyme arthritis; Lyme borreliosis

EPIDEMIOLOGY

Incidence

- 96% of U.S. cases in 2014 were reported from Connecticut, Massachusetts, New York, New Jersey, Delaware, Pennsylvania, Virginia, Maryland, Maine, Minnesota, Wisconsin, New Hampshire, Vermont, and Rhode Island (1).
- In endemic states, the incidence is 0.5 per 1,000 but can be substantially higher in local areas.

- Cases have been reported from all 50 states.
- Estimated 329,000 cases/year reported in the United States
- Fifth most common reportable disease in the United States

Prevalence

- The most reported vector-borne illness in the United States
- Estimated 106 cases per 100,000 persons
- Predominant age: most common in children ages 5 to 14 years and in adults aged 55 to 70 years of age
- Predominant sex: male > female in the United States

ETIOLOGY AND PATHOPHYSIOLOGY

- Infection with spirochete *Borrelia burgdorferi* in the United States, or *Borrelia afzelii* or *Borrelia garinii* in Europe, transmitted by the bite of ixodid ticks
- Approximately 90% of cases are transmitted during the nymph stage of the tick life cycle.
- Average incubation period 7 to 10 days
- Most transmissions occur in late May to September when nymphal tick activity is highest.
- If a tick is infected, the chance of transmission increases with time attached: 12% at 48 hours, 79% at 72 hours, and 94% at 96 hours of attachment.
- Primary animal reservoir is the white-footed mouse.
- Spirochetes multiply and spread within dermis. Host response results in characteristic (EM) rash. Hematogenous dissemination results in disease within CNS, cardiovascular, or other organ systems.
- Star ticks (*Amblyomma americanum*), the American dog tick (*Dermacentor variabilis*), the Rocky Mountain wood tick (*Dermacentor andersoni*), and the brown dog tick (*Rhipicephalus sanguineus*) are not known to transmit Lyme disease.

Genetics

Human leukocyte antigen: Patients with haplotype DR4 or DR2 may be more susceptible to prolonged arthritis.

RISK FACTORS

- Exposure in tick-infested area, particularly from April to November
- Those who reside or are employed in endemic areas where ixodid ticks are found are at increased risk.
- Ixodid ticks are commonly found on deer. Hunters may be at an increased risk.

GENERAL PREVENTION

- "Tick checks": Examine skin after outdoor activities.
- Remove ticks within 36 hours to limit transmission.
- Wear clothing covering the ankles in endemic areas.
- Use insect repellents containing DEET.
- Apply permethrin to clothes, shoes, and tents.
- Antibiotic prophylaxis is recommended for the prevention of Lyme disease in endemic areas following an *Ixodes* tick bite.
- Prophylactic treatment with 1 dose of 200 mg of doxycycline within 72 hours of a tick bite in highly endemic areas is 87% effective. Contraindicated in pregnancy and in children; no prophylactic agent is approved for these groups (1)[A].

COMMONLY ASSOCIATED CONDITIONS

- Coinfection with babesiosis has been reported. Suggested by high fever
- Southern tick–associated rash illness may be mistaken for Lyme disease. It is seen in the Southeastern and South Central United States and is associated with the bite of the lone star tick, *A. americanum*.
- Comorbid human granulocytic anaplasmosis and/or babesiosis in patients living in endemic regions

DIAGNOSIS

HISTORY

- History of a tick bite followed by EM and/or illness. About 1/3 of patients recall tick bite.
- Round, flat or raised, erythematous lesion that expands in diameter over days to weeks, may have area of central clearing, typically arises about 7 to 14 days after tick detaches.

- Common EM sites: axilla, back, abdomen, groin, or popliteal fossa
- 75–80% presenting with EM having a single lesion
- Early Lyme disease: incubation period 3 to 30 days
  - Some patients may be asymptomatic (2).
  - Fever; headache; myalgias; arthralgias, regional lymphadenopathy
- Disseminated Lyme disease
  - Carditis (pleuritic chest pain; palpitations)
  - Facial palsies or other cranial neuropathies
  - Joint pain (polyarthritis/algias; late disease: monoarthritis-like knee)
  - Iritis, conjunctivitis
  - Migratory musculoskeletal pain
- Late untreated Lyme disease arises months after exposure, occurring in up to 60% of untreated patients.
  - Recurrent synovitis
  - Recurrent tendonitis and bursitis
  - Encephalopathic symptoms
    - Headaches
    - *Cognitive slowing*
    - Confusion
    - Profound fatigue
  - Symptoms mimicking other CNS diseases
    - Multiple sclerosis–like symptoms
    - Stroke-like symptoms
    - Transverse myelitis
  - Peripheral neuropathic symptoms; motor, sensory, or autonomic neuropathies
  - Meningitis
  - Acrodermatitis chronic atrophicans: fibrosing skin process often involving extremities

PHYSICAL EXAM

- Early Lyme disease
  - EM
- Disseminated Lyme disease
  - Multiple EM

- Facial palsies or other cranial neuropathies
- Heart block—irregular pulse
- Pericarditis—friction rub
- Arthritis
- Other focal neurologic findings

DIFFERENTIAL DIAGNOSIS

- Other rickettsial disease (Rocky Mountain spotted fever [RMSF])
- Juvenile rheumatoid arthritis; systemic lupus erythematosus (SLE); rheumatoid arthritis (RA)
- Viral syndromes
- Contact dermatitis; cellulitis; granuloma annulare (mimic EM)
- Syphilis
- AV block
- Malignant neoplastic diseases

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Testing and treatment not indicated if tick attached for <48 hours
- Diagnosis is based mainly on clinical findings in endemic areas (2).
- Serology: enzyme-linked immunosorbent assay (ELISA) for IgM and IgG *B. burgdorferi* antibodies, followed by a Western blot test, if positive or equivocal, or an indirect immunofluorescence assay
- Culture of CSF for *B. burgdorferi*
- Plasma polymerase chain reaction (PCR) testing is of little value (only exception is synovial fluid analysis).
- No imaging routinely indicated
- For non-EM presentations: 2-tier serologic testing is recommended, synovial fluid when arthritis is suspected, and CSF analysis when neurologic involvement suspected.

Follow-Up Tests & Special Considerations

Disorders that may alter lab results: False-positive response with RMSF, syphilis, SLE, and RA.

- Arthritis: Serology + PCR of synovial fluid is both sensitive and specific.
- Neuroborreliosis: serology + CSF pleocytosis (PCR of CSF has a very low

sensitivity)

- Late-stage disease with negative serology may be seen in patients receiving early antibiotic treatment.
- After an infection, antibodies may persist for months to years. *Serologic tests do not distinguish active from past infection* (3).
- Antibodies are not protective.

Diagnostic Procedures/Other

Lumbar puncture when neurologic findings are present, with ELISA or CSF for *B. burgdorferi* antibodies (2)

Test Interpretation

Culture of *B. burgdorferi* from blood or skin has low yield.

TREATMENT

GENERAL MEASURES

Early and disseminated Lyme disease can usually be treated as an outpatient except when complicated by carditis or meningitis (requires parenteral antibiotics).

MEDICATION

First Line

- EM (4,5)[A]
  - Doxycycline (Vibramycin) 100 mg PO BID for 10 to 21 days (do not use in children <8 years old or in pregnant women) (3)[A]; *or*
  - Amoxicillin 500 mg PO TID for 14 to 21 days (pediatric dose 50 mg/kg/day); *or*
  - Cefuroxime axetil 500 mg PO BID for 14 to 21 days
    - Doxycycline has the advantage of covering other tick-borne infections such as ehrlichiosis, anaplasmosis, and RMSF.
    - Alternative: azithromycin 500 mg QD for 7 to 10 days or clarithromycin 500 mg BID for 14 to 21 days
- Neurologic disease
  - Normal CSF, treat for 14 to 21 days.

  - Doxycycline 100 mg PO BID or amoxicillin 500 mg PO TID
  - Abnormal CSF, treat for 4 weeks: ceftriaxone 2 g QD IV, cefotaxime 2 g q8h, *or* penicillin G 5 mIU q6h
  - Cardiac disease
    - Mild (first-degree AV block, PR <300 ms): doxycycline 100 mg PO BID or amoxicillin 500 mg PO TID for 14 to 21 days
    - More serious: ceftriaxone 2 g QD IV for 30 days
- Arthritis without neurologic disease
  - Oral treatment for 28 days with doxycycline 100 mg BID or amoxicillin 500 mg TID
  - If oral treatment fails, repeat oral regimen for 28 days or begin IV treatment with ceftriaxone 2 g QD for 2 to 4 weeks.
- Contraindications
  - Allergy to specific medication
  - Doxycycline is contraindicated in children and in women who are pregnant or breastfeeding.
- Precautions
  - In ~15% of patients treated with IV therapy, a Jarisch-Herxheimer–type reaction develops within 24 hours of initiation of therapy.
- Significant possible interactions:
  - Oral anticoagulants may require dose adjustments.
  - Oral contraceptives may be less effective.

Pediatric Considerations

- Amoxicillin is the drug of choice in children.
- Tetracyclines are contraindicated.

Pregnancy Considerations

- Because *B. burgdorferi* can cross the placenta, pregnant patients with active disease should be treated with parenteral antibiotics.
- Doxycycline should not be used in pregnancy.

Second Line

- Azithromycin, 500 mg PO daily for 7 days, can be used for those allergic to *β*-lactams and unable to take tetracyclines but is less effective (4,5)[A].

- There is no evidence for meaningful clinical benefit from prolonged treatment or retreatment of patients with persistent unexplained symptoms despite previous antibiotic treatment of Lyme disease.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Admission is recommended for patients with Lyme carditis and symptoms of chest pain, syncope, or dyspnea and for those with second- or third-degree heart block or first-degree heart block of ≥300 ms.
- Admission is also recommended for patients with symptoms of meningitis.

 ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Based on the severity of symptoms, patients with Lyme carditis, neurologic syndromes, or arthritis may require prolonged follow-up.

DIET

No restrictions

PATIENT EDUCATION

- In endemic areas, patients should be advised to protect themselves against tick exposure.
- https://www.rheumatology.org/Practice/Clinical/Patients/Diseases_And_Condi
- Prevention
  - Use repellents that contain 20–30% DEET (N,N-diethyl-meta-toluamide) on exposed skin and clothing for protection lasting several hours.
  - Use 0.5% permethrin on clothing.
  - Bathe or shower as soon as possible after coming indoors (preferably within 2 hours) and perform regular tick checks after outdoor activities.
  - https://www.cdc.gov/lyme/

PROGNOSIS

- Early treatment with antibiotics can shorten the duration of symptoms and

prevent later disease.

- Response of late-stage disease to treatment is variable. Symptoms may take weeks to resolve after beginning treatment.
- Untreated rash usually resolves in 3 to 4 weeks.
- Excellent long-term prognosis with early antibiotic treatment

COMPLICATIONS

- Recurrent synovitis, tendonitis, bursitis
- Chronic neurologic symptoms
- Peripheral neuropathies
- Posttreatment Lyme disease syndrome: 10–20% lingering symptoms of fatigue, pain, or joint and muscle aches. Can last for 6 months
- Lyme carditis >40% syncopal presentation

CODES

ICD10

- A69.20 Lyme disease, unspecified
- A69.23 Arthritis due to Lyme disease
- A69.21 Meningitis due to Lyme disease

CLINICAL PEARLS

- The presence of EM following a tick bite in an endemic area is an indication for empiric antibiotic treatment for presumptive Lyme disease.
- Repeat episodes of EM in appropriately treated patients are due to reinfection and not relapse.
- Lyme disease during pregnancy may lead to infection of the placenta and possible stillbirth. Amoxicillin is the preferred treatment during pregnancy.
- Ticks must be attached for at least 24 hours or more to transmit Lyme disease.
- There is no evidence that Lyme disease can be transmitted by breastfeeding or close personal contact.
- The vaccine for Lyme disease is no longer available in humans.
- Neurologic symptoms arise in about 15% of untreated Lyme disease patients.

LYMPHANGITIS

Amar Kapur, DO, CPT, MC, USA

BASICS

DESCRIPTION

Acute or chronic inflammation of lymphatic channels due to a skin breach or local trauma. Presents as red, tender streaks along lymphatic channels and extending to regional lymph nodes

- May result from compromised lymphatic drainage due to surgical procedures
- May be infectious or noninfectious

ETIOLOGY AND PATHOPHYSIOLOGY

- Acute infection
  - Usually caused by group A β-hemolytic *Streptococcus*
  - Less commonly caused by:
    - *Staphylococcus aureus*
    - *Pasteurella multocida*
    - *Erysipelothrix*
    - *Spirillum minus* (rat bite disease)
    - *Pseudomonas*
    - Other *Streptococcus* sp.
    - Immunocompromised patients can be infected with gram-negative rods, gram-negative bacilli, or fungi.
    - In fresh water exposures, *Aeromonas hydrophila*
- Nodular lymphangitis
  - Also known as sporotrichoid lymphangitis
  - Presents as painful or painless nodular subcutaneous swellings along lymphatic vessels
  - Lesions may ulcerate with accompanying regional lymphadenopathy.
  - Typical of infections from the following: *Sporothrix schenckii*, *Nocardia brasiliensis*, *Mycobacterium marinum*, leishmaniasis, tularemia, and systemic mycoses
  - Pathology may show granulomas.

- Noninfectious granulomatous lymphangitis
  - Rare-acquired lymphedema of the genitalia in children
  - May be due to atypical Crohn disease or sarcoidosis (1)[C]
- Filarial lymphangitis
  - Mosquito bites transmit parasites causing inflammation and dilatation in the lymphatic vessels; can predispose to secondary bacterial infection
  - Usually caused by nematodes *Wuchereria bancrofti*. Other causes are *Brugia malayi* and *Brugia timori*.
- Lymphangitis due to surgery
  - May occur after surgical procedures and lymph node dissection
- Cutaneous lymphangitis carcinomatosa is rare. Represents ~5% of all skin metastases; caused by occlusion of lymphatic channels of dermis by neoplastic cells (2)
- Sclerosing lymphangitis of the penis
  - Swelling around coronal sulcus of penis usually resulting from vigorous sexual activity or masturbation

RISK FACTORS

- Impaired lymphatic drainage due to surgery, nodal dissection, or irradiation
- Diabetes mellitus
- Chronic steroid use
- Peripheral venous catheter
- Varicella infection
- Immunocompromising condition
- Human, animal, or insect bites
- Fungal, bacterial, or mycobacterial skin infections
- Any trauma to the skin
- IV drug abuse
- Residence in endemic areas of filariasis

GENERAL PREVENTION

- Reduce chronic lymphedema with compression devices or by treating underlying process
- Insect repellant
- Proper wound and skin care

COMMONLY ASSOCIATED CONDITIONS

- Lymphedema
- Prior lymph node dissection
- Tinea pedis (athlete's foot)
- Sporotrichosis
- Cellulitis, erysipelas
- Filarial infection (*W. bancrofti*)

DIAGNOSIS

HISTORY

- History of trauma to skin, cut, abrasion, or fungal infection
- Systemic symptoms:
  - Malaise
  - Fever and chills
  - Loss of appetite
  - Headache
  - Muscle aches
- Travel to a tropical region or region with known filariasis

PHYSICAL EXAM

Local signs:

- Erythematous, macular linear streaks from site of infection toward the regional lymph nodes
- Tenderness and warmth over affected skin or lymph nodes
- May have blistering of affected skin
- Fluctuance, swelling, or purulent drainage
- Nodular lymphangitis can present with subcutaneous swellings along the lymphatic channels.
- Sporotrichosis may present with papulonodular lesions that may ulcerate.
- Sites may be nonpainful.

DIFFERENTIAL DIAGNOSIS

- Superficial thrombophlebitis
  - Thrombus or infection within the thrombosis (septic thrombophlebitis)

- Contact dermatitis
- Allergic reaction: less likely to be allergic if >24 hours after exposure (e.g., insect bite)
- Lymphangitis carcinomatosa
- Malignancy-related inflammation

DIAGNOSTIC TESTS & INTERPRETATION

- CBC may show leukocytosis; blood smear may show filarial infection.
- Blood or wound cultures
- Biopsy cultures
- FNAC for filariasis of testiculoscrotal swelling but not for other superficial locations (3)

Initial Tests (lab, imaging)

Plain radiology unnecessary; may consider lymphangiography for lymphedema (4)[C]

Diagnostic Procedures/Other

- Swab, aspirate, and/or biopsy primary site, purulent discharge, nodule or distal ulcer for culture, acid fast staining, histology, and microscopy
- Blood cultures if systemically ill
- Serology (e.g., *Francisella tularensis*, histoplasma)
- Blood film/smear (e.g., filaria)
- Lymphangiography to determine lymphedema or lymphatic obstruction

TREATMENT

GENERAL MEASURES

- Hot, moist compresses to affected area
- If lymphedema is involved, compression garments and weight loss may help.
- Abstinence from sexual activity (for sclerosing lymphangitis)

MEDICATION

- Treat common organisms empirically. Use culture and susceptibility to guide subsequent antibiotic treatment (5)[B].

- If mild disease, use outpatient oral antibiotics.
- If no improvement after 48 hours of oral antibiotics, reassess and consider IV antibiotics and/or hospitalization.
- If systemic involvement, start IV antibiotics.
- If necrotizing fasciitis due to group A β-hemolytic *Streptococcus* is suspected, treat aggressively with antibiotics and surgical intervention.

First Line

- Antibiotics for group A streptococcal infection
  - Amoxicillin (if patient known to have only group A *Streptococcus*)
    - Dosing
      - Adults
        - Mild to moderate: 500 mg PO q12h
        - Severe: 875 mg PO q12h or 500 mg PO q8h
      - Children <3 months: 30 mg/kg/day PO divided q12h
      - Children ≥3 months, ≤40 kg
        - Mild to moderate: 25 mg/kg/day PO divided q12h or 20 mg/kg/day divided q8h
        - Severe: 45 mg/kg/day PO divided q12h or 40 mg/kg/day divided q8h
      - Children ≥40 kg same as adult dosing
    - Common adverse effects
      - Diarrhea
    - Serious adverse effects
      - Anaphylaxis, Stevens-Johnson syndrome (SJS), toxic epidermal necrolysis (TEN)
    - Drug interactions
      - Methotrexate, venlafaxine, warfarin, hormonal contraceptives
    - Contraindications
      - Hypersensitivity to penicillin
- Ampicillin/sulbactam
  - Dosing
    - Adults and children ≥40 kg: 1.5 to 3 g (ampicillin + sulbactam component) IV/IM q6h
    - Children <40 kg: 200 mg/kg/day IV infusion, in divided doses q6h;

maximum 8 g ampicillin per day
  - Common adverse effects
    - Diarrhea, injection site reactions
  - Serious adverse effects
    - *Clostridium difficile* diarrhea, pseudomembranous enterocolitis
  - Drug interactions
    - Hormonal contraceptives
  - Contraindications
    - Hypersensitivity reactions
- Ceftriaxone
  - Dosing
    - Adults: 1 to 2 g IV/IM q24h
    - Children: 50 to 75 mg/kg/day IV/IM once daily or in divided doses q12h; maximum 2 g/day
  - Common adverse effects
    - Injection site reactions, diarrhea
  - Serious adverse effects: same as amoxicillin or ampicillin
  - Drug interactions
    - Do not administer calcium-containing solutions in the same IV line.
  - Contraindications
    - Hypersensitivity to cephalosporins
    - Concurrent calcium-containing IV fluids
    - Increased risk of kernicterus, salt precipitation in lungs and kidneys in neonates <28 days (use cefotaxime instead)
- Cephalexin
  - Dosing
    - Adults: 500 mg PO q12h
    - Children: 25 to 50 mg/kg/day divided q12h
  - Common adverse effects
    - Diarrhea
  - Serious adverse effects
    - SJS, TEN, interstitial nephritis, renal failure, pseudomembranous enterocolitis, anaphylaxis
  - Contraindications

    - Hypersensitivity to cephalosporins
- Azithromycin (if penicillin or cephalosporin allergy)
  - Dosing
    - Adults: 500 mg PO on day 1 followed by 250 mg/day PO on days 2 to 5
    - Children ≥2 years: 12 mg/kg/day PO (maximum dose: 500 mg/day) once daily for 5 days (FDA off-label use for skin infections in children)
  - Common adverse effects
    - Abdominal pain, nausea, vomiting, diarrhea, headache
  - Serious adverse effects
    - Prolonged QT interval, torsades de pointes, liver failure, Lambert-Eaton syndrome, myasthenia gravis, corneal erosion, anaphylaxis
  - Drug interactions
    - Nelfinavir, warfarin, other medications with potential to prolong QT interval
  - Contraindications
    - Hepatic dysfunction or cholestatic jaundice with prior treatment
    - Hypersensitivity to macrolide (azithromycin, erythromycin, clarithromycin)
- Diethylcarbamazine, ivermectin, albendazole, and doxycycline are used to treat filarial infection.
- Acetaminophen or ibuprofen (NSAIDs) for pain and fever

SURGERY/OTHER PROCEDURES

- Incision and drainage of abscess if present
- Necrotizing fasciitis needs surgical evaluation and likely débridement
- Nodular lymphangitis may benefit from I&D
- With severe lymphedema, consider surgical drainage

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Admit for signs of serious illness: fluids if in hypotensive shock.
- Fever, chills, systemic toxicity
- IV antibiotics
- ICU or surgery as indicated
- Patient can be discharged on oral antibiotics after systemic symptoms resolve.

Home IV antibiotics are an option depending on clinical setting.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Elevate affected area.
- 48-hour follow-up to ensure improvement
- Recurrent lymphangitis should prompt workup to ascertain underlying cause (other infectious organism, anatomic abnormality, etc.).

Patient Monitoring

Close follow-up to ensure decreasing inflammation

PATIENT EDUCATION

Instruct patients on proper wound and skin care.

PROGNOSIS

- Good prognosis for uncomplicated cases
- Antimicrobial therapy is effective in 90% of patients.
- Untreated, can spread rapidly, especially group A *Streptococcus*

COMPLICATIONS

Sepsis, cellulitis, necrotizing fasciitis, myositis

CODES

ICD10

- I89.1 Lymphangitis
- L03.91 Acute lymphangitis, unspecified
- N48.29 Other inflammatory disorders of penis

CLINICAL PEARLS

- Lymphangitis classically presents with erythematous linear streaks of the skin from the inciting site (e.g., bite, cut, abrasion) to regional lymph nodes.
- Patients with prior surgical lymph node dissection are predisposed to lymphangitis.
- Patients with severe systemic symptoms should be admitted and treated with IV antibiotics.
- Parasitic or fungal infections can cause acute or chronic lymphangitis.
- Treatment of underlying skin infection (such as tinea pedis) may prevent recurrence.

LYMPHEDEMA

Jon S. Parham, DO, MPH • Sandra N. New, DNP

BASICS

DESCRIPTION

- Accumulation of lymphatic fluid in the interstitial tissue causing swelling
- Lymphedema can develop when lymphatic vessels are missing or impaired (primary) or when lymph vessels are damaged or lymph nodes are removed (secondary).
- Most common in the lower limb(s) (80%) but also can occur in the arm(s), face, trunk, and external genitalia

EPIDEMIOLOGY

Incidence

- Predominant sex: female > male
- Predominant age: any age
- 13% of patients with breast cancer treated with surgery; 42% of those treated with surgery and radiation therapy; 25% after GYN cancer surgery
- Milroy disease presents at birth; estimated to be between 1/6,000 and 1/300 live births
- Meige disease develops during puberty.

Prevalence

- 120 million people worldwide are affected with lymphatic filariasis in 73 countries but no primary infections in United States.
- 10 million people are affected by nonfilarial secondary lymphedema in the United States.

ETIOLOGY AND PATHOPHYSIOLOGY

Secondary lymphedema:

- Postoperative: gradual failure of distal lymphatics, which have to “pump” lymph at a greater pressure through damaged proximal ducts
- Risk is higher with postoperative radiation because radiation reduces regrowth

of ducts due to fibrous scarring.
- Trauma; recurrent infection; malignancy, including metastatic disease, and marked obesity
- Developing countries: Most common cause is filariasis (*Wuchereria bancrofti*).

Genetics

- Milroy disease: autosomal dominant; diagnosed either at birth or the 1st year of life
- Lymphedema praecox has onset between the ages of 1 and 35 years.
- Lymphedema tarda occurs in those >35 years of age.

RISK FACTORS

- Filariasis: most common cause worldwide
- Mastectomy
- Prior trauma, infection of affected limb
- History of prior surgical (particularly if lymph nodes were removed) or radiation therapy for malignancy (radiation can damage lymph nodes and cause skin dermatitis)
- Obesity (>50 body mass index)

GENERAL PREVENTION

Healthy body weight maintenance; treatment of congestive heart failure (CHF) and venous insufficiency

COMMONLY ASSOCIATED CONDITIONS

Venous disease, morbid obesity, regional cancer, filarial disease (Africa and Asia)

DIAGNOSIS

HISTORY

Recent surgery: Vein stripping can significantly exacerbate mild lymphedema:

- First symptom: painless swelling
- Feeling of heaviness in the limb, especially at the end of the day and in hot weather

PHYSICAL EXAM

- Initial: pitting edema, can spread proximally
- Later: nonpitting; after 1st year, does not spread proximally/distally but spreads radially
- Hyperkeratosis (thicker skin)
- Papillomatosis (rough skin)
- Increase in skin turgor
- Positive Stemmer sign (inability to pinch the skin of the dorsum of the second toe between the thumb and forefinger); must exclude heart failure

DIFFERENTIAL DIAGNOSIS

- CHF, renal failure, lipedema
- Hypoalbuminemia, protein-losing nephropathy
- DVT, chronic venous disease
- Postoperative complications following ipsilateral surgery
- Cellulitis, Baker cyst, idiopathic edema

DIAGNOSTIC TESTS & INTERPRETATION

- Lack of response to elevation or diuretic therapy may indicate a lymphatic insufficiency.
- Diuretics increase excretion of salt and water, thereby decreasing plasma volume, venous capillary pressure, and filtration. Diuretics improve filtration edema but do not improve lymph drainage over the long term.
- Some relevant protein biomarkers for lymphedema have been identified and show promise for early- and latent-stage diagnosis.

Initial Tests (lab, imaging)

- Comprehensive chemistry panel: hepatic or renal impairment
- TSH: hypothyroidism
- Urinalysis: protein-losing nephropathy
- Ultrasound: evaluates for acute/chronic DVT; gives information about soft tissue changes but does not inform about truncal anatomy of the lymphatics
- Duplex ultrasound: Lymphedema causes gradual impedance of venous return that aggravates the edema; 82% of patients with unexplained limb edema were diagnosed using a combination of duplex ultrasound and lymphoscintigram.

Follow-Up Tests & Special Considerations

- Lymphangiogram: direct cannulation of lymphatics through the skin; risk for infection, local inflammation. Rarely used now.
- Fluorescence microlymphography may be highly sensitive (91.4%) and specific (85.7%), atraumatic and is without radiation in diagnosis of leg lymphedema.
- Lymphoscintigram: radiolabeled protein technetium-99m–labeled colloid
  - Measures lymphatic function, lymph movement, lymph drainage, and response to treatment
  - Sensitivity, 73–97%; specificity, 100%
  - Best to use 1 hour and delayed images together
- Indocyanine green lymphography: reported
  - Superior to lymphoscintigraphy in early diagnosis of arm
  - Accurately screens postsurgically for subclinical lymphedema (1)[B]
- CT scan: calf skin thickening, thickening of the SC compartment, increased fat density, thickened perimuscular aponeurosis; typical honeycomb appearance
- MRI: circumferential edema, increased volume of SC tissue, honeycomb pattern above the fascia between the muscle and subcutis; cannot differentiate primary from secondary lymphedema

TREATMENT

GENERAL MEASURES

- Seek optimal weight, early treatment of cellulitis, avoid trauma to affected area (direct injury, venipunctures, inept nail care, extreme heat/cold).
- Achieve mechanical reduction and maintenance of limb size: compression garments via professionals.
- Elevate affected limb/area but avoid stasis.
- Avoid BP cuffs in affected limbs.
- Prevent skin infection with daily cleansing, inspection, and skin care (with emollients).
- Treatment of varicose veins may benefit some.
- Doubtful that air travel is associated with increased limb volumes.

MEDICATION

- Diuretics of limited benefit and may lead to volume depletion
- Therapeutic skin care, including careful hygiene and emollients

ISSUES FOR REFERRAL

- Refer to physical therapist with lymphedema training for manual decongestive therapy.
  - In patients with recurrent or metastatic disease, discuss with oncologist prior to initiation of complete decongestive therapy in order not to promote the spread of cancer.
- Provide education for patient/family for self-administration of therapy in future.
- Education for family about bandaging
- Fitting for compression garments (2)[A]

ADDITIONAL THERAPIES

- Exercise: Lymph flow occurs as a result of inspiratory reduction in the intrathoracic pressure associated with inspiration. Best results are achieved with combination of flexibility, strength, and aerobic training.
- Compression with custom-made elastic stocking (minimum pressure is 40 mm Hg)
  - Protection against external incidental trauma
  - Decreases the intrinsic trauma on the skin due to chronically increased interstitial pressures, which cause stretch of the skin and SC tissues
  - No data on preference of custom-made versus prefabricated
  - Replace every 3 to 6 months or when starting to lose elasticity.
- Multilayer bandaging: inner layer of tubular stockinette followed by foam and padding to protect the joint flexures and to even out the contours of the limb so that pressure is distributed evenly; outer layer of at least two short-stretch extensible bandages; more effective than hosiery alone.
- Pneumatic pumps develop high pressures like systolic BP and can reduce limb girth significantly; wear a compression sock afterward (2)[A].
- Advanced pneumatic compression devices (APCDs) are programmable, offer a more individualized fit, reduced rates of cellulitis by at least 75%, and reduce early treatment costs by 37–54% depending on health care setting (3)

[B].

SURGERY/OTHER PROCEDURES

- Bypass procedures: creation of lymphatic–venous anastomosis or lymph node transplantation (most effective) via microsurgery showed a reduction in use of conservative compression therapy (4)[C]: reserved for refractory cases only.
- Low-level laser therapy in smaller studies was shown to be noninferior to manual lymphatic drainage or in combination in arm volume reduction among breast cancer patients in half the treatment time (4)[C].
- Axillary reverse mapping during axillary node dissection in selected preclinical breast cancer can significantly reduce lymphedema incidence (5) [A].
- Thoracic sympathetic ganglion block for breast cancer–related lymphedema, a new treatment showed better life quality and arm size reduction >50%, especially in patients with high grade lymphedema.
- Debulking procedures (Charles procedure): radical excision of SC tissue with primary or staged skin grafting
  - Men had less improvement than women.
  - Main risk is infection and necrosis of the skin graft.
  - Liposuction is cosmetically preferred to debulking (4)[C].

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Heat therapy: Microwave and electromagnetic irradiation may be helpful.
- Selenium ingestion has been reported to reduce lymphedema volume (not approved indication in United States).
- Benzopyrene oral medicine (flavonoids and coumarin; neither are approved in the United States)
  - Flavonoids: Micronized purified flavonoid fraction (Daflon 500 mg) reported to decrease venous stasis and idiopathic cyclic edema, chronic venous insufficiency, and postmastectomy lymphedema.
  - Coumarin reduces edema fluid by increasing the number of macrophages and enhancing proteolysis, resulting in the removal of protein, some reports of bleeding, and hepatotoxicity (4)[C].

ADMISSION, INPATIENT, AND NURSING

CONSIDERATIONS

- Systemic signs of infection
  - May admit to specialized rehabilitation unit for combination treatment in patients with heart failure or severe pulmonary disease
  - IV antibiotics for infection; cellulitis is most common.
- Affected extremity positioning with some distal elevation
- Encourage patient mobilization/exercise.
- Patient education for bandaging/wound care
- Discharge criteria
  - Improved signs/symptoms of infection (e.g., elevated WBC count, fever, abnormal vital signs)
  - Clinical improvement in wound appearance

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Lymphedema will return in several days if patient stops wearing compression garments during the day and bandaging at night.

Patient Monitoring

- Daily visit to therapist for acute treatment
- Monthly visits for maintenance care

DIET

Lower sodium, healthy protein, and weight loss-oriented (if needed)

PATIENT EDUCATION

- Use compression garments, especially when exercising.
- Avoid affected limb(s) being dependent for long period of time: Patient should perform daily skin examination.
- http://www.nlm.nih.gov/medlineplus/lymphedema.html

PROGNOSIS

No cure, but treatment can produce good results with daily care.

COMPLICATIONS

- Infection (local vs. systemic): common
- Risk of wound formation (punctures/abrasions) that are difficult to heal: common
- Lymphangiosarcoma: Found in lymphedematous arms of patients following radical mastectomy; also in patients with Milroy disease. Treatment is radiotherapy with surgery, reserved for patients with discrete nonmetastatic disease.

CODES

ICD10

- I89.0 Lymphedema, not elsewhere classified
- Q82.0 Hereditary lymphedema
- I97.89 Oth postproc comp and disorders of the circ sys, NEC

CLINICAL PEARLS

- Affected skin with heavy feeling, painless swelling initially, later nonpitting swelling
- Rule out DVT if unilateral limb or CHF if bilateral
- Early referral to lymphedema therapist for manual therapy, compression devices/wrappings
- Aggressive weight loss and health promotion as needed
- High risk for cutaneous-sourced infections, so promote therapeutic skin care.
- Lymphoscintigram is standard diagnostic if clinically diagnosis is uncertain.

MACULAR DEGENERATION, AGE-RELATED

Richard W. Allinson, MD

BASICS

DESCRIPTION

- Age-related macular degeneration (ARMD) is the leading cause of irreversible, severe visual loss in persons age >65 years.
- ARMD results in pigmentary changes in the macula or typical drusen associated with visual loss to the 20/30 level or worse, not caused by cataract or other eye disease, in individuals >50 years of age, although some definitions exclude age or visual acuity criteria.
- Stages
  - Atrophic/nonexudative
  - Neovascular/exudative
- System(s) affected: nervous
- Synonym(s): senile macular degeneration; subretinal neovascularization

EPIDEMIOLOGY

- Neovascular/exudative form is rare in blacks and more common in whites.
- Predominant sex: female

Incidence

- In the Framingham Eye Study (FES), drusen were noted in 25% of all participants who were ≥52 years of age. ARMD-associated visual loss was noted in 5.7%.
- Atrophic/nonexudative stage accounts for 20% of cases of severe visual loss.
- Neovascular/exudative stage accounts for 80% of cases of severe visual loss.

Prevalence

Per FES study:

- People 65 to 74 years old: 11%
- People ≥75 years old: 27.9%

ETIOLOGY AND PATHOPHYSIOLOGY

- Breaks in the Bruch membrane allow choroidal neovascular membranes (CNVMs) to invade the retinal pigment epithelium (RPE) and grow into the subretinal space.
- Atrophic/nonexudative: drusen and/or pigmentary changes in the macula
- Neovascular/exudative: growth of blood vessels underneath the retina
- Visible light can result in the formation and accumulation of metabolic by-products in the RPE, a pigment layer underneath the retina that normally helps remove metabolic by-products from the retina. Excess accumulation of these metabolic by-products interferes with the normal metabolic activity of the RPE and can lead to the formation of drusen.
- Neovascular stage generally arises from the atrophic stage.
- Most do not progress beyond the atrophic/nonexudative stage; however, those who do are at a greater risk of severe visual loss.

Genetics

- Genetic susceptibility may be a factor in ARMD: ~25% genetically determined.
- Complement factor H is an important susceptibility gene for ARMD.
- Although the development of ARMD may be predicted by specific alleles, the clinical response to antivascular endothelial growth factor is not.

RISK FACTORS

- Obesity
- Ethnicity: non-Hispanic whites
- Cigarette smoking
- *Chlamydia pneumoniae* infection
- Family history
- Excess sunlight exposure
- Blue or light iris color
- Hyperopia
- History of cardiovascular disease
- Short stature
- Aspirin use
- Female sex

GENERAL PREVENTION

- Ultraviolet (UV) protection for eyes
- Routine ophthalmologic visits
  - Every 2 to 4 years for patients age 40 to 64 years
  - Every 1 to 2 years after age 65 years
- Patients who take statins, which modify lipid profiles, may have a reduced risk.

COMMONLY ASSOCIATED CONDITIONS

- Presumed ocular histoplasmosis syndrome
- Exudative retinal detachment
- Vitreous hemorrhage
- Other causes of CNVMs

DIAGNOSIS

HISTORY

- Patients frequently notice distortion of central vision.
- Patients may notice straight lines appear crooked (e.g., telephone poles).

PHYSICAL EXAM

- Atrophic/nonexudative stage retinal exam
  - Drusen (small yellowish white lesions)
    - Subtypes: hard drusen and soft drusen
  - Atrophy of the RPE
- Neovascular/exudative stage retinal exam
  - Blood vessels growing underneath the retina from the choroid are called *CNVMs* or *subretinal neovascularization* (SRN). The choroid is the vascular layer underneath the RPE.
  - Subretinal fluid or hemorrhage
  - Exudates
  - On Amsler grid testing, the horizontal or vertical lines may become broken, distorted, or missing.
- Disciform scar: an advanced stage resulting in a fibrovascular scar

DIFFERENTIAL DIAGNOSIS

- Idiopathic SRN
- Presumed ocular histoplasmosis syndrome
- Diabetic retinopathy
- Hypertensive retinopathy

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other

- Amsler grid testing
- Fluorescein angiography
  - Detection of CNVMs
  - Differentiate between atrophic and neovascular ARMD.
- Indocyanine green video angiography: may identify occult or hidden CNVMs
- Optical coherence tomography (OCT) is useful in determining the presence of subretinal fluid, the degree of retinal thickening, and the presence of a pigment epithelial detachment (PED).
  - Fluorescein angiography is better than time-domain OCT in detecting new-onset CNVMs.
  - Newer generation OCT modalities, including Spectral Domain OCT (SD-OCT) are preferred for evaluating ARMD.

Test Interpretation

Drusen: deposits of hyaline material between the RPE and Bruch membrane (the limiting membrane between the RPE and the choroid)

TREATMENT

MEDICATION

First Line

- Ranibizumab (Lucentis)
  - Antibody fragment that inhibits all active forms of vascular endothelial growth factor (VEGF)
  - Approved for neovascular (wet) ARMD
  - Injected intravitreally, at a dose of 0.5 mg, every 4 weeks

- 1 year after treatment, up to 40% of patients treated with ranibizumab gained at least three lines of vision, and ~95% maintained vision.
- Ranibizumab is superior to verteporfin in the treatment of predominately classic CNVMs.
- The PrONTO study demonstrated OCT-guided, variable-dosing regimen with ranibizumab resulted in similar results to the MARINA and ANCHOR studies with monthly injections.
- When comparing ranibizumab and bevacizumab in a multicenter study, both treatments were effective in stabilizing visual loss, and no difference was found in the visual outcome between the two treatment groups. A slightly higher rate of serious systemic adverse events was noted in the bevacizumab group (1)[A].
  - In this study, treatment as needed resulted in less gain in visual acuity, whether instituted at enrollment or after 1 year of monthly treatment.
  - Visual gains during the first 2 years were not maintained at 5 years. At the 5-year visit, 50% of eyes had vision of 20/40 or better and 20% had vision of 20/200 or worse (2)[A].
  - Cystoid macular edema is a marker for poorer visual outcomes in patients with CNVMs. (3)[A].
- Eyes with ≥50% of the lesion composed of blood had a similar visual prognosis compared to other treated eyes in the Comparison of Age-related Macular Degeneration Treatments Trials (CATT). Neovascular ARMD lesions composed of >50% blood can be managed similarly to those with less or no blood (4)[A].
- The treat and extend regimen (TER) is commonly used to decrease the treatment burden. Once no signs of CNVM activity are detected, patient follow-ups and treatments are then extended by intervals of 2 weeks as long as no signs of CNVM activity are present, up to a maximum interval of 12 weeks. If examination shows any sign of recurrence, the interval is shortened by 2 weeks at a time, until the disease is considered to be inactive. Interval extension is then restarted, with the maximum final interval being 2 weeks less than the period when the previous recurrence was observed.
- Ranibizumab and bevacizumab had equivalent effects on visual acuity at 1

year using the TER. The visual acuity results at 1 year were comparable to those of other clinical trials with monthly treatment (5)[A].

- VEGF Trap-Eye/aflibercept (Eylea)
  - A decoy VEGF receptor that inhibits all isoforms of VEGF-A and placental growth factor (PGF), the members of the VEGF family in mammals primarily involved in ocular neovascularization
  - Approved for neovascular (wet) ARMD
  - Injected intravitreally, at a dose of 2 mg, every 4 weeks for 12 weeks and then every 8 weeks
  - Dosed as needed after the 12-week fixed dosing schedule resulted in a 5.3-letter gain in best corrected visual acuity at 52 weeks (6)[B].
  - Routine use of prophylactic antibiotics after intravitreal injections may be unnecessary.
  - May be beneficial in patients who are not responding to ranibizumab or bevacizumab (7)[C]
  - Anti-VEGF treatment with either ranibizumab or aflibercept showed limited efficacy for the complete resolution of PED.
    - Patients with a PED tend to have worse outcomes when switched from a fixed regimen to a PRN strategy (8)[A].
    - Patients with PEDs and intraretinal cysts have a worse visual prognosis.
    - PEDs treated with aflibercept showed a better anatomical response than eyes treated with ranibizumab, but the visual outcomes were the same (9)[B].

Second Line

- Bevacizumab (**Avastin**) is a full-length antibody to VEGF, administered intravitreally at a dose of 1.25 mg; widely used off-label because of its lower cost.
- Agents that block platelet-derived growth factor (PDGF) are being investigated.

GENERAL MEASURES

Low-vision aids may be helpful.

SURGERY/OTHER PROCEDURES

- Laser treatment for CNVMs located ≥200 microns from the center of the macula has been evaluated in the Macular Photocoagulation Study (MPS).
  - Anti-VEGF treatment is first-line therapy for subfoveal CNVMs.
- Vitrectomy has been used to remove CNVMs, but this is generally not recommended.
- CNVMs can bleed spontaneously, leaving blood underneath the retina. Vitrectomy to remove subretinal blood may be of benefit and should be performed within 7 days of the bleed. Tissue plasminogen activator (tPA) instilled into the eye may help remove a subretinal hemorrhage. In some cases, intravitreal gas with or without tPA may displace submacular blood:
  - Intravitreal anti-VEGF monotherapy may be helpful in the treatment of neovascular ARMD associated with a submacular hemorrhage (10)[C].
- Photodynamic therapy (PDT) with verteporfin reduces vision loss in patients with >50% "classic" subfoveal CNVMs. Verteporfin is administered IV, and a diode laser at 689 nm is applied to the CNVM.
  - Patients should be informed of a <4% risk of acute, severe vision loss after PDT.
  - Ranibizumab has greater clinical efficacy than PDT.
  - Combination treatment with intravitreal ranibizumab and PDT appears to offer similar gain in visual acuity when compared with ranibizumab monotherapy.
  - Combination treatment with ranibizumab and PDT may reduce the number of ranibizumab retreatments.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Free radical formation in the retina, induced by visible light, may play a role in cellular damage that results in atrophic/nonexudative macular degeneration. The Age-Related Eye Disease Study (AREDS) found that a high-dose regimen of antioxidant vitamins and mineral supplements reduced progression of ARMD in some cases.

- Recommended daily doses: vitamin C 500 mg, vitamin E 400 IU, β-carotene 15 mg, zinc oxide 80 mg, and cupric oxide 2 mg
- Exercise caution with β-carotene use in smokers due to potential link to lung cancer.
- The Age-Related Eye Disease Study 2 (AREDS2) found the addition of lutein

with zeaxanthin alone or in combination with omega-3 fatty acids had no overall effect in further reducing the risk of progression to advanced ARMD.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Amsler grid can aid in discovering visual disturbances.
- Patients with soft drusen or pigmentary changes in the macula are at an increased risk of visual loss. They should monitor their vision, such as by daily Amsler grid testing, and subjective measures of visual acuity, such as reading ability. If no new symptoms, follow-up examination in 6 to 12 months.

DIET

- Eating dark green, leafy vegetables (spinach/collard greens), which are rich in carotenoids, may decrease the risk of developing the neovascular/exudative stage.
- Fish consumption with omega-3 fatty acid intake reduces the risk of ARMD.
- A Western-type diet characterized by higher intake of red meat, processed meat, high-fat dairy products, French fries, refined grains, and eggs increases the risk of ARMD as compared to an Oriental-type diet characterized by higher intake of vegetables, legumes, fruit, whole grains, tomatoes, and seafood which decreases the risk of ARMD.

PATIENT EDUCATION

Instruct visually impaired patients to check with the local low-vision center for aids.

PROGNOSIS

- Patients with bilateral soft drusen and pigmentary changes in the macula, but no evidence of exudation, have an increased likelihood of developing CNVMs and subsequent visual loss.
- Patients with bilateral drusen carry a cumulative risk of 14.7% over 5 years of suffering significant visual loss in one eye from the neovascular stage of

ARMD.

- Patients with neovascular stage in one eye and drusen in the opposite eye are at an annual risk of 5–14% of developing the neovascular stage in the opposite eye with drusen.
- Macular atrophy progression and severity were the primary anatomic determinants of visual outcomes 7 years after treatment with ranibizumab (11) [A].
- High incidence of recurrence after thermal laser treatment for CNVMs

COMPLICATIONS

- Blindness
- The intraocular pressure should be monitored in eyes receiving intravitreal anti-VEGF injections.

CODES

ICD10

- H35.30 Unspecified macular degeneration
- H35.32 Exudative age-related macular degeneration
- H35.31 Nonexudative age-related macular degeneration

CLINICAL PEARLS

- Patients frequently notice distortion of central vision.
- Patients may notice straight lines appear crooked (e.g., telephone poles).
- Hyperopia is a risk factor for ARMD.
- The AREDS study found that a high-dose regimen of antioxidant vitamins and

mineral supplements reduces progression of ARMD in some cases.

- Tobacco cessation should be strongly encouraged.

MALARIA

Paul M. Arguin, MD

BASICS

DESCRIPTION

- Acute or chronic infection transmitted to humans by *Anopheles* spp. mosquitoes
- Most morbidity and mortality is caused by *Plasmodium falciparum*. An estimated 214 million cases occur annually, including 438,000 deaths, most of which occur in children <5 years of age in sub-Saharan Africa (1).
- Nonimmune individuals are most susceptible to rapid progression to severe disease.
- System(s) affected: cardiovascular, hematologic, renal, respiratory, cerebral, lymphatic, immunologic

EPIDEMIOLOGY

- Cases imported to the United States: 61% *P. falciparum*; 14% *Plasmodium vivax*; 3% *Plasmodium malariae*; 4% *Plasmodium ovale*; 2% mixed; 17% unknown
- Occurs worldwide in tropical latitudes: *P. falciparum*, *P. malariae*, *P. vivax*, and *P. ovale*. *Plasmodium knowlesi* in parts of Southeast Asia.

Incidence

- Most U.S. cases (>99%) are imported.
- ~1,500 cases and 5 deaths per year in the United States (2)

Prevalence

- Predominant age: all ages
- Predominant sex: male = female

ETIOLOGY AND PATHOPHYSIOLOGY

- Malarial parasites digest red blood cell (RBC) proteins and alter the RBC membrane, causing hemolysis, increased splenic clearance, and anemia.
- RBC lysis stimulates release of cytokines and tumor necrosis factor-α (TNF-

α) causing fever and systemic symptoms.
- *P. falciparum* alters RBC viscosity, causing obstruction and end-organ ischemia.

Genetics

Unknown genetic predilection but inherited conditions may affect disease severity and susceptibility (glucose-6-phosphate dehydrogenase deficiency, sickle cell disease or trait, and hereditary elliptocytosis)

RISK FACTORS

- Travel to or migration from endemic areas (primarily sub-Saharan Africa)
- Rarely, blood transfusion, mother-to-fetus transmission, and local autochthonous transmission

GENERAL PREVENTION

- Mosquito avoidance: Use of insect repellent, wear clothing to cover exposed skin, use mosquito nets treated with permethrin, and avoid outdoor activity from dusk to dawn.
- *Malarial chemoprophylaxis when in endemic area*
  - Mefloquine: Begin at least 2 weeks before arrival and continue for 4 weeks after leaving area. Adults, 250 mg (1 tablet) weekly; children ≤9 kg, 5 mg/kg; children >9 to 19 kg, 1/4 tablet weekly; children >19 to 30 kg, 1/2 tablet weekly; children >30 to 45 kg, 3/4 tablet weekly; children >45 kg as adult
    - Caution: mefloquine-resistant areas
  - Atovaquone/proguanil: Begin 1 to 2 days before arrival and continue for 1 week after leaving area. Adults, 1 adult tablet daily; children 5 to 8 kg, 1/2 pediatric tablet daily; children 9 to 10 kg, 3/4 pediatric tablet daily; children 11 to 20 kg, 1 pediatric tablet daily; children 21 to 30 kg, 2 pediatric tablets daily; children 31 to 40 kg, 3 pediatric tablets daily; children >40 kg, 1 adult tablet daily
  - Doxycycline: Begin 1 to 2 days before arrival and continue for 4 weeks after leaving area. Adults, 100 mg daily; children, 2 mg/kg up to 100 mg daily (not for children <8 years old)
  - Chloroquine: Begin 1 to 2 weeks before arrival and continue for 4 weeks

after leaving area. Adults, 500 mg (300-mg base) weekly; children, 8.3 mg/kg (5-mg base/kg) weekly up to 300 mg
    - Caution: chloroquine-resistant areas
  - Primaquine: Begin 1 to 2 days before arrival and continue for 1 week after leaving area; adults, 30 mg/day; children, 0.5 mg/kg/day up to adult dose
    - For use only in areas predominantly endemic for *P. vivax*
    - Caution: Glucose-6-phosphate dehydrogenase deficiency must be excluded prior to first use.

COMMONLY ASSOCIATED CONDITIONS

Bacterial coinfections sometimes occur.

DIAGNOSIS

HISTORY

- Initial symptoms of malaria are nonspecific. Suspect malaria in ill patients returning from endemic area presenting with
  - Fever, malaise, myalgias, chills, headache, nausea, splenomegaly (with chronic infection), hypotension, anemia (with chronic or severe disease), thrombocytopenia, jaundice, vomiting, and/or diarrhea (resembling gastroenteritis)
- *P. falciparum*
  - Incubation usually 12 to 14 days, symptoms within 1 month of infection in most individuals (partially immune individuals such as immigrants may become ill up to 1 year after last exposure)
  - Severe disease and complications: vascular collapse, CNS impairment, renal failure, and acute respiratory distress syndrome
- *P. vivax* and *P. ovale*
  - Incubation period 12 to 18 days for primary infection and up to 12 months (and longer) for relapses; generally presents with fevers
  - Dormant parasites may remain in liver and reactivate years after initial infection.
  - Can be severe
- *P. malariae*

  - Incubation period ~35 days
  - May become chronic; untreated can persist asymptomatically in human host for years
- *P. knowlesi*
  - Incubation period ~12 days
  - Possibly severe

PHYSICAL EXAM

- Often not specific
- General: elevated temperature, fatigue, tachycardia, tachypnea, jaundice
- Neurologic: mental status and motor–sensory exam (cerebral malaria)
- Cardiopulmonary exam: hemodynamic stability and signs of vascular leak (effusion)
- Skin exam: pallor, rash
- Abdominal exam: organomegaly

DIFFERENTIAL DIAGNOSIS

- Infections (disseminated or localized): abscess, viral, gastroenteritis, typhoid/paratyphoid, other bacteremias, rickettsial disease, mycobacteria
- Collagen vascular disease (systemic lupus erythematosus [SLE], vasculitides)
- Neoplasms (lymphoma, leukemia, other blood dyscrasias, other tropical causes of splenomegaly)
- Severe malaria infection may mimic hepatitis, pneumonia, stroke, or sepsis.

DIAGNOSTIC TESTS & INTERPRETATION

- Malarial smear thick and thin preparations (3)[A]
  - Microscopy to evaluate for presence of parasite forms, determine species, and quantify the percentage of RBCs that are infected. Relatively easy to perform with proper training
  - Test should be performed on site, immediately, with results quickly available.
- Rapid antigen capture enzyme: can detect the presence of malaria parasites within minutes. Cannot determine species or quantify parasitemia. Positive and negative results must always be confirmed by microscopy.
- Other tests: species-specific PCR; species confirmation by PCR is

encouraged.

- General laboratory findings (nonspecific)
  - In uncomplicated infection
    - Elevated liver function tests and lactate dehydrogenase
    - Thrombocytopenia, anemia, and leukopenia
- Note: a low to low-normal platelet count or a slightly high bilirubin should alert the clinician to the diagnosis after exposure in an endemic setting.
- Note: Antimalarial prophylaxis may reduce parasitemia.

Initial Tests (lab, imaging)

- CBC with differential and platelets
- Basic chemistry panel including bilirubin
- Malaria thick and thin blood films (if negative, repeat q12–24h for at least three sets)
- Imaging necessary only for respiratory disease (chest x-ray) or cerebral malaria (CT scan prior to lumbar puncture)

Follow-Up Tests & Special Considerations

- Nonimmune individuals with suspected or confirmed *P. falciparum* should be hospitalized.
- Clinical specimens from suspected or confirmed malaria cases in the United States can be submitted to the Centers for Disease Control and Prevention (CDC) for diagnostic confirmation, speciation, and drug resistance surveillance free of charge.

Test Interpretation

Interpretation of microscopy: Spread blood on a microscope slide as a thick/thin prep and stain with Giemsa (most commonly). View slide under 100X oil immersion to examine for ring, gametocyte, trophozoite, and schizont forms. The thick film is better for detecting parasites. The thin film is used to determine species and calculating the percentage of RBCs infected. Both should always be performed.

TREATMENT

MEDICATION

First Line

- For uncomplicated chloroquine-resistant *P. falciparum* (most *P. falciparum*), chloroquine-resistant *P. vivax*, or when species is unknown, the following regimens are recommended (4)[A]:
  - Atovaquone-proguanil (Malarone): adult tablet: 250 mg atovaquone and 100 mg proguanil. Pediatric tablet: 62.5 mg atovaquone and 25 mg proguanil. Adults: 4 adult tablets once per day for 3 days. Children 5 to 8 kg: 2 pediatric tablets once per day for 3 days; children 9 to 10 kg: 3 pediatric tablets once per day for 3 days; children 11 to 20 kg: 1 adult tablet once per day for 3 days; children 21 to 30 kg: 2 adult tablets once per day for 3 days; children 31 to 40 kg: 3 adult tablets once per day for 3 days; children >40 kg: 4 adult tablets once per day for 3 days
  - Artemether-lumefantrine (Coartem): tablet contains 20 mg artemether and 120 mg lumefantrine. Persons 5 to <15 kg: 1 tablet BID for 3 days; persons 15 to <25 kg: 2 tablets BID for 3 days; persons 25 to <35 kg: 3 tablets BID for 3 days; persons ≥35 kg: 4 tablets BID for 3 days
  - Quinine sulfate plus doxycycline or clindamycin: adults: quinine sulfate 650 mg (salt) TID for 3 days (should be extended to 7 days for infections acquired in Southeast Asia). Doxycycline 100 mg BID for 7 days. Clindamycin 20 mg (base)/kg/day divided TID for 7 days. Children: quinine sulfate 10 mg (salt)/kg TID for 3 days (should be extended to 7 days for infections acquires in Southeast Asia) plus clindamycin dosed as above.
  - Mefloquine: adults: 750 mg followed by 500 mg 8 hours later. Children: 15 mg/kg followed by 10 mg/kg 8 hours later (maximum total dose: 1,250 mg)
- PO therapy for *P. ovale*, *P. malariae*, chloroquine-sensitive *P. falciparum* (rare), and chloroquine-sensitive *P. vivax* (New Guinea has highest rates of chloroquine-resistant *P. vivax*); in addition to the treatment regimens listed above, other options are as follows:
  - Chloroquine: adults: 1 g (600-mg base) followed by 500 mg (300-mg base) at 6, 24, and 48 hours after first dose. Children: 16.6 mg/kg (10-mg base/kg) on day 1 (max 1,000 mg [600-mg base]), then 8.3 mg/kg (5-mg/kg base) at 6, 24, and 48 hours after first dose

  - Primaquine (should be added to the acute treatment regimen for cure of dormant forms of *P. vivax* and *P. ovale*): adults: 30-mg base (52.6 mg) daily for 2 weeks. Children: 0.6-mg base/kg/day for 2 weeks
- Therapy for severe malaria
  - Clinical features defining severe malaria:
    - Impaired level of consciousness (LOC)
    - Respiratory distress, jaundice
    - Repeated convulsions, shock
    - Renal failure
  - Laboratory features:
    - Parasitemia >5%
    - Hypoglycemia
    - Acidosis (usually lactic acidosis)
- Parenteral therapy
  - Quinidine gluconate 10 mg/kg in normal saline over 1 to 2 hours followed by 0.02 mg/kg/min continuous infusion
  - Intensive care monitoring is necessary, especially when initiating quinidine therapy.
- In severe malaria, contact the CDC for assistance; CDC Malaria Branch: 770-488-7100; http://www.cdc.gov/Malaria/
- In 2007, the CDC made artesunate available in the United States for severe malaria in special circumstances under an investigational protocol. Contact the CDC for assistance.

ISSUES FOR REFERRAL

Infectious disease or tropical medicine consultation advised. Malaria is a reportable disease (http://www.cdc.gov/malaria/features/new_report_form.html).

ADDITIONAL THERAPIES

None

Pediatric Considerations

- Children are particularly susceptible to severe disease.
- All children, even infants, should receive chemoprophylaxis if traveling to an endemic area.

- Malaria commonly resembles acute gastroenteritis in children.
- Children with severe disease are particularly prone to hypoglycemia. Use IV fluids with glucose for maintenance and monitor blood glucose frequently.

Pregnancy Considerations

- Chloroquine is safe in the doses recommended for prevention and treatment of malaria; FDA pregnancy Category C.
- Mefloquine is safe in the doses recommended for prevention and treatment of malaria; FDA pregnancy Category B.
- Atovaquone-proguanil (Malarone) has not been studied in pregnant women; it has not been shown to cause birth defects or other problems in animal studies; FDA pregnancy Category C.
- No primaquine (FDA class undetermined) or tetracyclines (FDA pregnancy Category D) in pregnancy
- Quinine/quinidine (FDA pregnancy Category C, respectively) should be used during pregnancy because benefit outweighs risk.

COMPLEMENTARY & ALTERNATIVE MEDICINE

None. Deaths have resulted from using unapproved alternatives to recommended medications.

SURGERY/OTHER PROCEDURES

Rarely, splenectomy must be performed in patients with splenic rupture.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Inpatient care for all cases of *P. falciparum* malaria. Hospitalize patients with signs of severe illness, regardless of species; outpatient care for others
- Nonimmune patients with *P. falciparum* may progress from mild symptoms to death within 12 hours.
- All patients treated on outpatient basis should have follow-up within 24 hours.
- Maintenance IV fluids with glucose because of risk of hypoglycemia are recommended if unable to tolerate fluids by mouth. Excess fluids may result in iatrogenically induced pulmonary edema.
- Observe for fluid excess, renal insufficiency (urine output), and hypoglycemia.

- Discharge criteria: clinical improvement and ability to tolerate oral medications and fluids, with documented decreasing parasitemia levels

ONGOING CARE

PATIENT EDUCATION

- Malarial chemoprophylaxis prior to travel
- Travel information may be obtained at the CDC travel Web site: http://www.cdc.gov/travel
- http://www.cdc.gov/malaria/new_info/2014/malaria_ebola.htm

PROGNOSIS

Malaria infection (particularly *P. falciparum*) can carry a high mortality if untreated. If diagnosed early and treated appropriately, the prognosis is excellent.

COMPLICATIONS

- If not treated early: cerebral malaria, acute renal failure, acute gastroenteritis, respiratory distress syndrome, and massive hemolysis
- Other complications: seizures, anuria, delirium, coma, dysentery, algid malaria, blackwater fever, hyperpyrexia
- *P. malariae*: Nephrotic syndrome may develop in patients with chronic infection.

CODES

ICD10

- B54 Unspecified malaria
- B50.9 Plasmodium falciparum malaria, unspecified
- B51.9 Plasmodium vivax malaria without complication

CLINICAL PEARLS

- Consider malaria in travelers returning from endemic areas who present with fever or nonspecific flulike illness.
- Early identification (sometimes requiring a high index of suspicion) and aggressive treatment, particularly of nonimmune persons with suspected or confirmed *P. falciparum* malaria, is essential.
- Patients who develop clinical malaria despite chemoprophylaxis should be treated with a medication different than their chemoprophylaxis agent.
- *P. falciparum* malaria can be rapidly fatal and should be cared for in the inpatient setting.

MARIJUANA (CANNABIS) USE DISORDER

Kara C. Farley, MD

BASICS

DESCRIPTION

Marijuana or cannabis use disorder is classified in *DSM-5* into different categories (mild, moderate, or severe) depending on how many symptoms are present. Mild: 2 to 3; moderate: 4 to 5; severe: 6+ (1). The definition is used when use leads to clinically significant impairment or distress, manifested by two or more of the following symptoms within a 12-month period:

- Taken in larger amounts and over a longer period of time than intended
- Persistent desire or unsuccessful efforts to cut down or control amount used
- A great deal of time spent in activities is necessary to obtain, use, or recover.
- Presence of craving for the substance
- Recurrent use resulting in failure to fulfill major role obligations at work, school, or home
- Continued use despite having persistent or recurrent social or interpersonal problems due to cannabis use
- Important social, occupational, or recreational activities are given up or reduced.
- Recurrent use in physically hazardous situations
- Use is continued despite knowledge of having a persistent physical or psychological problem caused or exacerbated by cannabis.
- Tolerance, defined by using increased amounts of cannabis to achieve the desired effect or intoxication or diminished effect with continued use of the same amount of cannabis
- Withdrawal

EPIDEMIOLOGY

- The United States is ranked first among 17 European and North American countries by the World Health Organization for prevalence of marijuana use.
- Cannabis is the most widely used illicit psychoactive substance in the United States (2).

- ~42% of teens will have tried marijuana by the time they graduate from high school.
- Approximately 30% of students report having used marijuana at college entry (3).
- In the United States, 10% of those who ever used marijuana become daily users, and 20–30% became weekly users.
- In the United States, some states have approved medical marijuana use, and two states (Washington and Colorado) have approved recreational use of marijuana.
- Other states in the United States are currently trying to pass legislation to legalize the use of recreational marijuana.

ETIOLOGY AND PATHOPHYSIOLOGY

- Main active ingredient in marijuana: delta-9-tetrahydrocannabinol (THC)
- When marijuana is smoked, THC rapidly passes from the lungs into the blood and to the brain, where it binds to cannabinoid receptors (CBRs).
- CBRs are responsible for memory, thinking, concentration, sensory and time perception, pleasure, movement, and coordination.
- THC artificially stimulates the CBRs, disrupting the function of endogenous cannabinoids. A marijuana “high” results from overstimulation of these receptors.
- Over time, overstimulation alters the function of CBRs, which can lead to addiction and to withdrawal symptoms when drug use stops.
- Effects of smoked marijuana occur within minutes and can last 1 to 3 hours.
- Effects from marijuana consumed in foods or beverages appear later, usually in 30 minutes to 1 hour but can last up to 4 hours.
- Smoking marijuana delivers significantly more THC into the bloodstream than eating or drinking the drug.

RISK FACTORS

- Age (highest use among those 18 to 25 years)
- Male sex
- Comorbid psychiatric disorders (i.e., bipolar disorder, posttraumatic stress disorder [PTSD])
- Other substance use (i.e., alcohol, cocaine)

- Lower educational achievement (rates of dependence are lowest among college graduates)

DIAGNOSIS

- Screen for marijuana use along with other lifestyle questions such as tobacco and alcohol use.
- Ask for frequency and amount used (e.g., “How long does a nickel bag last you?”).
- Unexplained deterioration in school or work performance may be a red flag for abuse.
- Problems with, or changes in, social relationships (e.g., spending more time alone or with persons suspected of using drugs) and recreational activities (e.g., giving up activities that were once pleasurable) may indicate abuse.
- If available, information from concerned parents or spouses should be obtained.

HISTORY

- Clinical presentation of acute intoxication:
  - Euphoria, elation, laughter, heightened sensory perception, altered perception of time, increased appetite
  - Poor short-term memory, concentration
  - Fatigue, depression
  - Occasionally, distrust, fear, anxiety, panic
  - With large doses, acute psychosis: delusions, hallucinations, loss of sense of personal identity (4)
- Withdrawal symptoms include the following:
  - Nausea
  - Weight loss
  - Decreased appetite
  - Insomnia
  - Depressed mood

PHYSICAL EXAM

- Evaluate for:

  - Conjunctival injection
  - Xerostomia
  - Nystagmus
  - Increased heart rate
  - Altered pulmonary status
  - Altered body temperature
  - Reduced muscle strength
  - Decreased coordination
- Withdrawal findings include the following:
  - Restlessness/agitation
  - Irritability
  - Tremor
  - Diaphoresis
  - Increased body temperature

DIAGNOSTIC TESTS & INTERPRETATION

Positive urine drug screen; cannabinoids can be detected in urine weeks to months after marijuana use.

TREATMENT

- Several methods of behavioral-based interventions:
  - Cognitive-behavioral therapy
  - Motivational interviewing
  - Counseling
  - Contingency management
  - Social network behavior therapy
  - Twelve-step approach
  - Family-oriented therapy
  - Brief intervention
  - Relapse prevention
  - Community reinforcement approach
- No intervention to date has proved consistently effective for marijuana abuse.
- Despite this, trials on cognitive-behavioral therapy and contingency

management have shown better outcomes in reducing marijuana use and maintaining abstinence (5).

- Trials also show that addition of a comprehensive parenting training curriculum did not further enhance efficacy (5).
- With marijuana abuse, most prevalent among patients suffering from other psychiatric disorders, studies indicate that treating the mental health disorder may help reduce marijuana use, particularly among heavy users and those with more chronic mental disorders.
- Advice to give to patients for management of withdrawal:
  - Gradually reduce amount of marijuana used before cessation.
  - Delay first use of marijuana until later in the day.
  - Consider use of nicotine replacement therapy if planning to stop; separate tobacco use at the same time.
  - Relaxation, distraction
  - Avoid cues and triggers associated with cannabis use.
- Prescribe short-term analgesia and sedation for withdrawal symptoms, if required.
- If irritability and restlessness are marked, consider prescribing very-low-dose diazepam for 3 to 4 days.
- Provide user and family members with information regarding marijuana abuse and withdrawal to increase understanding of the abuse and reduce likelihood of relapse.
- Withdrawal symptoms peak on day 2 or 3, and most are over by day 7. Sleep and vivid dreams can continue for 2 to 3 weeks.

MEDICATION

- No effective medication for the treatment of marijuana abuse
- One study suggested oral THC could be used to abate marijuana withdrawal in individuals who are trying to quit.
- Another study concluded medications used to treat other drug use disorders, such as buspirone, lithium, and fluoxetine, may have therapeutic benefit.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Monitor cessation of marijuana use with urine tests over several weeks for the inactive metabolite of cannabis (carboxy-THC).
- Heavy smokers may continue to be positive for marijuana for up to 6 weeks.

PATIENT EDUCATION

To learn more about marijuana abuse, visit the National Institute on Drug Abuse (NIDA) Web site at http://www.drugabuse.gov. Other NIDA Web sites include the following:

- https://drugpubs.drugabuse.gov/promotions/back-to-school
- http://www.drugabuse.gov/drugs-abuse/marijuana
- https://teens.drugabuse.gov/

COMPLICATIONS

- Acute adverse effects
  - Anxiety and panic, especially in naïve users, depression
  - Psychotic symptoms at high doses
  - Motor vehicle accidents if a person drives while intoxicated
  - Chronic adverse effects: abnormal brain development; diminished lifetime achievement
  - Chronic bronchitis and impaired respiratory function in regular smokers
  - Psychotic symptoms and disorders in heavy users, especially those with a history of psychotic symptoms or a family history of these disorders (schizophrenia)
  - Addiction to marijuana and other substances
  - A recent cohort of 50,373 Swedish men showed an overall increased risk of mortality among heavy adolescent cannabis users versus nonusers. However, this data should be interpreted with caution due to lack of information on confounders.

CODES

ICD10

- F12.10 Cannabis abuse, uncomplicated
- F12.20 Cannabis dependence, uncomplicated
- F12.288 Cannabis dependence with other cannabis-induced disorder

CLINICAL PEARLS

- Marijuana abuse may result in poor performance in school or work, legal problems, and arguments with family.
- Patients with schizophrenia are frequently found to be using marijuana and their use hindering the treatment for schizophrenia. Management of these dual diagnoses is important for the successful treatment of schizophrenia.
- Effects of smoked marijuana can last 1 to 3 hours. Effects from foods or beverages containing marijuana appear later, usually in 30 minutes to 1 hour, but can last up to 4 hours.
- Smoking marijuana delivers significantly more THC into the bloodstream than eating or drinking the drug.
- Acute marijuana intoxication is manifested by conjunctival injection, increased heart rate, euphoria, heightened sensory perception, altered perception of time, increased appetite, poor short-term memory and concentration, and fatigue. Large doses may result in acute psychosis, delusions, or hallucinations.
- Withdrawal symptoms include nausea, weight loss, decreased appetite, insomnia, and depressed mood. Peaks on day 2 or 3, and most are over by day 7.
- Cognitive-behavioral therapy, motivational interviewing, motivational

enhancement therapy, and contingency management are four methods of behavioral-based interventions used in the treatment of marijuana abuse.

- Some recent research finds that adolescents with cannabis use disorder may not be susceptible to THC neuropsychological deficits once they achieve remission from all drugs for at least 30 days.

MASTITIS

Anne Claire Adams, MD • Montiel T. Rosenthal, MD

BASICS

DESCRIPTION

- Mastitis is an inflammation of the breast parenchyma and possibly associated tissues (areola, nipple, subcutaneous [SC] fat).
- Usually associated with bacterial infection (and milk stasis in the postpartum mother)
- Usually an acute condition but can become chronic cystic mastitis

EPIDEMIOLOGY

- Predominantly affects females
- Mostly in the puerperium; epidemic form rare in the age of reduced hospital stays for mothers and newborns
- Neonatal form
- Posttraumatic: ornamental nipple piercing increases risk of transmission of bacteria to deeper breast structures: *Staphylococcus aureus* is the predominant organism.

Incidence

- 3–20% of breastfeeding mothers develop nonepidemic mastitis.
- Greatest incidence among breastfeeding mothers 2 to 6 weeks postpartum
- Neonatal form occurs at 1 to 5 weeks of age, with equal gender risk and unilateral presentation.
- Pediatric form
- Around or after puberty
- 82% of cases in girls

ETIOLOGY AND PATHOPHYSIOLOGY

- Microabscesses along milk ducts and surrounding tissues
- Inflammatory cell infiltration of breast parenchyma and surrounding tissues
- Nonpuerperal (infectious)

  - *S. aureus*, *Bacteroides* sp., *Peptostreptococcus*, *Staphylococcus* (coagulase neg.), *Enterococcus faecalis*
  - *Histoplasma capsulatum*
  - *Salmonella enterica*
  - Rare case of *Actinomyces europaeus*
- Puerperal (infectious)
  - *Staphylococcus aureus*, *Streptococcus pyogenes* (group A or B), *Corynebacterium* sp., *Bacteroides* sp., *Staphylococcus* (coagulase neg.), *Escherichia coli*, *Salmonella* sp.
  - Methicillin-resistant *S. aureus* (MRSA)
- Rare secondary site for tuberculosis in endemic areas (1% of mastitis cases in these areas): single breast nodule with mastalgia
- *Corynebacterium* sp. associated with greater risk for development of chronic cystic mastitis
- Granulomatous mastitis
  - Idiopathic
    - Predilection for Asian and Hispanic women
    - Association with α-1-antitrypsin deficiency, hyperprolactinemia with galactorrhea, oral contraceptive use, *Corynebacterium* sp. infection, and breast trauma
    - Most women have a history of lactation in previous 5 years.
  - Lupus; autoimmune
- Puerperal
  - Retrograde migration of surface bacteria up milk ducts
  - Bacterial migration from nipple fissures to breast lymphatics
  - Secondary monilial infection in the face of recurrent mastitis or diabetes
  - Seeding from mother to neonate in cyclical fashion
- Nonpuerperal
  - Ductal ectasia
  - Breast carcinoma
  - Inflammatory cysts
  - Chronic recurring SC or subareolar infections
  - Parasitic infections: *Echinococcus*; filariasis; Guinea worm in endemic areas

  - Herpes simplex
  - Cat-scratch disease
- Lupus

RISK FACTORS

- Breastfeeding
- Milk stasis
  - Inadequate emptying of breast
    - Scarring of breast due to prior mastitis
    - Scarring due to previous breast surgery (breast reduction, biopsy, or partial mastectomy)
  - Breast engorgement: interruption of breastfeeding
- Nipple trauma increases risk of transmission of bacteria to deeper breast structures: *S. aureus* predominant organism
- Neonatal colonization with epidemic *Staphylococcus*
- Neonatal
  - Bottle-fed babies
  - Manual expression of “witch’s milk”
  - Can predispose to lethal necrotizing fasciitis
- Maternal diabetes
- Maternal HIV
- Maternal vitamin A deficiency (in animal models)

GENERAL PREVENTION

Regular emptying of both breasts and nipple care to prevent fissures when breastfeeding. Also good hygiene including hand washing and washing breast pumps after each use. (1)[A].

COMMONLY ASSOCIATED CONDITIONS

Breast abscess

DIAGNOSIS

- Fever >38.5°C and malaise
- Nausea ± vomiting

- Localized breast tenderness, heat, swelling, and redness
- Possible breast mass

HISTORY

- Breast pain
- “Hot cords burning in chest wall”
- Consider yeast infection if nipple pain and burning and/or infant with thrush

PHYSICAL EXAM

- Breast tenderness
- Localized breast induration, redness, and warmth
- Peau d’orange appearance to overlying skin

DIFFERENTIAL DIAGNOSIS

- Abscess (bacterial, idiopathic granulomatous mastitis, fungal, tuberculosis)
- Tumor
  - Idiopathic granulomatous mastitis
  - Inflammatory breast cancer
  - Wegener granulomatosis
  - Sarcoidosis
  - Foreign body granuloma
  - Vasospasm (may be presentation for Reynaud) (2)[B]
- Ductal cyst (ductal ectasia)
- Consider monilial infection in lactating mother, especially if mastitis is recurrent.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

Mastitis is typically a clinical diagnosis. Labs rarely needed. In those ill enough to need hospitalization, consider the following:

- CBC
- Blood culture
- In epidemic puerperal mastitis
  - Milk leukocyte count
  - Milk culture
  - Neonatal nasal culture

- No imaging required for postpartum mastitis in a breastfeeding mother that responds to antibiotic therapy.
- Mammography for women with nonpuerperal mastitis
- Breast ultrasound to rule out abscess formation in women
  - Special consideration for this in women with breast implants who have mastitis

Follow-Up Tests & Special Considerations

Lactating mothers produce salty milk from affected side (higher Na and Cl concentrations) as compared with unaffected side. Consider breast milk culture if suspect MRSA. Also consider testing for tuberculosis as may be initial presentation.

Diagnostic Procedures/Other

Options if further progression to abscess formation

- Needle aspiration
- Incision and drainage
- Excisional biopsy
- US-guided core needle biopsy is diagnostic method of choice for idiopathic granulomatous mastitis

TREATMENT

A recent Cochrane review found that insufficient evidence exists to confirm or refute the effectiveness of antibiotic therapy for the treatment of lactational mastitis (3)[A]. If present <24 hours and symptoms are mild, conservative management with milk removal and supportive measures is recommended.

MEDICATION

- Prioritized on the basis of likelihood of MRSA as etiologic factor and clinical severity of condition.
- Treat for 10 to 14 days.
- For idiopathic granulomatous mastitis and localized infection, usually resolves with antibiotics and drainage

First Line

- Outpatient
  - Effective milk removal is the most important management step (4)[A].
  - Dicloxacillin 500 mg QID
  - Cephalexin 500 mg QID
  - Trimethoprim/sulfamethoxazole (TMP/SMX); DS BID (if mastitis not improving within 48 hours after starting first-line treatment consider MRSA)
  - *Lactobacillus fermentum* or *Lactobacillus salivarius* 9 log 10 CFU/day
- Inpatient
  - Nafcillin 2 g q4h
  - Oxacillin 2 g q4h
  - Vancomycin 1 g q12h (MRSA possible)
- Breastfeeding beyond 1 month
  - Penicillin, ampicillin, or erythromycin

If idiopathic granulomatous mastitis, consider corticosteroids ± methotrexate (5) [B]

Pediatric Considerations

TMP/SMX given to breastfeeding mothers with mastitis can potentiate jaundice for neonates.

Second Line

- If mastitis is odoriferous and localized under areola, add metronidazole 500 mg TID IV or PO.
- If yeast is suspected in recurrent mastitis, add topical and oral nystatin.

ISSUES FOR REFERRAL

- Abscess formation
- Need for breast biopsy

ADDITIONAL THERAPIES

- Warm packs to improve blood flow and milk let down and/or ice packs to reduce inflammation to affected breast for comfort
- The use of a breast pump may aid in breast emptying, especially if the infant is unable to assist in doing this.
- Wear supporting bra that is not too tight.

SURGERY/OTHER PROCEDURES

In cases of biopsy-proven idiopathic granulomatous mastitis, surgical removal can result in a 5–50% chance of recurrence, fistula formation, and poor wound healing.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- If a new mother is admitted to the hospital for treatment of her mastitis, rooming-in of the infant with the mother is mandatory so that breastfeeding can continue (4)[C]. In some hospitals, rooming-in may require hospital admission of the infant.
- Admission criteria/initial stabilization
  - Failure of outpatient/oral therapy
    - Patient unable to tolerate oral therapy
    - Patient noncompliant with oral therapy
    - Severe illness without adequate supportive care at home
  - Neonatal mastitis
  - Antibiotics
  - Frequent emptying of breasts, if breastfeeding
  - Analgesics for pain
    - Ibuprofen
    - Acetaminophen
- Breastfeeding/pumping of breasts encouraged
- Start infant with feedings on affected side.
- Abscess drainage is not a contraindication for breastfeeding.
- Massage in direction from blocked area toward nipple.
- Positioning infant at breast with chin or nose pointing to blockage will help drain affected area.
- Discharge criteria
  - Afebrile
  - Tolerating oral antibiotics well

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Rest for lactating mothers, up to bathroom

DIET

- Encourage oral fluids.
- Multivitamin, including vitamin A

PATIENT EDUCATION

- Encourage oral fluids.
- Rest is essential
- Regular emptying of both breasts with breastfeeding
- Nipple care to prevent fissures

PROGNOSIS

- Puerperal
  - Good with prompt (within 24 hours of symptom onset) antibiotic treatment and breast emptying; 96% success rate
  - 11% risk of abscess if left untreated with antibiotics
  - Antibodies develop in breast glands within first few days of infection, which may provide protection against infection or reinfection.
- Rare risk of abscess formation beyond 6 weeks postpartum if no recurrent mastitis

COMPLICATIONS

- Breast abscess 3% of women with puerperal mastitis
- Recurrent mastitis with resumption of breastfeeding or with breastfeeding after next pregnancy
- Bacteremia
- Sepsis

CODES

ICD10

- N61 Inflammatory disorders of breast
- O91.22 Nonpurulent mastitis associated with the puerperium
- O91.23 Nonpurulent mastitis associated with lactation

CLINICAL PEARLS

- Complete emptying of the breasts on a regular schedule, avoiding constrictive clothing or bras that might obstruct breast ducts, meticulous attention to nipple care, “adequate rest,” and a liberal intake of oral fluids for the mother can all reduce the risk of a breastfeeding mother’s developing mastitis.
- First-line treatment for puerperal mastitis is dicloxacillin 500 mg PO QID for 10 to 14 days. Most mastitis can be treated with oral therapy.
- Among breastfeeding mothers, if the symptoms of mastitis fail to resolve within several days of appropriate management, including antibiotics, further investigations may be required to confirm resistant bacteria, abscess

formation, an underlying mass, or inflammatory or ductal carcinoma.

- More than two recurrences of mastitis in the same location or with associated axillary lymphadenopathy warrant evaluation with ultrasound or mammography to rule out an underlying mass.

MASTOIDITIS

Adam Anglyn, DO • Robert M. Hasty, DO, FACOI, FACP

BASICS

An inflammatory process of the mastoid air cells or posterior process of the temporal bone, most commonly a suppurative complication of acute otitis media (AOM)

DESCRIPTION

- Acute mastoiditis typically presents following AOM or may be the first sign of AOM. Symptoms are present for <1 month.
- Subdivided into two stages
  - Acute mastoiditis with periostitis: involves the mastoid periosteum with purulence in the mastoid air cells
  - Acute mastoid osteitis (coalescent mastoiditis): destruction of bony septae separating air cells; leading to empyema and more serious head/neck complications
- Subacute mastoiditis (masked mastoiditis): indolent process, may occur with insufficiently treated AOM
- Chronic mastoiditis: due to failed treatment of chronic otitis media. Usually associated with cholesteatoma; symptoms last months to years.

EPIDEMIOLOGY

- Children > adults
- Most common in children <2 years of age
- In children: males > females
  - Incidence is reduced after introduction of antibiotics but may again be increasing with rise of antibiotic-resistant *Streptococcus pneumoniae*. Introduction of PVC 13 vaccine may mitigate this rise (1)[C].

Incidence

1 to 4 cases/100,000 persons/year (2)

ETIOLOGY AND PATHOPHYSIOLOGY

- Subclinical stage begins with AOM causing inflammation of mastoid air cells (likely present in all cases of AOM)
- Obstruction of the aditus ad antrum (connecting the tympanic cavity and mastoid)
  - Blocks outflow tract of mastoid air cells
  - Edema and accumulation of purulent material with penetration of periosteum (acute mastoiditis with periostitis)
- Increased pressure from fluid within the air cells leads to destruction of bony septae (acute mastoid osteitis/acute coalescent mastoiditis).
- Acute mastoid osteitis can spread to adjacent areas in head and neck with abscess formation:
  - Subperiosteal abscess (most common complication), Bezold abscess, suppurative labyrinthitis, suppurative CNS complications
- AOM: *Haemophilus influenzae*, *S. pneumoniae*
- Acute mastoiditis: *Streptococcus pneumoniae* (most common), *Streptococcus pyogenes*, *H. influenzae*, *Staphylococcus aureus* (including methicillin-resistant *Staphylococcus aureus* [MRSA])
- Chronic mastoiditis: *Pseudomonas aeruginosa*, *S. aureus,* Enterobacteriaceae, anaerobic bacteria, polymicrobials (3)

Genetics

No known genetic pattern

RISK FACTORS

- Cholesteatoma
- Recurrent AOM or chronic suppurative otitis media
- Immunocompromised state

GENERAL PREVENTION

- Pneumococcal conjugate vaccine
- Early referral to ENT for chronic otitis media
- Appropriate diagnosis and treatment of AOM
- Prevention of recurrent AOM
- Treat chronic eustachian tube dysfunction (pressure equalization tubes).
- Identify cholesteatoma early.

DIAGNOSIS

HISTORY

- Most common symptoms in infancy (2)[A]
  - Lethargy/malaise/irritability
  - Fever
  - Poor feeding/decreased appetite
- Otalgia/possible otorrhea
- Hearing loss
- Headache
- Pain/redness/swelling noted over mastoid.
- At the time of admission (2)[A]
  - 42% of children have history of otologic disease.
  - 54% on antibiotic therapy
  - Average duration of symptoms: 10 days
- Suspicion for mastoiditis increases when symptoms of AOM persist >2 weeks.

PHYSICAL EXAM

- Postauricular changes: erythema, tenderness, edema, and/or fluctuance (81–85%) (2)[A]
- Bulging, erythematous, or dull tympanic membrane (60–71%)
- Protrusion of auricle (79%)
- Fever (76%)
- Otorrhea if tympanic membrane is perforated
- Edema of external auditory canal
- Tympanic membrane (TM) can be normal in 10% of patients.

DIFFERENTIAL DIAGNOSIS

- Postauricular cellulitis or inflammatory adenopathy
- Severe otitis externa
- Benign neoplasm: aneurysmal bone cyst, fibrous dysplasia
- Malignant neoplasm: rhabdomyosarcoma, neuroblastoma
- Deep neck space infections
- Parotitis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- CBC with differential: increased WBC count (4)[C]
- Elevated erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) (3,4)
- Blood cultures
- Myringotomy/tympanocentesis: Send for cultures, Gram stain, acid-fast stain (2)[B].
- Mastoiditis is often a clinical diagnosis. CT confirms diagnosis and identifies regional complications.
- If obvious physical exam and/or historical findings are absent, temporal bone imaging is recommended for patients with cervical or postauricular findings (5).
- Plain radiographs of mastoid have low diagnostic yield but may show distortion of mastoid outline or clouding of mastoid air cells. These changes are not diagnostic and can also be seen in AOM.
- CT findings (97% sensitivity; 94% positive predictive value) (6)
  - Clouding/opacification of air cells (also in AOM)
  - Mastoid air cell coalescence
  - Cortical bone erosion
  - Rim-enhancing fluid collections
- CT of temporal bone with contrast helps identify suppurative extension (5)[C].
- Technetium-99m bone scan is more sensitive to osteolytic changes than CT.
- Indications for CT scan in children (6)[C]
  - Neurologic signs
  - Vomiting/lethargy
  - Suspected cholesteatoma
  - Fever after 48 to 72 hours of therapy
  - Concern for local disease progression
- MRI use increasing; may see increased fluid signal of mastoid air cells on T2-weighted MRI—an incidental finding in the absence of clinical signs

Follow-Up Tests & Special Considerations

Interpret normal WBC with caution in symptomatic immunocompromised

patients.

Diagnostic Procedures/Other

- Tympanocentesis to obtain middle ear fluid for culture and sensitivity (2)[B]
- Myringotomy with culture (also therapeutic)
- Audiography if suspected hearing loss
- Obtain CSF if intracranial extension suspected.
- Biopsy tissue protruding through TM or tympanostomy tube

TREATMENT

- IV antibiotics and myringotomy (± tympanostomy tubes) is the preferred treatment for uncomplicated acute mastoiditis (reflecting a shift away from more invasive surgical treatment).
- Simple mastoidectomy is recommended for patients not responding to treatment after 3 to 5 days to avoid intracranial complications (7)[C].

GENERAL MEASURES

- Inpatient care during acute phase for IV antibiotics
- Keep the affected ear dry.

MEDICATION

First Line

- Empiric antibiotics against most common organisms: *Streptococcus pneumoniae* (including multiple resistant strains), *Streptococcus pyogenes*, *Staphylococcus aureus* (including MRSA), *P. aeruginosa*
- Use combination therapy with 3rd generation cephalosporin (ceftriaxone or cefotaxime) plus clindamycin with additional coverage for resistant strains (5,7)[C].
- Ceftriaxone 1 to 2 g IV q24h
  - Pediatric dosing: 50 to 75 mg/kg/day IV divided q12–24h
  - Precaution: Adjust dose with renal impairment.
- Clindamycin for coverage of ceftriaxone-resistant *S. pneumoniae* in pediatric patients (5)[C]:
  - Clindamycin pediatric dosing: 20 to 40 mg/kg/day IV divided q6–8h

- Cefotaxime 1 to 2 g IV q4–8h, depending on severity
  - Pediatric dosing: 100 to 200 mg/kg/day divided q6–8h
- Add vancomycin 30 to 60 mg/kg/day divided q8–12h if concerned for MRSA:
  - Pediatric dosing: 15 mg/kg/dose q6–8h
  - Precaution: Adjust dose with renal impairment.
- For patients with a history of recurrent AOM or recent antibiotic administration, treat with piperacillin–tazobactam 3.375 g IV q6h:
  - Pediatric dosing: 300 mg/kg/day based on piperacillin component divided q6–8h
- For other significant contraindications, precautions, or interactions, please refer to the manufacturer's literature.

Second Line

- Oral antibiotics are given after 7 to 10 days of IV antibiotics and once myringotomy/blood cultures identify pathogen and sensitivities. Common oral antibiotics include:
  - Amoxicillin–clavulanate (Augmentin) or clindamycin + 3rd-generation cephalosporin for 3 weeks or total treatment duration of 4 weeks
- For chronic mastoiditis: Use topical drops, ofloxacin otic solution (0.3%) or neomycin, polymyxin B, hydrocortisone three drops, 3 to 4 times per day.

ISSUES FOR REFERRAL

Consult ENT for mastoiditis in adults and children.

SURGERY/OTHER PROCEDURES

- Perform tympanocentesis to obtain cultures and guide antibiotic choice (2)[B].
- Myringotomy and tympanostomy tubes allow drainage of middle ear (7)[C].
- Mastoidectomy is a definitive treatment for patients who fail to improve within 24 to 48 hours despite IV antibiotics and myringotomy and for those with meningeal or intracranial complications (6,7)[C].
- Simple mastoidectomy is most effective for management of subperiosteal abscesses, if a trial of conservative therapy with drainage, myringotomy, and IV antibiotics fails (8)[C].
- Clean ear canal under microscope to ensure pressure-equalization tube patency and adequate drainage of middle ear.

- Topical antibiotic drops usually used after insertion of pressure-equalization tubes.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Admission criteria/initial stabilization
  - Clinical or imaging evidence of acute mastoiditis
  - Hospitalize patients with acute mastoiditis and start IV antibiotics immediately.
- Avoid getting affected ear wet.
- Discharge criteria
  - Afebrile for 48 hours before IV antibiotics are discontinued
  - Clinical improvement
  - Able to take oral antibiotics

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Oral antibiotics for 3 weeks following course of IV antibiotics (total duration of antibiotics is 4 weeks)
- For chronic mastoiditis, consider several months of antimicrobial prophylaxis with amoxicillin.

Patient Monitoring

- Assess for hearing loss postoperatively (audiogram) after acute condition has subsided.
- Follow-up with ENT, particularly patients with intracranial complications or hearing loss

PATIENT EDUCATION

Avoid getting the affected ear wet.

PROGNOSIS

- Depends on severity and stage of disease
- Conductive hearing loss may require reconstructive surgery.

- Most cases of mastoiditis recover fully if the diagnosis is made early and treated appropriately.

COMPLICATIONS

Total estimated complication rate is 18% (3).

- Extracranial
  - Subperiosteal abscess (most common)
  - Bezold abscess (abscess of sternocleidomastoid muscle, insidious, risk of mediastinitis)
  - Citelli abscess (osteomyelitis of the calvaria)
  - Osteomyelitis of the temporal bone
  - Suppurative labyrinthitis (resulting in deafness)
  - Facial nerve paralysis
- Intracranial
  - Intracranial abscess: epidural/subdural/cerebral
  - Meningitis/cerebritis/periostitis
  - Gradenigo syndrome (palsy of the 6th cranial nerve, draining ear, and retro-orbital pain)
  - Sigmoid sinus thrombophlebitis
  - Central venous sinus thrombosis

CODES

ICD10

- H70.90 Unspecified mastoiditis, unspecified ear
- H70.009 Acute mastoiditis without complications, unspecified ear
- H70.099 Acute mastoiditis with other complications, unspecified ear

CLINICAL PEARLS

- Suspect mastoiditis when symptoms of AOM persist >2 weeks despite a normal-appearing TM.
- Hospitalize all patients with acute mastoiditis for IV antibiotics. Consult ENT for drainage procedure.
- Treat with broad-spectrum IV antibiotics; collect middle ear fluid cultures to guide-specific therapy.
- If conservative treatment fails after 3 to 5 days, perform mastoidectomy to

avoid intracranial complications.

MEASLES, GERMAN (RUBELLA)

Cody D. Mead, DO • Jeffrey M. Milch, DO, CPT, MC, FS, USA

BASICS

DESCRIPTION

- A generally self-limited viral infection of children and adults, characterized by a mild, maculopapular rash, lymphadenopathy, and slight fever. Complications in normal populations are rare; however, nonimmune women who become infected with rubella while pregnant may have devastating fetal effects.
- 25–50% of all rubella infections are asymptomatic (1,2)[A].
- System(s) affected: hematologic; nervous; pulmonary; exocrine; ophthalmologic; skeletal
- Synonym(s): German measles; 3-day measles

Pregnancy Considerations

- Pregnancy-associated rubella infection may lead to congenital rubella syndrome (CRS) with potentially devastating fetal outcomes.
- CRS is present in up to 90% of fetuses exposed during the 1st trimester (2)[A].
- Screening pregnant women for rubella immunity and vaccinating nonimmune women is the most effective means to prevent CRS (2)[A].
- Although no case of vaccine-associated CRS has been reported, women should not become pregnant for at least 28 days after vaccination because vaccine-type virus can cross the placenta (2)[A].
- Polymerase chain reaction (PCR) detection of viral RNA in amniotic fluid and fetal blood sampling allow for rapid diagnosis of fetal infection after 15 weeks' gestation (3)[B].

EPIDEMIOLOGY

- 50- to 70-nm RNA togavirus of genus *Rubivirus* (1)[A]
- 13 genotypes have been identified (4)[A].
- A live attenuated vaccine has been available in United States since 1969—

primarily to prevent CRS.

- Since 2004, all cases of rubella in United States have been imported, typically in travelers with inadequate immunity (1)[A].
- Average incubation: 14 days; range 12 to 23 days
- Infectious period between 7 days before and 5 to 7 days after rash onset
- Transmitted primarily via respiratory droplets
- Most common in late winter and early spring
- Humans are only natural hosts (1)[A].

Incidence

- U.S. incidence: <10/100,000 since 2001
- Declared eliminated (the absence of endemic transmission for 12 months or more) from the United States in 2004. However, primarily due to disease in international travelers, <10 cases are still reported in the United States annually (1)[A].
- Still occurs in developing countries with 100,000 cases of CRS reported annually worldwide

ETIOLOGY AND PATHOPHYSIOLOGY

- Virus invades the respiratory epithelium, replicates in nasopharynx and regional lymph nodes, and spreads hematogenously. Infected patients shed virus from the nasopharynx 3 to 8 days after inoculation. Shedding lasts 7 or more days after onset of rash.
- Disease typically progresses from a prodromal stage (1 to 5 days) to lymphadenopathy (5 to 10 days) to an exanthematous, pruritic, maculopapular rash. Petechiae on the soft palate (*Forchheimer spots*), may precede or accompany the rash. Rash starts on the face and spreads outward to the trunk and extremities, sparing the palms and soles (14 to 17 days after onset of prodromal symptoms). The rash typically lasts an average of 3 days.
- Rubella first described by German scientists in the early 1800s as a variant of measles or scarlet fever
- 1962 to 1965: global pandemic resulting in an estimated 12.5 million cases in the United States, with 2,000 cases of encephalitis; 11,250 cases of therapeutic or spontaneous abortions; 2,100 neonatal deaths; and 20,000 infants born with CRS (1)[A]

Genetics

Children with CRS and children with type 1 diabetes share a high frequency of HLA-DR3 histocompatibility Ag and a high prevalence of islet cell Ab.

RISK FACTORS

Inadequate immunization, inadequate immunity after prior vaccination, immunodeficiency states, immunosuppressive therapy, crowded living/working conditions, international travel (1)[A]

GENERAL PREVENTION

- Vaccination is the most effective preventive strategy.
- Available combined with measles and mumps (MMR) or with varicella (MMR-V). Isolated rubella vaccine is not available in the United States.
  - Adults: 1- or 2-dose MMR vaccine schedule is recommended for those born after 1957. When 2 doses are used, each must be ≥28 days apart.
  - Pediatric: A 2-dose MMR vaccine schedule is recommended with the 1st dose given at ages 12 to 15 months; 2nd dose recommended either at 4 to 6 years or at 11 to 12 years of age.
  - Special pediatric cases: In special circumstances (e.g., upcoming international travel), the second dose may be given prior to 4 years of age, but no sooner than 28 days since the initial dose. Children 6 to 11 months of age may also receive a single dose prior to international travel but should be revaccinated with full 2-dose schedule starting at 12 months of age. Children with HIV should receive MMR vaccine at 12 months of age if no contraindications exist. In the event of an outbreak, immediate vaccination of infants 6 to 11 months old is also recommended (2)[A].
  - Vaccination is recommended for nonimmune people in the following groups: prepubertal boys and girls, all women of reproductive age, college students, daycare personnel, health care workers, and military personnel.
- Contraindicated: pregnancy, immunodeficiency (except HIV infection), within 3 months of IVIG or blood administration, severe febrile illness, or hypersensitivity to vaccine components. Patients who receive rubella vaccine do not transmit rubella to others, although the virus can be isolated from the pharynx. Breastfeeding is not a contraindication to vaccination (1)[A].
- During outbreaks, serologic screening before vaccination is *NOT*

recommended because rapid mass vaccination is necessary to stop disease spread (2)[A].

- The MMR vaccine *is not associated with autism* (4)[A],(5)[B].
- Children who receive the MMR-V vaccine have a 2-fold increase in risk of febrile seizures compared with those who receive MMR and varicella vaccines separately (5)[B].
- Routine rubella antibody (IgG) screening is recommended during pregnancy (4)[A].

DIAGNOSIS

Council of State and Territorial Epidemiologists (CSTE) Case Definition Classifications of Rubella (1)[A]

- Clinical case definition
  - Acute onset of pink, coalescent macules on the face spreading to the trunk and extremities, becoming discrete macules then fading in previously affected areas, on average, within 3 days
  - Temperature >99°F (37.2°C; if measured)
  - Arthralgia or arthritis, lymphadenopathy, or conjunctivitis
- Laboratory criteria for diagnosis
  - Isolation of virus from throat or nasopharynx, serum, CSF, urine, or cataracts (postmortem)
  - 4-fold rise in acute- and convalescent-phase titers of serum IgG Ab
  - Positive serologic test for IgM Ab
  - PCR positive for virus

HISTORY

- Most cases of postnatal rubella are due to inadequately immunized travelers returning from endemic areas.
- Rubella can spread quickly among persons residing in close quarters.
- Postnatal rubella: low-grade fever, lymphadenopathy (postcervical, occipital, and postauricular), sore throat, nausea, anorexia, arthritis, arthralgia, malaise. 25–50% are asymptomatic.
- CRS: parental concerns about hearing or vision impairment, jaundice, or

developmental delay

- Deafness could be the only manifestation and not be noticed until 2nd year of life (2)[A].

PHYSICAL EXAM

- Postnatal rubella: low-grade fever, lymphadenopathy (posterior auricular, occipital, posterior cervical), exanthem (mild, pink, discrete 1- to 4-mm maculopapular rash), soft palate petechiae (Forchheimer sign) (20%) (1)[A]
- CRS: microcephaly, large anterior fontanelle, sensorineural hearing loss (58%), cataracts, glaucoma, microphthalmia, pigmentary retinopathy, purpuric ("blueberry muffin") skin lesions, murmur (50%) consistent with patent ductus arteriosus (PDA), hepatosplenomegaly, jaundice, cryptorchidism, inguinal hernia, radiolucent bone disease (2)[A]

DIFFERENTIAL DIAGNOSIS

- Postnatal rubella
  - Measles virus (rubeola)
  - Scarlet fever (strep A)
  - Infectious mononucleosis
  - Erythema infectiosum (parvovirus B19)
  - Roseola infantum (i.e., exanthem subitum)
  - Toxoplasmosis
  - Drug eruptions
  - Other exanthematous enteroviral infections
- Congenital rubella
  - Measles
  - Parvovirus B19
  - Human herpesvirus 6
  - Other exanthematous entero- or arboviruses

DIAGNOSTIC TESTS & INTERPRETATION

- Because 50% of cases are subclinical, laboratory testing is preferred to confirm the diagnosis (1,2)[A].
- Detection of wild-type virus is gold standard (1)[A].
- Enzyme immunoassay (EIA): preferred testing for IgM antibodies, which may

not be detectable before 5 days after the onset of rash (1)[A]

- Hemagglutination inhibition (HAI) test: A 4-fold increase of IgG Ab levels from acute to convalescent phase is diagnostic for recent infection (1)[A].
- Latex agglutination (LA) test: sensitive and specific but dependent on experience of lab personnel (1)[A]
- Immunofluorescent antibody (IFA) assay: used for detection of viral IgG and IgM Ab (1)[A]
- Avidity test: not routinely used. Should only be performed in reference labs. Used to distinguish between recent and past infections (1)[A]
- Most rubella cases are virus positive on the day of the rash onset and remain positive for the following 7 to 10 days. Serum collection should be performed during this period. When testing for IgM, repeat collection may be necessary if the sample was taken before day 5. When testing for seroconversion, a 2nd IgG sample should be collected 2 to 3 weeks after the first (acute to convalescent phase). In most cases, IgG is detectable 8 days after rash onset (1)[A].
- Virus may also be isolated from 1 week prior to 2 weeks after the onset of rash. Maximal viral shedding occurs up to day 4 after rash onset. Best results are from throat swab samples (1)[A].
- Epidemiologically, viral genotyping by reverse transcription (RT)-PCR helps determine the country of origin. Throat swabs should be collected 4 days after the rash onset and sent to the CDC (1)[A].
- Viral cultures of CSF are reserved for suspected cases of CRS or rubella encephalitis (1)[A].
- If a pregnant female is exposed, amniotic fluid PCR or fetal blood sampling may be done at 15 weeks' gestation for viral detection. Placental biopsy (less common) may be done at 12 weeks' gestation. If positive, offer genetic counseling (1)[A].
- As the incidence of rubella decreases, the positive predictive value (PPV) of IgM results decreases. False-positive findings occur in patients with parvovirus B19, mononucleosis, and positive rheumatoid factor (1)[A].
- After reexposure, a person with a low level of Ab from past infection or prior vaccination may experience an acute, small rise in Ab levels. This is not associated with a high risk of contagion to others or fetal complications (1)

[A].

Initial Tests (lab, imaging)

Follow-Up Tests & Special Considerations

- Reporting: state-dependent. Samples should be sent to the CDC for genotyping. Cases of CRS are reported to the National Congenital Rubella Syndrome Registry (1,2)[A].
- Infants with CRS may shed virus up to 1 year. Observe contact isolation during all hospitalizations until child turns 1 year old (unless child has two negative throat cultures and urine specimens a month apart after 3 months of age) (2)[A].

TREATMENT

- Supportive for mild cases
- Isolate patients for 5 to 7 days after rash onset.
- Postnatal rubella: mild and self-limited; treat symptomatically. Hospitalize for complications: idiopathic thrombocytopenic purpura (ITP) or encephalitis (1) [A].
- CRS: supportive care unless neurologic or hemorrhagic complications develop; phototherapy may be indicated for jaundice; multidisciplinary management of long-term complications (2)[A]

MEDICATION

No specific therapy available for mild cases.

First Line

- Age- and dose-appropriate antipyretics
- NSAIDs can be used for arthritis and arthralgias in adults and infants age >6 months.
- IVIG can be given for severe thrombocytopenia; most cases, however, are self-limited.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Individuals immune to rubella through natural infection or vaccine may be reinfected when reexposed; such infection is usually asymptomatic and detectable only by serology. Those who have received the vaccine have lower measurable IgG levels than those who had the natural disease.
- In CRS, it is important to detect auditory and visual impairment early (2)[A].
- 2/3 of internationally adopted children have no written record of immunizations (4)[A].

PATIENT EDUCATION

http://www.cdc.gov/rubella/

PROGNOSIS

- Postnatal rubella: Complete recovery is typical.
- CRS
  - Varied and unpredictable spectrum, ranging from stillbirth to normal infancy/childhood (1,2)[A]
  - Detectable levels of IgG persist for years and then may decline (does not drop at the expected 2-fold dilution/month). By age 5 years, 20% have no detectable antibody (2)[A].
  - IgM may not be detectable until 1 month after birth and may persist for 6 to 12 months (2)[A].
  - Overall mortality (up to 10%) is greatest during first 6 months.
  - 70% of encephalitis cases develop residual neurologic defects, including autistic syndrome.
  - Prognosis is excellent if only minor congenital defects are present.

COMPLICATIONS

- Frequently leads to arthralgia/arthritis in women (up to 70%) (6)
- Postinfectious encephalitis (1/5,000 cases)
- Thrombocytopenic purpura (1/3,000 cases)
- CRS: incidence dependent on trimester exposed
- Rubella vaccine may rarely cause encephalitis or ITP.
  - ITP is self-limited and is not a contraindication to vaccination.

CODES

ICD10

- B06.9 Rubella without complication
- B06.00 Rubella with neurological complication, unspecified
- P35.0 Congenital rubella syndrome

CLINICAL PEARLS

- Rubella is typically a self-limited viral exanthematous infection of children and adults.
- Nonimmune women who are infected with rubella while pregnant may have devastating fetal effects (CRS).
- Immunization is the key prevention strategy.

MEASLES (RUBEOLA)

Herbert L. Muncie, Jr., MD • Nicholas E. Seeliger, MD

BASICS

DESCRIPTION

- A highly communicable, acute viral illness characterized by an exanthematous maculopapular rash that begins at the head and spreads inferiorly to the trunk and extremities
- Rash is preceded by fever and the classic triad of cough, coryza, and conjunctivitis (3 Cs). Koplik spots are pathognomonic lesions of the oral mucosa.
- Public health problem in the developing world, with significant morbidity and mortality
- System(s) affected: hematologic; lymphatic; immunologic; pulmonary; skin
- Synonym: rubeola

EPIDEMIOLOGY

- Transmission: direct contact with infectious droplets; highly contagious; 90% of nonimmune close contacts likely to become infected on exposure
  - Droplets can remain in the air for hours.
- Infectivity is greatest during the prodromal phase.
  - Patients are considered contagious from 4 days before symptoms until 4 days after rash appears.
  - Immunocompromised patients are considered contagious for the entire duration of disease.
- Incubation period: averages 12.5 days from exposure to onset of prodromal symptoms
- Predominant age: varies based on local vaccine practices and disease incidence. In developing countries, most cases occur in children <2 years.

Incidence

- United States: no longer considered an endemic disease by the CDC; isolated outbreaks still occur.

  - In the first half of 2016, 48 people from 13 states were reported to have measles. Many cases were in vaccine-eligible patients who declined due to philosophic or religious beliefs.
  - Children aged 6 to 23 months traveling abroad are at increased risk if unvaccinated.
- Worldwide: An estimated 20 million measles cases occur each year, with 122,000 measles deaths in 2012. Over 95% of measles deaths occur in poor countries with limited health infrastructure (1).

ETIOLOGY AND PATHOPHYSIOLOGY

Measles virus enters through the respiratory mucosa and replicates locally. It spreads to regional lymphatic tissues and other reticuloendothelial sites via the bloodstream.

- Measles virus is a spherical, enveloped, nonsegmented, single-stranded, negative-sense RNA virus of genus *Morbillivirus*, family *Paramyxoviridae*.
- Humans are the only natural host.

RISK FACTORS

- For developing measles:
  - Lack of adequate vaccination (two doses)
  - Travel to countries where measles is endemic
  - Contact with exposed individuals, travelers, or immigrants
- For severe measles or measles complications:
  - Immunodeficiency
  - Malnutrition
  - Pregnancy
  - Vitamin A deficiency
  - Age <5 years or >20 years

GENERAL PREVENTION

- 100% preventable with proper vaccination
- Measles vaccine (active immunization)
  - Vaccine is usually given in combination with mumps and rubella (MMR) or with added varicella (MMR-V; ProQuad)
  - Primary vaccination requires two doses:

- First dose given at 12 to 15 months of age; 95% develop immunity.
- Second dose given at time of school entry (4 to 6 years of age) or any time >4 weeks after first measles vaccine; the 5% of initial nonresponders almost always develop immunity after the second dose.
- Health care workers should have immunity verified and, if not immune, receive the vaccine (if not otherwise contraindicated).

– Common adverse vaccine reactions
- Fever
- Febrile seizures are rare (<5%) and occur 6 to 12 days after vaccination. Risk of febrile seizures increases if initial immunization is delayed past age 15 months (2)[B].
- Transient, mild, measles-like rash 7 to 10 days after vaccination (2%, with decreasing incidence after second vaccination)
- If hypersensitivity reaction occurs, test for immunity; if immune, second dose is not needed.
- There is no substantiated link between MMR vaccine and autism (3)[A].

– Contraindications
- Live viral vaccines are contraindicated in immunosuppressed patients. For MMR, however, asymptomatic HIV-infected children with adequate CD4 count should be vaccinated.
- Pregnancy (theoretical risk of fetal infection)
- Anaphylactic reaction to gelatin or neomycin; consult allergist before vaccination.
- Egg anaphylaxis is not considered a contraindication.

COMMONLY ASSOCIATED CONDITIONS

- Immunosuppression
- Malnutrition

DIAGNOSIS

HISTORY

- Prodromal period: usually 2 to 3 days before rash (may be up to 8 days)
  – Fever

    - May begin 8 to 12 days after exposure; can persist until 2 to 3 days after rash onset
    - Temperature often >102°F (39–40.5°C); can precipitate febrile seizures
    - Fever onset >3 days after rash suggests complicated course.
  - "3 Cs" triad: cough, coryza, and conjunctivitis
  - Cough may persist for 2 weeks.
  - Prodromal symptoms typically intensify over 2 to 4 days, peaking on first day of rash before subsiding.
- Other symptoms include loose stools, malaise, irritability, photophobia (from iridocyclitis), sore throat, headache, and abdominal pain.

PHYSICAL EXAM

- Koplik spots
  - Pathognomonic of prodromal measles
  - 2- to 3-mm, gray–white, raised lesions on erythematous base on buccal mucosa
  - Occur ~48 hours before measles exanthem
- Exanthematous rash (characteristic but not pathognomonic)
  - Maculopapular blanching rash
  - Begins at ears and hairline and spreads head to toe, reaching hips by day 2
  - Discrete erythematous patches become confluent over time, particularly on the upper body.
  - Clinical improvement usually occurs within 48 hours after rash appears.
  - Rash fades in 3 to 4 days changing to a brownish color, followed by fine desquamation.
- Lymphadenopathy and pharyngitis may be seen during exanthematous period.

DIFFERENTIAL DIAGNOSIS

- Drug eruption
- Rubella
- *Mycoplasma pneumoniae* infection
- Infectious mononucleosis
- Parvovirus B19 infection, roseola
- Enteroviruses
- Rocky Mountain spotted fever, dengue

- Toxic shock syndrome
- Meningococcemia
- Kawasaki disease

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Obtain serum sample and throat (or nasopharyngeal) swab. Molecular testing of serum and respiratory specimens is the most accurate method to confirm measles infection. IgM assay and measles RNA by real-time polymerase chain reaction (RT-PCR)
- Measles virus–specific IgM assay from serum and saliva. Antibodies may be undetectable on first day of exanthem but are usually detectable by day 3.
  - Sensitivity: 77% within 72 hours of rash onset; 100% within 4 to 11 days after rash onset. If negative but rash lasts >72 hours, repeat.
  - IgM falls to undetectable levels 4 to 8 weeks after rash onset.
- Measles virus–specific IgG may be undetectable up to 7 days after exanthem; levels peak 14 days after exanthem.
  - A 4-fold increase in IgG titers 14 days after an initial titer that was measured at least 7 days after rash onset is confirmatory.
- Viral cultures for measles are not usually performed.
- Mild neutropenia is common.
- Liver transaminases and pancreatic amylase may be elevated, particularly in adults.
- Chest x-ray if concern for secondary pneumonia

ALERT

Report suspected measles cases to public health authorities.

TREATMENT

GENERAL MEASURES

- Place all patients with measles in respiratory isolation until 4 days after onset of rash; immunocompromised patients should be isolated for duration of illness.

- Supportive therapy (i.e., antipyretics, antitussives, humidification, increased oral fluid consumption)

MEDICATION

- No approved antiviral therapy is available.
- Ribavirin
  - Measles virus is susceptible to ribavirin in vitro; data is limited.
  - Immunosuppressed children with severe measles have been treated with IV or aerosolized ribavirin.This use is not FDA approved.
  - In one trial of 100 children with measles treated with ribavirin or supportive care, ribavirin group had a shorter duration of fever, constitutional symptoms, and length of hospitalization.
- Vitamin A: WHO recommends two consecutive days of dosages if living in vitamin A deficient region:
  - Children <6 months of age 50,000 IU
  - Children 6 to 12 months of age 100,000 IU
  - Children >12 months of age 200,000 IU
- Antibiotics
  - Reserved for patients with clinical signs of bacterial superinfection (pneumonia, purulent otitis, pharyngitis/tonsillitis) (4)[B]
  - A small randomized, double-blinded trial resulted in an 80% (number needed to treat [NNT] = 7) decrease in measles-associated pneumonia with prophylactic antibiotics; consider in patients with a high risk of complications.
- Outbreak control
  - A single measles case constitutes an outbreak.
  - Immunize contacts (individuals exposed or at risk of having been exposed) within 72 hours.
    - Monovalent vaccine may be given to infants 6 months to 1 year of age, but two further doses of vaccine after 12 months must be given for immunization to be considered adequate.
    - Monovalent or combination vaccine may be given to all measles-exposed susceptible individuals age >1 year if not contraindicated.
    - Individuals not immunized within 72 hours of exposure should be

excluded from school, child care, and health care settings (social quarantine) until 2 weeks after onset of rash in the last reported case of measles.

- Immunoglobulin therapy (passive immunity) may be necessary for the following high-risk individuals exposed to measles and for whom vaccination is inappropriate:
  - Children age <1 year (infants 6 to 12 months of age may receive MMR vaccine in place of IG if given within 72 hours of exposure)
  - Pregnant women
  - Individuals with severe immunosuppression
  - IM immunoglobulin should be given within 6 days of measles exposure; CDC recommends 0.25 mL/kg to maximum of 15 mL for infants and pregnant women; immunocompromised individuals receive 0.5 mL/kg to a maximum of 15 mL.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Outpatient care is appropriate, except where complications develop (e.g., encephalitis, pneumonia).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Signs of complications needing close follow-up include:

- Difficulty breathing or noisy breathing
- Changes in vision
- Changes in behavior, confusion
- Chest or abdominal pain

PATIENT EDUCATION

- Adhere to recommended immunization schedules.
- Avoid exposure, particularly to unimmunized children and adults, pregnant women, and immunocompromised persons, until 4 days after rash onset.
- Avoid contact with potential sources of secondary bacterial pathogens until

respiratory symptoms resolve.

- Centers for Disease Control and Prevention. Measles. https://www.cdc.gov/measles/

PROGNOSIS

- Typically self-limited; prognosis good
- High fatality rates may be seen among malnourished or immunocompromised children, particularly in developing countries.

COMPLICATIONS

- Otitis media (5–15%)
- The immune response to measles infection paradoxically depresses response to non–measles-virus antigens, which renders individuals more susceptible to pneumonia and diarrhea.
- Respiratory complications:
  - Bronchopneumonia (5–10%)
    - Accounts for most measles-related deaths
    - May be viral or bacterial
  - Interstitial pneumonitis (immunocompromised patients)
  - Laryngotracheobronchitis (“measles croup”): occurs in younger age group (<2 years)
- GI complications: diarrhea (may lead to dehydration)
- Neurologic complications
  - Febrile seizures
  - Acute disseminated encephalomyelitis with seizures and neurologic abnormalities (occurs in 1/1,000 cases): presents within 2 weeks of rash, probably an autoimmune response
  - Inclusion body encephalitis is rare but fatal in those with defective cellular immunity.
  - Subacute sclerosing panencephalitis
    - Rare degenerative CNS disease resulting from persistent measles infection following natural disease; usually fatal
    - Presents 5 to 15 years after infection
    - Most often in persons infected before age 2 years
- Ocular complications

  - Keratitis
    - Can lead to permanent scarring, blindness
    - Vitamin A deficiency predisposes to more severe keratitis and its complications.
- Other secondary bacterial infections
- Death: results from complications, mainly pneumonia, rather than the virus itself. CDC statistics show that for every 1,000 children who get measles, 1 or 2 will die.

CODES

ICD10

- B05.9 Measles without complication
- B05.2 Measles complicated by pneumonia
- B05.89 Other measles complications

CLINICAL PEARLS

- There is no substantiated link between MMR vaccine and autism.
- Measles is a highly communicable viral disease whose natural transmission has largely been halted in the United States by mass immunization.
- A single case of measles constitutes an outbreak.
- Suspected measles cases must be reported to state or local health departments to contain outbreak.
- Immunization requires two doses: one at 12 to 15 months of age and one at school age (4 to 6 years of age).
- Presentation includes a prodrome of fever, cough, coryza, and conjunctivitis, followed by a descending maculopapular rash beginning on the face and progressing to the chest and lower body (centrifugal).
- Consider measles in the differential diagnosis of a febrile rash illness (especially in unvaccinated individuals with recent international travel).
- Treatment is primarily supportive unless complications develop.
- Measles-associated pneumonia is the most common cause of mortality.
- Measles is a self-limiting disease.

MEDIAL TIBIAL STRESS SYNDROME (MTSS)/SHIN SPLINTS

Michael Y. Yang, MD • Marc W. McKenna, MD

BASICS

DESCRIPTION

- The term medial tibial stress syndrome (MTSS) is currently preferred to "shin splints." MTSS is aching pain along the inner edge of the tibial shaft that develops when the musculature and/or periosteum in the (lower) leg become irritated by repetitive activity. The condition is part of a continuum of stress-related injuries to the lower leg. MTSS does not encompass pain from ischemia (compartment syndrome) or stress fractures.
- Tendonitis/periostitis of the medial soleus muscles, anterior tibialis, and posterior tibialis muscles
- Synonyms: tibial stress reaction, anterior muscle syndrome, periostitis, perimyositis, soleus syndrome, shin splints

EPIDEMIOLOGY

Incidence

Common, can account for between 5% and 35% of novice-running injuries. Frequently occurs bilaterally (1).

Pediatric Considerations

MTSS may account for up to 31% of all overuse injuries in high school athletes.

ETIOLOGY AND PATHOPHYSIOLOGY

- Multifactorial anatomic and biomechanical factors
  - Overuse injuries causing or limited by
    - Microtrauma from repetitive motion leading to periosteal inflammation
    - Overpronation of the subtalar joint and tight gastrocnemius/soleus complex with increased eccentric loading of musculature inserting along the medial shin
    - Interosseous membrane pain

    - Periostitis
    - Tears of collagen fibers
    - Enthesopathy
  - Anatomic structures affected include:
    - Flexor hallucis longus
    - Tibialis anterior
    - Tibialis posterior
    - Soleus
    - Crural fascia
- Pathogenesis: theorized to be due to persistent repetitive loading, which leads to inadequate bone remodeling and possible microfissures causing pain without evidence of fracture or ischemia

RISK FACTORS

- Intrinsic (personal) risk factors:
  - Greater ranges of internal and external (>65 degrees) hip rotation
  - Significant overpronation at the ankle
  - Imbalance of musculature of the ankle and foot (inversion/eversion misbalance)
  - Female gender
  - Lean calf girth
  - Femoral neck anteversion
  - Navicular drop
  - Genu varum
  - History of previous MTSS
- External (environmental) risk factors
  - Lack of physical fitness
  - Inexperienced runners—particularly those with rapid increases in mileage and inadequate prior conditioning
  - Excessive overuse or distance running, particularly on hard or inclined (crowned) surfaces
  - Prior injury
  - Equipment (shoe) failure
- Other risk factors
  - Elevated BMI

  - Lower bone mineral density
  - Tobacco use
- Those typically affected by MTSS include:
  - Runners
  - Military personnel—common in recruit/boot camp
  - Gymnasts, soccer, and basketball players
  - Ballet dancers

GENERAL PREVENTION

- Proper technique for guided calf stretching and lower extremity strength training
- Rehabilitate prior injuries adequately.
- Other recommendations
  - Gait analysis and retraining, particularly for overpronation
  - Orthotic footwear inserts

COMMONLY ASSOCIATED CONDITIONS

- Rule out stress fracture and compartment syndrome.
- Pes planus (flat feet)

DIAGNOSIS

HISTORY

- Patients typically describe dull, sharp, or deep pain along the lower leg that is resolved with rest.
- Patients are often able to run through the pain in early stages.
- Pain is commonly associated with exercise (also true with compartment syndrome), but in severe cases, pain may persist with rest.

PHYSICAL EXAM

- Tenderness to palpation is typically elicited along the posteromedial border of the middle-to-distal third of the tibia.
- Pain with plantar flexion
- Ensure neurovascular integrity of the lower extremity, examining distal pulses, sensation, reflexes, and muscular strength.

DIFFERENTIAL DIAGNOSIS

- Bone
  - Tibial stress fractures
    - Typically, pain persists at rest or with weight-bearing activities.
    - Focal tenderness over the anterior tibia
- Muscle/soft tissue injury
  - Strain, tear, tendinopathy
  - Muscle hernia
- Fascial
  - Chronic exertional compartment syndrome (2)[C]
    - Pain without direct tenderness on exam
    - Pain increases with exertion and resolves at rest.
    - Pain is described as cramping or squeezing.
    - Pain with possible weakness or paresthesias on exam
  - Interosseous membrane tear
- Nerve
  - Spinal stenosis
  - Lumbar radiculopathy
  - Common peroneal nerve entrapment
- Vascular
  - DVT
  - Popliteal arterial entrapment
    - Rare but limb-threatening disease
    - History of intermittent unilateral claudication
    - MRI reveals compression of the artery by the medial head of the gastrocnemius muscle.
- Infection
  - Osteomyelitis
- Malignancy
  - Bone tumors

DIAGNOSTIC TESTS & INTERPRETATION

- Plain radiographs help rule out stress fractures if >2 weeks of symptoms (3).
- Bone scintigraphy

  - Diffuse linear vertical uptake in the posterior tibial cortex on the lateral view.
  - Stress fractures demonstrate a focal ovoid uptake.
- High-resolution MRI reveals abnormal periosteal and bone marrow signals, which are useful for early discrimination of tibial stress fractures.
- Increased pain and localized tenderness warrants further imaging with MRI due to concern for tibial stress fracture.
- Exclude compartment syndrome using intracompartmental pressure testing.

TREATMENT

GENERAL MEASURES

- Activity modification with a gradual return to training based on improvement of symptoms
- Patients should maintain fitness with low-impact activities such as swimming and cycling.
- Continue activity modification until pain free on ambulation.
- Good supportive footwear is recommended.

MEDICATION

- Analgesia with acetaminophen or other oral nonsteroidal anti-inflammatory agent
- Cryotherapy (ice massage) is also advised to relieve acute-phase symptoms (4)[C].

ADDITIONAL THERAPIES

- Stretching of the gastrocnemius, soleus, and peroneal muscles are treatment mainstays (4)[C].
- Calf stretch, peroneal stretch, TheraBand exercises, and eccentric calf raises may improve endurance and strength (5)[A].
- Compression stockings have been used to treat MTSS with mixed results.
- Structured running programs with warm-up exercises have not been demonstrated to reduce pain in young athletes (6)[B].

SURGERY/OTHER PROCEDURES

- Surgical intervention includes a posterior medial fascial release in individuals with both
  - Severe limitation of physical activity and
  - Failure of 6 months of conservative treatment
  - Counsel patients that complete return of activity to sport may not be always achieved postoperatively. Surgical risks include infection and hematoma formation.
- Extracorporeal shock wave therapy (ESWT) may decrease recovery time when added to a running program (5)[A].

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Individualized polyurethane orthoses may help chronic running injuries.
- Special insoles, low-energy laser treatment, pulsed electromagnetic field, and knee braces have not been shown to improve outcomes (5)[A].
- Ultrasound, acupuncture, aquatic therapy, electrical stimulation, whirlpool baths, cast immobilization, taping, and steroid injection may help improve pain.
- Physical therapy approaches including Kinesio tape and fascial distortion massage may yield quicker return to activity.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Avoid premature return to preinjury running pace.
- Maintain stretching and strengthening exercises.
- Identify and correct preinjury training errors.
- Allow a gradual return to activity dictated by symptoms (pain).

PROGNOSIS

The condition is usually self-limiting, and most patients respond well with rest and nonsurgical intervention.

COMPLICATIONS

- Stress fractures and compartment syndrome

- Undiagnosed MTSS or chronic exertional compartment syndrome can lead to a complete fracture or tissue necrosis, respectively.

CODES

ICD10

- S86.899A Other injury of other muscle(s) and tendon(s) at lower leg level, unspecified leg, initial encounter
- S86.891A Other injury of other muscle(s) and tendon(s) at lower leg level, right leg, initial encounter
- S86.892A Other injury of other muscle(s) and tendon(s) at lower leg level, left leg, initial encounter

CLINICAL PEARLS

- MTSS is the preferred term for “shin splints.”
- Diagnosis is based on a reliable history of repetitive overuse accompanied by characteristic shin pain.
- MTSS pain is typically along the middle and distal third of the posteromedial tibial surface, worsened with activity, and relieved with rest.
- Treatment includes ice, activity modification, analgesics, eccentric stretching, gait retraining, and a gradual return to activity.
- Symptoms recur if return to activity is “too much too fast.”

MELANOMA

Carl Bryce, MD • Matthew J. Snyder, DO

BASICS

DESCRIPTION

- Melanoma is a tumor arising from malignant transformation of cells from the melanocytic system.
  - Most arise in the skin but may also present as a primary lesion in any tissue: ocular, GI, GU, lymph node, and leptomeninges.
  - Metastatic spread to any site in the body
- Main types of cutaneous melanoma include the following (1):
  - Superficial-spreading melanoma: 50–80% cases; occurs in sun-exposed areas (trunk, back, and extremities); most ~6 mm diameter at diagnosis; when seen in younger patients, presents as a flat, slow growing, irregularly bordered lesion
  - Nodular: 20–30%, present in older patients, often ulcerate and hemorrhage, most commonly thick and pigmented
  - Lentigo maligna (subtype of melanoma in situ): slowest growing; older population; occurs in sun-exposed areas (head, neck, forearms). Lentigo maligna melanoma (LMM) is its invasive counterpart.
  - Amelanotic melanoma (<5%): can be missed and diagnosed at a later stage, as it can mimic benign skin conditions
  - Acral-lentiginous: 2–8% of all melanomas; however, most common melanoma in black or Asian patients; found in palmar, plantar, and subungual areas
  - Subungual melanoma (0.7–3.5%): dark longitudinal band in nail bed; Hutchinson sign when proximal nail fold involved
  - Desmoplastic melanoma (~1%): sarcoma-like tendencies with increased hematogenous spread
- System(s) affected: skin/exocrine

Geriatric Considerations

Lentigo maligna, slowly enlarging pigmented lesion, is most common in elderly

patients. This type is usually found on face, beginning as a circumscribed macular patch of mottled pigmentation showing shades of dark brown, tan, or black.

Pediatric Considerations

Large congenital nevi (>5 cm) are risk factors and have a >2% lifetime risk of malignant conversion. Blistering sunburns in childhood significantly increase risk.

Pregnancy Considerations

No increased risk of melanoma in pregnancy. However, it is suggested waiting 1 to 2 years if further pregnancy is desired in case of recent melanoma. Melanoma can spread to the placenta.

EPIDEMIOLOGY

Incidence

- In 2016, an estimated 76,380 Americans were diagnosed with melanoma, with 10,130 expected deaths (2).
- Predominant age: median age: 62 and 54 years for men and women respectively, >50% of all individuals with melanoma are between 20 and 40 years of age.
- Predominant sex: male > female (1.5 times)
- Incidence among whites greater than that among minority groups; ~20 times higher than blacks (1)
- Minority groups demonstrate increased rates of metastasis, advanced stages at diagnosis, thicker initial lesions, earlier age at diagnosis, and overall poorer outcomes.
- Low socioeconomic status associated with higher incidence of melanoma

Prevalence

- Lifetime risk: men: 1/37; female: 1/56
- 2% of all cancer deaths
- The most common cancer affecting women 25 to 29 years of age and second only to breast cancer in women 30 to 34 years of age (1)

ETIOLOGY AND PATHOPHYSIOLOGY

- DNA damage by UV-A/UV-B exposure
- Tumor progression: initially may be confined to epidermis with lateral growth, may then grow into dermis with vertical growth

Genetics

- Dysplastic nevus syndrome is a risk factor for development of melanoma. Close surveillance is warranted.
- 8–12% of patients with melanoma have a family history of disease.
- Mutation in *CDKN2A (p16)* is found in 1/3 of patients with family incidence of melanoma.
- Mutations in *BRAF (V600E)* implicated in 50–60% of cutaneous melanomas
- Familial atypical mole malignant melanoma (FAMMM) syndrome characterized by >50 atypical moles, +FH of melanoma, clinical diagnosis (3)

RISK FACTORS

- Genetic predisposition
- UV-A and UV-B exposure
- History of >5 sunburns during lifetime
- History of intense intermittent sun exposure
- Previous pigmented lesions (especially dysplastic melanocytic nevi)
- Fair complexion, freckling, blue eyes, blond/red hair
- Highest predictor of risk is increased number of nevi (>100).
- Family/personal history of melanoma
- Tanning bed use: 75% increased risk if first exposure before age 35 years
- Changing nevus
- Large (>5 cm) congenital nevi
- Other skin cancers
- Chronic immunosuppression (chronic lymphocytic leukemia, non-Hodgkin lymphoma, AIDS, or posttransplant)
- Blistering sunburns in childhood
- Living at high altitude (>700 meters or 2,300 feet above sea level)
- Occupational exposure to ionizing radiation

GENERAL PREVENTION

- Avoidance of sunburns, especially in childhood

- Use of sunscreen with at least SPF 30 to all skin exposed to sunlight, reapplying regularly and after toweling or swimming
- Avoid tanning beds; class 1 carcinogen by World Health Organization (WHO)
- Screening of high-risk individuals, especially males >50 years
- Education for proper diagnosis plays a large factor in prevention.
- Any suspicious lesions should be biopsied with a narrow excision encompassing the entire breadth plus sufficient depth of the lesion. Options include elliptical excisions, punch, or shave biopsies.

COMMONLY ASSOCIATED CONDITIONS

- Dysplastic nevus syndrome
- >50 nevi. These individuals have higher lifetime risk of melanoma than the general population, as 50% of all melanoma arise in preexisting nevi.
- Giant congenital nevus: 6% lifetime incidence of melanoma
- Xeroderma pigmentosum is a rare condition associated with an extremely high risk of skin cancers, including melanoma.
- Psoriasis after psoralen-UV-A (PUVA) therapy

DIAGNOSIS

HISTORY

- Change in a pigmented lesion: either hypo- or hyperpigmentation, bleeding, scaling, ulceration, or changes in size or texture
- Obtain family and personal history of melanoma or nonmelanoma skin cancer.
- Obtain social history including occupation, sunbathing, tanning, and other sun exposure.

PHYSICAL EXAM

- ABCDE: **A**symmetry, **B**order irregularity, **C**olor variegation (especially red, white, black, blue), **D**iameter >6 mm, **E**volution over time
- Any new and/or changing nevus, bleeding/ulcerated
- Location on Caucasians is primarily back and lower leg; on African Americans is the hands, feet, and nails
- May include mucosal surfaces (nasopharynx, conjunctiva)
- Individuals at high risk for melanoma should have careful ocular exam to

assess for presence of melanoma in the iris and retina.

DIFFERENTIAL DIAGNOSIS

- Dysplastic and blue nevi
- Vascular skin tumor
- Pigmented actinic keratosis
- Traumatic hematoma
- Pigmented squamous cell and basal cell carcinomas, seborrheic keratoses, other changing nevi

DIAGNOSTIC TESTS & INTERPRETATION

- Lactate dehydrogenase (LDH), chest/abdomen/pelvic CT, MRI, and/or PET CT at baseline and in monitoring progression in metastatic disease (stage IV) (4)
- Imaging studies only helpful in detecting and evaluating for progression of metastatic disease

Diagnostic Procedures/Other

- Dermoscopy allows for magnification of lesions, allowing for a decreased number of biopsies of benign skin lesions in addition to providing increased sensitivity in detecting melanoma and basal cell carcinoma (5)[B].
- Surgical biopsy remains the standard of care. Any suspicious nevus should be excised, either by elliptical excision; a scoop shave (saucerization) technique may be appropriate, as long as a full-thickness can be achieved (1)[C].
- Sentinel lymph node biopsy, a staging procedure, remains an important factor for prognosis (4)[A].

Test Interpretation

- Nodular melanoma is primarily vertical growth, whereas the other three types are horizontal.
- Estimated that 1/10,000 dysplastic nevi become melanoma annually
- Immunohistochemical testing increases sensitivity of lymph node biopsies.
- Staging is based on the tumor-node-metastasis (TNM) criteria by current American Joint Committee on Cancer (AJCC) criteria, including:
  - (T) Thickness (mm) and ulceration
  - (N) Number of regional lymph nodes involved

- (M) Distant metastases and serum LDH

TREATMENT

GENERAL MEASURES

Full surgical excision of melanoma is the standard of care. See below for recommended surgical margins.

MEDICATION

- For stages I to III, surgical excision is curative in most cases; in patients with stage IV disease, systemic treatment with chemotherapy is recommended.
- Preferred regimens (4)[A] include the following:
  - Ipilimumab (monoclonal antibody against CTLA-4) in combination with nivolumab (anti-PD-1 monoclonal antibody) demonstrated 61% response versus ipilimumab alone (6)[A].
  - Vemurafenib (Zelboraf) or dabrafenib are BRAF inhibitors approved for metastatic, unresectable melanoma expressing BRAF V600E or V600K mutations.
  - High-dose interleukin-2 controversial (significant toxicity, 1–2% mortality related to treatment)
  - Referral for enrollment in clinical trials
- Additional active regimens (e.g., dacarbazine [DTIC], temozolomide, paclitaxel, carmustine [BCNU], cisplatin, carboplatin, vinblastine); often limited to those who are not candidates to preferred regimens.
- Imatinib (Gleevec) in tumors with C-KIT mutation
- Interferon-α as adjuvant therapy received FDA approval in 1995 (high dose) and 2011 (pegylated) to treat stage IIB to III melanoma; shown to improve 4-year relapse rate but no overall effect on survival; 1/3 of patients will discontinue due to toxicity (granulocytopenia, hepatotoxicity). Biochemotherapy is advocated by some (i.e., chemo + immunotherapy combination), although optimal regimen remains uncertain given disease heterogeneity (4)[B].

ISSUES FOR REFERRAL

- Consultation with oncologist for consideration of chemotherapeutic options
- Plastic surgery sometimes needed after final excision

ADDITIONAL THERAPIES

Targeted immunotherapy using various vaccine preparations continues to demonstrate promising results, and randomized prospective trials are needed (7) [B].

SURGERY/OTHER PROCEDURES

- Standard of care for melanoma includes early surgical excision with the following recommended margins (4)[A]:
  - In situ tumors: 0.5 cm margin has been the standard of care but may be insufficient in lentigo maligna.
  - Thickness of 1.01 to 2.00 mm: 1 to 2 cm margins
  - Thickness of >2.00 mm: 2 cm margins
- Sentinel lymph node biopsy is indicated in patients with T2-, T3-, and T4-staged melanomas.
  - Selected patients with stage T1b melanoma should also be considered for sentinel lymph node biopsy.
  - Not recommended in melanoma in situ or T1a
- Mohs surgery is often used for lesions with ill-defined borders or lesions of head and neck.
- Radiotherapy can be used to treat lentigo maligna in addition to certain head and neck lesions.
- Palliative radiation therapy can be used with metastatic melanoma.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Molecular and mouse tumor model studies support role of topical silymarin (milk thistle derivative) in decreasing UV radiation–induced inflammation, oxidative stress, and carcinogenesis.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Most treatments are done as outpatients with no stabilization needed.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

After diagnosis and treatment, close follow-up and skin protection (i.e., sunblock, UV protective clothing) are highly advised.

Patient Monitoring

- Routine screening clinical skin examination annually for all persons >40 years is controversial and without proven benefit.
- Total body photography and dermoscopy should be used for surveillance of skin lesions, most commonly used for patients with >5 atypical nevi.
- For patients with a history of cutaneous melanoma, specialty guidelines suggest every 3 to 12 months depending on recurrence risk (4)[C], general agreement to plan annual examinations after 5 years stable.
- Lab and imaging tests after diagnosis and treatment of stage I to II melanoma are low yield, have high false-positive rates, and are not recommended (4)[B].

DIET

No data to support specific dietary manipulations; general recommendations from American Cancer Society for cancer prevention

PATIENT EDUCATION

- Teach patients who are at risk, or have had melanoma, the principles of ABCDE examinations.
- High-risk patients should perform monthly skin self-examinations and be taught to examine inaccessible areas.
- Educating patients and their significant others to perform skin examinations regularly is of proven benefit to melanoma survivors.
- Patients with a history of melanoma or dysplastic nevus syndrome should have regular total body examinations.

PROGNOSIS

- Breslow depth (thickness) in millimeters remains among strongest predictors of prognosis.
- Median age at death 68 years

- Highest survival seen in women <45 years of age at diagnosis
- Metastatic melanoma has an average survival of 6 to 9 months; 15–20% 5-year survival with current treatment
- Stages I and II, appropriately treated, have 20-year survival rates of 90% and 80%, respectively.

COMPLICATIONS

- Metastatic spread
- Unsatisfactory cosmetic results following the primary surgery

SEE ALSO

Dysplastic Nevus Syndrome

CODES

ICD10

- C43.9 Malignant melanoma of skin, unspecified
- C43.30 Malignant melanoma of unspecified part of face
- C43.4 Malignant melanoma of scalp and neck

CLINICAL PEARLS

- Remember that amelanotic melanomas exist; pigmentation is not required.
- 80% of cutaneous melanomas arise in existing nevi. Any changing nevi should be considered for full-thickness biopsy.
- Excellent prognosis with early detection and treatment
- A common cancer affecting young adult women

MÉNIÈRE DISEASE

Jason E. Cohn, DO, MS • Nadir Ahmad, MD, FACS • Thomas C. Spalla, MD

BASICS

DESCRIPTION

- An inner ear (labyrinthine) disorder characterized by recurrent attacks of hearing loss, tinnitus, vertigo, and sensations of aural fullness due to an increase in the volume and pressure of the inner ear endolymph fluid (endolymphatic hydrops)
- Often unilateral initially, nearly half become bilateral over time.
- Severity and frequency of vertigo may diminish with time, but hearing loss is often progressive and/or fluctuating.
- Usually idiopathic (Ménière disease) but may be secondary to another condition causing endolymphatic hydrops (Ménière syndrome)
- System(s) affected: nervous
- Synonym(s): Ménière syndrome; endolymphatic hydrops

EPIDEMIOLOGY

- Predominant age of onset: 40 to 60 years
- Predominant gender: female > male (1.3:1)
- Race/ethnicity: white, Northern European > blacks

Incidence

Estimates 1 to 150/100,000 per year

Prevalence

Varies from 7.5 to >200/100,000

ETIOLOGY AND PATHOPHYSIOLOGY

- Not fully understood; theories include increased pressure of the endolymph fluid due to increased fluid production or decreased resorption. This may be caused by endolymphatic sac pathology, abnormal development of the vestibular aqueduct, or inflammation caused by circulating immune

complexes. Increased endolymph pressure may cause rupture of membranes and changes in endolymphatic ionic gradient.
- Ménière syndrome may be secondary to injury or other disorders (e.g., reduced middle ear pressure, allergy, endocrine disease, lipid disorders, vascular, viral, syphilis, autoimmune). Any disorder that could cause endolymph hydrops could be implicated in Ménière syndrome.

Genetics

Some families show increased incidence, but genetic and environmental influences are incompletely understood.

RISK FACTORS

May include

- Stress
- Allergy
- Increased salt intake
- Caffeine, alcohol, or nicotine
- Chronic exposure to loud noise
- Family history of Ménière
- Certain vascular abnormalities (including migraines)
- Certain viral exposures (especially herpes simplex virus [HSV])

GENERAL PREVENTION

Reduce known risk factors: stress; salt, alcohol, and caffeine intake; smoking; noise exposure; ototoxic drugs (e.g., aspirin, quinine, aminoglycosides).

COMMONLY ASSOCIATED CONDITIONS

- Anxiety (secondary to the disabling symptoms)
- Migraines
- Hyperprolactinemia
- Hypothyroidism

DIAGNOSIS

Diagnosis is clinical.

HISTORY

- Symptomatic episodes are typically spontaneous but may be preceded by an aura of increasing fullness in the ear and tinnitus. These may occur in clusters, with long periods of symptom-free remissions.
- Formal criteria for diagnosis from American Academy of Otolaryngology–Head and Neck Surgery:
  - At least two episodes of rotational-horizontal vertigo >20 minutes in duration
  - Tinnitus or aural fullness
  - Hearing loss: Low frequency (sensorineural) is confirmed by audiometric testing.
  - Other causes (e.g., acoustic neuroma) excluded.
  - During severe attacks: pallor, sweating, nausea, vomiting, falling, prostration
  - Symptoms are exacerbated by motion.

PHYSICAL EXAM

- Physical exam rules out other conditions; no finding is unique to Ménière disease.
- Horizontal nystagmus may be seen during attacks.
- Otoscopy is typically normal.
- Triggering of attacks in the office with Dix-Hallpike maneuver suggests diagnosis of benign paroxysmal positional vertigo, not Ménière disease.

DIFFERENTIAL DIAGNOSIS

- Acoustic neuroma or other CNS tumor
- Syphilis
- Third window syndromes
- Endolymphatic sac tumor
- Viral labyrinthitis
- Transient ischemic attack (TIA), migraine
- Vertebrobasilar disease
- Other labyrinthine disorders (e.g., Cogan syndrome, benign positional vertigo, temporal bone trauma)
- Diabetes or thyroid dysfunction

- Vestibular neuronitis
- Medication side effects
- Otitis media
- Autoimmune inner ear disease
- Autosomal dominant sensorineural hearing loss

DIAGNOSTIC TESTS & INTERPRETATION

Testing is done to rule out other conditions but does not necessarily confirm or exclude Ménière disease.

Initial Tests (lab, imaging)

- Consider serologic tests specific for Treponema pallidum in at-risk populations.
- Thyroid, fasting blood sugar, and lipid studies
- Consider MRI to rule out acoustic neuroma or other CNS pathology, including tumor, aneurysm, and multiple sclerosis (MS).

Diagnostic Procedures/Other

- Auditory
  - Audiometry using pure tone and speech to show low-frequency sensorineural (nerve) loss and impaired speech discrimination; usually shows low-frequency sensorineural hearing loss
  - Tuning fork tests (i.e., Weber and Rinne) ABR or MRI to rule out acoustic neuroma
  - Electrocochleography may be useful to confirm etiology.
- Vestibular
  - Caloric testing: Reduced activity on either side is consistent with Ménière diagnosis but is not itself diagnostic.
  - Head-impulse testing (1)[C]

Test Interpretation

- Histologic temporal bone analysis (at autopsy); dilation of inner ear fluid system, neuroepithelial damage with hair cell loss, basement membrane thickening, and perivascular microvascular damage
- Cytochemical analysis can reveal altered AQP4 and AQP6 expression in the supporting cell, altered cochlin, and mitochondrial protein expression (2)[B].

- Familial Ménière disease has been associated with DTNA and FAM136A genes (3)[B].

TREATMENT

- Usually managed in outpatient setting
- A paucity of evidence-based guidelines exists; therefore, there is no gold standard treatment.
- Medications are primarily for symptomatic relief of vertigo and nausea.
- During attacks, bed rest with eyes closed prevents falls. Attacks rarely last >4 hours.

MEDICATION

First Line

- Acute attack: Initial goal is stabilization and symptom relief. For severe episodes
  - Benzodiazepines (such as diazepam): decrease vertigo and anxiety
  - Antihistamines (meclizine/dimenhydrinate): decrease vertigo and nausea
  - Anticholinergics (transdermal scopolamine): reduces nausea and emesis associated with motion sickness
  - Antidopaminergic agents (metoclopramide, promethazine): decrease nausea, anxiety
  - Rehydration therapy and electrolyte replacement
  - Steroid taper for acute hearing loss
- Maintenance (goal is to prevent/reduce attacks)
  - Lifestyle changes (e.g., low-salt diet) are needed.
  - Diuretics may help reduce attacks by decreasing endolymphatic pressure and volume; there is insufficient evidence to recommend routine use:
    - Hydrochlorothiazide; hydrochlorothiazide/triamterene (Dyazide, Maxzide)
    - Acetazolamide (Diamox)
- Contraindications/warnings:
  - Atropine: cardiac disease, especially supraventricular tachycardia and other arrhythmias, prostatic enlargement

  - Scopolamine: children and elderly, prostatic enlargement
  - Diuretics: electrolyte abnormalities, renal disease
- Precautions:
  - Sedating drugs should be used with caution, particularly in the elderly. Patients are cautioned not to operate motor vehicles or machinery. Atropine and scopolamine should be used with particular caution.
  - Diuretics: Monitor electrolytes.
- Significant possible interactions: transdermal scopolamine: anticholinergics, antihistamines, tricyclic antidepressants, other

Second Line

- Steroids, both intratympanic and systemic (PO or IV) have been used for longer treatment of hearing loss:
  - Addition of prednisone 30 mg/day to diuretic treatment reduced severity and frequency of tinnitus and vertigo in one pilot study.
- In Europe, betahistine, a histamine agonist is routinely used (unavailable in the United States). Other vasodilators, such as isosorbide dinitrate, niacin, and histamine, have also been used; evidence of their effectiveness is incomplete.
- Evidence is lacking for routine use of Famvir; may improve hearing more than balance
- Intratympanic gentamicin has shown to improve vertigo (4)[B].

ISSUES FOR REFERRAL

- Consider ear, nose, throat/neurology referral.
- Patients should have formal audiometry to confirm hearing loss.

ADDITIONAL THERAPIES

- Application of intermittent pressures via a myringotomy using a Meniett device has been shown to relieve vertigo (5)[B]:
  - Safe; requires a long-term tympanostomy tube
- Vestibular rehabilitation may be beneficial for patients with persistent vestibular symptoms:
  - Safe and effective for unilateral vestibular dysfunction

SURGERY/OTHER PROCEDURES

- Interventions that preserve hearing:

- Endolymphatic sac surgery, either decompression or drainage of endolymph into mastoid or subarachnoid space
  - Less invasive; may decrease vertigo; may influence hearing/tinnitus
- Endolymphatic sac surgery is effective in controlling vertigo in short- and long-term follow-up in at least 75% of patients with Ménière disease who failed medical therapy (6)[A].
- Vestibular nerve section (intracranial procedure)
  - More invasive
  - Decreases vertigo and preserves hearing
- Tympanostomy tube: may decrease symptoms by decreasing the middle ear pressure

- Interventions for patients with no serviceable hearing:
  - Labyrinthectomy: very effective at controlling vertigo but causes deafness
  - Vestibular neurectomy
  - Endoscopic vestibular nerve section (7)[B]
  - Cochlear implantation has shown to improve tinnitus and quality of life (8)[B].

COMPLEMENTARY & ALTERNATIVE MEDICINE

Insufficient evidence to support effectiveness, but many integrative techniques have been tried, including the following:

- Acupuncture, acupressure, tai chi
- Niacin, bioflavonoids, Lipoflavonoids, ginger, ginkgo biloba, and other herbal supplements

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Due to the possibility of progressive hearing loss despite decrease in vertiginous attacks, it is important to monitor changes in hearing and to monitor for more serious underlying causes (e.g., acoustic neuroma).

DIET

- Diet is usually not a factor, unless attacks are brought on by certain foods.
- A low salt is often recommended but not proven effective in randomized controlled trials.

PROGNOSIS

- Alert patients about the nature of alternating attacks and remission.
- Between attacks, patient may be fully active but is often limited due to fear or lingering symptoms. This can be severely disabling.
- 50% resolve spontaneously within 2 to 3 years.
- Some cases last >20 years.
- Severity and frequency of attacks diminish, but hearing loss is often progressive.
- 90% can be treated successfully with medication; 5–10% of patients require surgery for incapacitating vertigo.

COMPLICATIONS

Loss of hearing; injury during attack; inability to work

- Algorithm: Vertigo

CODES

ICD10

- H81.09 Meniere's disease, unspecified ear
- H81.01 Meniere's disease, right ear
- H81.02 Meniere's disease, left ear

CLINICAL PEARLS

- Ménière disease is characterized by vertigo, hearing loss, and tinnitus +/− aural fullness.
- There is a wide differential diagnosis for Ménière disease; therefore, one must fully investigate symptoms.
- Multiple medical, surgical, and rehabilitative treatments are available to decrease the severity and frequency of attacks.

MENINGITIS, BACTERIAL

Felix B. Chang, MD, DABMA, FAAMA

BASICS

DESCRIPTION

- A potentially life-threatening bacterial infection of the meninges
- System affected: nervous

EPIDEMIOLOGY

- Predominant age: neonates, infants, and elderly
- Predominant sex: male = female

Incidence

- <2 months: 80/100,000
- 2 to 23 months: 7/100,000
- 2 to 10 years: 0.5/100,000
- 11 to 17 years: 0.4/100,000
- 18 to 34 years: 0.66/100,000
- 35 to 49 years: 0.95/100,000
- 50 to 64 years: 1.73/100.000
- ≥65 years: 1.92/100,000
- Varies with pathogen
  - *Streptococcus pneumoniae*: 0.81/100,000
  - Group B *Streptococcus*: 0.25/100,000
  - *Neisseria meningitidis*: 0.19/100,000
  - *Haemophilus influenzae*: 0.08/100,000
  - *Listeria monocytogenes*: 0.05/100,000

ETIOLOGY AND PATHOPHYSIOLOGY

Bacterial infection causes inflammation of the pia mater, arachnoid, and the fluid of the ventricles. Age and likely pathogens guide empiric choice of antibiotics. Tailor therapy by culture results whenever possible (1):

- Newborns (<2 months)

  - Group B *Streptococcus*
  - *Escherichia coli*
  - *L. monocytogenes*
- Infants and children
  - *S. pneumoniae*
  - *N. meningitidis*
  - *H. influenzae*
- Adolescents and young adults
  - *N. meningitidis*
  - *S. pneumoniae*
- Immunocompromised adults
  - *S. pneumoniae, L. monocytogenes*, gram-negative bacilli such as *Pseudomonas aeruginosa*
  - *Mixed bacterial infection in <1% of cases*
- Older adults
  - *S. pneumoniae* 50%
  - *N. meningitidis* 30%
  - *L. monocytogenes* 5%
  - 10% gram-negatives bacilli*: E. coli, Klebsiella, Enterobacter, P. aeruginosa*

Genetics

Navajo Indians and American Eskimos appear to have genetic or acquired susceptibility to invasive disease.

RISK FACTORS

- Immune compromise
- Alcoholism, diabetes, chronic disease
- Neurosurgical procedure/head injury
- Abdominal surgery
- Neonates: prematurity, low birth weight, premature rupture of membranes, maternal peripartum infection, and urinary tract abnormalities
- Abnormal communication between nasopharynx and subarachnoid space (congenital, trauma), dural fistula
- Parameningeal source of infection: otitis, sinusitis, mastoiditis
- Trauma: skull fracture

GENERAL PREVENTION

- Treat infections appropriately.
- Strict aseptic techniques for patients with head wounds or skull fractures
- Consider CSF fistula in patients with recurrent meningitis.
- Meningitis caused by *H. influenzae* type B has decreased 55% with routine vaccination.
- Conjugate vaccines against *S. pneumoniae* may reduce the burden of disease in childhood and produce herd immunity among adults.
- Close contacts of meningococcal meningitis patients should receive chemoprophylaxis (2)[A].

COMMONLY ASSOCIATED CONDITIONS

Conditions associated with a worse prognosis:

- Alcoholism, old age, infancy
- Diabetes mellitus, multiple myeloma
- Head trauma, seizures
- Coma, bacteremia, sepsis
- Bacteremia, sepsis, sinusitis

DIAGNOSIS

HISTORY

- Antecedent upper respiratory infection
- Fever, headache, vomiting, photophobia
- Seizures, confusion, nausea, rigors
- Profuse sweats, weakness
- Elderly: subtle findings including confusion
- Infants: irritability, lethargy, poor feeding
- Altered mental status

PHYSICAL EXAM

The triad of fever, neck stiffness, and altered mental status has low sensitivity (44%) (3). 95% of patients present with at least two of the following: headache, fever, neck stiffness, and altered mental status.

- Meningismus

- Focal neurologic deficits
- Meningococcal rash: macular and erythematous at first, then petechial or purpuric
- Purpura fulminans: more common with meningococcus
- Papilledema
- Brudzinski sign: Passive flexion of neck elicits involuntary flexing of knees in supine position.
- Kernig sign: resistance or pain with passive knee extension following 90-degree hip flexion in supine position
- Late signs and symptoms: hemiparesis, stroke, cognitive impairment, coma, epilepsy, hearing loss, permanent visual impairment

DIFFERENTIAL DIAGNOSIS

- Bacteremia, sepsis, brain abscess
- Seizures, other nonbacterial meningitides
- Aseptic meningitis
- Drug-induced: NSAIDs, cotrimoxazole, amoxicillin, cephalosporin, isoniazid
- Inflammatory noninfectious: Behçet disease, systemic lupus erythematosus (SLE), sarcoidosis
- Stroke

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Prompt lumbar puncture (1)[A]
  - Head CT first if focal neuro findings, papilledema, or altered mentation
- Typical CSF analysis: turbid
  - Adults
    - >500 cells/mL WBCs
    - Glucose <40 mg/dL
    - <2/3 blood-to-glucose ratio
    - CSF protein >200 mg/dL
    - CSF opening pressure >30 cm
    - Suspect ruptured brain abscess when WBC count is unusually high (>100,000).
- CSF Gram stain and cultures

- Polymerase chain reaction (PCR) of CSF (particularly in suspected viral meningitis)
- Bacterial antigen tests should be reserved for cases in which the initial CSF Gram stain is negative and CSF culture is negative at 48 hours of incubation.
- Serum blood cultures, serum electrolytes
- Evaluate clotting function when petechiae or purpura are present.
- Chest radiograph may reveal pneumonitis or abscess.
- Later in course: Head CT if hydrocephalus, brain abscess, subdural effusions, and subdural empyema are suspected or if no clinical response after 48 hours of appropriate antibiotics
- C-reactive protein (CRP): Normal CRP has high negative predictive value (3) [A].
- Lactate concentration not recommended for suspected community-acquired bacterial meningitis

Diagnostic Procedures/Other

Lumbar puncture

- IDSA head CT recommendations (prior to LP): immunocompromised, history of central nervous system disease (stroke, mass lesion, focal infection), papilledema, focal neurologic defect including fixed dilated pupil, gaze palsy, weakness of extremity, visual field cut, new-onset seizure <12 weeks prior to presentation, abnormal level of consciousness (3)[A]
- Contraindications to LP: signs of increased intracranial pressure (decerebrate posturing, papilledema), skin infection at site of lumbar puncture, CT or MRI evidence of obstructive hydrocephalus, cerebral edema, herniation

TREATMENT

GENERAL MEASURES

- Initiate empiric antibiotic therapy immediately after lumbar puncture (LP > Abx), or if head CT scan is needed, then immediately after blood cultures (Abx > CT > LP).
- Vigorous supportive care to ensure prompt recognition of seizures and prevention of aspiration

MEDICATION

Empiric antibiotic IV therapy (with dexamethasone when indicated) until culture results are available

- Consider local patterns of bacterial sensitivity.

First Line

- Neonates
- Ampicillin: 150 mg/kg/day divided q8h *AND*
- Cefotaxime 150 mg/kg/day divided q8h
- Infants >4 weeks of age (3,4)[A]
  - Ceftriaxone: 100 mg/kg/day divided q12–24h or cefotaxime 225 to 300 mg/kg/day divided q6–8h *AND*
  - Vancomycin: 60 mg/kg/day divided q6h
- Adults (3,4)[A]
  - Vancomycin: loading dose 25 to 30 mg/kg IV then 15 to 20 mg/kg q8–12h with goal trough of 15 to 20 *AND*
  - Ceftriaxone: 2 g IV q12h *OR*
  - Cefotaxime: 2 g IV q4–6h
  - >50 years, add ampicillin: 2 g IV q4h for *Listeria*
  - Immunocompromised use vancomycin, ampicillin, ceftazidime, and acyclovir.
- Precaution: aminoglycoside ototoxicity
- Penicillin-allergic patients (3,4)[A]
  - Chloramphenicol: 1 g IV q6h *AND*
  - Vancomycin: loading dose 25 to 30 mg/kg IV then 15 to 20 mg/kg q8–12h (goal trough of 15 to 20)
- Treatment duration
  - *S. pneumoniae*: 10 to 14 days
  - *N. meningitidis*, *H. influenzae*: 7 to 10 days
  - Group B *Streptococcus* organisms, *E. coli*, *L. monocytogenes*: 14 to 21 days
  - Neonates: 12 to 21 days or at least 14 days after a repeated culture is sterile
- Corticosteroids (5)[A]
  - Pediatrics
    - Early treatment with dexamethasone (0.15 mg/kg IV q6h for 2 to 4 days)

decreases mortality and morbidity for patients >1 month of age with acute bacterial meningitis with no increased risk of GI bleeding.
    - Corticosteroids are associated with lower rates of hearing loss and neurologic sequelae.
- Adults (5)[A]
    - Initiate in adults, and continue only if CSF Gram stain is gram-positive diplococcus or if blood or CSF positive for *S. pneumoniae*.
    - Nonsignificant reduction in mortality (RR) 0.90, 95% CI 0.53–1.05. *p*-value = 009
    - Lower rates of severe hearing loss (RR 0.67, 95% CI 0.51–0.88), any hearing loss (RR 0.74, 95% CI 0.63–0.87), and neurological sequelae (RR.0.83, 95% CI 0.69–1.00)
    - Decreased mortality in *Streptococcus* pneumonia (RR 0.8, 95% CI 0.20–0.59) but not in *H. influenza* or *N. meningitidis*
    - Associated with increased recurrent fever (RR 1.27, 95% CI 1.09–1.47)
- Dexamethasone: 0.15 mg/kg IV q6h (start 15 to 20 minutes before or with antibiotic) for 4 days
- Dexamethasone should only be continued if the CSF Gram stain and/or CSF or blood culture reveal *Streptococcus* pneumonia.

Second Line

Antipseudomonal penicillins

- Aztreonam
- Quinolones (e.g., ciprofloxacin)
- Meropenem

ISSUES FOR REFERRAL

Consultation from infectious disease and/or critical care specialist

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Bacterial meningitis requires hospitalization.
    - ICU monitoring may be needed.
    - Patients with suspected meningococcal infection require respiratory isolation for 24 hours.

- Consider home therapy to complete IV antibiotics once clinically stable and culture/sensitivity results are known.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Brainstem auditory—evoked response hearing test for infants before hospital discharge
- Vaccinations
  - 4 doses *Hib* conjugate vaccine recommended during infancy
  - Meningococcal conjugate vaccine quadrivalent (MCV4) is given to children aged 11 to 12 years with a booster at 16 years.
  - Immunizing infants <3 months old with MCV4 does not reduce morbidity or mortality, and vaccinating pregnant women does not reduce infant infections.
  - Administer 2 doses MCV4 at least 2 months apart to adults with the following:
    - HIV, functional asplenia
    - Persistent complement deficiencies
  - Administer 1 dose of meningococcal vaccine to:
    - Military recruits
    - Microbiologists routinely exposed to isolates of *N. meningitidis*
    - Those who travel to or live in countries where meningitis is hyperendemic or epidemic
    - 1st-year college students up through age 21 years who live in residence halls if they have not received a dose on or after their 16th birthday
  - MCV4 is preferred for adults with any of the preceding indications who are ≤55 years of age; meningococcal polysaccharide vaccine (MPSV4) is preferred for adults aged ≥56 years.
  - Revaccination with MCV4 every 5 years is recommended for adults previously vaccinated with MCV4 or MPSV4 who are at increased risk.
- Prophylaxis (2)[A]

  - Only for close contacts of patients
  - Rifampin is effective in eradicating *N. meningitidis* up to 4 weeks after treatment but may lead to resistance.
  - Rifampin: 600 mg PO BID for 2 days
    - Ciprofloxacin and ceftriaxone are effective up to 2 weeks after treatment without leading to resistance.
    - Ciprofloxacin: 500 mg PO for 1 dose
    - Ceftriaxone: 250 mg IM for 1 dose

DIET

Regular, as tolerated, except with syndrome of inappropriate secretion of antidiuretic hormone

PROGNOSIS

Overall case fatality: 21%

- Fatality rate increases linearly with age.

COMPLICATIONS

- Seizures: 20–30%; focal neurologic deficit
- Cranial nerve palsies (III, VI, VII, VIII)
  - Comprises 10–20% of the cases
  - Usually disappear within a few weeks
- Sensorineural hearing loss: 10% in children
- Neurodevelopmental sequelae: 30% have subtle learning deficits.
- Obstructive hydrocephalus, subdural effusion
- Syndrome of inappropriate secretion of antidiuretic hormone
- Elevated intracranial pressure: herniation, brain swelling

CODES

ICD10

- G00.9 Bacterial meningitis, unspecified
- G00.2 Streptococcal meningitis
- G00.8 Other bacterial meningitis

CLINICAL PEARLS

- Initiate antibiotic therapy immediately (following diagnostic lumbar puncture) if meningitis is suspected.
- Repeat lumbar puncture if patients don’t respond to antimicrobial therapy after 48 hours.
- Classic triad of fever, neck stiffness, and altered mental status has low sensitivity for bacterial meningitis. Meningeal signs are unreliable for diagnosing or ruling out meningitis.
- 50–90% of patients with bacterial meningitis have positive blood cultures.
- Hypotension, altered mental status, and seizures are associated with adverse outcomes including in-hospital death or neurologic deficits at discharge.
- Sensorineural hearing loss is typically not appreciated until after patients have recovered from acute illness.

MENINGITIS, VIRAL

Christine M. Broszko, MD • James E. Hougas, III, MD, FAAFP

BASICS

DESCRIPTION

- A clinical syndrome characterized by signs/symptoms of acute meningeal inflammation
- Viral meningitis (VM) is the most common cause of aseptic meningitis (no identifiable bacterial pathogen in CSF).
- System(s) affected: nervous

EPIDEMIOLOGY

Incidence

- Estimated 30,000 to 75,000 VM cases and 26,000 to 42,000 VM hospitalizations annually in United States
- Most common form of infectious meningitis
  - Annual incidence of VM is higher than all other causes of meningitis combined.
- Peaks June 1 to October 31
  - Nonpolio enteroviruses and arthropod-borne viruses predominate in warm months (70% of cases July to October).
  - Mumps usually occur in the winter and spring, often in epidemics.
- Occurs in both outbreak and sporadic forms

ETIOLOGY AND PATHOPHYSIOLOGY

- In immunocompetent hosts, VM is generally caused by a systemic viral infection with neurotropic predilection.
- Less commonly, direct neural transmission occurs from an acute flare of a chronic viral illness (such as HSV) already present in an immunocompetent host.
- 85–95% of cases are caused by enterovirus family, (often transmitted by the fecal–oral route) including coxsackievirus A and B, echovirus, and nonpolio E

variants: E9 and E30. Most recently, outbreak of E68 in 2014
- Less common: HSV-1, HSV-2, varicella-zoster virus (VZV), adenovirus, lymphocytic choriomeningitis virus (LCMV), cytomegalovirus (CMV), Epstein-Barr virus (EBV), HIV, parvovirus B19, and mumps virus
- Parechovirus 3 is the most common cause of viral meningitis in infants <90 days old.
- Arthropod-borne viruses: West Nile virus, St. Louis encephalitis virus, California encephalitis virus
- Recurrent benign lymphocytic (Mollaret) meningitis: 80% associated with HSV-2

Genetics
None identified

RISK FACTORS
- Close contact with known cases of VM
- Age (common in children <5 years)
- Immunocompromised hosts may be more susceptible to CMV, HSV, and adenovirus.
- LCMV is transmitted via exposure to rodent feces, bite, bodily fluids, or nesting materials.

Geriatric Considerations
Cases of VM in the elderly are rare; consider alternative diagnoses (e.g., carcinomatous meningitis, NSAID- or medication-induced meningitis).

GENERAL PREVENTION
Limit exposure to known hosts. Observe hand washing and general hygiene procedures.

COMMONLY ASSOCIATED CONDITIONS
Encephalitis; neurologic deficits; myopericarditis; neonatal enteroviral sepsis

DIAGNOSIS
HISTORY

Predominant symptoms include acute onset (hours to days) of:

- Fever (in 76–100% of patients)
- Headache (prominent early symptom)
- Photophobia
- Myalgias
- Nausea, vomiting
- Malaise
- Nuchal rigidity (>50%)
- Mental status changes
  - Encephalitis is associated with other neurologic dysfunction, such as behavioral change, focal neurologic deficits, seizure, etc. There is a continuum between meningitis and encephalitis that can be labeled as one or the other according to predominant symptom type, or jointly labeled "meningoencephalitis."

Also document the following:

- Travel and exposure history
- Sexual activity (e.g., HSV, HIV)
- Outdoor activities (Lyme disease)
- Exposure to rodent feces and/or urine (LCMV)
- Solid-organ transplant (LCMV, CMV)
- Immunocompromised host (CMV, HSV, adenovirus)
- History of VZV infection
- Immunization status (mumps virus, VZV)

PHYSICAL EXAM

- Altered mental status (AMS)
  - AMS is more common in encephalitis than meningitis.
- Fever (>100.4°F/38°C)
- Perform full neurologic exam.
- Meningeal signs (should not be used exclusively to diagnose or rule out meningitis):
  - Nuchal rigidity: new neck stiffness
  - Brudzinski sign: Neck flexion elicits involuntary hip and knee flexion in supine patient.
  - Kernig sign: resistance to knee extension following flexion of hips to 90

degrees by physician
  - Jolt accentuation test: Rapid horizontal rotation of the head accentuates the headache.
- Genital lesions (HSV2; can precede meningeal symptoms by up to a week)
- Parotitis (mumps)
- Asymmetric flaccid paralysis (West Nile virus)
- Mucocutaneous findings
  - Vesicular rash in hand, foot, and mouth disease (coxsackie)
  - Herpangina (coxsackie A)
  - Herpes zoster rash (VZV)
  - Erythema chronicum migrans or cranial neuropathy (Lyme disease [*Borrelia burgdorferi*])
  - Generalized maculopapular rash (echovirus 9, syphilis, HIV, Rocky Mountain spotted fever)
  - Oropharyngeal thrush (HIV)
  - Petechial rash (*Neisseria meningitidis*)

DIFFERENTIAL DIAGNOSIS

- Bacterial meningitis (BM)
- Encephalitis
- Other infectious agents:
  - Tuberculosis; syphilis; leptospirosis; Lyme disease; Rocky Mountain spotted fever; ehrlichiosis; *Coccidioides*; *Cryptococcus neoformans*; amebiasis; Rickettsial infection
- Parameningeal infections (e.g., subdural empyema)
- Postinfectious encephalomyelitis
- Viral syndrome (e.g., influenza)
- Leukemia or carcinomatous meningitis
- Migraine/tension headache
- Acute metabolic encephalopathy
- Chemical meningitis
- Drug-induced meningitis (NSAIDs, IVIG, Bactrim, cetuximab, lamotrigine)
- Brain/epidural abscess

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Rule out BM:
  - There is debate over whether patients with low suspicion of BM need a lumbar puncture (LP). Some contend that if meningeal symptoms have been present >48 hours with normal neurologic exam in an immunocompetent patient with confirmed normal level of alertness, BM is extremely unlikely and LP is not warranted. Others argue that BM cannot be excluded clinically and to exercise caution discharging meningitic patients without LP.
  - Bacterial Meningitis Score (BMS): The BMS is a validated clinical decision rule to identify children (≥29 days of age) at very low risk of BM with sensitivity of 99.6%. Low-risk features include negative CSF Gram stain, CSF absolute neutrophil count (ANC) <1,000 cells/μL, CSF protein <80 mg/dL, peripheral blood ANC <10,000 cells/μL, and no seizure around the time of initial presentation (1)[B].
  - CSF bacterial culture is positive in 80–90% of BM patients who haven't received antibiotics for 2 to 4 hours prior to LP.
- LP is the standard of care for suspected BM:
  - If BM is suspected, start antibiotics immediately.
  - Contraindications for LP: signs of increased intracranial pressure (e.g., focal neurologic findings, papilledema, altered mental status, vomiting), known ventricular obstruction, new-onset seizure, immunocompromised state, local infection over potential LP site or suspected epidural abscess, use of anticoagulation or coagulopathy, and possibility of cardiorespiratory compromise due to patient positioning during procedure
  - Post-LP headache: occurs in 37% of patients within 48 hours
  - CSF analysis: glucose, protein, WBC count with differential, RBC count, Gram stain, culture; consider CSF lactate:
    - CSF lactate elevation helps differentiate BM from VM (decreased sensitivity if pretreated with antibiotics) (2,3)[A].
- Typical CSF findings in VM
  - Elevated WBC count: 10 to 1,000/mm^3, classically lymphocyte predominance (less consistent in younger patients). May show neutrophilic predominance in first 48 hours

  - Decreased or normal glucose (relative to concurrent serum glucose)
  - Protein normal to slightly elevated (<150 mg/dL)
  - Negative Gram stain and bacterial culture
  - Elevated opening pressure
  - RBCs in CSF (consider HSV meningitis/encephalitis)
  - Pathogen identification
    - Historic gold standard: CSF viral culture for enteroviruses, HSV, and mumps has low sensitivity (<6–20%); viral culture may yield no additional information over nucleic acid amplification alone.
    - Current practice: polymerase chain reaction (PCR): sensitivity of 95–100% for HSV-1 and 2, EBV, enterovirus
    - RT PCR test is approved for enteroviral meningitis. Results in 2 to 3 hours
    - Serology can be performed for many arthropod-borne viruses.
- Other labs: CBC, blood culture, blood glucose; consider serum CRP and procalcitonin (PCT).
  - CBC: normal or mildly elevated WBC
  - Serum PCT elevation has been correlated with BM. PCT levels of >0.25 to 2.13 are 90% sensitive and 98% specific for BM. Elevated serum CRP was 82% sensitive and 81% specific (2,4)[B].
  - PCT has also been validated in the pediatric population (sensitivity 87.5–100%, specificity 66–100%); however, cutoff range variable from 0.2 to 3.3 ng/mL between studies and values are assay dependent (5)[A].
- Consider EEG if concern for encephalitis.
- Indication for imaging depends on clinical scenario. Perform CT prior to LP if papilledema, spinal cord trauma, altered mental status, or focal neurologic findings. CT scan not typically clinically necessary in the absence of risk factors

Follow-Up Tests & Special Considerations

Disorders that may alter lab results:

- Diabetes: Consider current blood sugar level to correlate with CSF glucose level.
- Preexisting neurologic diseases (e.g., intracranial neoplasm, demyelinating disease)

TREATMENT

GENERAL MEASURES

Management is largely supportive care (e.g., pain control, IV fluids).

MEDICATION

First Line

- Analgesics (adult doses; titrate doses to pain relief)
  - Morphine 2.5 to 5 mg IV q3–4h
  - Hydromorphone (Dilaudid) 0.2 to 2 mg IV q2–3h
  - Hydrocodone (Norco) 5/325 mg 1 to 2 tablets PO q6h *OR* oxycodone (Percocet) 5/325 mg 1 to 2 tablets PO q4–6h
- Antiemetics
  - Ondansetron (Zofran) 4 to 8 mg IV q8h
  - Metoclopramide (Reglan) 10 to 20 mg IV/IM q4–6h
- Antipyretics: acetaminophen (Tylenol) 650 mg PO or rectal suppository q4h
- Antiviral agents: Initiate empiric acyclovir at 10 mg/kg IV q8h for patients with CSF pleocytosis, negative Gram stain, and suspicion for HSV while awaiting results of definitive (e.g., HSV PCR) testing.
- Antibiotics
  - Not indicated for treatment of VM
  - If unclear etiology but low risk for BM, treat symptomatically and follow the patient closely in the hospital setting pending laboratory results.
  - If in doubt, initiate broad-spectrum antibiotic with good CSF penetration. Consider especially in elderly, <3 months old, or immunocompromised patient.
- Corticosteroids
  - Not indicated for treatment in VM
  - Consider if concerned for BM.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Generally, VM is treated as outpatient once BM is excluded. Hospitalize for VM with complications (e.g., encephalitis), empiric antibiotic therapy,

pain/fluid control, immunocompromised patient, or <1 year old.
  - Study of ED visits found that most children diagnosed with VM were hospitalized (91%).
- IV fluids: crystalloid bolus or continuous infusion, based on hydration status and clinical presentation
- Neurologic monitoring for changes in mental status, fever, neck stiffness, HA, etc., to assess disease progression
- Contact precautions, private room indicated until BM is ruled out
- Encourage hand washing.
- Discharge depends on likelihood of BM, WBC count, and clinical parameters such as dehydration, functional level, social circumstances, and ability to follow up.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Primary care follow-up to ensure resolution

Patient Monitoring

- Monitor for relapse or exacerbation of symptoms.
- Monitor for neurologic/neuroendocrine complications:
  - Seizures, cerebral edema, syndrome of inappropriate antidiuretic hormone (SIADH)
  - Assess ability to have companion monitor change in mental/neurologic status if patient discharged.

DIET

Consider NPO if nausea or vomiting. Advance to clear fluids/regular diet as tolerated.

PATIENT EDUCATION

- Discuss low probability of transmission to contacts.
- Expected duration of illness is 5 to 10 days.
- Recurrence of headache, myalgia, weakness is possible over 2 to 3 weeks.

PROGNOSIS

- Complete recovery generally within 7 to 10 days
- Headaches and other neurologic symptoms may intermittently persist for weeks to months.
- Only 0.6% of hospitalizations for VM result in death.
- European studies suggest potential residual postmeningeal cognitive impairment.
- In neonatal population, enteroviral meningitis has been associated with normal growth and development at 1 year in most patients.

COMPLICATIONS

- Common: fatigue, irritability, muscle weakness
- Rare: seizures, abscess, mastoiditis

SEE ALSO

- Algorithm: Delirium
- Meningitis, Bacterial

CODES

ICD10

- A87.9 Viral meningitis, unspecified
- A87.1 Adenoviral meningitis
- A87.0 Enteroviral meningitis

CLINICAL PEARLS

- Viral meningitis cannot always be reliably distinguished from BM based on clinical findings.
- Potential cases of BM should be hospitalized for evaluation and treatment with broad-spectrum antibiotics until BM has been ruled out.
- VM is more common than BM.
- Antibiotic administration >2 to 4 hours prior to LP and CSF analysis may result in "partially treated" BM that mimics VM.

- IV acyclovir should be administered if there is high clinical suspicion for HSV.
- Morbidity with VM is low but increases if there is associated encephalitis.

MENINGOCOCCAL DISEASE

Han Q. Bui, MD, MPH

BASICS

DESCRIPTION

- Meningococcemia is a blood-borne infection caused by *Neisseria meningitidis*.
- Bacteremia without meningitis: Patient is acutely ill and may have skin manifestations (rashes, petechiae, and ecchymosis) and hypotension.
- Bacteremia with meningitis: sudden onset of fever, nausea, vomiting, headache, decreased ability to concentrate, and myalgias
- Disease progresses rapidly within a matter of hours.
- Skin findings and hypotension may be present.
  - A petechial rash appears as discrete lesions 1 to 2 mm in diameter; most frequently on the trunk and lower portions of the body and will be seen in >50% of patients on presentation.
  - Purpura fulminans is a severe complication of meningococcal disease and occurs in up to 25% of cases. It is characterized by acute onset of cutaneous hemorrhage and necrosis due to vascular thrombosis and disseminated intravascular coagulopathy.

EPIDEMIOLOGY

Incidence

- The mortality rate is ~13%.
  - 11–19% of survivors suffer serious sequelae, including deafness, neurologic deficit, or limb loss due to peripheral ischemia.
- Disease is seasonal, peaking in December/January.
- Annually, ~1,000 cases of invasive meningococcal disease occur in the United States (1).
  - Most common in adolescents and young adults, followed by infants <1 year

ETIOLOGY AND PATHOPHYSIOLOGY

- *N. meningitidis* is a gram-negative diplococcus with at least 13 serotypes.

- *N. meningitidis* has an outer coat that produces disease—causing endotoxin.
- Major serogroups in the United States are B, C, Y, and W-135
  - Serogroup B is the predominant cause of meningococcemia in children <1 year.
  - Serogroup C is the most common cause of meningococcal disease in the United States.
  - Serogroup Y is the predominant cause of meningococcemia in the elderly (2).
- Major serogroups worldwide are A, B, C, Y, and W-135
  - W-135 is the major cause of disease in the "meningitis belt" of sub-Saharan Africa.

Genetics

Late complement component deficiency has an autosomal recessive inheritance.

RISK FACTORS

- Age: 3 months to 1 year
- Late complement component deficiency (C5, C6, C7, C8, or C9)
- Asplenia (1)
- Living in close quarters (e.g., household contacts, nursery/daycare centers, dormitories, military barracks)
- Exposure to active and passive tobacco smoke (1)

GENERAL PREVENTION

- Two vaccines are currently licensed for use in the United States. Each contains antigens to serogroups A, C, Y, and W-135. Neither provides immunity against serotype B, which is responsible for 1/3 of U.S. cases (3).
  - Meningococcal polysaccharide vaccine (MPSV4): recommended for patients ≥55 years who are at elevated risk (1)
    - Duration of protection is short: 1 to 3 years for patients <5 years; 3 to 5 years for adolescents and adults (3)
    - Often used for patients requiring short duration of protection—traveling to endemic areas, college freshmen, community outbreaks (3)
  - Meningococcal conjugate vaccine (MCV4): recommended for patients 2 to 55 years (1)

- In October 2014, the U.S. Food and Drug Administration (FDA) licensed the first serogroup B meningococcal (MenB) vaccine (MenB-FHbp) as a 3-dose series. In January 2015, FDA licensed a second MenB vaccine (MenB-4C) as a 2-dose series. Both vaccines were approved for use in persons aged 10 to 25 years. Individuals aged ≥10 years who are at increased risk for meningococcal disease due to persistent complement component deficiencies, anatomic or functional asplenia should receive MenB vaccine (3).
- Protective levels of antibody are achieved ~7 to 10 days after primary immunization (2).
- Vaccine is recommended for all persons 11 to 18 years and persons 19 to 55 years at increased risk for the disease.
  - Guillain-Barré syndrome has been associated with the MCV4 vaccine, so a personal history of Guillain-Barré is a relative contraindication for receiving this vaccine.
- CDC International Travel Advisory
  - Vaccine is required by the government of Saudi Arabia for Hajj pilgrims >2 years of age.
  - The vaccine should be given to travelers to sub-Saharan Africa ("meningitis belt").

DIAGNOSIS

HISTORY

- Symptoms
  - Sudden onset of fever, nausea, vomiting, headache, myalgias, chills, rigor, and/or sore throat (nonsuppurative)
    - Pharyngitis may be mistaken for streptococcal pharyngitis.
    - Myalgia may be mistaken for severe "flu," with a peak incidence coinciding in winter months.
  - Changes in mental status, decreased ability to concentrate, stiff neck, convulsions
  - Atypical presentations include acute arthritis or neuritis (4).
- Assess possible exposures.

PHYSICAL EXAM

- Fever, hypotension, tachycardia
- Neurologic: nuchal rigidity, focal neurologic findings, coma, seizure
  - Focal neurologic findings and seizures are more commonly seen with *Haemophilus influenzae* or *Streptococcus pneumoniae*.
- Cardiopulmonary: signs of heart failure with pulmonary edema—gallop, rales
- Dermatologic: maculopapular rash, petechiae, ecchymosis, purpura
- Median time of onset of specific meningitis symptoms (e.g., neck stiffness, photophobia, bulging fontanelle) is as fast as 12 to 15 hours after onset of illness (4).
- Late signs of meningitis (e.g., unconsciousness, delirium, or seizures) occur ~15 hours in infants <1 year and ~24 hours in older children (5).

DIFFERENTIAL DIAGNOSIS

- Sepsis; bacterial meningitis (other organisms)
- Gonococcemia
- Acute bacterial endocarditis
- Rocky mountain spotted fever
- Hemolytic uremic syndrome
- Gonococcal arthritis dermatitis syndrome
- Influenza

DIAGNOSTIC TESTS & INTERPRETATION

ALERT

- Isolation of *N. meningitidis* from a sterile site (blood or CSF) is the gold standard for diagnosing systemic meningococcal infection.
- Antibiotic administration may render blood and/or CSF culture negative within 2 hours. Treat and then test.

Initial Tests (lab, imaging)

- CBC with differential
  - Leukocytosis (left shift; toxic granulation) or leukopenia, thrombocytopenia
- Lactic acidosis
- Procalcitonin; often elevated in bacterial meningitis (6)
- Coagulation studies

  - Prolonged prothrombin time/partial thromboplastin time
  - Low fibrinogen
  - Elevated fibrin degradation products
- Blood culture
  - Blood culture positive for *N. meningitidis*
  - Cultures positive in 50–60% of cases
- CSF
  - Grossly cloudy
  - Increased WBCs with polymorphonuclear predominance
  - Gram stain showing gram-negative diplococci
  - Glucose-to-blood glucose ratio <0.4
  - Protein >45 mg/dL
  - Positive for *N. meningitidis* antigen (MAT or PCR)
  - CSF culture for *N. meningitidis*: positive in 80–90% of cases
- CT scan of head if concern for space-occupying lesions

Test Interpretation

- Disseminated intravascular coagulation (DIC)
- Exudates on meninges
- Polymorphonuclear infiltration of meninges
- Hemorrhage of adrenal glands

TREATMENT

MEDICATION

First Line

- Antibiotics
  - Begin treatment as soon as meningococcal meningitis is suspected.
  - Age influences empiric treatment based on common etiologic organisms.
    - Preterm to <1 month: ampicillin plus cefotaxime or ampicillin plus gentamicin
      - Cefotaxime
        - 0 to7 days: 50 mg/kg q12h
        - 8 to 28 days: 50 mg/kg q8h

        - Ampicillin
            - >2,000 g
                - 0 to 7 days: 50 mg/kg q8h
                - 8 to 28 days: 50 mg/kg q6h
            - <2,000 g
                - 0 to 7 days: 50 mg/kg q12h
                - 8 to 28 days: 50 mg/kg q8h
    - 1 month to 50 years: cefotaxime or ceftriaxone plus vancomycin
        - If severe penicillin allergy: chloramphenicol plus trimethoprim-sulfamethoxazole (TMP-SMX) plus vancomycin
    - >50 years of age or patients with alcoholism, debilitating disease, or impaired immunity: ampicillin plus ceftriaxone plus vancomycin
        - Ampicillin: 2 g IV q4h
        - Ceftriaxone: 2 g IV q12h
        - Vancomycin: 30 to 45 mg/kg/day IV divided q6h
        - If severe penicillin allergy: TMP-SMX plus vancomycin
- Penicillin G
    - Effective if the isolate is penicillin sensitive
    - Penicillin can be used if the isolate has a penicillin minimum inhibitory concentration (MIC) of <0.1 μg/mL.
    - For isolates with a penicillin MIC of 0.1 to 1 μg/mL, treatment with high-dose penicillin is effective, but a 3rd-generation cephalosporin is preferred (5).
    - Penicillin G: 4 million units IV q4h (pediatric dose: 0.25 mU/kg/day IV divided q4–6h) *OR* ampicillin: 2 g IV q4h (pediatric dose: 200 to 300 mg/kg/day IV divided q6h)

- Duration of treatment: 7 days (6)
- Dexamethasone
    - Indications
        - Known or suspected pneumococcal meningitis in selected adults
        - Children with *H. influenzae* type B meningitis
- Dexamethasone is often given initially in adults and children with suspected bacterial meningitis while awaiting microbiologic data.
- Dexamethasone has not been shown to be of benefit in meningococcal

meningitis and should be discontinued once this diagnosis is established.

- Dosage
  - Infants and children >6 weeks: IV 0.15 mg/kg/dose q6h for the first 2 to 4 days of antibiotic treatment
  - Start 10 to 20 minutes before or with the first dose of antibiotic.
- Chemoprophylaxis
  - Indications
    - Close contacts: Those who have had prolonged (>8 hours) contact while in close proximity (<3 feet) to the patient or who have been directly exposed to the patient's oral secretions between 1 week before the onset of the patient's symptoms and until 24 hours after initiation of appropriate antibiotic therapy (2).
      - Examples: household members and personnel in nurseries, daycare centers, nursing homes, dormitories, military barracks, correctional facilities, and other closed institutional settings
    - No chemoprophylaxis is indicated for casual contacts, including most health care workers, unless there is exposure to respiratory secretion.
  - Timing
    - Ideally <24 hours after case identification
    - Chemoprophylaxis should not be administered if identified >14 days after exposure.
  - Prophylactic regimens
    - Rifampin, ciprofloxacin, and ceftriaxone
      - Ceftriaxone
        - Recommended for pregnant women
        - Adults: 250 mg IM as a single dose
      - Rifampin (meningococcal meningitis prophylaxis)
        - Adult: 600 mg IV or PO q12h for 2 days
        - Pediatric
          - <1 month: 10 mg/kg/day in divided doses q12h for 2 days
          - Infants and children: 20 mg/kg/day in divided doses q12h for 2 days (max 600 mg/dose)
      - Ciprofloxacin
        - Adults: 500 mg PO as a single dose

- Vaccination
  - For household contacts (if the case is from a vaccine-preventable serogroup)
- Precautions
  - Adjust the dosage of medications in patients with severe renal dysfunction.

Second Line

- For meningitis
  - Chloramphenicol: 1 g IV q6h (pediatric dose: 75 to 100 mg/kg/day divided q6h) or ceftriaxone 2 g IV q12h (pediatric dose: 80 to 100 mg/kg/day divided q12–24h)
  - In large outbreaks, a single dose of long-acting chloramphenicol has been used. Single-dose ceftriaxone shows equal efficacy in one randomized controlled trial.
- Precautions
  - Ceftriaxone should not be used in patients with a history of anaphylactic reactions to penicillin (e.g., hypotension, laryngeal edema, wheezing, hives).
  - Chloramphenicol may cause aplastic anemia.

ISSUES FOR REFERRAL

Potential complications

- Seizure activity
- DIC
- Acute respiratory distress syndrome
- Renal failure
- Adrenal failure
- Multisystem organ failure

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- If meningitis is suspected, initiate antibiotics (± corticosteroids) and proceed immediately to lumbar puncture.
- Droplet isolation for 24 hours from the beginning of antibiotic therapy
- IV fluids: Replace volume as needed; with septic shock, large volumes of

crystalloid may be required.

ONGOING CARE

PATIENT EDUCATION

Educate family and close contacts regarding the risk of contracting meningococcal infections.

PROGNOSIS

Overall mortality is 13%.

COMPLICATIONS

- DIC
- Acute tubular necrosis
- Neurologic: sensorineural hearing loss, cranial nerve palsy, seizures
- Obstructive hydrocephalus
- Subdural effusions
- Acute adrenal hemorrhage
- Waterhouse-Friderichsen syndrome.

CODES

ICD10

- A39.4 Meningococcemia, unspecified
- A39.0 Meningococcal meningitis
- A39.2 Acute meningococcemia

CLINICAL PEARLS

- Invasive meningococcal disease can be rapidly fatal. Rapid identification and early treatment is essential for good clinical outcomes. Treat then test in suspected cases.
- Provide chemoprophylaxis to close contacts.
- Vaccinate at-risk populations to prevent disease.

MENISCAL INJURY

Jennifer B. Schwartz, MD

BASICS

DESCRIPTION

- The menisci are fibrocartilaginous structures located between the femoral condyles and tibial plateaus.
- Each meniscus has a body, anterior and posterior horn.
- The menisci help stabilize the knee, distribute forces across the joint, and aid joint lubrication.
- After age 10 years, the menisci begin to devascularize.
- In adults, the outer 1/3 remains vascularized.
- The inner 2/3 is avascular and heals poorly.

Geriatric Considerations

Meniscal tears in older patients are typically due to chronic degeneration

Pediatric Considerations

- Meniscal injuries are rare in children <10 years old (prior to physeal fusion).
- Meniscal tears in young children are often due to a *discoid meniscus* (anatomic variant with thicker and wider meniscus—usually the lateral meniscus).
- MRI is less sensitive and specific for diagnosing meniscal tears in children <12 years of age.

EPIDEMIOLOGY

- More common in the 3rd to 5th decades of life
- More common in males

Incidence

Medial meniscus more commonly injured

Prevalence

One of the most common musculoskeletal injuries

ETIOLOGY AND PATHOPHYSIOLOGY

- Acute tears typically occur due to a twisting motion of the knee with foot planted.
  - More common <40 years old
- Degenerative tears occur with minimal trauma.
  - More common >40 years old

Genetics

Presence of a discoid meniscus increases the risk for a meniscal tear. No specific gene locus has been identified.

RISK FACTORS

- Increased age (>60 years), male
- Obesity
- High degree of physical activity (especially cutting sports like soccer, football, basketball, and rugby)
- Anterior cruciate ligament (ACL), posterior cruciate ligament (PCL) insufficiency/injury

GENERAL PREVENTION

- Treatment and rehabilitation of previous knee injuries, particularly ACL injuries
- Strengthening and increased flexibility of quadriceps and hamstring muscles

COMMONLY ASSOCIATED CONDITIONS

- ACL is concomitantly torn in 1/3 of cases.
- Medial and lateral collateral ligament tears
- Tibial plateau or femoral shaft fractures
- Baker cyst—strong association with medial meniscal tears

DIAGNOSIS

HISTORY

- Noncontact twisting or hyperflexion mechanism
- Delayed swelling, typically >24 hours postinjury
- Knee pain (on affected side):

  - Increased with knee flexion (i.e., stairs, squatting)
  - Increased with weight bearing
- Locking, catching, popping
- Sensation of buckling or giving out

PHYSICAL EXAM

- Effusion (mild–moderate)
- Joint line tenderness
- Decreased range of motion, locking
- Pain with full flexion (posterior horn tear) or extension (anterior horn tear)
- Accuracy of special tests varies (1)[C].
  - Positive McMurray test: pain, clicking of meniscus being stressed.
  - Positive Apley grind test is neither sensitive nor specific.
- Thessaly test reported with higher sensitivity and specificity. To conduct the test, support the patient by holding his or her outstretched hands while the patient is standing. The patient then flexes the knee to 20 degrees and rotates his or her knee and body, internally and externally, three times, keeping the knee flexed at 20 degrees. Patients with suspected meniscal tears will experience discomfort along the joint line.

DIFFERENTIAL DIAGNOSIS

- ACL or collateral ligament tear
- Pathologic plica
- Osteochondritis dissecans
- Loose body or fracture
- Osteoarthritis (OA)—symptoms of OA may be caused by meniscal tears (2)[C].
- Patellofemoral syndrome
- Gout, pseudogout, rheumatoid arthritis

DIAGNOSTIC TESTS & INTERPRETATION

- Laboratory evaluation not indicated unless signs of septic arthritis
- Plain radiographs can detect fractures, loose bodies, or arthritic changes.
- Ultrasound may help identify meniscal tears.

Follow-Up Tests & Special Considerations

- MRI is the primary imaging study for meniscal tears.
- Increased signal within a meniscus corresponds to degenerative changes; signal contacting the articular surface indicates an acute tear.
- Meniscal tears are often found incidentally on MRI and may not be the cause of patient's symptoms. Asymptomatic tears increase with age and OA.
- Meniscal tears are present on MRI in ~20% of people without knee symptoms (3).

Diagnostic Procedures/Other

Arthroscopy may be needed if the MRI is indeterminate.

TREATMENT

GENERAL MEASURES

- Treatment depends on the type/location/extent of the tear as well as age and activity level of the patient.
- Conservative treatments (RICE [rest, ice, compression, elevation], activity modification, physical therapy, intra-articular corticosteroid injections) are effective first-line options for many patients, especially those with degenerative tears.
  - No increased benefit from surgery versus physical therapy for symptomatic meniscal tears in patients with mild to moderate OA.
  - Small, partial thickness, or peripheral tears may heal on their own or remain asymptomatic.
- Consider surgical intervention if:
  - Concurrent injuries (i.e., ACL tear)
  - Persistent symptoms following 3 to 6 months of conservative treatment
  - Young patients (<30 years) or very active patients with an acute tear
  - Mechanical symptoms/locking—may or may not be justification for arthroscopy with degenerative meniscal tears (4)[C]

MEDICATION

First Line

NSAIDs, opioid analgesics if severe pain

ISSUES FOR REFERRAL

Surgical consult for patients meeting operative criteria or wishing surgical repair

ADDITIONAL THERAPIES

- Rehabilitation is required for both surgical and nonsurgical patients.
- Electrical stimulation may help improve recovery when coupled with physical therapy.
- Weight control: Weight gain is associated with increased cartilage loss and pain in adults with medial meniscal tears.
- Platelet-rich plasma (PRP) may or may not improve symptoms of meniscal tears.

SURGERY/OTHER PROCEDURES

- Most surgeries can be performed arthroscopically.
- Meniscectomy (partial or total) removes the injured portion of the meniscus.
  - Can lead to articular cartilage degeneration and OA. Higher risk if 40 years of age, high BMI, valgus malalignment (5)[C]
- Meniscal repair or replacement decreases future OA and may have better outcomes than meniscectomy (6)[C].
- Arthroscopy has better long-term clinical outcomes when performed for traumatic (vs. nontraumatic/degenerative) tears (3)[C].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Return to play requires that the patient be pain-free, have full range of motion, and full strength.
- Following meniscal repair, patients can generally return to all activities in 3 to 6 months.
- Combined ACL and meniscal repair requires 6 months of postoperative rehabilitation before the patient can return to sports.

PATIENT EDUCATION

Patients should be aware of the risks and benefits of surgery compared with conservative treatment.

PROGNOSIS

Prognosis better if surgery is done within 8 weeks, patient is <30 years of age, or tear is peripheral/lateral <2.5 cm.

COMPLICATIONS

- Meniscectomies may eventually lead to OA. Consequently, meniscal repair is preferred to meniscectomy whenever possible.
- Risk of developing OA increases 6-fold 20 years after a meniscectomy.

SEE ALSO

Algorithm: Knee Pain

CODES

ICD10

- S83.209A Unsp tear of unsp meniscus, current injury, unsp knee, init
- S83.249A Oth tear of medial meniscus, current injury, unsp knee, init
- S83.289A Oth tear of lat mensc, current injury, unsp knee, init

CLINICAL PEARLS

- Degenerative meniscal tears are common in patients >40 years of age and generally do not require surgical repair.
- MRI is imaging modality of choice to identify meniscal tears.
- Functional outcomes following meniscal injury are improved with comprehensive rehabilitation.
- In patients opting for surgery, meniscal preservation is important. Meniscal repairs have a better functional outcome and decreased risk of OA compared with meniscectomy.

MENOPAUSE

Jill Patton, DO

BASICS

DESCRIPTION

- Natural menopause: defined retrospectively after 12 consecutive months of amenorrhea in a nonpregnant woman ≥40 years of age:
  - Results from loss of ovarian activity
  - Not associated with a pathologic etiology
- Perimenopause/menopausal transition (MT): defined as the period from the onset of irregular menses to the final menstrual cycle. Begins on average 4 years before menopause. Starts at mean age of 47 years.
- Postmenopause: usually >1/3 of a woman's life
- Primary ovarian insufficiency: irregular or cessation of menses before age 40 years

EPIDEMIOLOGY

- The median age of menopause is 51 years.
- 5% of women undergo menopause after age 55 years; another 5% between ages 40 and 45 years.
- Occurs earlier in Hispanic women and later in Japanese American women as compared with Caucasians

Incidence

In the United States, 1.3 million women reach menopause annually.

ETIOLOGY AND PATHOPHYSIOLOGY

Normal physiologic process:

- As women age, the number of ovarian follicles decreases: Ovarian production of estrogen varies and then decreases. Follicle-stimulating hormone (FSH) production varies and then increases.
- Inadequate estradiol production leads to absence of the luteinizing hormone (LH) surge and failure to ovulate. These cycles result in anovulation and lack

of progesterone production.
- Eventual failure to produce estradiol leads to thinning of endometrial lining and eventual menses cessation.
- Surgical menopause: Removal of functioning ovaries leads to immediate menopause.

RISK FACTORS

- Aging
- Oophorectomy
- Hysterectomy
- Sex chromosome abnormalities (e.g., Turner syndrome and fragile X syndrome)
- Family history of early menopause
- Smoking (earlier age of onset by 2 years)
- Chemotherapy and/or pelvic radiation (permanent or reversible)

GENERAL PREVENTION

Menopause is physiologic event. Increased risk of long-term medical issues include cardiovascular disease (CVD) and osteoporotic fractures:

- Decrease risk of CVD by:
  - Increased exercise
  - Avoiding smoking
  - Maintaining healthy diet and lose weight
  - Treating hyperlipidemia, diabetes, and hypertension
  - Taking daily low-dose aspirin
- Decrease risk of osteoporotic fractures by:
  - Weight-bearing exercise
  - Avoiding smoking
  - Avoiding excessive alcohol intake
  - Dietary calcium of 1,200 mg/day
  - Adequate vitamin D (800 to 1,200 IU daily)
  - Fall prevention

DIAGNOSIS

HISTORY

- Cessation of menses:
  - Generally preceded by a period of irregular cycles with heavy vaginal bleeding followed by diminished vaginal bleeding
- Vasomotor symptoms: sudden feeling of warmth, most commonly over face, neck, and chest, with average duration of ~3 minutes; intervals unpredictable
  - Most commonly reported symptom; reported by over 80% of women
  - Frequency and duration varies. 87% of women who report flushes experience them daily; ~33% have >10 per day. Mean duration of symptoms lasts 4 to 10.2 years and may begin during MT and extend well past menopause (1)[A].
  - Varies with ethnicity; greatest in African and Hispanic women and least in Asian women
  - More common in obese women
- Urogenital atrophy in up to 50% (2)[B]:
  - Vaginal/vulvar dryness discharge, itch, dyspareunia, and possible sexual dysfunction
  - Alkaline vaginal pH and atrophy increases risk of vaginal infections and UTIs.
  - Persists or worsens with aging
  - Urologic symptoms (urgency, frequency, dysuria, incontinence) not clearly correlated with MT
- Anxiety, depression: Some studies show a new diagnosis of depression is 2.5 times more likely to occur during the MT as compared to premenopause.
- Sleep disturbance: Arousal from sleep and chronic insomnia may be linked with vasomotor symptoms.
- Joint pain with unclear link to loss of estrogen
- Change in intensity and severity of migraines
- Skin thinning, mild hirsutism, brittle nails

Geriatric Considerations

Vaginal bleeding in postmenopausal women is abnormal; endometrial cancer/endometrioid adenocarcinoma (EAC) must be ruled out.

PHYSICAL EXAM

- Decrease in breast size and change in breast texture
- External, speculum, and bimanual pelvic exams: atrophic vulva and vaginal mucosa; increased risk for uterine prolapse

DIFFERENTIAL DIAGNOSIS

Pregnancy, hyperthyroidism and other thyroid disease, pituitary adenoma, Sheehan syndrome, hypothalamic dysfunction, anorexia nervosa, Asherman syndrome, obstruction of uterine outflow tract

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- U.S. Preventive Service Task Force (USPSTF) recommends mammogram every 2 years from ages 50 to 74 years.
- Lab testing for menopause is not required; the patient's age and symptoms establish the diagnosis.
- If laboratory confirmation is desired:
  - Elevated serum FSH level >30 mIU/mL indicates ovarian failure.
  - Symptoms may precede lab changes.
  - Infertility evaluation: may use elevated day 3 FSH, decreased anti-müllerian hormone levels, and decreased antral follicle count to predict decreased ovarian reserve
- Estrogens, androgens, and oral contraceptive pills (OCPs) may alter lab results.

Follow-Up Tests & Special Considerations

- Pregnancy test
- TSH and prolactin level if pituitary disease is suspected
- Vaginal bleeding in a postmenopausal patient should be evaluated by transvaginal ultrasound (TVUS) and/or endometrial biopsy (EMB). If endometrial stripe is <5 mm on TVUS, EAC is unlikely.
- USPSTF recommends bone mineral density (BMD) screening with dual energy x-ray absorptiometry (DEXA) scan in postmenopausal women >65 years, or <65 years if the risk for fracture is equivalent to that of a 65-year-old woman (using the FRAX tool to assess, http://www.shef.ac.uk/FRAX/). Risk factors include a previous history of fractures, low body weight, cigarette smoking, and family history of osteoporotic fracture.

Test Interpretation

- Abnormal BMD and DEXA scan results:
  - T-score on DEXA of −1 to −2.5 = osteopenia
  - T-score < −2.5 = osteoporosis
  - Defer to femoral neck T-score over spine T-score.
- Z-score measures age-matched mean bone density (not clinically useful).

TREATMENT

MEDICATION

First Line

Hormone therapy (HT): developing an individual risk–benefit profile is essential. Treatment goal is to minimize menopausal symptoms to improve quality of life.

- The primary indication for HT is the treatment of moderate to severe vasomotor symptoms.
  - Oral estrogen or estrogen-progestin mix can reduce weekly hot flush frequency ~75% (1)[A].
- HT also helpful with sleep disorders, urogenital atrophy, and lowers risk of osteoporotic fractures and colorectal cancer; may help with mood symptoms.
- In women with an intact uterus, give estrogen with progestin as unopposed estrogen carries an increased risk of EAC.
- Treatment regimens include, but are not limited to:
  - Standard dose: conjugated equine estrogen (CEE) 0.625 mg/day OR micronized estradiol 17β 1.0 mg/day OR transdermal estradiol 17β 0.0375 to 0.05 mg/day
  - Low dose: CEE 0.3 to 0.45 mg/day OR micronized estradiol 17β 0.5 mg/day OR transdermal estradiol 17β 0.025 mg/day
  - Ultra-low dose: micronized estradiol 17β 0.025 mg/day OR transdermal estradiol 17β 0.014 mg/day
  - Micronized progesterone 100 mg/day can be used as progestin. Alternative: medroxyprogesterone acetate (MPA) 2.5 mg/day. Combination estradiol/progestin transdermal treatments have either levonorgestrel or

norethindrone as progestin source. Although NOT approved for postmenopausal women, the levonorgestrel intrauterine system (IUS) has been used.
  - Bazedoxifene + conjugated estrogens for relief of vasomotor symptoms and bone loss prevention
- MenoPro app is free for iPhones and iPad from The North American Menopause Society (NAMS). It has two modes: one for clinicians and one for patients to aid in shared decision making. It allows users to progress through questions to evaluate cardiovascular and reproductive organ cancer risk (3).
- American Congress of Obstetricians and Gynecologists (ACOG) recommends HT should be individualized with lowest effect dose given for the shortest duration of time needed to relieve vasomotor symptoms. Lower doses have similar symptom reduction profiles for many patients. Results of ultra-low-dose regimens are mixed (4)[A].
- Although generally well tolerated, side effects of HT include breast tenderness, vaginal bleeding, bloating, and headaches.
- Precautions:
  - Women's Health Initiative (WHI) study demonstrate of every 10,000 women who take CEE with MPA, each year, there were 7 more CHD events, 8 more strokes, 8 more PEs, and 8 more invasive breast cancers independent of mammography screening frequency. Absolute risk reductions revealed 6 fewer colorectal cancers and 5 fewer hip fractures (5)[A].
  - Breast cancer risk not seen until 5 years of use.
  - Cardiovascular risks not seen until after age 60 years or 10 years from menopause.
  - Women on estrogen alone had no increased risk of breast cancer in the 8 years of the study and showed later cardiovascular risk compared to estrogen + progestin.
  - HT should NOT be used for cardioprotective benefit as risk outweighs benefit (6)[A].
  - Higher doses of estrogen can cause hypercoagulability, breast tenderness, gallbladder disease, and hypertension (HTN).
  - Contraindications to HT:

    - Estrogen-dependent malignancies
    - Unexplained uterine bleeding
    - History of thromboembolism or stroke
    - CAD
    - Active liver disease
- For osteoporosis: women with a history of hip or vertebral fracture or personal history of osteoporosis should be treated with one of the following:
  - Bisphosphonates to inhibit osteoclast action and resorption of bone:
    - Alendronate: 70 mg/week or 10 mg/day
    - Risedronate: 35 mg once a week or 5 mg/day
    - Zoledronic acid: 5 mg IV annually
    - Ibandronate:150 mg/month PO or 3 mg IV q3mo
  - Selective estrogen receptor modulators (SERMs) selectively inhibit or stimulate estrogen-like action with stimulation of osteoblasts:
    - Raloxifene: 60 mg/day
      - Decreases the risk of vertebral fracture but failed to demonstrate a decrease in the risk of extravertebral fractures.
    - Bazedoxifene + conjugated estrogens (0.45 mg/20 mg)
      - FDA approved for moderate to severe vasomotor symptoms and osteoporosis.
  - Denosumab (60 mg SC every 6 months) is a monoclonal antibody that prevents RANKL (receptor activator of nuclear factor kappa-B ligand) from accelerating osteoclast generation. Reduces incidence of vertebral and hip fractures in postmenopausal women
  - Parathyroid hormone—rarely used due to the adverse effect on bone but shown to reduce fracture risk in menopausal women with osteoporosis
- For vulvar/vaginal atrophy:
  - Topical estrogen therapy (ET) reverses vaginal atrophy, enhances blood flow, and reduces UTI. Continue for as long as distressing symptoms remain. Initiate treatment daily for 1 to 2 weeks, then decreased to 2 times weekly. Comes as estradiol cream, tablet, or ring. Apply vaginally:
    - Estradiol cream 0.01% (1 g), conjugated **estrogen** 0.625 mg/g (0.5 g), vaginal tablet (10 μg) used twice weekly, or vaginal ring (7.5 μg daily lasting for 3 months)

    - Ospemifene: 60 mg PO daily. SERM for moderate to severe dyspareunia associated with vaginal atrophy
- Although there is no increased risk of endometrial hyperplasia or EAC, women with bleeding on these treatments should be evaluated with TVUS or EMB. Patients with h/o hormone-dependent cancer should meet with a gynecologist before using medication.

Second Line

Nonhormonal treatments may be helpful to treat vasomotor symptoms in women who wish to or need to avoid HT (e.g., breast cancer):

- Paroxetine (7.5 mg/day) is approved for treatment of vasomotor symptoms. This SSRI demonstrated modest decrease in hot flushes.
- Other SSRI/SSNIs: venlafaxine (37.5 to 75 mg/day) or fluoxetine (20 mg/day) and citalopram (20 mg/day) shown to reduce hot flushes as compared to placebo
- Gabapentin (300 to 900 mg/day) shown to have an effect on lowering hot flushes compared to placebo
- Clonidine (.05 mg BID) may be used to treat mild hot flashes, less effective than SSRI/SRNIs.
- Note that most trials of second-line therapies have been brief (i.e., a few months).

COMPLEMENTARY & ALTERNATIVE MEDICINE

Trials of nonprescribed therapies are difficult to interpret due to variability of components and doses:

- Soy isoflavone in placebo-controlled trials showed a mixed effect in reducing hot flashes.
- Red clover, black cohosh, reflexology, aerobics, and magnet therapy showed no impact on hot flashes when compared with placebo.
- Small clinical trials of evening primrose, dong quai, ginseng, and wild yam do not support use for relief of hot flashes.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

A DEXA scan is indicated at age 65 years for all women and for younger women with risk equivalent to age 65 years.

DIET

Calcium-rich diet and vitamin D supplementation (800 to 1,200 IU/day). Calcium supplements may have adverse effects including increased risk of kidney stone and increased risk of cardiac events.

PATIENT EDUCATION

Encourage lifestyle modifications:

- Smoking cessation
- Weight-bearing exercise >30 minutes, 3 times weekly
- Healthy diet to maintain appropriate weight
- Avoid excess alcohol.
- Address cardiovascular risk factor modification.

PROGNOSIS

If untreated:

- Ultimate disappearance of vasomotor symptoms
- Worsening of vaginal/vulvar atrophy
- Osteoporosis: possible fractures of the hip, vertebrae, and wrists

COMPLICATIONS

- Osteoporosis: At menopause, women have accelerated bone loss up to 3–5% per year for 5 to 7 years.
- Increased risk of CVD following menopause

CODES

ICD10

- E28.310 Symptomatic premature menopause
- N95.1 Menopausal and female climacteric states
- Z78.0 Asymptomatic menopausal state

CLINICAL PEARLS

- Menopause is usually diagnosed by history alone.
- HT can be used short term for relief of moderate to severe vasomotor symptoms but should not be used for long-term prevention of CVD.

MENORRHAGIA (HEAVY MENSTRUAL BLEEDING)

Samantha M. Rupert, MD • Lorna Fountain, MD, FAAFP

BASICS

DESCRIPTION

- The current preferred terminology for menorrhagia is “heavy menstrual bleeding” (HMB), a subcategory of “abnormal uterine bleeding” (AUB).
- HMB is an excessive amount (≥80 mL/cycle, compared with normal average of 30 to 60 mL/cycle) or periods lasting longer than 7 days.
- HMB applies only to ovulatory menses.
- Other patterns of AUB which may overlap with HMB include:
  - Intermenstrual bleeding (IMB; previously metrorrhagia): bleeding between regular menses
  - Polymenorrhea: menstrual cycle length <21 days
- System affected: reproductive

EPIDEMIOLOGY

Prevalence

- AUB, including HMB, is thought to affect between 9% and 14% of women between menarche and menopause (1).
- AUB is more common close to menarche and menopause.

Pediatric Considerations

- Genital bleeding before puberty is not menstrual bleeding by definition and requires further evaluation.
- Due to immaturity of the hypothalamic-pituitary-ovarian axis, adolescents are at risk of irregular bleeding and HMB.
- Adolescents with HMB should be evaluated for possible bleeding disorders, especially von Willebrand disease (2)[C].

Pregnancy Considerations

Bleeding in pregnancy is not menstrual bleeding by definition and requires

further evaluation. Pregnancy test should be obtained as part of the evaluation of abnormal uterine bleeding.

Geriatric Considerations

Menopause is diagnosed after 12 months of amenorrhea in the absence of other causes and is typically preceded by irregular bleeding. All postmenopausal bleeding requires additional workup for malignancy.

ETIOLOGY AND PATHOPHYSIOLOGY

- No cause is identified in about 1/2 of patients.
- Bleeding disorders
  - Von Willebrand disease (present in about 13% of patients) (1)
  - ITP and other platelet disorders
  - Factor deficiencies
  - Medication side effect most commonly related to anticoagulants including warfarin
  - Renal failure leading to uremic platelet dysfunction
  - Cirrhosis leading to coagulopathy
- Uterine fibroids, typically submucosal
- Endometrial polyps
- Hypothyroidism
- Iatrogenic causes including copper IUD
- Endometriosis
- Adenomyosis
- Pelvic inflammatory disease
- Some causes more typically presenting as irregular menstrual bleeding include:
  - Polycystic ovarian syndrome (PCOS)
  - Hypothalamic-pituitary dysfunction, often postmenarchal or during menopausal transition
  - Endometrial or ovarian neoplasia
  - Some forms of hormonal birth control
  - Hyperthyroidism
  - Hyperprolactinemia
- HMB has been associated with increased production and sensitivity to

prostaglandins.

GENERAL PREVENTION

- Combined oral contraceptives may prevent HMB, particularly when progesterone is dominant. Lower estrogen doses result in less menstrual bleeding.
- NSAIDs including ibuprofen inhibit prostaglandin production and result in decreased blood loss and pain during menses.
- Progesterone-only contraceptives may reduce overall blood loss but often result in irregular bleeding.

COMMONLY ASSOCIATED CONDITIONS

Iron deficiency anemia

DIAGNOSIS

HISTORY

- Suggestive historical features for HMB:
  - Bleeding substantially heavier than patient's usual flow
  - Changing sanitary products every 1 to 2 hours or the need to change protection overnight
  - Menses lasting >7 days
  - Passage of clots larger than a quarter in diameter
- Symptoms that suggest bleeding is ovulatory:
  - Regular menstrual interval
  - Midcycle pain (mittelschmerz)
  - Premenstrual symptoms: breast soreness, mood changes
- Abdominal pain or cramps at other times of the cycle may be associated with structural causes:
  - Polyps
  - Adenomyosis
  - Leiomyoma
  - Ovarian tumors
- Symptoms that suggest an underlying bleeding disorder include:
  - Epistaxis

  - Mucosal bleeding (e.g., gums)
  - Easy bruising
  - Family history of bleeding disorder
- Review of medications, with particular attention to contraceptive and anticoagulant medication
- Other medical conditions that may relate to HMB:
  - Renal or hepatic disease
  - Thyroid disease
- Evaluate for symptoms of anemia including fatigue and dyspnea.

PHYSICAL EXAM

- Prompt assessment for signs of hemodynamic instability, including orthostatic vital signs (3).
- Thyroid nodule or goiter suggests thyroid disease.
- Signs of a bleeding disorder include petechiae and ecchymoses.
- Pelvic examination, including speculum and bimanual examination, may reveal the following:
  - Cervical or vaginal source of bleeding
  - Pelvic or adnexal mass
  - Evidence of reproductive tract infection such as cervical motion tenderness
  - Uterine enlargement
- Hirsutism, acne, and obesity are suggestive of PCOS.

DIFFERENTIAL DIAGNOSIS

- Normal menses
- Anovulatory bleeding
- Intermenstrual bleeding
- Complications of pregnancy
  - Spontaneous abortion
- Other sources of bleeding:
  - Cervical
  - Vaginal
  - Gastrointestinal

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Pregnancy test
- CBC to assess for:
  - Anemia
  - Thrombocytopenia
  - Leukocytosis may suggest infection.
- Thyroid-stimulating hormone (TSH) test
- Labs to consider in select cases:
  - Coagulation panel for evaluation for bleeding disorder in adolescent or adult with history suggestive of bleeding disorder
  - Workup of anovulatory bleeding may also include prolactin, androgens, FSH, LH, and estrogen.
  - Appropriate cervical cancer screening
  - Evaluation for infection including gonorrhea and chlamydia
- Imaging should be obtained based on clinician judgment and should begin with transvaginal ultrasonography.
- Transabdominal ultrasonography should be performed if transvaginal approach does not provide full assessment of anatomy.

Follow-Up Tests & Special Considerations

- Saline infusion sonohysterography recommended if ultrasound suggests intracavitary pathology and is more sensitive and specific than transvaginal ultrasound (1)[C]
- Hysteroscopy can be performed if direct visualization is desired.

Diagnostic Procedures/Other

Endometrial biopsy to assess for malignancy and hyperplasia is recommended in some situations including (3)[C]:

- Any AUB, including HMB, after age 45 years in an ovulatory (premenopausal) woman
- Woman <45 years with persistent or refractory AUB, risk factors such as unopposed estrogen exposure, or concerning endometrial imaging

TREATMENT

GENERAL MEASURES

Treat underlying conditions (e.g., hypothyroidism) when possible.

MEDICATION

First Line

- For acute control of severe bleeding (4):
  - Obtain IV access and consider blood transfusion or clotting factor administration.
  - Estrogen, conjugated equine: 25 mg IV every 4 to 6 hours for 24 hours
  - Monophasic combined oral contraceptive that contains 35 μg ethinyl estradiol: 3 times per day for 7 days
  - Medroxyprogesterone acetate: 20 mg orally 3 times per day for 7 days
  - Tranexamic acid: 1.3 g orally or 10 mg/kg IV 3 times per day for 5 days, antifibrinolytic agent
- For less severe bleeding (typical case) or after control of acute bleeding has been achieved (1):
  - Levonorgestrel intrauterine device (Mirena IUD): typically results in light bleeding or amenorrhea with patient satisfaction similar to hysterectomy and endometrial ablation (5)[A]
  - Combination estrogen-progestin oral contraceptive: may be prescribed in cyclic, extended, or continuous dosing and typically results in regular, lighter, and less painful menses
  - Depot medroxyprogesterone acetate: 150 mg/1 mL IM every 3 months, typically results in amenorrhea or light irregular bleeding
  - Tranexamic acid: 1.3 g orally for 5 days during menses; antifibrinolytic agent that is option for women who desire nonhormonal treatment.
  - NSAIDs (e.g., naproxen, mefenamic acid, ibuprofen) can reduce blood loss and dysmenorrheal (1)[B].

Second Line

- Noncontraception estrogen-progestin oral contraceptives (ultra-low-dose estrogen): may be considered when a relative contraindication to estrogen is present
- Oral progestins: multiple formulations and dosing; typically used in women who have contraindications to estrogen or are trying to conceive

SURGERY/OTHER PROCEDURES

- Dilation and curettage can be considered in the setting of acute severe bleeding.
- For women who desire fertility, myomectomy may be considered for treatment of uterine leiomyomas (fibroids).
- For women who do not desire fertility, consider endometrial ablation, uterine artery embolization, or hysterectomy.
  - Endometrial ablation shows similar outcomes to levonorgestrel IUD, patients still require contraception.
  - Uterine artery embolization is used to treat uterine leiomyomas.
  - Hysterectomy is curative but with significant complications and long recovery, typically reserved for failure of medical management or presence of another indication such as malignancy.

ONGOING CARE

DIET

Iron supplementation may help correct for increased blood loss.

PATIENT EDUCATION

Patient and provider should engage in informed decision making with understanding of treatment risks and benefits

PROGNOSIS

Most patients respond well to medical management, and hysterectomy is curative option in appropriate cases.

COMPLICATIONS

- Iron deficiency anemia
- Acute severe blood loss

5. Lethaby A, Hussain M, Rishworth JR, et al. Progesterone or progestogen-releasing intrauterine systems for heavy menstrual bleeding. *Cochrane Database Syst Rev*. 2015;(4):CD002126.

CODES

ICD10

- N92.0 Excessive and frequent menstruation with regular cycle
- N92.3 Ovulation bleeding
- N92.2 Excessive menstruation at puberty

CLINICAL PEARLS

- Women with heavy menstrual bleeding are at high risk for iron deficiency anemia.
- A thorough menstrual history is critical to differentiate heavy menstrual bleeding from similar conditions including anovulatory bleeding.
- Teenagers presenting with heavy menstrual bleeding should be evaluated for an underlying bleeding disorder.
- All postmenopausal bleeding and bleeding during pregnancy requires additional workup.
- The Levonorgestrel (Mirena, generics) intrauterine device may be used for heavy menstrual bleeding and is associated with high patient satisfaction rates.

MESENTERIC ADENITIS

Anne Walsh, MMSc, PA-C, DFAAPA • Kashyap Trivedi, MD

BASICS

Inflammation of the mesenteric lymph nodes. A common cause of self-limited RLQ abdominal pain.

DESCRIPTION

- Characterized by benign inflammation of the mesenteric lymph nodes; can be acute or chronic
- May clinically mimic acute appendicitis

EPIDEMIOLOGY

- Commonly misdiagnosed, making definitive incidence unknown
- Most common cause of appendicitis-like pain in children (1)
  - 20% in patients presenting for appendectomy (2)
- More common in children <15 years old than in adults
  - Primary adenitis is more common in children.
  - Secondary adenitis is more common in adults.
    - Rule out diverticulitis, appendicitis, Crohn disease, or systemic infectious/inflammatory disease (e.g., HIV, SLE).

Prevalence

Affects males and females equally.

- Adenitis secondary to *Yersinia* infection is more prevalent in boys than girls.
  - *Yersinia enterocolitica* is most common in North America, Eastern Europe, and Australia.

ETIOLOGY AND PATHOPHYSIOLOGY

- Primary: underlying inflammatory process not present; presumed due to acute infectious gastroenteritis (specifically, terminal ileitis)
- Secondary: underlying inflammatory process present (see "Commonly Associated Conditions")

- In infectious etiologies, pathogens are ingested, translocate through the intestinal epithelium via Peyer patches, and gain access to mesenteric lymph nodes. An inflammatory reaction within mesenteric lymph nodes causes symptoms and clinical disease. Infectious agents include:
  - *Y. enterocolitica*
  - *Campylobacter jejuni*
  - *Salmonella typhi*
  - *β-Hemolytic Streptococcus* spp.
  - *Staphylococcus* spp.
  - *Streptococcus viridans*
  - *Escherichia coli*
  - *Mycobacterium tuberculosis*
  - *Giardia lamblia*
  - Epstein-Barr virus (EBV)
  - Acute HIV infection
  - Rubeola virus
  - Cat-scratch disease
  - Adenovirus species

Genetics

No known genetic susceptibility

RISK FACTORS

- Typically preceded by URI or pharyngitis
- History of ingesting undercooked pork particularly in areas where *Yersinia* is endemic (parts of Europe).

GENERAL PREVENTION

Minimize risk by fully cooking foods, especially meat.

COMMONLY ASSOCIATED CONDITIONS

- Appendicitis
- Diverticulitis
- Crohn disease
- Celiac disease
- Other systemic inflammatory/autoimmune disease

DIAGNOSIS

HISTORY

The onset of symptoms is variable; nausea or abdominal pain is usually the initial presenting symptom. Symptoms are often nonspecific.

- Nausea and vomiting (may precede abdominal pain)
- Abdominal pain: periumbilical, RLQ
- Diarrhea
- Fever, malaise, fatigue, anorexia
- Recent history of upper respiratory tract infection

PHYSICAL EXAM

- Fever; can have toxic appearance
- Abdominal tenderness; (with or without rebound and often in the RLQ)
- Peripheral/generalized lymphadenopathy
- Rectal tenderness
- Rhinorrhea
- Pharyngeal hyperemia

DIFFERENTIAL DIAGNOSIS

- Appendicitis, intussusception, intestinal duplication, regional enteritis (Crohn disease), Meckel diverticulitis, ulcerative colitis
- Epiploic appendagitis, mesenteric ischemia
- UTI, pyelonephritis
- Salpingitis, PID, ectopic pregnancy
- Neoplasm (e.g., lymphoma)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- CBC: leukocytosis with left shift
- Basic metabolic panel may show electrolyte disturbances and azotemia if dehydrated and/or alkalotic from recalcitrant vomiting.
- β-HCG in women of childbearing potential
- Stool cultures if diarrhea
- Serologies if specific infectious agent suspected

- Blood cultures if septic
- CT scan: enlarged mesenteric lymph nodes (larger in size, number, and distribution than appendicitis)
  - Specific CT appearance includes ≥3 clustered lymph nodes measuring at least 5 mm in the short axis, most commonly to the right of the psoas muscle (3)[B].
  - May or may not have evidence of ileal or ileocecal wall thickening
  - Appendix appears normal.
- Ultrasound: less sensitive; used for exclusion of other potential diagnoses
  - Preferred in children and women (1)[C]
  - Used to evaluate for signs of appendicitis (96% positive predictive value in children) (2)[B]

Diagnostic Procedures/Other

Lymph node biopsy: only for those undergoing laparotomy can isolate the causative organism

Test Interpretation

- Lymph nodes are enlarged and soft.
- Adjoining mesentery may be edematous.
- Microscopically, lymph nodes display nonspecific hyperplasia. If a suppurative infection is present, lymph nodes may contain necrotic material with pus formation.
  - Lymphatic sinuses may be enlarged.
  - If *Y. enterocolitica* infection, lymph node capsule may be thickened, with surrounding edema; lymph node hyperplasia, with plasma cell infiltration also occur.

TREATMENT

MEDICATION

First Line

- Supportive and symptomatic treatment for uncomplicated cases
- IV fluid resuscitation if hypovolemic

- Correct underlying electrolyte aberrations.
- Pain control

Second Line

- Broad-spectrum antibiotic therapy for moderately to severely ill patients if diagnosis is unclear pending workup and/or surgical evaluation
- Treatment duration varies based on cause and severity of illness. For uncomplicated cases, antibiotic treatment is not necessary.

SURGERY/OTHER PROCEDURES

Surgery is usually indicated in cases of suppuration and/or abscess formation, with signs of peritonitis, or if acute appendicitis cannot be excluded with certainty.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Admit patients with complications and/or hemodynamic instability.
- Volume resuscitation and correction of underlying electrolyte abnormalities
- IV fluids may be indicated for patients who cannot tolerate PO intake due to nausea or vomiting.
- Aggressive fluid hydration is indicated if there is any evidence of sepsis.
- Discharge criteria: hemodynamic stability, able to tolerate PO diet, able to follow up in the outpatient setting

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Close outpatient monitoring is needed to ensure total resolution of symptoms.

DIET

There are no specific dietary recommendations. Hold oral intake as necessary until nausea and vomiting resolve. Advance diet slowly as tolerated.

PATIENT EDUCATION

In cases of *Yersinia* infection, patients should avoid unpasteurized milk, raw

pork, and contaminated water.

PROGNOSIS

- Generally self-limiting and benign condition
- Increased morbidity/mortality for patients presenting with sepsis

COMPLICATIONS

- Increased GI losses leading to hypovolemia and electrolyte imbalance
- Abscess formation, peritonitis, sepsis
- Latent extraintestinal manifestations, including arthralgias, truncal and extremity rashes, and erythema nodosum with *Y. enterocolitica* infection
- Postinfectious chronic complications of *Yersinia* infection including reactive arthritis, conjunctivitis, urethritis; postinfectious irritable bowel syndrome

CODES

ICD10

I88.0 Nonspecific mesenteric lymphadenitis

CLINICAL PEARLS

- Mesenteric adenitis is an inflammatory process that mimics appendicitis. Diagnosis requires imaging to distinguish from acute appendicitis.
- The condition is more common in children, often following a URI.
- The treatment is generally supportive care.

MESOTHELIOMA

Khalid Bashir, MD

BASICS

DESCRIPTION

- Mesothelioma is a rare, aggressive malignancy of the mesothelial or serous tissues primarily found in the pleura (65–70%) or peritoneum (20–33%), tunica vaginalis (1–2%) or pericardium (1–2%) (1).
- Inhalation of asbestos is the predominant cause of mesothelioma, most often from occupational exposure.

EPIDEMIOLOGY

Incidence

- The incidence in the United States is decreasing, but it is increasing in other countries, particularly Great Britain and Australia.
- It is expected that rates of mesothelioma will start to drop after 2015 to 2025 related to reduced exposure and better understanding of the process of development of mesothelioma after exposure to asbestos (2).
- The incidence increases with age, peaking in the 6th decade, with 70% of pleural disease occurring in males. Peritoneal involvement is slightly higher in women.
- Main risk factor is asbestos exposure, but tumors have arisen after prior radiation or exposure to talc, erionite, or mica or in patients with familial Mediterranean fever and diffuse lymphocytic leukemia.

Prevalence

There are 3,300 cases of mesothelioma diagnosed in the United States annually (3).

ETIOLOGY AND PATHOPHYSIOLOGY

- The predominant cause of mesothelioma is exposure to asbestos (hydrated magnesium silicate fibrous minerals).
- There is a long latent period of up to 44 years between exposure and

development of mesothelioma (2).
- Inhaled or ingested asbestos fibers become trapped in pleural or peritoneal membranes causing changes of irritation and inflammation.

Genetics

Loss of nuclear deubiquitinase BAP1 is associated with incidence of mesothelioma in some families as well as with other cancers such as melanoma.

RISK FACTORS

- The predominant risk factor is exposure to asbestos.
- Occupational exposures involve mining or milling of fibers, work with textiles, cement, friction materials, insulation, or shipbuilding.
- Nonoccupational exposures include renovation or destruction of asbestos-containing buildings, exposure to industrial sources in the community or natural geologic sources, or exposure to soiled clothing of asbestos workers (1,3,4).
- Radiation exposure, smoking, proximity to naturally occurring asbestos deposits, or inhalation of other fibrous silicates can contribute to malignant mesothelioma.

GENERAL PREVENTION

- Avoidance of asbestos exposure
- Strict adherence to protective protocols for workers in buildings where asbestos is found
- Continued aggressive remediation of asbestos-affected buildings and homes

DIAGNOSIS

HISTORY

- Symptoms are usually nonspecific and occur when disease is advanced. General fatigue, night sweats, and weight loss may be present.
- Pleural mesothelioma presents with gradual onset of pulmonary symptoms, chest pain, dyspnea, and cough.
- Peritoneal disease presents with vague abdominal pain, increased abdominal girth, nausea, anorexia, and weight loss.

PHYSICAL EXAM

- Pulmonary findings consistent with pleural effusion including decreased breath sounds, dullness to percussion, asymmetric chest wall expansion are found.
- Abdominal findings consistent with ascites including abdominal distension, fluid wave, and tenderness are found.

DIFFERENTIAL DIAGNOSIS

- Pleural mesothelioma's differential diagnosis includes inflammatory reactions (empyema, pleural effusion), metastatic tumor from other sites, fibrosarcoma, malignant fibrous histiocytoma, sarcomatoid carcinoma, and synovial sarcoma.
- Peritoneal mesothelioma's differential diagnosis includes peritoneal carcinomatosis, serous peritoneal carcinoma, ovarian carcinoma in women, lymphomatosis, and tuberculous peritonitis.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- At present, there is no tumor marker or serum chemistry that is of value in establishing the diagnosis of mesothelioma.
- Biomarkers that may be elevated in mesothelioma include fibulin-3, mesothelin, and osteopontin. However, they do not have an established role in diagnosis or monitoring response to therapy (2)[A].
- Pleural mesothelioma diagnosis requires tissue. Thoracentesis for cytology and closed pleural biopsy may be adequate, but often, more invasive procedures such as video-assisted thoracoscopic surgery (VATS) is needed to obtain an adequate specimen (1,2)[A].

Follow-Up Tests & Special Considerations

Seeding of biopsy sites and tracks may occur in mesothelioma, which can be prevented with prophylactic radiation therapy to the scar or biopsy site (5)[A].

Diagnostic Procedures/Other

- CT, MRI, PET, or integrated PET-CT helps with clinical staging in pleural and peritoneal disease (1,2,3,4),(5)[A].
- Mediastinoscopy, bronchoscopy, and laparoscopy can assist in full surgical

staging of pleural disease (2)[A].

- Endobronchial ultrasound for staging is under investigation for pleural disease.

Test Interpretation

- The tumor, node, metastasis (TNM) staging system is most commonly used although some centers use other staging systems.
- Butchart staging system is the oldest and still used in some parts of the world.
- Brigham staging system attempts to define resectability and lymph node involvement.

TREATMENT

GENERAL MEASURES

- A multidisciplinary team is important in management and should include thoracic surgery, oncology, pathology, pulmonary, and radiology for patient-specific planning of management.
- Pain assessment and control should follow principles of cancer pain management (5).

MEDICATION

First Line

- In pleural disease, combined therapy with cisplatin + gemcitabine or cisplatin + pemetrexed are associated with longer median survival than cisplatin alone (2),(4)[A].
- Vinflunine is showing some potential for first-line treatment in pleural disease (2)[A].
- Hyperthermic intraoperative or early postoperative intraperitoneal chemotherapy can increase drug concentration in the peritoneum and decrease systemic side effects. Use cisplatin, mitomycin C, fluorouracil, doxorubicin, and/or paclitaxel (1,2),(3)[A].

Second Line

- Palliative benefit in pleural disease with mitomycin C, vinblastine, cisplatin, and pemetrexed alone or in combination with carboplatin (2,3),(4)[A]

- Systemic therapy for peritoneal disease may include pemetrexed + cisplatin; vinorelbine or gemcitabine alone or in combination (1),(5)[A]

ISSUES FOR REFERRAL

- Pulmonary, oncology, and surgical follow-up after discharge as indicated
- Anger and depression may require psychological or psychiatric services (5).

ADDITIONAL THERAPIES

Immunotherapy in pleural disease uses humanized anti-CB3 AB (OKT3), cytotoxic T lymph (CTL), interferon α-2a, and autovaccine in advanced disease (1,2,3,4,5)

- Gene therapy
- Photodynamic therapy
- Radiotherapy in some cases of pleural disease
- Vascular endothelial growth factor (anti-VEGF-2) in combination with chemotherapy (2)
  - Vaccines are under study (5).

SURGERY/OTHER PROCEDURES

- For pleural mesothelioma, the role of surgery is not as clear cut. Pleurectomy with tumor decortication and extrapleural pneumonectomy reduce the tumor load, but there remains no clear effect on mortality (2,4,5).
- Radical resection of the peritoneum and cytoreductive surgery is associated with a better prognosis (1).

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Based on overall condition
- IV fluids as indicated by general condition
- Nursing as indicated by condition
- Discharge criteria as indicated by general condition

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Smoking cessation
- Immunization for pneumococcal pneumonia and influenza

Patient Monitoring

Monitor for paraneoplastic phenomenon including fever, thrombocytosis, malignancy-related thrombosis, hypoglycemia, and rare Coombs-positive hemolytic anemia.

DIET

No specific restrictions

PROGNOSIS

- Prognosis is based on gender, stage, and level of completeness of cytoreduction.
- Poorly differentiated tumor grade, failure to undertake surgical resection, advanced age, and male gender are all independent predictors of poorer prognosis (2,3).
- Average survival is 17 to 92 months, with 5-year survival rate at 63%.

COMPLICATIONS

Relapses and progression, infection and dysphagia

Geriatric Considerations

Age >65 years is associated with significantly increased morbidity and mortality.

Pediatric Considerations

Rarely a pediatric issue, as most disease occurs after the 5th decade of life.

Pregnancy Considerations

Rarely an issue with pregnancy, as most disease occurs after the 5th decade of life.

CODES

ICD10

- C45.9 Mesothelioma, unspecified
- C45.0 Mesothelioma of pleura
- C45.1 Mesothelioma of peritoneum

CLINICAL PEARLS

- Mesothelioma remains a rare but universally fatal disease in part due to long latency.
- Multimodal treatment has decreased recurrence rates and has extended survival time.

METABOLIC SYNDROME

Naomi Parrella, MD

BASICS

DESCRIPTION

- Progressive metabolic abnormalities including insulin resistance, a proinflammatory and prothrombotic state that manifest with at least 3 of:
  - Increased waist circumference (WC)
  - Elevated blood pressure (BP)
  - Elevated triglycerides (TG)
  - Decreased high-density lipoprotein (HDL-C)
  - Elevated fasting glucose
- Metabolic syndrome (MetS) predicts increased risk for type 2 diabetes mellitus (T2DM), cardiovascular disease, stroke, nonalcoholic fatty liver disease (NAFLD), and certain cancers.

EPIDEMIOLOGY

- Predominant age: >60 years old (~50% of cases)
- Predominant sex: male = female
- Ethnicity: Mexican Americans (highest risk)

Prevalence

- Affects 34% of U.S. adults aged >20 years; increasing with the aging population and the prevalence of obesity (1).
- Data vary among race and ethnicity with different trends for women and men. The available literature suggests that MetS is a rapidly growing epidemic worldwide.

Pediatric Considerations

- Obese children and adolescents are at high risk of MetS (prevalence of 6.4% in the United States). Risk factors in children and adolescents include heredity, low birth weight, childhood weight gain and obesity, endocrine abnormalities, hostility, maternal gestational diabetes, and poor health habits.

- International Diabetes Federation consensus report defined criteria in three age groups (6 to ≤10 years; 10 to ≤16 years; 16+ years, adult criteria applicable). Obesity defined by WC ≥90th percentile; rest of the diagnostic criteria TG, HDL-C, hypertension [HTN], and fasting blood sugar/T2DM) are largely the same as in adults for children ≥10 years, with some exceptions, and warrant treatment to optimize diet and physical activity.
- Clinical significance of MetS in pediatric population is not well established using these criteria. WC alone is better than using IDF criteria to predict development of MetS, abnormal BP, dyslipidemia, and insulin resistance (2). Focus on promoting healthy lifestyle habits and weight management rather than diagnosis.

ETIOLOGY AND PATHOPHYSIOLOGY

- Increase in intra-abdominal and visceral adipose tissue
- Adipose tissue dysfunction and insulin resistance
- Decreased levels of adiponectin, an adipocytokine, known to protect against T2DM, HTN, atherosclerosis, and inflammation
- Abnormal fatty acid metabolism, endothelial dysfunction, systemic inflammation, oxidative stress, elevated renin-angiotensin system activation, and a prothrombotic state (increased tissue plasminogen activator inhibitor-1) are also associated.
- The main etiologic factors are the following:
  - Central obesity (particularly abdominal)/excess visceral adipose tissue
  - Insulin resistance
  - Other contributing factors:
    - Advancing age
    - Proinflammatory state
    - Genetics
- Endocrine (e.g., postmenopausal state)

Genetics

Genetic factors contribute significantly to causation. Most identified genes are transcription factors or regulators of transcription and translation. It is a multifactorial disease with evidence of complex interactions between genetics and environment.

RISK FACTORS

- Obesity/intra-abdominal obesity
- Childhood obesity
- Insulin resistance
- Older age
- Ethnicity
- Family history
- Physical inactivity
- High-carbohydrate diet
- Sugar-sweetened beverages daily
- Smoking
- Postmenopausal status
- Low socioeconomic status
- Alteration of gut flora

GENERAL PREVENTION

- Effective weight loss and maintenance of normal body weight long term
- Regular and sustained physical activity
- Diet low in processed carbohydrates and simple sugars

COMMONLY ASSOCIATED CONDITIONS

- Polycystic ovary syndrome
- NAFLD
- Acanthosis nigricans
- Chronic renal disease
- Depression
- Cognitive impairment
- Obstructive sleep apnea
- Gallstones (cholesterol)
- Erectile dysfunction (in men)
- Hyperuricemia and gout
- Vitamin D deficiency

DIAGNOSIS

HISTORY

Not necessary for diagnosis of MetS, useful in identifying risk factors and beneficial preventive strategies

- Family history of MetS, T2DM, and cardiovascular disease
- Symptoms indicating cardiovascular disease or diabetes
- Comprehensive lifestyle history:
  - Diet, including timing and intake of carbohydrates including sugars
  - Weight history, including onset of obesity and previous weight loss attempts
  - Exercise regimen, daily activity level
  - Alcohol intake
- Cigarette smoking
- Assess cardiovascular risk with cardiovascular risk assessment tool.

PHYSICAL EXAM

Various criteria-based definitions have been proposed and in 2009, harmonized (3). A diagnosis of MetS can be made when ≥3 of the following 5 characteristics are present:

- Abdominal obesity: men >102 cm, women >88 cm (ATP III recommends lowering threshold in population susceptible to insulin resistance, especially Asian Americans)
- BP ≥130/85 mm Hg or treatment
- TGs ≥150 mg/dL or treatment
- HDL: men >40 mg/dL, women <50 mg/dL or treatment
- Fasting glucose ≥100 mg/dL or treatment

DIFFERENTIAL DIAGNOSIS

- T2DM
- Obstructive sleep apnea, thyroid abnormalities, Cushing syndrome, medication effect (especially psychotropic, chronic steroids, β-blockers, and thiazide diuretic medications) may also be considered in the differential.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Fasting lipids (particularly TGs and HDL)
- Fasting glucose

Follow-Up Tests & Special Considerations

- Formal 75-mg oral glucose tolerance test or hemoglobin A1C for diagnosis of impaired glucose tolerance (IGT)
- Liver function tests (assess for NAFLD, consider use of statin)
- Measurement of fasting insulin levels is controversial.
- Microalbuminuria
- Increased WBC count
- Increased C-reactive protein
- Increased fibrinogen
- Increased proinflammatory cytokines (e.g., tumor necrosis factor-α)
- Increased uric acid
- Increased homocysteine
- Vitamin D deficiency

Diagnostic Procedures/Other

- Home BP monitoring or 24-hour BP monitoring may be used to rule out white coat HTN.
- ECG, stress test, and coronary angiography may be used for diagnosis of cardiovascular disease arising as a complication of the syndrome.

TREATMENT

Primary therapeutic goal is to prevent or reduce obesity and risk factors. Aggressive lifestyle modification (diet and exercise) is considered first-line therapy and most clinically effective (4)[C].

GENERAL MEASURES

- Aggressive treatment of individual risk factors
- Increase daily physical activity.
- Avoid or stop smoking.
- Avoid excess alcohol intake.
- Avoid sugar sweetened beverages.
- Avoid high glycemic load meals and snacks that cause rapid insulin release.
- Increase leafy green vegetables.

MEDICATION

- Daily treatment with aspirin is recommended for patients with cardiovascular disease or those at high risk.
- Consult clinical guidelines for treatment of dyslipidemia, HTN, IGT, and diabetes.
- Multiple medications may be required to achieve adequate BP control.
- Diagnosis and treatment of insulin resistance is controversial.

First Line

Lifestyle modification alone as initial strategy is applicable to individuals with low 10-year risk for coronary artery disease (CAD). In individuals with higher 10-year risk, more aggressive risk factor–based approach is recommended in addition to lifestyle modifications:

- Obesity: Lifestyle changes are the cornerstone of treatment. Aim for a ~5–10% weight reduction. Any amount of weight loss is associated with significant benefits.
  - Phentermine–topiramate (delayed release) (Qsymia) (5)[A] and lorcaserin (Belviq) (6)[A] have been approved by the FDA for nonpregnant, nonlactating adults for management of obesity with promising outcomes on weight, BP, dyslipidemia, and other metabolic/glycemic parameters.
- Physical activity: Endurance exercise may reverse MetS (7)[A]. 30 to 60 minutes of moderate-intensity aerobic activities such as brisk walking 5 to 7 days/week; increase in daily lifestyle activities and resistance training 1 to 2 days/week. In patients with established CAD, assess detailed history of physical activity and exercise tolerance to guide activity prescription. Advise medically supervised programs for high-risk population (recent acute coronary syndrome [ACS], congestive heart failure, recent revascularization). Cumulative exercise time over the day contributes to health benefit.
- Dyslipidemia: Drug therapy can be commenced after 6 weeks of lifestyle modification. See section on “Dyslipidemia.”
- HTN: Aim for similar targets to patients with diabetes (<140/80 mm Hg based on ADA guidelines). See section on “Hypertension.”
  - ACE inhibitor or angiotensin receptor blocker (e.g., losartan 50 mg/day if ACE inhibitor intolerance) is usually prescribed for patients with diabetes.

- IGT
  - Current evidence supports intensive lifestyle interventions (ILI) to decrease the development of diabetes. Metformin (875 mg twice daily), though less efficacious than ILI, has also been demonstrated to decrease the incidence of diabetes in patients with MetS (8)[A].
- If CAD or T2DM is already evident, treat as per guidelines. Use ASA 81 mg for primary prevention as indicated per USPSTF if benefits outweigh bleeding risk.

ISSUES FOR REFERRAL

- Obesity management
- Nutrition
- Exercise program
- Smoking cessation

SURGERY/OTHER PROCEDURES

- Bariatric surgery can treat MetS in severely obese patients who have failed trials of lifestyle modification and pharmacotherapy; surgery is recommended in appropriate individual if body mass index (BMI) >40 or BMI >35 with obesity-related comorbidities.
- Liposuction of abdominal adipose tissue does not reduce insulin resistance or cardiovascular risk factors.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Fish oils and plant sterol esters may be used for cardioprotective effects.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Management usually does not require admission.
- Admission criteria/initial stabilization
  - Serious complications (e.g., ACS, hypertensive crisis, diabetic coma)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Regular exercise will improve all components of the MetS. Cumulative small periods of exercise over the day provide significant health benefits. Encourage small increases in physical activity over time.
- Encourage replacing sedentary activity choices (e.g., sitting at desk, driving car, taking elevator, and the like) to more active ones (e.g., standing desk, walking, cycling, stationary walking during commercials).
- Weight reduction to correct abdominal obesity is a primary goal achieved by dietary modification and increased physical activity.
- Regular monitoring of weight, waist circumference, and BP. Fasting lipids and sugar levels should be checked at least annually.

DIET

- Dietary recommendations may include limiting simple carbohydrates in diet, eating a Mediterranean, or DASH (Dietary Approaches to Stop Hypertension) diet.
- Increased consumption of leafy green vegetables may decrease risk of developing T2DM (9)[A]. Encourage increasing intake of vegetables and fiber and keep fruit and alcohol in moderation.
- Avoid sugar-sweetened beverages.

PROGNOSIS

Increased risk of T2DM (~5-fold), CAD (~1.5- to 3-fold), acute myocardial infarction (~2.5-fold), and all-cause mortality (~1.5-fold)

COMPLICATIONS

Long-term complications are primarily CAD and T2DM. Recent evidence demonstrates an increased risk of NAFLD, stroke, chronic kidney disease, cognitive decline, and an increased risk of developing certain cancers, especially breast cancer in postmenopausal women.

CODES

ICD10

E88.81 Metabolic syndrome

CLINICAL PEARLS

- Routine WC should be measured as part of a cardiovascular risk assessment.
- Consider further evaluation for MetS when history and/or physical exam demonstrates findings consistent with sedentary lifestyle, sleep apnea, increasing WC, elevation of BP or treatment, evidence of insulin resistance, or abnormal screening labs or treatment for lipids or blood glucose.
- Recognizing MetS in the clinic can help prioritize treatment goals and guidance to work to reduce associated risk factors.
- Prevention or reduction of obesity is the cornerstone of management of metabolic syndrome.
- Consider alternatives for medications known to increase risk of metabolic syndrome such as atypical antipsychotic medications, chronic steroids, thiazide diuretics, and β-blockers.
- In addition to regular 30- to 60-minute exercise regimen, there is significant benefit to increasing cumulative physical activity over the day.
- Aggressive lifelong lifestyle modification is first-line and most potent treatment for all patients.

METATARSALGIA

Michael Y. Yang, MD • Marc W. McKenna, MD

BASICS

DESCRIPTION

- Metatarsalgia is a generic term referring to pain in the forefoot in the region of the metatarsal heads.
- System affected: musculoskeletal

EPIDEMIOLOGY

Incidence

Especially common in athletes engaging in high-impact sports (running, jumping, dancing), in rock climbers (12.5%), and in older active adults.

Prevalence

Common

ETIOLOGY AND PATHOPHYSIOLOGY

- The 1st metatarsal head bears significant weight when walking or running. A normal metatarsal arch ensures this balance. The 1st metatarsal head normally has adequate padding to accommodate increased forces.
- Reactive tissue can build a callus around the metatarsal head, compounding the pain.
  - Excessive or repetitive stress. Forces are transmitted to the forefoot during several stages (midstance and push-off) of walking and running. These forces are translated across the metatarsal heads at nearly three times the body weight (1)[C].
  - A pronated splayfoot disturbs this balance, causing equal weight bearing on all metatarsal heads.
  - Any foot deformity changes distribution of weight, impacting areas of the foot that do not have sufficient padding.
  - Soft tissue dysfunction: intrinsic muscle weakness, laxity in the Lisfranc ligament

  - Abnormal foot posture: forefoot varus or valgus, cavus or equinus deformities, loss of the metatarsal arch, splayfoot, pronated foot, inappropriate footwear
  - Dermatologic: warts, calluses (2)[C]
- Great toe
  - Hallux valgus (bunion), either varus or rigidus
- Lesser metatarsals
  - Freiberg infraction (i.e., aseptic necrosis of the metatarsal head usually due to trauma in adolescents who jump or sprint)
  - Hammer toe or claw toe
  - Morton syndrome (i.e., long 2nd metatarsal)

RISK FACTORS

- Obesity
- High heels, narrow shoes, or overly tight-fitting shoes (rock climbers typically wear small shoes)
- Competitive athletes in weight-bearing sports (e.g., ballet, basketball, running, soccer, baseball, football)
- Foot deformities or changes in ROM (e.g., pes planus, pes cavus, tight Achilles tendon, tarsal tunnel syndrome, hallux valgus, prominent metatarsal heads, excessive pronation, hammer toe deformity, tight toe extensors) (2)[C]

Geriatric Considerations

- Concomitant arthritis
- Metatarsalgia is common in older athletes.
- Age-related atrophy of the metatarsal fat pad may increase the risk for metatarsalgia.

Pediatric Considerations

- Muscle imbalance disorders (e.g., Duchenne muscular dystrophy) cause foot deformities in children.
- In adolescent girls, consider Freiberg infraction.
- Salter I injuries may affect subsequent growth and healing of the epiphysis.

Pregnancy Considerations

- Forefoot pain during pregnancy usually results from change in gait, center of

mass, and joint laxity.
- Wear properly fitted, low-heeled shoes.

GENERAL PREVENTION
- Wear properly fitted shoes with good padding.
- Start weight-bearing exercise programs gradually.

COMMONLY ASSOCIATED CONDITIONS
- Arthritis
- Morton neuroma
- Sesamoiditis
- Plantar keratosis–callous formation

DIAGNOSIS
HISTORY
- Pain gradually develops and persists over the heads of one or more metatarsals. Pain is usually on the plantar surface and worse during midstance gait phase.
- Pain is often chronic.
- Predisposition with pes cavus and hyperpronation
- Pain often described as walking with a pebble in the shoe; aggravated during midstance or propulsion phases of walking or running.

PHYSICAL EXAM
- Point tenderness over plantar metatarsal heads
- Pain in the interdigital space or a positive metatarsal squeeze test suggests Morton neuroma.
- Plantar keratosis
- Tenderness of the metatarsal head(s) with pressure applied by the examiner’s finger and thumb
- Erythema and swelling (occasionally)

DIFFERENTIAL DIAGNOSIS
- Stress fracture (most commonly 2nd metatarsal)
- Morton neuroma (i.e., interdigital neuroma)

- Tarsal tunnel syndrome
- Sesamoiditis or sesamoid fracture
- Salter I fracture in children
- Arthritis (e.g., gouty, rheumatoid, inflammatory, osteoarthritis, septic, calcium pyrophosphate dihydrate crystal deposit disease [CPPD])
- Lisfranc injury
- Avascular necrosis of the metatarsal head
- Ganglion cyst
- Foreign body
- Vasculitis (diabetes)
- Bony tumors

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Weight-bearing radiographs: anteroposterior, lateral, and oblique views:
  - Occasionally, metatarsal or sesamoid axial films (to rule out sesamoid fracture) or skyline view of the metatarsal heads to assess the plantar declination of the metatarsal heads: obtained with the metatarsophalangeal joints in dorsiflexion (to evaluate alignment)
- Ultrasound and MRI in recalcitrant cases especially if concern for stress fracture (3)[C]
- MR arthrography of the metatarsophalangeal (MTP) joint can delineate capsular tears, typically of the distal lateral border of the plantar plate (an often underrecognized cause of metatarsalgia.
- Only if diagnosis is in question
  - Erythrocyte sedimentation rate or C-reactive protein
  - Rheumatoid factor
  - Uric acid
  - Glucose
  - CBC with differential

Diagnostic Procedures/Other

Plantar pressure distribution analysis may help distinguish pressure distribution patterns due to malalignment.

TREATMENT

Treatment for metatarsalgia is typically conservative.

- Relieve pain
- Ice initially
- Rest: temporary alteration of weight-bearing activity; use of cane or crutch. For more physically active patients, suggest an alternative exercise or cross-training:
  - Moist heat later
  - Taping or gel cast
  - Stiff-soled shoes will act as a splint.
- Relieve the pressure beneath the area of maximal pain by redistributing the pressure load of the foot, which can be achieved by weight loss.

MEDICATION

Nonsteroidal anti-inflammatory medications for 7 to 14 days if no contraindications toward use

ISSUES FOR REFERRAL

High-level athletes may benefit from early podiatric or orthopedic evaluation.

ADDITIONAL THERAPIES

- Physical therapy to restore normal foot biomechanics
- Low-heeled (<2 cm height) wide-toe-box shoes
- Metatarsal bars, pads, and arch supports. Metatarsal bars are often more effective than pads.
- Orthotics/rocker bar (prescriptive orthotics have been shown to be effective treatment)
- Thick-soled shoes
- Shaving the callus may provide temporary relief. Callus excision is not recommended.
- Corticosteroid injection may benefit interdigital neuritis but should be used with caution as it may cause MTP instability and fat pad atrophy.
- Improve flexibility and strength of the intrinsic muscles of the foot with:
  - Exercises (e.g., towel grasps, pencil curls)

  - Physical therapy to maintain range of motion and restore normal biomechanics

SURGERY/OTHER PROCEDURES

- If no improvement with conservative therapy for 3 months, refer to foot/ankle orthopedic surgeon or podiatrist.
- Surgery may help correct anatomic abnormality: bunionectomy, partial osteotomy, or surgical fusion. Success rates vary depending on procedure.
- Direct plantar plate repair (grade II tear) combined with Weil osteotomy can restore normal alignment of the MTP joint, leading to diminished pain with improved functional scores.
- The Weil osteotomy (distal metatarsal oblique osteotomy) is safe and effective for metatarsalgia.
- Callus removal is generally not recommended (callus is a response to pressure change—not the cause).
- Morton neurectomy or ultrasound-guided alcohol ablation of Morton neuroma are options (4)[C].
- Surgery only as a last resort if no anatomic abnormality is present.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Magnetic insoles are not effective for chronic non-specific foot pain.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Patients generally admitted only for surgery

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

If stress fracture has been ruled out and patient's condition has not improved >3 months of conservative treatment, consider surgical evaluation.

PATIENT EDUCATION

- Instruct about wearing proper shoes and gradual return to activity.

- Cross-training until symptoms subside. Goal is to restore normal foot biomechanics, relieve abnormal pressure on the plantar metatarsal heads, and relieve pain (5)[C].

PROGNOSIS

Outcome depends on the severity of the problem and whether surgery is required to correct it.

COMPLICATIONS

- Back, knee, and hip pain due to change in gait
- Transfer metatarsalgia following surgical intervention, which subsequently transfers stress to other areas.

SEE ALSO

Morton Neuroma (Interdigital Neuroma)

CODES

ICD10

- M77.40 Metatarsalgia, unspecified foot
- G57.60 Lesion of plantar nerve, unspecified lower limb
- M77.42 Metatarsalgia, left foot

CLINICAL PEARLS

- Metatarsalgia refers to pain of the plantar surface of the forefoot in the region of the metatarsal heads.
- Metatarsalgia is common in athletes who participate in high-impact sports involving the lower extremities.
- Patients describe as "walking with a pebble in the shoe." Pain is worse during midstance or propulsion phases of walking or running.
- The most common physical finding is point tenderness over plantar metatarsal

heads.

- Pregnant patients should wear properly fitted, low-heeled shoes to reduce incidence of metatarsalgia.

METHICILLIN-RESISTANT *STAPHYLOCOCCUS AUREUS* (MRSA) SKIN INFECTIONS

Stephen A. Martin, MD, EdM • Paul P. Belliveau, PharmD

BASICS

DESCRIPTION

- Community-acquired methicillin-resistant *Staphylococcus aureus* (CA-MRSA) has unique properties allowing the organism to cause skin and soft tissue infections (SSTIs) in healthy hosts:
  - CA-MRSA has a different virulence and disease pattern than hospital-acquired MRSA (HA-MRSA).
- CA-MRSA infections impact patients who have not been recently (<1 year) hospitalized or had a medical procedure (e.g., dialysis, surgery, catheters).
- Incidence of CA-MRSA has increased in the United States, recently plateauing between 2005 and 2010.
- CA-MRSA typically causes mild to moderate SSTIs (abscesses, furuncles, and carbuncles):
  - Severe or invasive CA-MRSA disease is less frequent but can include:
    - Necrotizing pneumonia with abscesses
    - Necrotizing fasciitis
    - Septic thrombophlebitis
    - Sepsis
    - Osteomyelitis
- Although less frequent, HA-MRSA can still cause SSTIs in the community.
- System(s) affected: skin, soft tissue

EPIDEMIOLOGY

- Predominant age: all ages, generally younger
- Predominant sex: female > male

Incidence

- 316/100,000/year (2004 to 2005)
- 46/100,000/year pediatric MRSA SSTI hospitalizations (2009)

Prevalence

- Significantly affected by local epidemiology
- 25–30% of U.S. population are colonized with *S. aureus*; up to 7% are colonized with MRSA.
- CA-MRSA isolated in ~60% of SSTIs presenting to emergency departments (range 15–74%). In 1993, 1.5 million SSTIs were seen in U.S. emergency rooms. In 2005, this had increased to 3.4 million. Hospital admissions for SSTIs increased 29% between 2000 and 2004.
- CA-MRSA accounts for up to 75% of all community staphylococcal infections in children.

ETIOLOGY AND PATHOPHYSIOLOGY

- First noted in 1980. Current U.S. CA-MRSA epidemic began in 1999. The US-300 clone is predominant.
- CA-MRSA is distinguished from HA-MRSA by
  - Lack of a multidrug-resistant phenotype
  - Presence of exotoxin virulence factors
  - Type IV *Staphylococcus* cassette cartridge (contains the methicillin-resistance gene *mecA*)

RISK FACTORS

- ~50% of patients have no obvious risk factor.
- Use of any antibiotic in the past month
- Presence of an abscess
- Reported “spider bite”
- History of MRSA infection
- Close contact with a similar infection
- Children, particularly in daycare centers
- Competitive athletes
- Incarceration
- Hospitalization in the past 12 months

GENERAL PREVENTION

- Colonization (particularly of the anterior nares) is a risk factor for subsequent *S. aureus* infection. Not certain if similar for CA-MRSA. Oropharyngeal and inguinal colonization are equally prevalent.
- CA-MRSA may be transmitted more easily through environmental and household contact (1)[B].
- Health care workers are a primary MRSA vector for hospitalized patients, reinforcing the need for meticulous cleaning of hands and equipment.
- Research for a vaccine is underway.
- CDC guidance for prevention of MRSA in athletes: http://www.cdc.gov/mrsa/community/team-hc-providers/advice-for-athletes.html

COMMONLY ASSOCIATED CONDITIONS

Many patients are otherwise healthy.

DIAGNOSIS

HISTORY

- Review potential risk factors.
- "Spider bite" is commonly confused with MRSA—patients may report an unclear history of spider bite.
- Prior MRSA skin infection
- Risk factors alone cannot rule in or rule out a CA-MRSA infection.

PHYSICAL EXAM

- Furuncles and/or carbuncles, sometimes with surrounding cellulitis. A nonsuppurative cellulitis is also possible, although it is a less common presentation of CA-MRSA.
- Erythema, warmth, tenderness, swelling
- Fluctuance
- Folliculitis, pustular lesions
- Appearance like an insect or spider bite
- Tissue necrosis

DIFFERENTIAL DIAGNOSIS

SSTIs due to other organisms

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Wound cultures establish definitive diagnosis. Recent guidelines recommend cultures only when a purulent lesion is accompanied by systemic signs of illness or immunocompromise (2)[B].
- Susceptibility testing; many labs use oxacillin instead of methicillin.
- A “D-zone disk-diffusion test” evaluates for inducible clindamycin resistance in CA-MRSA resistant to erythromycin.
- In unclear cases, ultrasound may help identify abscesses (3,4)[A].
- CT or MRI may show fascial plane edema in suspected necrotizing fasciitis. DO NOT DELAY surgical intervention in such cases.

Diagnostic Procedures/Other

Purulent lesions should be incised and drained (I&D); needle aspiration is not recommended (2).

TREATMENT

- Recent guidelines recommend antibiotics that are active against MRSA for patients with carbuncles or abscesses if patients do not respond to initial antibiotic treatment, have markedly impaired host defenses, or present with systemic inflammatory response (SIRS) and hypotension (2).
- Routine use of agents to eliminate MRSA colonization for patients with active infection or their close contacts is not currently recommended.
- Most CA-MRSA infections are localized SSTIs and do not require hospitalization or vancomycin.
- Base initial empirical antibiotic coverage on local CA-MRSA prevalence and individual patient risk factors.
- http://www.cdc.gov/mrsa/pdf/Flowchart_pstr.pdf

GENERAL MEASURES

- Modify therapy based on culture and susceptibility.
- Determine if household or other close contacts have SSTI or other infections

and evaluate accordingly.
- Treat underlying conditions (e.g., tinea pedis).
- Restrict contact if wound cannot be covered.
- Elevate affected area.

MEDICATION

ALERT

For purulent infections, consider surgical drainage, wound culture, and narrow-spectrum antimicrobials:

- I&D may have more impact than antibiotics in mild cases for both adults and children.
- Patients with an abscess are frequently cured by incision and drainage alone.
- Packing does not appear to improve outcomes (3)[A].
- Moist heat may work for small furuncles.

First Line

CA-MRSA SSTIs: 7- to 14-day course (depends on severity and clinical response):

- Trimethoprim/sulfamethoxazole (TMP-SMX): DS (160 mg TMP and 800 mg of SMX) 1 to 2 tablet(s) PO BID daily (8 to 12 mg/kg/day of trimethoprim component in 2 divided doses for children)
- Doxycycline or minocycline: 100 mg PO BID (children >8 years and <45 kg; 2 to 5 mg/kg/day PO in 1 to 2 divided doses, not to exceed 200 mg/day; children >8 years and >45 kg, use adult dosing), taken with a full glass of water
- Clindamycin: 300 to 450 mg PO QID (30 to 40 mg/kg/day PO in 3 divided doses for children), taken with full glass of water. Check D-zone test in erythromycin-resistant, clindamycin-susceptible *S. aureus* isolates (a positive test indicates induced resistance—choose a different antibiotic).
- CA-MRSA is resistant to β-lactams (including oral cephalosporins and antistaphylococcal penicillins) and often macrolides, azalides, and quinolones.
- Although most CA-MRSA isolates are susceptible to rifampin, this drug should *never* be used as a single agent because of concerns regarding resistance. The role of combination therapy with rifampin in CA-MRSA

SSTIs is not clearly defined.
- There has been increasing resistance to clindamycin, both initial (~33%) and induced.
- Although CA-MRSA isolates are susceptible to vancomycin, oral vancomycin cannot be used for CA-MRSA SSTIs due to limited absorption.

Second Line

Treat severe CA-MRSA SSTIs requiring hospitalization and HA-MRSA SSTIs using:

- Vancomycin: Generally, 1 g IV q12h (30 mg/kg/day IV in 2 divided doses; in children: 40 mg/kg/day IV in 4 divided doses) vancomycin-like antibiotics that require only 1 or 2 doses may soon be more broadly available (5)[A].
- Linezolid: 600 mg IV/PO BID uncomplicated: children <5 years of age, 30 mg/kg/day in 3 divided doses; 20 mg/kg/day IV/PO in 2 divided doses for children 5 to 11 years of age; children >11 years, use adult dosing. Complicated: birth to 11 years, 30 mg/kg/day IV/PO in 3 divided doses; older, use adult dosing
  - Linezolid seems to be more effective than vancomycin for treating people with SSTIs, but current studies have high risk of bias.
- Clindamycin: 600 mg IV TID; in children, 10 to 13 mg/kg/dose q6–8h up to 40 mg/kg/day
- Daptomycin: 4 mg/kg/day IV (safety/efficacy not established in patients <18 years of age) if no pulmonary involvement
- Ceftaroline 600 mg BID IV (for adults)

Pediatric Considerations

- Tetracyclines not recommended <8 years of age
- TMP-SMX not recommended <2 months

Pregnancy Considerations

- Tetracyclines are contraindicated.
- TMP-SMX not recommended in 1st or 3rd trimester

Geriatric Considerations

A recent review notes no prospective trials in this age group and recommends use of general adult guidelines.

ISSUES FOR REFERRAL

Consider consultation with infectious disease in cases of

- Refractory CA-MRSA infection
- Plan to attempt decolonization

SURGERY/OTHER PROCEDURES

Progression to serious SSTIs, including necrotizing fasciitis, is possible and mandates prompt surgical evaluation.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Consider admission if:
  - Systemically ill
  - Systemically well with comorbidities that may delay or complicate resolution of SSTI
  - Presence of SSTI complications (sepsis, necrotizing fasciitis) and comorbidities
  - Alternatives to inpatient admission include observation units and outpatient parenteral antimicrobial therapy (OPAT) programs in carefully selected cases.
- Nursing: contact precautions
- If admitted for IV therapy, assess the following before discharge:
  - Afebrile for 24 hours
  - Clinically improved
  - Able to take oral medication
  - Has adequate social support and is available for outpatient follow-up

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

For outpatients:

- Return promptly with systemic symptoms, worsening local symptoms, or failure to improve within 48 hours. Consider a follow-up within 48 hours of

initial visit to assess response and review culture.

PATIENT EDUCATION

- Cover draining wounds with clean, dry bandages.
- Clean hands regularly with soap and water or alcohol-based gel; hot soapy shower daily
- Do not share items that may be contaminated (including razors or towels).
- Clean clothes, towels, and bed linens.
- National MRSA Education Initiative: www.cdc.gov/mrsa/
- A mixture of 1/4 cup household bleach diluted in 1 gallon of water can be used to clean surfaces.

PROGNOSIS

In outpatients, improvement should occur within 48 hours.

COMPLICATIONS

- Necrotizing pneumonia or empyema (after an influenza-like illness)
- Necrotizing fasciitis
- Sepsis syndrome
- Pyomyositis and osteomyelitis
- Purpura fulminans
- Disseminated septic emboli
- Endocarditis

CODES

ICD10

- A49.02 Methicillin resis staph infection, unsp site
- A41.02 Sepsis due to Methicillin resistant Staphylococcus aureus
- J15.212 Pneumonia due to Methicillin resistant Staphylococcus aureus

CLINICAL PEARLS

- Incise and drain abscesses and send purulent material for culture and sensitivity
- Local susceptibility patterns of CA-MRSA dictate antibiotic treatment. http://www.cdc.gov/mrsa/pdf/Flowchart_pstr.pdf
- CA-MRSA skin lesions are commonly misidentified as "spider bites."

MILD COGNITIVE IMPAIRMENT

Birju B. Patel, MD, FACP, AGSF • N. Wilson Holland, MD, FACP, AGSF

BASICS

DESCRIPTION

- Mild cognitive impairment (MCI) is defined as significant cognitive impairment in the absence of dementia, as measured by standard memory tests:
  - Concern regarding change in cognition
  - Preservation of independence in functional activities (ADLs)
  - Impairment in ≥1 cognitive domains (attention, executive dysfunction, memory, visuospatial, language)
  - Other terms used in the literature relating to MCI: isolated memory impairment; cognitive impairment not dementia (CIND); predementia; mild cognitive disorder; age-associated memory impairment; age-related cognitive decline; benign senescent forgetfulness. Some of these conditions do not progress to dementia (i.e., benign senescent forgetfulness, age-associated memory impairment, age-related cognitive decline). *DSM-5* mentions "mild neurocognitive disorder" (NCD) which may be a precursor to Alzheimer disease and has many of the same features as MCI.
- Annual rates of conversion of MCI to dementia are 2–15% in the elderly.

EPIDEMIOLOGY

Incidence

- Predominant sex: male > female
- Predominant age:
  - Higher in older persons and in those with less education
  - 12 to 15/1,000 person-years in those age ≥65 years
  - 54/1,000 person-years in those age ≥75 years

Prevalence

- MCI is more prevalent than dementia in the United States.

- 3–5% for those age ≥60 years
- 15% for those age ≥75 years

ETIOLOGY AND PATHOPHYSIOLOGY

- Subtypes of MCI:
  - Single-domain amnestic
  - Multiple-domain amnestic
  - Nonamnestic single-domain
  - Nonamnestic multiple-domain
- The amnestic subtype is higher risk for progression to Alzheimer disease.
- Vascular, degenerative, traumatic, metabolic, psychiatric, or a combination

Genetics

Apolipoprotein (APO) E4 genotype: Various pathways exist leading to amyloid accumulation and deposition thought to be associated with dementia.

RISK FACTORS

- Age
- Diabetes
- Hypertension
- Hyperlipidemia
- Cerebrovascular disease
- Smoking
- Sleep apnea
- APO E4 genotype

COMMONLY ASSOCIATED CONDITIONS

See “Risk Factors.”

DIAGNOSIS

HISTORY

- Focus on cognitive deficits and impairment.
- Review all medications that may affect cognition; give particular emphasis to anticholinergic medications (patients on these may mistakenly be classified as having MCI).

- Rule out depression.
- Assess function (ADLs, instrumental ADLs) and subtle changes in daily function (e.g., in the workplace).
- Impact on interpersonal relationships and caregiver stress
- Assess vascular risk factors (hypertension, diabetes, hyperlipidemia, and cerebrovascular disease).
- Assess behavioral changes.
- Olfactory dysfunction may be associated with amnestic MCI and progression to Alzheimer dementia. This can be easily evaluated in patients with memory impairment (1)[C].

PHYSICAL EXAM

- A general exam focusing on clinical clues to identifying vascular disease (e.g., bruits, abnormal BP)
- Neurologic exam to rule out reversible CNS causes cognitive impairment or other causes of cognitive impairment (e.g., Parkinson disease).
- Office measures of cognitive function, depression, and functional status

DIFFERENTIAL DIAGNOSIS

- Delirium
- Dementia
- Depression
- "Reversible" cognitive impairment
  - Medications (anticholinergics and medications with anticholinergic properties)
  - Hypothyroidism
  - Vitamin B_{12} deficiency
- Reversible CNS conditions
- Give consideration to sleep conditions, especially sleep apnea, that can contribute to cognitive deficits.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- CBC
- Comprehensive metabolic profile

- Thyroid-stimulating hormone
- Vitamin B_{12}
- Lipids
- Consider HIV testing in the appropriate risk setting.
- Imaging tests are helpful when there are focal neurologic deficits or rapid or atypical presentations:
  - CT scan can detect structural CNS conditions leading to cognitive impairment:
    - Subdural hematoma
    - Normal pressure hydrocephalus
    - Metastatic disease
  - MRI further evaluates vascular, infectious, neoplastic, and inflammatory conditions.
- Cognitive testing is important (e.g., Montreal Cognitive Assessment [MOCA] and Saint Louis University Mental Status [SLUMS]); MOCA may be more sensitive for detecting and following MCI.
- Neuropsychological testing for complex and atypical presentations
- Vascular risk factor reduction and treatment

Follow-Up Tests & Special Considerations

- Document progression of functional impairment, cognitive decline, concurrent depression, and comorbid conditions.
- Advanced planning while patient is competent
- Early education of caregivers on safety, maintaining structure, managing stress, and future planning

Test Interpretation

- Little is known about MCI pathology due to a lack of longitudinal studies.
- Alzheimer dementia pathophysiology:
  - Neurofibrillary tangles in hippocampus
  - Senile plaques (amyloid deposition)
  - Neuronal degeneration
- Those with MCI have intermediate amounts of pathologic findings of Alzheimer disease with amyloid deposition and neurofibrillary tangles in the mesial temporal lobes compared with those with dementia.

- Amnestic MCI is associated with white matter hyperintensity volume on MRI, whereas nonamnestic MCI is associated with infarcts.

TREATMENT

GENERAL MEASURES

Atherosclerotic risk factors should be treated aggressively.

MEDICATION

The use of cholinesterase inhibitors (ChEIs) in MCI is not associated with any delay in the onset of Alzheimer disease or dementia. Moreover, the safety profile showed that the risks associated with ChEIs are significant. Therefore, ChEIs are not routinely recommended (2)[A],(3)[C].

ISSUES FOR REFERRAL

Consider referral to a memory specialist (i.e., geriatrician, neurologist, geropsychiatrist, neuropsychologist) to evaluate and differentiate subtypes of MCI and specific cognitive deficits.

ADDITIONAL THERAPIES

There may be benefit in terms of improvement in performance on tests for global cognitive functioning with cognitive training and physical exercise.

COMPLEMENTARY & ALTERNATIVE MEDICINE

No evidence suggests the efficacy of vitamin E in the prevention or treatment of people with MCI. More research is needed to identify the role of vitamin E, if any, in the management of cognitive impairment.

- Long-term use of ginkgo biloba extract has shown to have no benefit in the treatment of MCI and in terms of progression to dementia. In addition, ginkgo biloba can be associated with increase in bleeding risk including CNS bleeds (4)[B].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Delirium is more common in patients hospitalized with all forms of cognitive impairment.

- Avoid medications that may worsen or precipitate cognitive decline (e.g., anticholinergics, antihistamines).
- Patients may be extremely sensitive to the hospital environment:
  - Moderate level of stimulation is best.
  - Avoid sensory deprivation. Make sure that patients have access to hearing aids and eyeglasses.
  - Use frequent cueing and have caregivers or family in the room whenever possible with patient.
  - Frequently orient patients to date and time.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patients should be reevaluated every 6 to 12 months to determine if symptoms are progressing.

Patient Monitoring

Appropriate cognitive and functional testing should be used to evaluate progression, along with clinical history and exam. If a medication is started, patients need to be followed more frequently to evaluate for efficacy, side effects, dose titration, and so forth. Declining executive function may be an early marker to progression of MCI to dementia, and clinicians should monitor and advise patients and families proactively to look for this. Impairments in ADL function is a good clue to progression to dementia from MCI.

DIET

Diets that are promoted by the American Heart Association to minimize atherosclerotic risk factors should be emphasized.

PATIENT EDUCATION

- Encourage lifestyle changes:
  - Physical activity, such as walking 30 minutes daily on most days of the week
  - Mental activity that stimulates language skills and psychomotor coordination should be encouraged. Computer activities, reading books,

crafts, crossword puzzles, and games may be linked to decreased risk of development of MCI (5)[C],(6)[B].

- Cognitive rehabilitation strategies may be beneficial in helping with daily activities relating to memory tasks in MCI.
- Participation in exercise programs modestly improved some measures of cognition in some studies.
- Treatment of vascular risk factors (hypertension, diabetes, cerebrovascular disease, and hyperlipidemia) is important in lowering risk of progression to dementia.

PROGNOSIS

- Conversion rates from MCI to dementia range from 5% to 15% annually.
- Amnestic subtypes of MCI are most likely to progress to dementia.
- MCI has prognostic value in that once it is diagnosed, there is a higher risk of progression to dementia (7)[B].

CODES

ICD10

G31.84 Mild cognitive impairment, so stated

CLINICAL PEARLS

- Amnestic MCI affects primarily memory and is more likely to progress to Alzheimer dementia.
- Screen for reversible factors, particularly anticholinergic medications, depression, and sleep disorders.
- Look closely at vascular risk factors and modify them as best as possible.
- ChEIs should not be used routinely unless memory complaints are affecting quality of life in patients. Potential side effects of these medications should be thoroughly discussed with patients and their families. A baseline ECG should be done prior to initiation of ChEIs due to risk of bradycardia and syncope.
- Encourage both physical and mental exercises.
- Olfactory impairment may be an early clue to predict progression of patients with MCI to Alzheimer dementia.

MITRAL REGURGITATION

Yongkasem Vorasettakarnkij, MD, MSc

BASICS

DESCRIPTION

- Disorder of mitral valve (MV) closure, either primary or secondary (functional), resulting in a backflow of the left ventricular (LV) stroke volume into the left atrium (LA); uncompensated, this leads to LV and LA enlargement, elevated pulmonary pressures, atrial fibrillation, heart failure, and sudden cardiac death
- Types of mitral regurgitation (MR):
  - Acute versus chronic
  - Primary versus secondary (functional)
    - Primary: MV structures include not only the mitral annulus, MV leaflets, chordae tendineae, and papillary muscles but also posterior LA wall and LV wall.
    - Secondary: No valvular abnormalities are found. The abnormal and dilated LV causes papillary muscle displacement, resulting in leaflet tethering with annular dilatation that prevents coaptation.
- System(s) affected: cardiac; pulmonary

EPIDEMIOLOGY

Moderate to severe MR affects 2.5 million people in the United States (2000 data). It is the most common valvular disease, and its prevalence is expected to double by 2030 (1).

Prevalence

- By severity on echocardiography:
  - Mild MR: 19% (up to 40% if trivial jets included)
  - Moderate MR: 1.9%
  - Severe MR: 0.2%
- By category (1)
  - Degenerative (myxomatous disease, annular calcification): 60–70%

- Ischemic: 20%
- Endocarditis: 2–5%
- Rheumatic: 2–5%

ETIOLOGY AND PATHOPHYSIOLOGY

- Acute MR: acute damage to MV leads to sudden LA and LV volume overload. Sudden rise in LV volume load without compensatory LV remodeling results in impaired forward cardiac output and possible cardiogenic shock.
- Chronic MR: LV eccentric hypertrophy compensates for increased regurgitant volume to maintain forward cardiac output and alleviate pulmonary congestion. However, ongoing LV remodeling can result in LV dysfunction. Simultaneously, LA compensatory dilatation for the larger regurgitant volume predisposes patients to develop atrial fibrillation (AF).
- Ischemic MR: papillary muscle rupture, ischemia during acute myocardial infarction (MI), and incomplete coaptation of valve leaflets or restricted valve movement resulting from ischemia
- Acute MR
  - Flail leaflet: myxomatous disease, infective endocarditis, or trauma
  - Ruptured chordae tendineae: trauma, spontaneous rupture, infective endocarditis, or rheumatic fever
  - Ruptured or displaced papillary muscle: acute MI, severe myocardial ischemia, or trauma
- Chronic MR
  - Primary
    - Degenerative: mitral annular calcification, mitral valve prolapse (MVP)
    - Infective endocarditis
    - Rheumatic heart disease (RHD)
    - Inflammatory diseases: lupus, eosinophilic endocardial disease
    - Anorectic drugs
    - Congenital (cleft leaflet)
  - Secondary (functional)
    - Ischemic: coronary artery disease (CAD)/MI
    - Nonischemic: cardiomyopathy, LV dysfunction from any cause, hypertrophic cardiomyopathy

RISK FACTORS

Age, hypertension, RHD, endocarditis, anorectic drugs

GENERAL PREVENTION

- Risk factor modification for CAD
- Antibiotic prophylaxis for poststreptococcal RHD
- Endocarditis prophylaxis for MR is no longer recommended.

COMMONLY ASSOCIATED CONDITIONS

MVP with MR common in Marfan syndrome

DIAGNOSIS

HISTORY

- Associated conditions: RHD, prior MI, connective tissue disorder
- Acute MR
  - Sudden onset of dyspnea
  - Orthopnea, paroxysmal nocturnal dyspnea
  - Chronic MR
    - Exertional dyspnea
    - Fatigue
    - Palpitation: paroxysmal/persistent AF

PHYSICAL EXAM

- Acute MR
  - Rapid and thready pulses
  - Sign of poor tissue perfusion with peripheral vasoconstriction
  - Hyperdynamic precordium without apical displacement
  - S_3 and S_4 (if in sinus rhythm)
  - Systolic murmur at left sternal border and base
    - Early, middle, or holosystolic murmur
    - Often soft, low-pitched decrescendo murmur
  - Rales
- Chronic MR
  - Brisk upstroke of arterial pulse

  - Leftward displaced LV apical impulse
  - Systolic thrill at the apex (suggests severe MR)
  - Soft S_1 and widely split S_2, S_3 gallop
  - Loud P_2 (if pulmonary hypertension)
  - Holosystolic murmur at apex that radiates to axilla
  - Ankle edema, jugular venous distension, and ascites, if development of right-sided heart failure

DIFFERENTIAL DIAGNOSIS

- Aortic stenosis (AS): usually midsystolic but can be long; difficult to distinguish from holosystolic, at apical area, and radiating to the carotid arteries (unlike MR)
- Tricuspid regurgitation: holosystolic but at left lower sternal border; does not radiate to axilla or increase in intensity with inspiration (unlike MR)
- Ventricular septal defect (VSD): harsh holosystolic murmur at lower left sternal border but radiates to right sternal border (not axilla)

DIAGNOSTIC TESTS & INTERPRETATION

- Chest x-ray (CXR)
  - Acute MR: pulmonary edema, normal heart size
  - Chronic MR: LA and LV enlargement
- ECG
  - Acute MR
    - Varies depending on etiologies (e.g., acute MI)
  - Chronic MR
    - P mitrale from LA enlargement, AF
    - LV hypertrophy
    - Q waves from prior MI

Initial Tests (lab, imaging)

- Cardiac enzymes and brain natriuretic peptide (BNP), if appropriate
- Transthoracic echocardiogram (TTE)
  - Indications for TTE (2)
    - Baseline evaluation of LV size and function, right ventricular function and LA size, pulmonary artery pressure, and severity of MR

    - Delineation of mechanism of MR
    - Surveillance of asymptomatic moderate to severe LV dysfunction (ejection fraction [EF] and end-systolic dimension [ESD])
    - Evaluate MV apparatus and LV size and function after a change in signs/symptoms in a patient with MR.
    - Evaluate after MV repair or replacement.
  - Findings in acute MR
    - Evidence of etiology: flail leaflet or infective vegetations
    - Normal LA and LV size
  - Findings in chronic MR
    - Evidence of degenerative, rheumatic, ischemic, congenital, and other causes
    - Enlarged LA and LV

Follow-Up Tests & Special Considerations

- Intervals for follow up TTE: See "Follow-Up Recommendations."
- Cardiovascular magnetic resonance (CMR):
  - TTE results are not satisfactory to assess LV and RV volumes, function, or MR severity (2)[C].
- Transesophageal echocardiogram (TEE)
  - Intraoperatively to define the anatomic basis of MR and to guide repair (2)[C]
  - Nondiagnostic information about severity, mechanism of MR, and/or status of LV function from noninvasive imaging (2)[C]
- Exercise hemodynamics with either doppler echo or cardiac catheterization (2)[C]
  - Discrepancy between symptoms and the severity of MR from resting TTE in symptomatic patients with chronic primary MR
- Exercise treadmill testing (2)[C]
  - To establish symptom status and exercise tolerance in asymptomatic patients with chronic primary MR.
- Noninvasive imaging (stress nuclear/position emission tomography, CMR, stress echocardiography), cardiac CT angiography, or cardiac catheterization, including coronary angiography
  - To establish etiology of chronic secondary MR and/or to assess myocardial

viability (2)[C]

Diagnostic Procedures/Other

Cardiac catheterization (2)

- Left ventriculography and hemodynamic measurement
  - Noninvasive tests are inconclusive regarding severity of MR, LV function, or the need for surgery.
- Coronary angiography: prior to MV surgery in patients at risk for CAD

Test Interpretation

Quantification of severe MR requires integration of the following:

- Structural parameters
  - LA size: dilated, unless acute
  - LV size: dilated, unless acute
  - Leaflets: abnormal
  - Doppler parameters
  - Quantitative parameter

TREATMENT

MEDICATION

- Acute, severe MR
  - Medical therapy has a limited role and is aimed primarily to stabilize hemodynamics preoperatively.
  - Vasodilators (nitroprusside, nicardipine): to improve hemodynamic compensation but is often limited by systemic hypotension (2)
- Chronic MR
  - Primary
    - Asymptomatic: no proven long-term medical therapy
    - Symptomatic: diuretics, β-blockers (carvedilol, metoprolol), angiotensin-converting enzyme inhibitors (ACEIs) or angiotensin receptor blockers (ARBs), and possibly aldosterone antagonists as indicated in standard therapy for heart failure (2)[C]
  - Secondary: LV dysfunction or symptomatic (stages B–D)
    - ACEIs or ARBs, β-blockers, and/or aldosterone antagonists as indicated

in standard therapy for heart failure (2)[C]

SURGERY/OTHER PROCEDURES

- Isolated MV surgery is not indicated for patients with mild to moderate MR.
- Acute, severe MR secondary to acute MI
  - Acute rupture of papillary muscle: emergency MV repair/replacement
  - Papillary muscle displacement
    - Aggressive medical stabilization and intra-aortic balloon pump
    - Valve surgery usually required in addition to revascularization.
- Chronic severe MR
  - MV repair in an experienced center is recommended over MV replacement in most circumstances (3):
    - Survival rate: early and overall mortality were lower after MV repair than after MV replacement
    - 10-year rate of stroke: 10% (repair) versus 12% (bioprosthetic valve replacement) versus 23% (mechanical valve replacement)
    - Risk of endocarditis: 1.5% at 15 years versus 0.3–1.2% per year
    - Overall rates of reoperation are similar.
  - Severe primary MR (2)
    - MV surgery
      - Symptomatic patients (stage D)
        - Absence of severe LV dysfunction (EF ≥30%) (2)[B]
        - Severe LV dysfunction (EF <30%) (2)[C]
      - Asymptomatic patients
        - Mild to moderate LV dysfunction (EF 30–60% and/or ESD ≥40 mm, stage C2) (2)[B]
        - MV repair is reasonable for asymptomatic patients (stage C1) with preserved LV function (EF >60% and ESD <40 mm):
          - The likelihood of successful repair without residual MR is >95% and expected mortality <1% when performed at a heart valve center of excellence (2)[C].
          - Nonrheumatic MR with new onset AF or resting pulmonary hypertension (pulmonary artery systolic pressure [PASP] >50 mm Hg) and the likelihood of a successful and durable repair is high

(2)[C].

- Transcatheter MV repair:
  - May be considered for severely symptomatic patients (NYHA class III/IV) despite optimal GDMT for HF, who have a reasonable life expectancy but a prohibitive surgical risk because of severe comorbidities (2)[C]

– Severe secondary MR (2)

- MV surgery
  - Undergoing coronary artery bypass graft (CABG) or aortic valve replacement (AVR) (2)[C]
  - Persistent symptom (NYHA class III-IV) despite optimal GDMT for HF (2)[C]
- Cardiac resynchronization therapy with biventricular pacing is recommended for symptomatic patients (stage B–D) who meet the indications for device therapy (2)[C].

Geriatric Considerations

- Medical therapy alone for patients >75 years of age with MR is preferred, owing to increased operative mortality and decreased survival (compared with those with AS), especially with preexisting CAD or need for MV replacement.
- MV repair is preferable than MV replacement.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Acute MR: Stabilize ABCs (airway, breathing, circulation). Initiate IV, O_2, and monitoring. Nitroprusside (+dobutamine and/or aortic balloon counterpulsation if hypotensive). Treat underlying causes (e.g., MI). Treat acute pulmonary edema with furosemide and morphine. Obtain urgent surgical consultation.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Chronic MR: asymptomatic

- Mild MR with normal LV size and function and no pulmonary hypertension:

Annual clinical evaluation to assess symptom progression and TTE every 3 to 5 years to assess MR severity, LV size and function.

- Moderate MR: annual clinical evaluation and TTE every 1 to 2 years
- Severe MR: clinical evaluation and TTE every 6 to 12 months
- Consider serial CXRs and ECGs, and consider stress test if exercise capacity is doubtful.

PATIENT EDUCATION

- Exercise after MV repair: Avoid sports with risk for bodily contact or trauma. Low-intensity competitive sports are allowed.
- Competitive athletes with MR
  - Asymptomatic with normal LV size and function, normal pulmonary artery pressures, and sinus rhythm: no restrictions
  - Mildly symptomatic and those with LV dilatation: Activities with low to moderate dynamic and static cardiac demand allowed
- AF and anticoagulation: no contact sports

PROGNOSIS

- Acute, severe MR: Mortality risk with surgery is 50%; mortality risk with medical therapy alone is 75% in first 24 hours and 95% at 2 weeks.
- Chronic MR: asymptomatic severe MR with normal LVEF: 10% yearly rate of progression to symptoms and subnormal resting LVEF. Symptomatic severe MR: 8-year survival rate, 33% without surgery; mortality rate, 5% yearly

Pregnancy Considerations

MR with NYHA functional class III–IV at high risk for maternal and/or fetal risk

COMPLICATIONS

Acute pulmonary edema, CHF, AF, bleeding risk with anticoagulation, endocarditis, sudden cardiac death

CODES

ICD10

- I34.0 Nonrheumatic mitral (valve) insufficiency
- I05.1 Rheumatic mitral insufficiency
- Q23.3 Congenital mitral insufficiency

CLINICAL PEARLS

- Follow-up for mild to moderate MR: serial exam and/or echo unless LV structural changes
- Severe MR is usually managed with MV repair.
- Endocarditis prophylaxis is not recommended.

MITRAL STENOSIS

Harish C. Devineni, MD • Gene Pershwitz, MD • Venkata M. Alla, MD

BASICS

DESCRIPTION

- The mitral valve apparatus is made up of anterior and posterior leaflets which are attached to the anterolateral and posteromedial papillary muscles via the chordae.
- Mitral stenosis (MS) is a narrowing of the valve area causing obstruction of the left ventricular inflow, resulting in increased left atrial pressures and consequent elevation of pulmonary venous and atrial pressures.
- Normal valve orifice 4 to 6 cm^2; symptoms typically seen when orifice is <2.5 cm^2 (1).
- Staging of the disease is used to guide appropriate treatment regimen. Stages vary from A (with risk factors), B (hemodynamic obstruction), C (severe but no symptoms), to D (symptomatic) (1).
- The most common etiology for MS is rheumatic heart disease (RHD), and MS is the most common valvular disease secondary to RHD.
- Other etiologies will be discussed below.

EPIDEMIOLOGY

- Globally, the prevalence of RHD is 15.6 million every year. Approximately 282,500 new cases are reported and 233,000 deaths have been attributed to RHD (2).
- Predominant age: Symptoms primarily occur in 3rd to 4th decades; predominant sex: female > male (2:3)

Incidence

Incidence of rheumatic disease in the continental United States remains very low. Annual incidence of acute rheumatic fever in the continental United States is 0.04 to 0.06 cases per 1,000 children. However, global burden remains significant (3).

ETIOLOGY AND PATHOPHYSIOLOGY

- Narrowing of the valve orifice leads to obstruction of blood flow between LA and LV. This impairs LV filling during diastole and causes increased LA pressure. Increased LA pressure is transmitted passively ("back pressure") to the pulmonary circulation causing pulmonary hypertension and pulmonary congestion over time.
- Chronic LA pressure overload results in atrial dilation and fibrosis and may cause Afib.
- Rheumatic fever: most common etiology (see "Risk Factors")
- Aging (extension of mitral annular calcification)
- Rare causes: congenital (associated with mucopolysaccharidoses), autoimmune: systemic lupus erythematosus (SLE); rheumatoid arthritis; malignant carcinoid; Whipple disease; methysergide therapy; and other acquired pathologies such as LA myxoma, LA thrombus, endomyocardial fibrosis

RISK FACTORS

- Rheumatic fever is the greatest risk factor.
  - 30–40% of rheumatic fever patients eventually develop MS, presenting 20 years after diagnosis of rheumatic fever.
  - Acute rheumatic fever occurs 2 to 3 weeks after an episode of untreated pharyngitis caused by rheumatogenic Group A streptococci (GAS) organism in a genetically susceptible host.
  - Recurrent infections can accelerate the progression of the disease.
  - Low socioeconomic status (i.e., crowded conditions) favors the spread of streptococcal infection.
- Aging (increasing valvular calcification)
- Chest irradiation (increasing tissue fibrosis)

GENERAL PREVENTION

- Prompt recognition and treatment of GAS infection; recognition of cardinal signs and symptoms of acute rheumatic fever via Jones criteria
- Ultrasound-based screening has been shown to increase diagnosis of RHD in asymptomatic patients residing in areas of high prevalence.

COMMONLY ASSOCIATED CONDITIONS

- Afib (30–40% of symptomatic patients)
- Associated valve lesions due to chronic inflammation (aortic stenosis, aortic insufficiency)
- Pulmonary HTN and right heart failure
- Systemic embolism, stroke, pulmonary embolism (10%)
- Infection, including infectious endocarditis (1–5%)
- Chronic rheumatic myocarditis

DIAGNOSIS

HISTORY

- History of rheumatic fever
- Severity depends on valve area; most early cases will be asymptomatic.
- Mean age of symptom onset in rheumatic valvular disease is in the late 30s to 40s. Latent period 20 to 40 years after infection. Rapid progression can be seen in some high prevalence areas.
- Presenting features usually include dyspnea on exertion, decreased exercise tolerance, chest pain, embolic events, palpitations, hoarseness, hemoptysis, fatigue, paroxysmal nocturnal dyspnea, Afib, and embolic events.
- In advanced disease, symptoms of pulmonary HTN and right heart failure predominate: jugular venous distention, hepatomegaly, ascites, and peripheral edema
- Other presentations: hemoptysis (due to increased collateralization between pulmonary and bronchial circulation causing intraparenchymal hemorrhage), hoarseness (compression of recurrent laryngeal nerve by enlarged pulmonary artery or LA), dysphagia (compression of bronchi), chronic cough (due to LA compressing the bronchi) and infective endocarditis. Not infrequently, symptoms are first noted in pregnancy.

PHYSICAL EXAM

- Elevated jugular venous pressure, left parasternal heave. Apical impulse may be displaced, diastolic thrill in the left lateral decubitus position
- Auscultation

- Classic murmur: accentuated S_1, opening snap, apical early decrescendo diastolic rumble with presystolic accentuation (presystolic accentuation of murmur is lost with AF). Murmur is low pitch and best heard at the apex in the left lateral decubitus position.
- Murmur is accentuated with exercise and decreased with rest and Valsalva.
  - With mobile, noncalcified valve, murmur persists throughout diastole and S_1, and the opening snap remains loud.
  - With increasing severity of MS, murmur often is difficult to hear. S_1 and the opening snap may be soft to absent.
  - A shorter S_2 to O_2 interval indicates more severe MS.
  - Further evaluation is required while looking for concomitant murmurs.

- If pulmonary HTN is present, increased P_2, high-pitched decrescendo diastolic murmur of pulmonic insufficiency is heard (Graham Steell murmur); may have signs of right heart failure
- May also find associated aortic or tricuspid murmurs due to involvement from RHD

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- ECG (4,5)[C]
  - LA enlargement (manifested by broad, notched P waves in lead II [P mitrale], with P wave duration >0.12 sec with a negative terminal deflection of the P wave in lead V_1)
  - Afib is a common finding.
  - Right ventricular hypertrophy (RVH), right axis deviation, and an R-to-S ratio greater than 1 in in V_1 are possible.
- Chest radiograph (4,5)[C]
  - LA enlargement, straightening of the left heart border, a “double density,” in the cardiac silhouette, and elevation of the left main stem bronchus
  - Prominent pulmonary arteries at the hilum with rapid tapering, RVH, and edema pattern with Kerley A and B lines (late presentation)
- Transthoracic echo (TTE) recommended in all patients with signs and symptoms of MS (1)[B]
  - Used for diagnosis of MS

    - Assess doming of the valve, mitral orifice size, and commissural fusion.
    - Extent of involvement based on degree of commissural fusion, calcification, and subvalvular fibrosis
  - Assess for concomitant valvulopathies.
- TEE should be performed if TTE images are nondiagnostic or if being considered for a percutaneous mitral balloon commissurotomy (PMBC) to exclude thrombus in left atrium and evaluate severity of MR (1)[B].
- Exercise stress testing can also be considered in patients with MS who have a discrepancy in their symptoms and signs and resting Echo findings (1)[C].
- Cardiac catheterization indications (1,5)[C]
  - Class I recommendation
    - When echo is inconclusive
    - Discrepancy between echo, symptoms, and severity
  - Class II recommendation
    - Assess cause of severe pulmonary HTN that is out of proportion to echo results.
  - Class III recommendation: satisfactory result of echo

Follow-Up Tests & Special Considerations

- If valve area >1.5 cm^2 and mean pressure gradient <5 mm Hg, clinical f/u in 3 to 5 years is recommended.
- Otherwise, f/u is usually symptom based. Symptomatic patients with severe MS need further evaluation for interventional/surgical treatment.
- Holter monitor placement in order to r/o paroxysmal Afib.

Diagnostic Procedures/Other

- Exercise testing is recommended for those with clinical discrepancy.
- Wilkin's score evaluates valvular anatomy from a TTE in order to see if patient is a candidate for surgery.

Test Interpretation

- Rheumatic fever–induced pathologic changes: leaflet thickening, leaflet calcification, commissural fusion, chordal shortening
- MV area defined (1)
  - Normal: 4 to 6 cm^2, progressive MS: >1.5 cm^2, severe MS: <1.5 cm^2, very

severe: <1.0 cm^2

TREATMENT

GENERAL MEASURES

- Treatment is dependent on severity of stenosis and symptoms.
- Patients who have a valvular area >1.5 cm^2 and no symptoms can be managed medically.
- MS is generally progressive, and medical therapy only delays the need for definitive therapy. It entails (i) treatment to prevent recurrence of rheumatic fever, (ii) treatments aimed at improving dyspnea and exercise tolerance, (iii) controlling the ventricular rate whether in sinus rhythm or Afib, (iv) and anticoagulation for prevention of thromboembolic events.

MEDICATION

First Line

- Antibiotic prophylaxis against rheumatic fever and/or carditis is recommended for patients with history of rheumatic fever (1)[C].
- Secondary prophylaxis is dependent on many factors: number of previous attacks, time since previous infection, risk for getting GAS, age of patient, and absence or presence of cardiac involvement (6).
  - Penicillin V (PCN) PO or penicillin G IM: IM is more effective than PO.
  - If allergic to PCN, can use sulfadiazine and macrolides alternatively
  - Duration of rheumatic fever prophylaxis is variable: (6)
    - Rheumatic fever without carditis: Take for 5 years or until age 21 years, whichever is longer.
    - Rheumatic fever with carditis but no residual heart disease: Take for 10 years or well into adulthood, whichever is longer.
    - Rheumatic fever with carditis plus residual heart disease: Take for 10 years or until 40 years old, whichever is longer.
- Antibiotic prophylaxis against infective endocarditis is not routinely recommended, unless there are other indications (1)[B].
- Diuretics for congestive symptoms (1)[A]
- β-Blockers or nondihydropyridine calcium channel blockers used for

controlling heart rate both in SR and AF to allow adequate diastolic filling and decrease LA diastolic pressure tachycardia or exertional symptoms (1)

- Consider cardioversion, especially in patients with mild MS and recent dx of Afib (<6 months).
- Use of anticoagulation (1)[B]
  - Class I recommendations
    - MS and Afib or history of Afib, MS and prior embolic event, or MS and LA thrombus
  - Class IIB recommendations
    - Patients with enlarged LA and spontaneous contrast on echo
- Warfarin is the only accepted modality for anticoagulation in patients with rheumatic mitral valve disease (international normalized ratio) range 2 to 3.
- Heparin in the acute Afib setting
- The new oral anticoagulants (factor Xa inhibitor and direct thrombin inhibitor) are not approved for use in Afib that is secondary to MS.

Second Line

One can also consider amiodarone or digitalis if β-blockers and CCBs are not proven beneficial (2)[C].

SURGERY/OTHER PROCEDURES

- Surgical techniques include balloon valvotomy, open mitral commissurotomy, or closed mitral commissurotomy and mitral valve replacement.
- Patients with severe MS and symptoms consistent with NYHA class III to IV are candidates for surgery.
- Any patient with a valve area >1.5 cm^2, LA thrombus, moderate MR, severe bicommissural calcifications, severe aortic valve disease, moderate TR or TS, concomitant coronary artery disease are not candidates for PMBC.
- PMBC is recommended for those with severe MS symptoms and favorable valve morphology (1)[A], in asymptomatic patient with very severe MS and favorable valve anatomy in the absence of symptoms (1)[C], and in patients with suboptimal valvular anatomy, with a high risk for surgery (1)[C].
- Balloon valvotomy: symptomatic patients with NYHA class II, III, or IV symptoms with valves that look favorable and with favorable comorbidities (1)[A]

- MV surgery: when MS is severe with severe symptoms (NYHA class III to IV) who are not high-risk surgical candidates and balloon valvotomy is contraindicated or failed PMBC (1)[B]
- Consider patient age, bleeding risk, and other comorbidities prior to deciding if patient should have a prosthetic versus mechanical valve.

Pregnancy Considerations

- Volume expansion during pregnancy can exacerbate heart failure symptoms. Patients with known severe MS, prepregnancy discussions should be pursued with a cardiologist.
- Pregnant patients can safely use β-blockers. Despite some concerns of teratogenic affects with diuretics, furosemide has been used in symptomatic MS patients during pregnancy with minimal adverse effects.
- Coumadin is considered relatively safe in the 2nd and 3rd trimesters if anticoagulation is required. However, unfractionated heparin is preferred prior to labor and delivery.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Counsel patients with MS that is usually slowly progressive but can have sudden onset of Afib, which could become rapidly fatal. Call 911 for marked worsening of symptoms.
- Echocardiographic surveillance in asymptomatic patients in any degree of MS: very severe (<1.0 cm^2) MS: yearly, severe (≤1.5 cm^2) MS: every 1 to 2 years, mild or moderate MS: every 3 to 5 years
- Follow-up will depend on the severity of the MS and the patient's symptoms.
  - Asymptomatic patients: annual history and examination
  - Symptomatic patients are followed closely based on clinical response to adjust therapy and plan-definitive treatment (1)[C].

DIET

Salt restriction for pulmonary congestion

PROGNOSIS

Natural history

- Asymptomatic latent period after rheumatic fever for 10 to 30 years. 10-year survival for asymptomatic or minimally symptomatic patients is 80%.
- 10-year survival after onset of debilitating symptoms is only 0–15%.
- Mean survival with significant pulmonary HTN is <3 years.
- Commissurotomy is an effective means of reducing stenosis but is not curative. Restenosis sometimes occurs and can be early (<5 years) or late (>20 years).

COMPLICATIONS

Left and right heart failure, Afib and systemic embolization, pulmonary HTN, hepatic congestion, and bacterial endocarditis

CODES

ICD10

- I05.0 Rheumatic mitral stenosis
- I05.8 Other rheumatic mitral valve diseases
- I34.2 Nonrheumatic mitral (valve) stenosis

CLINICAL PEARLS

- Asymptomatic patients may be followed clinically with yearly exams for development of symptoms with periodic echo to evaluate valve area.
- Once symptoms of MS develop, initiate appropriate medical therapy but advise patient that for most, surgical therapy will be needed to prolong survival. Almost all cases of MV stenosis progress in severity over time.
- MS often presents during the intrapartum period. For patients with known severe MS, intervention should be pursued prior to pregnancy. Pregnancy in a patient with severe MS has a high rate of both maternal and fetal complications, including death.

MITRAL VALVE PROLAPSE

Jeremy Golding, MD, FAAFP

BASICS

DESCRIPTION

- Mitral valve prolapse (MVP) is a systolic billowing of one or both mitral leaflets into the left atrium (LA) during systole ± mitral regurgitation (MR).
- More specifically, MVP is a single or bileaflet prolapse of at least 2 mm superior displacement into the LA during systole on the parasternal long-axis annular plane of the valve on echocardiogram ± leaflet thickening.
  - Classic: prolapse with >5 mm of leaflet thickening
  - Nonclassic: prolapse with <5 mm of leaflet thickening
- Synonym(s): systolic click-murmur syndrome; billowing mitral cusp syndrome; myxomatous mitral valve; floppy valve syndrome; redundant cusp syndrome; Barlow syndrome

EPIDEMIOLOGY

Incidence

- Predominant age: MVP has been described in all age groups.
- Initial descriptions based on clinical examinations suggested a 2:1 female predominance. Using modern echocardiogram criteria, men and women are affected equally (1).
- The most serious consequences of hemodynamically significant MR occur in men age >50 years.

Prevalence

MVP is the most common valvular abnormality, affecting 1.0–2.5% of the general population, depending on the precise definition (1,2).

ETIOLOGY AND PATHOPHYSIOLOGY

- The pathology causing MVP is multifactorial and includes the following:
  - Abnormal valve tissue
    - Myxomatous degeneration: redundant layers of leaflet “hooding” the

cords, chordal elongation, and annular dilatation
    - Myxoid leaflets are more elastic and less stiff than normal valves.
    - Chordal rupture is more common.
  - Disparity in size between the mitral valve and the left ventricle (LV)
  - Connective tissue disorders
- MVP is often associated with variable degrees of MR.
- Frequently, there is enlargement of the LA and LV.
- Mitral annulus is often dilated.
- Involvement of other valves may occur (tricuspid valve prolapse 40%, pulmonic prolapse and aortic prolapse 2–10%).
- Possible increased vagal tone
- Possible increased urine epinephrine and norepinephrine
- MVP patients often have orthostatic hypotension and tachycardia.
- Genetics causes proliferation of the spongiosa layer of the leaflets (2).
- Fibrosis on surface of leaflets (2)
- Thinning and elongation of chordae tendineae
- The mitral valve differentiates during days 35 to 42 of fetal development, the same time as differentiation of the vertebrae and ribs.

Genetics

- Familial MVP is inherited as an autosomal dominant trait but with variable expressivity and incomplete penetrance.
- Two genetic loci identified
  - *MMVP1* on chromosome 16p11.2–p12.1
  - *MMVP2* on chromosome 11p15.4

RISK FACTORS

- MVP is a primary cardiovascular disorder.
- MVP is more likely to occur in patients with connective tissue disorders (see "Commonly Associated Conditions").
- Physical characteristics associated with MVP
  - Straight thoracic spine
  - Pectus excavatum
  - Asthenic body habitus
  - Low body mass index (BMI)

  - Scoliosis or kyphosis
  - Hypermobility of the joints
  - Arm span > height
  - Narrow anteroposterior (AP) diameter of the chest

COMMONLY ASSOCIATED CONDITIONS

- Marfan syndrome (91% of Marfan syndrome patients have MVP, although large majority of MVP patients do not meet criteria for Marfans.)
- Ehlers-Danlos syndrome
- Hypertrophic cardiomyopathy
- Pseudoxanthoma elasticum
- Osteogenesis imperfecta
- von Willebrand disease
- Primary hypomastia

DIAGNOSIS

Physical exam and echocardiography

HISTORY

- Most patients are asymptomatic.
- The most frequent symptom is palpitations.
- Symptoms related to autonomic dysfunction
  - Anxiety and panic attacks
  - Arrhythmias
  - Exercise intolerance
  - Palpitations and chest pains that are atypical for coronary artery disease (CAD)
  - Fatigue
  - Orthostasis, syncope, or presyncope
  - Neuropsychiatric symptoms
- Symptoms related to progression of MR
  - Fatigue
  - Dyspnea
  - Exercise intolerance

  - Orthopnea
  - Paroxysmal nocturnal dyspnea
  - Congestive heart failure (CHF)
- Symptoms occur as a result of an associated complication (stroke, arrhythmia).

PHYSICAL EXAM

- Auscultatory examination
  - Mid-to-late systolic click
    - May vary in timing and intensity based on ventricular beat-to-beat volume variations
    - At low ventricular volumes, the valve may prolapse earlier during systole and further into the LA than during volume overload.
    - It may or may not be followed by a high-pitched, mid- to late systolic murmur at the cardiac apex.
  - Murmur: a mid-to late crescendo systolic murmur best heard at apex, middle- to high-pitched, occasionally musical or honking in quality
  - Occasionally, only the ejection click is present.
  - The duration of the murmur corresponds with the severity of MR.
- Dynamic auscultation
  - Maneuvers that move the click and murmur toward S_1
    - Arterial vasodilation
    - Amyl nitrite
    - Valsalva
    - Augmented contractility
    - Decreased venous return (which can be induced by standing up)
  - Maneuvers that move the click and murmur toward S_2
    - Squatting
    - Leg raise
    - Isometric exercise
  - Valsalva maneuver may help differentiate hypertrophic obstructive cardiomyopathy (HOCM) from MVP because it increases the intensity of the murmur in HOCM whereas it makes it longer but not louder in MVP.

DIFFERENTIAL DIAGNOSIS

- MR
- Tricuspid regurgitation
- Tricuspid valve prolapse
- Papillary muscle dysfunction
- Hypertrophic cardiomyopathy
- Ejection clicks (do not change timing with systole)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Echocardiogram (test of choice) (3)[B]
  - In asymptomatic individuals with physical signs of MVP, an echocardiogram is indicated for diagnosis (3)[B].
  - Follow-up echocardiograms are not indicated for asymptomatic patients who have MVP with no changes clinically, even if they had mild MR (4) [C].
  - Parasternal long-axis view is most specific for diagnosis (3).
  - Findings that may be seen with MVP
    - Anterior leaflet billowing
    - Leaflet thickening of ≥5 mm
    - Leaflet redundancy
    - MR
    - Posterior leaflet displacement
  - Nondiagnostic transthoracic echocardiogram: ≤10%
  - Transesophageal echocardiography particularly with 3D imaging may be considered to further visualize the anatomy if an intervention is being planned (4)[B].
  - Stress echocardiograms may reveal exercise-induced MR or latent LV dysfunction.
- Angiography
  - Rarely used for diagnostic purposes
  - MVP may be incidentally seen on a catheterization.
- ECG is usually normal.
  - May be nonspecific ST to T wave changes
  - T-wave inversions, prominent Q waves, or prolonged QT may also occur.

- A chest x-ray (CXR) is not necessary for diagnosis.
  - Typically, the CXR is normal.
  - Other findings
    - Possible pulmonary edema: Pulmonary edema may be asymmetric with acute chordal rupture and flail leaflet.
    - Possible calcification of the mitral annulus
- Holter monitoring is optional if patient has palpitations. Order Holter monitoring as usual for syncope or dizziness.
- Tilt table testing may be of value in patients with MVP who presents with syncope of unknown etiology.

Follow-Up Tests & Special Considerations

Patients with a family history of MVP should be screened with echocardiography (3)[B].

Test Interpretation

- Myxomatous proliferation of the middle layer (spongiosa) of the valve, resulting in increased mucopolysaccharide deposition and myxomatous degeneration
- By electron microscopy, the collagen fibers in the valve leaflets are disorganized and fragmented.
- With increased stroma deposition, the valve leaflets enlarge and become redundant.
- The endothelium is usually noncontiguous and a frequent site for thrombus or infective vegetation.

TREATMENT

GENERAL MEASURES

Treat MVP with orthostatic symptoms by liberalizing fluid and salt intake. If severe, mineralocorticoids may rarely be used. Support stockings may also be beneficial.

MEDICATION

- Asymptomatic MVP is treated with reassurance; normal lifestyle and regular

exercise is encouraged.

- MVP with palpitations is treated with β-blockers and/or recommendation to discontinue alcohol, cigarettes, and caffeine.
- MVP and transient ischemic attacks are treated with aspirin 75 to 325 mg daily (3)[C].
- MVP with history of cryptogenic stroke, or atrial fibrillation with $CHADS_2$ (acronym for **C**ongestive heart failure, **H**ypertension, **A**ge >75 years, **D**iabetes mellitus, and prior **S**troke or transient ischemic attack) score <2, is generally treated with aspirin 75 to 325 mg daily (3)[C].
- MVP with atrial fibrillation with $CHADS_2$ score ≥2 is treated with warfarin (3)[C].
- MVP with high-risk echocardiographic features (thickening >5 mm or valve redundancy) and a history of stroke, warfarin therapy may be considered (3)[C].

ADDITIONAL THERAPIES

- Endocarditis prophylaxis is no longer recommended for patients with MVP.
- Patients with prior endocarditis undergoing dental, respiratory tract, infected skin, or musculoskeletal procedures should receive prophylaxis for endocarditis with amoxicillin 30 to 60 minutes prior to procedure. Ampicillin, cefazolin, or ceftriaxone IM or IV may be used if unable to tolerate oral medications (3)[B].

SURGERY/OTHER PROCEDURES

- Referral for surgery is recommended for patients with severe MR with impaired LV systolic function or flail leaflet owing to ruptured chordae tendineae (3)[C].
- One recent meta-analysis of observational studies suggests a benefit for an early surgical approach to MVP with severe MR (5)[A] even for asymptomatic patients; prospective studies are lacking.
- Minimally invasive mitral valve repair patients have shorter postoperative hospital stay compared with conventional median sternotomy open repair for patients with bileaflet prolapse and severe MR.
- Surgical repair of MR due to isolated posterior leaflet prolapse is associated with a low reoperation rate (6)[A].

- Asymptomatic patients with atrial fibrillation or pulmonary hypertension should be considered for intervention as well (2)[C].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Asymptomatic MVP patients with no significant MR can be followed clinically every 3 to 5 years (3)[C].
- Patients who are symptomatic or have high-risk features on initial echocardiogram, including moderate to severe MR, may need serial echocardiograms and should be followed clinically once per year (3)[C].
- Patients with MVP and severe MR may require coronary angiography and transesophageal echocardiography if cardiac surgical referral is planned (3)[C].

PATIENT EDUCATION

- No contraindication to pregnancy
- Restriction from competitive sports if patient has MVP with one of the following features:
  - A history of syncope associated with documented arrhythmia
  - A family history of MVP-related sudden cardiac death
  - Sustained or repetitive and nonsustained supraventricular tachycardia or frequent and/or complex ventricular tachyarrhythmias on ambulatory Holter monitoring
  - Severe MR
  - A prior embolic event
  - LV systolic dysfunction
- Explain the hereditary nature of familial MVP.

PROGNOSIS

- Excellent prognosis for asymptomatic patients
- For patients with severe MR or reduced ejection fraction, the prognosis is similar to that for nonischemic MR.

COMPLICATIONS

- Sudden cardiac death: not clearly established. May be secondary to ventricular arrhythmias especially if significant MR is present
- Chordae rupture with acute mitral insufficiency (higher risk of cardiac death; up to 2% per year)
- Infectious endocarditis (risk increased if murmur present)
- Cerebrovascular ischemic event
- Fibrin emboli
- Heart failure with progressive MR
- Arrhythmias such as atrial and ventricular premature beats, paroxysmal supraventricular tachycardias may all be seen. Risk increases with coexistent MR.
- Pulmonary hypertension

CODES

ICD10

I34.1 Nonrheumatic mitral (valve) prolapse

CLINICAL PEARLS

- MVP patients may have orthostatic hypotension and tachycardia.
- Asymptomatic MVP patients with no significant MR can be followed clinically every 3 to 5 years. Patients who are symptomatic or have high-risk features on initial echocardiogram, including moderate to severe MR, may need serial echocardiograms and should be followed clinically once per year.
- Consider an early surgical approach for MVP with severe MR.
- Endocarditis prophylaxis is no longer recommended for MVP.

MOLLUSCUM CONTAGIOSUM

Erica F. Crannage, PharmD, BCPS, BCACP • Rupal Trivedi, MD

BASICS

DESCRIPTION

Molluscum contagiosum is a common, benign, viral (poxvirus) skin infection, characterized by small (2 to 5 mm), waxy white or flesh-colored, dome-shaped papules with central umbilication. When lesions are opened, a creamy, white-gray material can be expressed. Molluscum contagiosum is highly contagious and spreads by autoinoculation, skin-to-skin contact, sexual contact, and shared clothing/towels. Molluscum contagiosum is a self-limited infection in immunocompetent patients but can be difficult to treat and disfiguring in immunocompromised patients.

EPIDEMIOLOGY

Prevalence

- 1% in the United States, occurring mainly in children 2 to 15 years and sexually active young adults
- 5–18% HIV population

ETIOLOGY AND PATHOPHYSIOLOGY

- DNA virus; Poxviridae family
- Four genetic virus types, clinically indistinguishable
- Virions invade and replicate in cytoplasm of epithelial cells causing abnormal cell proliferation
- Genome encodes proteins to evade host immune system.
- Incubation period: 2 to 6 weeks
- Time to resolution: 6 to 24 months
- Not associated with malignancy
- No cross-hybridization or reactivation by other poxviruses

RISK FACTORS

- Skin-to-skin contact with infected person
- Contact sports
- Swimming
- Eczema, atopic dermatitis
- Sexual activity with infected partner
- Immunocompromised: HIV, chemotherapy, corticosteroid therapy, transplant patients

GENERAL PREVENTION

- Avoid skin-to-skin contact with host (e.g., contact sports, sexual activity).
- Avoid sharing clothing and towels.

COMMONLY ASSOCIATED CONDITIONS

- Atopic dermatitis
- Immunosuppression medications: corticosteroids, chemotherapy
- HIV/AIDS

DIAGNOSIS

HISTORY

- Contact with known infected person
- Participation in contact sports
- Sexual activity

PHYSICAL EXAM

- Perform thorough skin exam including conjunctiva and anogenital area
- Discrete, firm papules with a central umbilication
- Umbilication is not obvious in small children.
- White curdlike core under umbilicated center
- Lesions are flesh, pearl, or red in color.
- May have surrounding erythema or dermatitis
- Immunocompetent hosts: average of 11 to 20 lesions, 2 to 5 mm diameter (range: 1 to 10 mm)
- Hosts with HIV/AIDS: hundreds of widespread lesions
- Children: trunk, extremities, face, anogenital region

- Sexually active: inner thighs, anogenital area

Pediatric Considerations

- Infants <3 months, consider vertical transmission
- Children: fever, >50 lesions, limited response to therapy, consider immunodeficiency
- Children: anogenital lesions, consider autoinoculation/possible sexual abuse

DIFFERENTIAL DIAGNOSIS

- AIDS patients: cryptococcus, penicilliosis, histoplasmosis, coccidioidomycosis
- Basal cell carcinoma
- Benign appendageal tumors: syringomas, hydrocystomas, ectopic sebaceous glands
- Condyloma acuminatum
- Dermatofibroma
- Eyelid: abscess, chalazion, foreign-body granuloma
- Folliculitis/furunculosis
- Keratoacanthoma
- Oral squamous cell carcinoma
- Trichoepithelioma
- Verruca vulgaris
- Warty dyskeratoma

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Virus cannot be cultured.
- Culture lesion if concern is secondary infection
- Sexual transmission: Test for other sexually transmitted infections, including HIV.
- Microscopy: scrape lesion
  - Core material has characteristic Henderson-Paterson intracytoplasmic viral inclusion bodies.
  - Crush prep with 10% potassium hydroxide will show characteristic inclusion bodies as well.

- Alternatively, hematoxylin-eosin-stained formalin-fixed tissue shows same confirmatory features.

Diagnostic Procedures/Other

Clinical; using magnifying lens

Tests Interpretation

Molluscum cytoplasmic inclusion bodies within keratinocytes

TREATMENT

GENERAL MEASURES

- In healthy patients, molluscum contagiosum is generally self-limited and heals spontaneously.
- No single intervention is shown to be convincingly more effective than any other in treating molluscum contagiosum (1)[B].
- No treatment is FDA-approved for treatment of molluscum contagiosum.
- Three categories of treatment: destructive, immune-enhancing, and antiviral

MEDICATION

First Line

- Cantharidin 0.7–0.9% solution: In office application to lesions, cover with dressing; wash off in 2 to 6 hours or sooner if blistering. Repeat treatment every 2 to 4 weeks until lesions resolve (1)[B],(2,3)[C].
  - Not commercially available in the United States but may be obtained from Canada
  - Adverse effects: blistering, erythema, pain, pruritus
  - Precautions: Do not use on face or on genital mucosa.

Second Line

- Benzoyl peroxide 10% cream: Apply to each lesion twice daily for 4 weeks (1)[B].
  - Inexpensive
  - Adverse effects: mild dermatitis
- For immunocompromised patients with refractory lesions, consider

- Starting or maximizing HAART therapy in patients with HIV/AIDS (4)[C]
- Cidofovir
  - 3% cream applied to lesions once daily, 5 days/week for 8 weeks (4)[C]
  - 1% cream applied to lesions once daily, 5 days/week for 2 weeks, repeat in 1 month, if necessary (4)[C]
  - Adverse effects with topical use: erythema, pain, pruritus, erosions
  - 3 to 5 mg/kg IV weekly for 1 to 2 weeks, followed by IV infusions every other week, until clinical clearance or up to 9 infusions (5)[C]
  - Adverse effects with IV use: nephrotoxicity, neutropenia
  - Monitoring with IV use: renal function and complete blood counts prior to and 24 to 48 hours after infusions
  - Precaution: Must coadminister oral probenecid and provide IV hydration with each IV infusion; refer to cidofovir manufacturer's recommendations on dosing.
- Ingenol mebutate 0.015% gel applied to lesions once daily for 3 days; may repeat once if needed (6)[C] very expensive
  - Adverse effects: erythema, irritation

SURGERY/OTHER PROCEDURES

Considered first line

- Cryotherapy: 5 to 10 seconds with 1- to 2-mm margins; repeat every 3 to 4 weeks as needed until lesions disappear (7)[B].
  - Adverse effects: erythema, edema, pain, blistering
  - Contraindications: cryoglobulinemia, Raynaud disease
- Curettage under local or topical anesthesia (1)[A],(8)[B]
  - Adverse effects: pain, scarring

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Australian lemon myrtle oil: Apply 10% solution once daily for 21 days (9) [B].
- Potassium hydroxide 5–10% solution: Apply 1 to 2 times a day until the lesions disappeared completely (10)[B].

Pediatric Considerations

- Surgical interventions: Second line in small children due to associated pain

- Pain control: Pretreat with topical lidocaine or EMLA before surgical treatment.
- Note: Adverse effect:
  - Lidocaine or EMLA over large body surface area: Methemoglobinemia and CNS toxicity. Refer to manufacturer's recommendations on dosing and use in children.

Pregnancy Considerations

Safe in pregnancy: curettage, cryotherapy, incision, and expression

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Depends on type of treatment

PATIENT EDUCATION

- Cover lesions to prevent spread.
- Avoid scratching.
- Avoid contact sports.
- Avoid sharing towels and clothing.
- Avoid sexual activity when lesions present.

PROGNOSIS

- Immunocompetent: self-limited, resolves in 3 to 12 months (range: 2 months to 4 years)
- Immunocompromised: lesions difficult to treat; may persist for years

COMPLICATIONS

- Secondary infection
- Scarring, hyper-/hypopigmentation

CODES

ICD10

B08.1 Molluscum contagiosum

CLINICAL PEARLS

- Natural resolution is preferred treatment in healthy patients.
- Reassure parents that lesions will heal naturally and generally resolve without scarring.
- No specific treatment has been identified as superior to any other.
- Consider topical corticosteroids for pruritus or associated dermatitis.

MORTON NEUROMA (INTERDIGITAL NEUROMA)

Catherine Mygatt, MD • J. Herbert Stevenson, MD

BASICS

DESCRIPTION

- Perineural fibrosis of the common digital nerve as it passes between metatarsals
  - The interspace between the 3rd and 4th metatarsals is most commonly affected.
  - Between the 2nd and 3rd metatarsals is the next most common site.
- System(s) affected: musculoskeletal, nervous
- Synonym(s): plantar digital neuritis; Morton metatarsalgia; intermetatarsal neuroma

EPIDEMIOLOGY

Prevalence

- Unknown
- Mean age: 45 to 50 years
- Predominant sex: female > male (8:1)

ETIOLOGY AND PATHOPHYSIOLOGY

- Lateral plantar nerve joins a portion of medial plantar nerve, creating a nerve with a larger diameter than those going to other digits.
- Nerve lies in SC tissue, deep to the fat pad of foot, just superficial to the digital artery and vein.
- Overlying, the nerve is the strong, deep transverse metatarsal ligament that holds the metatarsal bones together.
- With each step the patient takes, the inflamed nerve becomes compressed between the ground and the deep transverse metatarsal ligament. This can generate perineural fibrotic reaction with subsequent neuroma formation.

RISK FACTORS

- High-heeled shoes
  - Transfer more weight to the forefoot.
- Shoes with tight toe boxes
  - Cause lateral compression
- Pes planus (flat feet)
  - Pulls nerve medially, increasing irritation
- Obesity
- Female gender
- Ballet dancing, basketball, aerobics, tennis, running, and similar activities

GENERAL PREVENTION

- Wear properly fitting shoes.
- Avoid high heels and shoes with narrow toe boxes.

DIAGNOSIS

HISTORY

- Most common complaint is pain localized to interspace between 3rd and 4th toes.
- Pain is less severe when not bearing weight.
- Pain, cramping, or numbness of the forefoot during weight bearing or immediately after strenuous foot exertion
- Radiation of pain to the toes
- Pain is relieved by removing shoes and massaging the foot.
- Patients often complain of “walking on a marble.”
- Burning pain in the ball of the foot radiating to the toes
- Tingling or numbness in the toes
- Aggravated by wearing tight or narrow shoes

PHYSICAL EXAM

- Intense pain when pressure applied between metatarsal heads, sometimes with a palpable nodule
- Assess midfoot motion and digital motion to determine if arthritis or synovitis.
- Palpate along metatarsal shafts to assess for metatarsalgia or stress fractures.

DIFFERENTIAL DIAGNOSIS

- Stress fracture
- Hammer toe
- Metatarsophalangeal synovitis
- Metatarsalgia
- Arthritis
- Bursitis
- Foreign body

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Predominantly a clinical diagnosis; imaging should be reserved for when the diagnosis is unclear or more than one web space is involved (1)[A],(2)[B].
- Radiographs may help to rule out osseous pathology if diagnosis is in question, but films usually are normal in patients with a Morton neuroma (1) [A].
- US has 79% specificity and 99% sensitivity for Morton neuromas but is poor at assessing the size of the lesion. Specificity declines to 50% for lesions <6 mm (1)[A].
- MRI can rule out an osseous tumor and help determine how much of the nerve to resect surgically; it has a sensitivity of 83% and a specificity of 99% (1)[A].

Diagnostic Procedures/Other

- Five special tests have been described: thumb index finger squeeze test, Mulder sign, foot squeeze test, plantar percussion test, and toe tip sensation deficit.
  - Thumb index finger squeeze test is the most sensitive and specific (96% and 96%, respectively). Positive when pain elicited by squeezing the symptomatic intermetatarsal space between the index finger and thumb (3) [B].
  - Mulder sign is a painful “click” produced by squeezing the metatarsal heads together while compressing the neuroma between the thumb and index finger of the other hand; sensitivity 40–84% (1)[A].
  - Foot squeeze test is positive when pain is induced in the symptomatic web space when the metatarsal heads are compressed by grasping the foot;

sensitivity 40% (3)[B].

- Plantar and dorsal percussion tests are positive when percussion of the affected webspace is painful.
- Toe tip sensation deficit exists when the sensation of the toe distal to the affected web space is decreased relative to the other toes.

- More than one of the above tests being positive increases the diagnostic accuracy (4)[B].

Test Interpretation

Chronic fibrosis and thickening of the digital nerve

TREATMENT

GENERAL MEASURES

- Wear flat shoes with a roomy toe box.
- Plantar pads may help with alignment of metatarsal heads and provide relief.
- NSAIDs for temporary symptom relief

MEDICATION

First Line

Injectable steroids (e.g., betamethasone phosphate/acetate or methylprednisolone): use if general measures fail; number needed to treat (NNT) for significant benefit over conservative measures = 2.3 (5,6)[A].

Second Line

- US-guided alcohol ablation therapy to sclerose the nerve is safe, reduces pain, and may offer an alternative to surgery (7,8)[B].
- A pilot study has demonstrated that injection with onabotulinumtoxina is of possible usefulness to relieve the pain and improve function in Morton neuroma (9)[B].
- There is no evidence for the use of supinatory insoles (10)[A].

ISSUES FOR REFERRAL

Continued pain despite conservative treatments and injections.

SURGERY/OTHER PROCEDURES

Surgical removal of the neuroma or shortening of the metatarsals, with or without release of the transverse metatarsal ligament, have a 61–100% success rate defined by satisfaction scores (11)[A].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

At diagnosis, or if no improvement after 3 months of conservative treatment, consider corticosteroid injection.

- May repeat injection if no improvement after 2 to 4 weeks, or consider referring for surgical management.
- 21–51% of patients receiving a single corticosteroid injection require surgical intervention within 2 to 4 years (12)[B].
- Size >5 mm and younger patients are more likely to undergo invasive treatment (12)[B].

PATIENT EDUCATION

Wear properly fitting comfortable shoes.

PROGNOSIS

- 40–50% improve with 3 months of conservative treatment.
- 45–60% improve with steroid injection (6)[A].
- 96% improve with surgery.

COMPLICATIONS

Hip and knee pain related to gait changes

CODES

ICD10

- G57.60 Lesion of plantar nerve, unspecified lower limb
- G57.61 Lesion of plantar nerve, right lower limb
- G57.62 Lesion of plantar nerve, left lower limb

CLINICAL PEARLS

- Morton neuroma is usually a clinical diagnosis.
- Footwear modification is the mainstay of treatment.
- Corticosteroid injection into, or US-guided alcohol ablation of the neuroma may be helpful.
- Neurectomy is the definitive treatment. Patients should be aware of the likelihood of postoperative dysesthesias.

MOTION SICKNESS

Courtney I. Jarvis, PharmD • Allison Hargreaves, MD

BASICS

DESCRIPTION

- Motions sickness is not a true sickness but a normal response to a situation in which sensory conflict about body motion exists among visual receptors, vestibular receptors, and body proprioceptors.
- Also can be induced when patterns of motion differ from those previously experienced
- System affected: nervous
- Synonym(s): car sickness; sea sickness; air sickness; space sickness; physiologic vertigo

EPIDEMIOLOGY

Incidence

Predominant sex: female > male

Prevalence

Estimation is complex; syndrome occurs in ~25% due to travel by air, ~29% by sea, and ~41% by road. Estimates for vomiting are 0.5% by air, 7% by sea, and 2% by road.

ETIOLOGY AND PATHOPHYSIOLOGY

- Precise etiology unknown; thought to be due to a mismatch of vestibular and visual sensations
- Rotary, vertical, and low frequency motions produce more symptoms than linear, horizontal, and high-frequency motions.
- Nausea and vomiting occur as a result of increased levels of dopamine and acetylcholine, which stimulate chemoreceptor trigger zone and vomiting center in CNS.

Genetics

Heritability estimates range from 55% to 75%.

RISK FACTORS

- Motion (auto, plane, boat, amusement rides)
- Travel
- Visual stimuli (e.g., moving horizon)
- Poor ventilation (fumes, smoke, carbon monoxide)
- Emotions (fear, anxiety)
- Zero gravity
- Pregnancy, menstruation, oral contraceptive use
- History of migraine headaches, especially vestibular migraine
- Other illness or poor health

GENERAL PREVENTION

See "General Measures."

Pediatric Considerations

- Rare in children <2 years of age
- Incidence peaks between 3 and 12 years of age.
- Antihistamines may cause excitation in children.

Geriatric Considerations

- Age confers some resistance to motion sickness.
- Elderly are at increased risk for anticholinergic side effects from treatment.

Pregnancy Considerations

- Pregnant patients are more likely to experience motion sickness.
- Treat with medications is thought to be safe during morning sickness (e.g., meclizine, dimenhydrinate).

COMMONLY ASSOCIATED CONDITIONS

- Migraine headache
- Vestibular syndromes

DIAGNOSIS

HISTORY

Presence of the following signs and symptoms in the context of a typical

stimulus (1)[C]:

- Nausea
- Vomiting
- Stomach awareness (feeling of fullness in epigastrium)
- Diaphoresis
- Facial and perioral pallor
- Hypersalivation
- Yawning
- Hyperventilation
- Anxiety
- Panic
- Malaise
- Fatigue
- Weakness
- Confusion
- Dizziness

PHYSICAL EXAM

No specific findings

DIFFERENTIAL DIAGNOSIS

- Mountain sickness
- Vestibular disease, central and peripheral
- Gastroenteritis
- Metabolic disorders
- Toxin exposure

DIAGNOSTIC TESTS & INTERPRETATION

None indicated

TREATMENT

- Follow guidelines under “General Measures” section to prevent motion sickness (1)[C].
- Premedicate before travel with antidopaminergic, anticholinergic, or

antihistamine agents (1)[A]:
  - For extended travel, consider treatment with scopolamine transdermal patch (2)[A].
  - 2nd-generation (nonsedating) antihistamines are not effective at preventing motion sickness (3)[B].
  - Serotonin (5-HT3) antagonists (e.g., ondansetron) are not effective in preventing motion sickness (4)[B].
- Conflicting data exist on the efficacy of acupressure for nausea and vomiting associated with motion sickness (5)[B].
- Benzodiazepines suppress vestibular nuclei but would not be considered first line due to sedation and addiction potential (6)[C].
- Serotonin receptor agonist (rizatriptan) may be effective for migraineurs with motion sickness (7)[C].

GENERAL MEASURES

- Avoid noxious types of motions.
- Choose locations within vehicle that minimizes motion (airplanes: over the wing; automobiles: driver's or front passenger seat, facing forward; boat: facing toward the waves, away from rocking bow, near surface of the water; buses: near the front, at lowest level, facing forward; trains: at lowest level, facing forward).
- Improve ventilation; avoid noxious stimuli.
- Use semirecumbent seating or lay supine.
- Fix vision on horizon; avoid fixation on moving objects; keep eyes fixed on still, distant objects.
- Avoid reading while actively traveling.
- Frequent and graded exposure to stimulus that triggers nausea (habituation).
- Eat before travel, avoid empty stomach; eat light, soft, bland, low-fat, and low-acid foods; avoid alcohol.
- Increase airflow around face.
- Acupressure on point PC6 has been shown to reduce feelings of nausea but not the incidence of vomiting during pregnancy, after surgery, and in cancer chemotherapy. However, conflicting evidence of efficacy has been found for motion sickness. Point PC6 (*Neiguan* on pericardium meridian): 2 cm

proximal of transverse crease of palmar side of wrist between tendons of the palmaris longus and the flexor carpi radialis (5)[B]

MEDICATION

First Line

- Scopolamine transdermal patch (Transderm Scop): Apply 2.5-cm^2 (4 mg) patch behind ear at least 4 hours (preferably 6 to 12 hours) before travel and replace every 3 days (2)[A].
- Dimenhydrinate (Dramamine): take 30 to 60 minutes before travel
  - Adults and adolescents: 50 to 100 mg q4–6h, maximum 400 mg/day
  - Children 6 to 12 years of age: 25 to 50 mg q6–8h, maximum 150 mg/day
  - Children 2 to 5 years of age: 12.5 to 25 mg q6–8h, maximum 75 mg/day
- Meclizine (Antivert): take 60 minutes before travel
  - Adults and adolescents >12 years of age: 25 to 50 mg q24h
  - Children <12 years of age: not recommended
- Diphenhydramine (Benadryl): take 30 to 60 minutes before travel
  - Adults and adolescents: 25 to 50 mg q6–8h, maximum 300 mg/day
  - Children 6 to 12 years of age: 5 mg/kg or 12.5 to 25 mg q6–8h, maximum 300 mg/day
- Promethazine (Phenergan): take 30 to 60 minutes before travel
  - Adults and adolescents: 25 mg q12h; 25 to 50 mg IM if already developed severe motion sickness
  - Children 2 to 12 years of age: 0.5 mg/kg q12h, maximum 25 mg BID. *Caution*: increased risk of dystonic reaction in this age group
- Contraindications: patients at risk for acute angle-closure glaucoma
- Precautions:
  - Young children
  - Elderly
  - Pregnancy
  - Urinary obstruction
  - Pyloric-duodenal obstruction
- Adverse reactions:
  - Drowsiness
  - Dry mouth

  - Blurred vision
  - Confusion
  - Headache
  - Urinary retention
- Significant possible interactions:
  - Sedatives (antihistamines, alcohol, antidepressants)
  - Anticholinergics (belladonna alkaloids)

Second Line

- Benzodiazepines: take 1 to 2 hours before travel
  - Diazepam 2 to 10 mg PO q6–12h
  - Lorazepam 1 to 2 mg PO q8h
- Contraindications:
  - Severe respiratory dysfunction
  - Severe liver dysfunction
- Precautions:
  - Alcohol/drug abuse
  - Elderly
  - Sedation
  - Addiction is possible.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Ginger: 940 mg or 1 g; take 4 hours before travel (evidence controversial) (8)[B]

ONGOING CARE

DIET

- Eat before travel, avoid empty stomach; eat light, soft, bland, low-fat, and low-acid foods.
- Avoid alcohol.

PROGNOSIS

- Symptoms should resolve when motion exposure ends.
- Resistance to motion sickness seems to increase with age.

COMPLICATIONS

- Hypotension
- Dehydration
- Depression
- Panic
- Syncope

CODES

ICD10

T75.3XXA Motion sickness, initial encounter

CLINICAL PEARLS

- The scopolamine patch should be applied at least 4 hours before travel, although it may be more effective if placed 6 to 12 hours before departure.
- Oral medications should be administered 30 to 60 minutes before departure.
- Although acupressure wristbands have been found to be effective by systematic reviews in postoperative and chemotherapy-induced nausea and vomiting, conflicting data exist for motion sickness.

MULTIPLE MYELOMA

Jasmine S. Beria, DO, MPH • Maria M. Plummer, MD

BASICS

DESCRIPTION

- Multiple myeloma (MM) is a clonal proliferation of malignant plasma cells.
- This clonal proliferation in the bone marrow can cause extensive skeletal destruction with osteolytic lesions and pathologic fractures.
- The malignant plasma cells produce monoclonal protein in the blood and urine.
- MM is also characterized by hypercalcemia, increased susceptibility to infections, renal impairment, and end-organ damage.
- Monoclonal gammopathy of undetermined significance (MGUS) is a common disorder with limited monoclonal plasma cell proliferation that progresses to MM at rate of ~1% per year.
- MGUS progresses to smouldering or asymptomatic MM and eventually to symptomatic MM.
- Synonym(s): plasma cell myeloma; plasma cell leukemia

EPIDEMIOLOGY

- Accounts for ~1% of all cancers and slightly >10% of hematologic malignancies in the United States
- Median age of diagnosis is 69 years.
- Slight male predominance. Blacks about 2 to 3 times more commonly affected than whites; less common in Asians.

Incidence

4 to 5 new cases/100,000 annually

Prevalence

In 2012, there were 89, 658 cases in the United States.

ETIOLOGY AND PATHOPHYSIOLOGY

- Clonal proliferation of plasma cells derived from postgerminal center B cells

- Plasma cells undergo multiple chromosomal mutations to progress to MM.
- Genetic damage in developing B lymphocytes at time of isotype switching, transforming normal plasma cells into malignant cells, arising from single clone
- Earliest chromosomal translocations involve immunoglobulin heavy chains on chromosome 14q32, with the translocation at t(4;14), t(14;16), t(14;20), and deletion, del(17p) having a poorer prognosis.
- Malignant cells multiply in bone marrow, suppressing normal bone marrow cells and producing large quantities of monoclonal immunoglobulin (M) protein.
- Malignant cells stimulate osteoclasts that cause bone resorption and inhibit osteoblasts that form new bone, causing lytic bone lesions.

Genetics

Rare family clusters; the hyperphosphorylated form of Paratarg-7, a protein of unknown significance, is inherited as an autosomal dominant trait in familial cases of MM and MGUS, suggesting a potential pathogenic role.

RISK FACTORS

- Most cases have no known risks associated.
- Older age; immunosuppression; and chemicals like dioxin, herbicides, insecticides, petroleum, heavy metals, plastics, and ionizing radiation increase the risk of MM.
- MGUS stage consistently precedes MM.

COMMONLY ASSOCIATED CONDITIONS

Secondary amyloidosis commonly due to MM

DIAGNOSIS

HISTORY

- 34% of patients are asymptomatic at the time of presentation.
- Hypercalcemia (28%): anorexia, nausea, somnolence, and polydipsia
- Renal failure (20–50%)
- Anemia (73%)

- Bony lesions (80%): lytic lesions causing bone pain (58%) (1), osteoporosis, or pathologic fracture (26–34%)
- Other symptoms: fatigue (32%), peripheral neuropathy, weight loss (24%), recurrent infections, hyperviscosity syndrome, and cord compression

PHYSICAL EXAM

- Dehydration
- Skin findings of amyloidosis: waxy papules, nodules, or plaques that may be evident in the eyelids, retroauricular region, neck, or inguinal and anogenital regions; petechiae and ecchymosis; “pinch purpura”
- Extramedullary, plasmacytomas can present as large, purplish, subcutaneous masses.
- Hyperviscosity syndrome in 7%: retinal hemorrhages, prolonged bleeding, neurologic changes
- Tender bones and masses

DIFFERENTIAL DIAGNOSIS

- MGUS
- Smoldering MM
- Metastatic carcinoma (kidney, breast, non–small cell lung cancer)
- Waldenström macroglobulinemia
- AL amyloidosis
- Solitary plasmacytoma
- Polyneuropathy, organomegaly, endocrinopathy, M protein, skin changes (POEMS) syndrome

DIAGNOSTIC TESTS & INTERPRETATION

Criteria for diagnosis: The diagnosis of MM requires the following (2)[A]:

- Bone marrow (BM) involvement with ≥10% of plasma cells (PC) or the presence of a plasmacytoma and any one or more of the following myeloma defining events:
- Evidence of end-organ damage that can be attributed to the underlying plasma cell proliferative disorder, specifically:
  - Hypercalcemia: serum calcium >0.25 mmol/L (>1 mg/dL) higher than the upper limit of normal or >2.75 mmol/L (>11 mg/dL)

- Renal insufficiency: creatinine clearance <40 mL/min or serum creatinine >177 μmol/L (>2 mg/dL)
- Anemia: hemoglobin value of >20 g/L below the lower limit of normal or a hemoglobin value <100 g/L
- Bone lesions: one or more osteolytic lesions on skeletal radiography, CT, or PET-CT
- Any one or more of the following biomarkers of malignancy:
  - Clonal bone marrow plasma cell percentage ≥60%
  - Involved: uninvolved serum free light chain (FLC) ratio ≥100
  - >1 focal lesions on MRI studies

Initial Tests (lab, imaging)

- CBC with differential to evaluate anemia and other cytopenias with evaluation of peripheral blood smear
- BUN, creatinine (elevated creatinine due to myeloma cast nephropathy)
- Serum electrolytes, serum albumin, serum calcium
- Serum lactate dehydrogenase (LDH), β_2-microglobulin
- Serum protein electrophoresis (SPEP), serum immunofixation electrophoresis (SIFE): M protein level elevated
- Quantitative serum immunoglobulin levels: immunoglobulin (Ig) G, IgA, and IgM
- Quantitative serum FLC levels: κ and λ chains
- Elevated ESR, C-reactive protein
- Urine analysis: 24-hour urine for protein, urine protein electrophoresis (UPEP), urine immunofixation electrophoresis (UIFE); 20% positive urine protein (3)[A]:
  - Urinalysis dip is often negative for protein, as this test identifies albumin, and the protein in MM is Bence-Jones (BJ) monoclonal protein.
- Bone marrow aspirate and biopsy for histology, immunohistochemistry, flow cytometry, cytogenetics, and fluorescence in situ hybridization (FISH)
- Skeletal survey: for lytic bone lesions, osteopenia, osteoporosis, or compression fractures
- MRI for any back pain or earliest signs/symptoms of spinal cord compression
- Bone scan can be falsely negative in myeloma; use MR to confirm lesions

from skeletal survey

Follow-Up Tests & Special Considerations

- CT scan: if high suspicion for bone lesions despite normal skeletal survey; can differentiate malignant from benign vertebral compression fractures in patients who are not MRI candidates
- PET scans: used if bone involvement is suspected despite a normal skeletal survey, MRI, and CT
- Baseline bone densitometry may be indicated (3)[A].
- Bone marrow aspiration and biopsy to monitor response to treatment
- SPEP with SIFE: M protein helps to track progression of myeloma and response to treatment.
- Serum immunoglobulins and FLCs can be used to monitor response or relapse.
- Plasma cell labeling index may be helpful to identify the fraction of the myeloma cell population that is proliferating (3)[A].

Diagnostic Procedures/Other

Staging:

- Durie Salmon stage
  - Stage I: low cell mass: $<0.6 \times 10^{12}$ cells/m^2 plus all of the following: hemoglobin >10 g/dL, M protein <5 g/dL if IgG or <3 g/dL if IgA, normal serum calcium, urine BJ protein <4 g/24 hr, no generalized lytic bone lesions
  - Stage II: neither stage I nor stage III
  - Stage III: high cell mass: $>1.2 \times 10^{12}$ cells/m^2 plus one or more of the following: hemoglobin <8.5 g/L, serum calcium >12 mg/dL, bone lesions, M protein >7g/dL if IgG and >5 g/dL if IgA, urine BJ protein >12 g/24 hr, advanced lytic bone lesions
- International staging system (ISS)
  - Stage I: albumin ≥3.5 g/dL and β_2-microglobulin <3.5 μg/mL
  - Stage II: neither stage I nor stage III
  - Stage III: β_2-microglobulin ≥5.5 μg/ml
- Mayo Clinic risk stratification (mSMART)
  - Standard risk: t(11:14), t(6:14), and hyperdiploidy

- Intermediate risk: t(4:14), del(13q) by cytogenetics, hypodiploidy
- High risk: t(14:16), t(14:20), del(17 p), and plasma cell labeling index >3%

Test Interpretation

Bone marrow involvement with plasma cells ≥10%; Russell bodies

TREATMENT

- Treatment varies depending on level of disease activity and stage of MM.
- Key determinant factor in choosing chemotherapy regimen is to establish if the patient is an autologous stem cell transplant (ASCT) candidate or not.
- Treatment protocols vary by institution and patient.
- ASCT following induction chemotherapy is standard of care for patients with symptomatic disease.

GENERAL MEASURES

Maintain adequate hydration to prevent renal insufficiency. All patients receiving primary melanoma therapy should be given bisphosphonates initially (3)[A].

MEDICATION

- Induction chemotherapy for ASCT-eligible patients (1)[C]:
  - Standard risk: (lenalidomide/low-dose dexamethasone)
  - Intermediate risk: (bortezomib/cyclophosphamide/dexamethasone)
  - High risk: (bortezomib/lenalidomide/dexamethasone)
  - After ASCT, maintenance can include a bortezomib compound for the high- or intermediate-risk group; lenalidomide can be considered for the standard group. Maintenance lenalidomide after ASCT has shown to improve progression-free survival (PFS) of 41 versus 23 months with placebo and has shown to be an effective treatment for MM (4)[A].
- Induction chemotherapy for ASCT-ineligible patients:
  - Same regimens as ASCT-eligible patients, however, the number of treatment cycles are increased (1)[C].

First Line

- Bortezomib
  - A proteasome inhibitor; it blocks the ubiquitin-proteasome catalytic pathway in cells by binding to the 20S proteasome complex.
  - Toxicity: peripheral neuropathy, cytopenia, nausea
  - Consider herpes simplex virus (HSV) prophylaxis.
- Cyclophosphamide
  - Nitrogen mustard–derivative alkylating agent
  - Often used in combination with prednisone or thalidomide in cases of relapsed disease
  - Toxicity: cytopenia, anaphylaxis, interstitial pulmonary fibrosis, secondary malignancy, impaired fertility
- Immunomodulators
  - Thalidomide and lenalidomide
    - Works by antiangiogenesis inhibition, immunomodulation, and inhibition of tumor necrosis factor
    - Toxicity: birth defects, deep vein thrombosis (DVT), neuropathy, rash, nausea, bradycardia
    - DVT prophylaxis, usually with aspirin
- Dexamethasone
  - Low doses (40 mg/week) superior to higher doses
  - Increases risk of DVT
- Bisphosphonates (5)[A]
  - No effect on mortality but decrease pain, pathologic vertebral fractures, and fractures of other bones
  - IV pamidronate or zoledronic acid can be used; evidence that zoledronic acid may be superior in preventing skeletal-related events.
  - Dose-adjust/monitor renal function.
  - Monitor for osteonecrosis of jaw.
- Alternative options:
  - As first-line treatment for transplant-ineligible patients with newly diagnosed MM, bortezomib/melphalan/prednisone was associated with significantly increased PFS compared with melphalan/prednisone (6)[A].

Second Line

- May be treated with any of the agents not already used
- The following agents can be used as salvage therapy to treat relapsed or refractory MM:
  - Bortezomib/lenalidomide
  - Liposomal doxorubicin
  - Carfilzomib: 2nd-generation selective proteasome inhibitor
- Emerging options: pomalidomide, thalidomide analog
- Bortezomib is a highly effective option in previously treated/relapse patients and is well-tolerated.
- Interferon-α may be appropriate in selected patients, but because of its toxicity and availability of better alternatives, it has a limited role in treating MM.

ISSUES FOR REFERRAL

For spinal or other bone pathology, refer to orthopedics for support.

ADDITIONAL THERAPIES

- Local radiation therapy for bone pain
- Effective pain management: Avoid NSAIDs due to nephrotoxicity.
- Kyphoplasty/vertebroplasty: consider for symptomatic vertebral compressions
- Plasmapheresis: for hyperviscosity syndrome (a rare complication)
- Erythropoietin: for selected patients with anemia
- Patients should receive vaccines for pneumococcus and influenza.
- Do not administer zoster vaccine and other live-virus vaccines.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Indications: pain, infections, cytopenia, renal failure, bone complications, spinal cord compression

- Avoid IV radiographic contrast materials due to risk for contrast-induced nephropathy.
- Adequate hydration
- Manage hypercalcemia and control hyperuricemia.

ONGOING CARE

PATIENT EDUCATION

- http://myeloma.org/Main.action
- http://www.nccn.org/patients/guidelines/myeloma/index.html

PROGNOSIS

- Median survival overall is 3 years. The 5-year survival rate is around 35%.
- Median survival by ISS stage:
  - Stage I: 62 months
  - Stage II: 44 months
  - Stage III: 29 months
- Median survival in patients with high-risk MM (see staging for definition) is <2 to 3 years, even after ASCT; standard risk has median overall survival of 6 to 7 years.

COMPLICATIONS

Many; including infection, pain, lytic bone lesions, hypercalcemia, hyperuricemia, spinal cord compression, anemia, hyperviscosity syndrome, amyloidosis, renal insufficiency

CODES

ICD10

- C90.00 Multiple myeloma not having achieved remission
- C90.01 Multiple myeloma in remission
- C90.02 Multiple myeloma in relapse

CLINICAL PEARLS

- MM is a plasma cell malignancy that causes end-organ damage.
- Look for presence of “CRAB” (hypercalcemia, renal insufficiency, anemia, and bone lesions).
- Suspect MM if high total protein-to-albumin ratio is present.
- Maintain high index of suspicion for spinal cord compression.
- Avoid nephrotoxins (radiographic contrast material, NSAIDs, dehydration).
- Patients with MM are immunocompromised.

MULTIPLE SCLEROSIS

Robert A. Baldor, MD, FAAFP

BASICS

DESCRIPTION

- An autoinflammatory disease causing demyelination, neuronal loss, and scarring within the white matter of the brain and spinal cord
- Four recognized forms of multiple sclerosis (MS) (1):
  - Relapsing-remitting multiple sclerosis (RRMS): episodic flare-ups occurring over days to weeks between periods of neurologic stability. During attacks, new symptoms may present, whereas previous symptoms may worsen. Complete recovery or residual deficits may ensue following each bout.
  - Secondary progressive multiple sclerosis (SPMS): beginning as RRMS, progressive deterioration of neurologic function ensues; not associated with attacks (progression may continue or halt). ~2% risk per year of RRMS becoming SPMS
  - Primary progressive multiple sclerosis (PPMS): steady decline of neurologic function from onset of disease without episodic flares
  - Progressive relapsing multiple sclerosis (PRMS): steady decline of neurologic function from onset of disease with episodic flare-ups

Pregnancy Considerations

- Most patients experience lower exacerbation rates during pregnancy. Following delivery, the immune system reverts and MS flares become more likely.
- Breastfeeding does not affect the risk of MS relapse.
- Relapse during postpartum can be safely treated by IVIG and corticosteroids (2)[C].

EPIDEMIOLOGY

- Age: peak incidence ages 15 to 45 years, mean age 28 to 31 years (slightly earlier in women than men)

- Gender: Studies suggest F:M between 1.4:1 and 3:1.
- Latitude: Prevalence tends to rise with increasing distance from the equator, although newer data reveals this latitude gradient may be declining (3,4).

Incidence

- Women (worldwide): 3.6 cases/100,000 person-years
- Men (worldwide): 2.0 cases/100,000 person-years

Prevalence

- United States: ~350,000 MS patients
- Worldwide: ~2,500,000 MS patients

ETIOLOGY AND PATHOPHYSIOLOGY

- MS lesions: Inflammatory cells, mainly T lymphocytes and macrophages, surround vasculature within the CNS, creating sites of inflammation. These cells then disrupt the blood–brain barrier and infiltrate the surrounding white matter, meanwhile preserving the vessel wall. B lymphocytes, as well as myelin-specific autoantibodies, also infiltrate the CNS and cause degeneration of the myelin sheaths.
- Following demyelination, faster salutatory nerve conduction velocities (impulses jumping between nodes of Ranvier) are replaced with considerably slower continuous nerve velocities.
- Astrocytes begin to proliferate and cause gliosis.
- Oligodendrocytes, which have survived, or ones formed from precursor cells, are able to partially remyelinate stripped axons, producing irreversible scars.
- In each MS lesion, axonal damage may occur, but it is the cumulative axonal loss over time that is responsible for the progressive and irreversible neurologic disability seen in MS patients.
- Most axons are typically lost from the lateral corticospinal (motor) tracts of the spinal cord.

Genetics

- Strong predisposition: HLA DRB1 (5)
- Proposed predisposition: IL2RA and IL7RA
- Race: Caucasian > Africans or Asians

RISK FACTORS

- Genetic: DRB1 locus on chromosome 6 has strongest MS risk association; DRB1*15 and *16 produce major histocompatibility complexes (MHC) with high binding affinity to myelin basic proteins (MBPs) (3,5).
- Geographic: Previously, distance from equator showed association with increased risk, though now declining. However, sun exposure (ultraviolet B [UVB] radiation necessary for endogenous vitamin D production) appears to have inverse relation to MS incidence (3).
- Infectious: viral infections (especially EBV, HHV) (3,5)
- Race: Caucasian > African, Asian, Native American, although this is decreasing (5)
- Others: tobacco smoking (6)

GENERAL PREVENTION

No known preventive strategies

COMMONLY ASSOCIATED CONDITIONS

- Internuclear ophthalmoplegia (INO): Injury to the medial longitudinal fasciculus (MLF) causes impaired adduction to the affected eye.
- Optic neuritis: inflammation of optic nerve resulting in loss of vision
- Uhthoff phenomenon: Symptoms worsen with exposure to higher than usual temperature.
- Lhermitte sign: electric-like shocks extending down the spine caused by neck movement, especially flexion

DIAGNOSIS

- A person with MS can present with a number of neurologic signs and symptoms depending on the locations of the lesions within the CNS (5)[C].
- Clinical diagnosis: ≥2 attacks; objective clinical evidence of ≥2 lesions or objective clinical evidence of 1 lesion with history of a previous episode. Flare-up duration must be at least >24 hours. Relapses must be separated by ≥1 month. ≥1 out of 2 neurologic signs must be present. The second clinical sign may be obtained through an abnormal paraclinical exam such as MRI or evoked potentials (EPs) or may be supported by an abnormal paraclinical

exam (5,7)[C].

- For patients with steady decline of neurologic function for ≥6 months without flares, intrathecal IgG may be used to support the diagnosis (5)[C].

HISTORY

Symptoms may include fatigue, depression, emotional instability, epilepsy, memory loss, diplopia, sudden vision loss, facial palsy, dysarthria, dysphagia, muscle weakness or spasms, ataxia, vertigo, falls, hyperesthesia or paresthesia, pain, bowel or bladder incontinence, urinary frequency or retention, or impotence (5)[C].

PHYSICAL EXAM

- Optic disc swelling or pallor
- INO
- Nystagmus in abducting eye
- Ataxia
- Intention tremor
- Hypesthesia or paresthesia
- Cerebellar dysarthria (scanning speech)
- Spasticity (especially in lower extremities)

DIFFERENTIAL DIAGNOSIS

- Lyme disease
- Systemic lupus erythematosus (SLE)
- Antiphospholipid antibody syndrome
- Epilepsy
- Progressive multifocal leukoencephalopathy (PML)
- CNS neoplasms
- Guillain-Barré syndrome
- Metachromatic leukodystrophy
- Sarcoidosis
- Stroke
- Vascular malformation
- HIV, neurosyphilis
- Cobalamin (vitamin B_{12}) deficiency

- Acute disseminated encephalomyelitis (ADEM)
- Behçet disease
- Normal pressure hydrocephalus

DIAGNOSTIC TESTS & INTERPRETATION

- CSF: increased monocyte cell count and intrathecally formed IgG levels. Total protein within CSF may be normal or increased. The presence of oligoclonal bands (OCB) is used to determine amount of IgG intrathecally synthesized. ≥2 OCBs is diagnostic (5)[B].
- Tests used for exclusion of alternative diagnoses: antinuclear antibodies (ANAs), serum cobalamin level, erythrocyte sedimentation rate (ESR), and testing for syphilis
- MRI of head/spine (more sensitive than CT):
  - T_2 (spin-echo) image: hyperintense lesions
  - T_2 image: hypointense lesions
  - Gadolinium (Gd): Given IV, leakage of Gd into the parenchyma represents an increase in BBB permeability due to vascular breakdown.
- McDonald criteria (5):
  - Dissemination in space: ≥1 T_2 lesion on MRI in at least 2 out of 4 CNS regions typically affected by MS: periventricular, juxtacortical, infratentorial, or spinal cord or by waiting for another clinical attack implying a different CNS location
  - Dissemination in time: simultaneous presentation of asymptomatic Gd-enhanced and nonenhancing lesions at any moment or a new T_2 and/or Gd-enhanced lesion on an MRI when compared baseline scans.

Diagnostic Procedures/Other

EPs: Assess function in visual, auditory, and somatosensory or motor CNS pathways by measuring CNS electric potentials evoked by stimulation of either the brain or selected peripheral nerves; a marked delay in a provoked CNS EP, without a clinical manifestation, is suggestive of a demyelinating disorder (5).

TREATMENT

GENERAL MEASURES

- Three main categories currently exist for MS treatment: treatment for acute relapses, treatment for reducing MS-related activity using disease-modifying agents and symptomatic therapy (2,5)[B]
- For apparent acute relapse, rule out infectious etiology prior to treatment.

MEDICATION

- Acute relapses (2)[B]
  - Methylprednisolone 1 g/day IV for 3 to 5 days; without subsequent oral tapering; a second course may be given.
    - Adverse effects: fluid retention, potassium loss, weight gain, GI disturbances, acne, and emotional lability
- Reduction of MS biologic activity, interferon-β (IFN-β) (1,5,8)
  - Avonex (IFN-β1a) 30 μg IM weekly
  - Rebif (IFN-β1a) 22 or 44 μg SC 3 times per week
  - Betaseron (IFN-β_{1b}) 0.25 mg SC every other day
  - Extavia (IFN-β_{1b}) 0.25 mg SC every other day
    - CBC w/ diff., Plt, LFTs at 1, 3, and 6 months after starting Tx
    - TFTs every 6 months if Hx of thyroid dysfunction. Reduction of MS biologic activity, non-IFN-β (1,5,8)
    - Glatiramer acetate (Copaxone) 20 mg SC daily or 40 mg 3 times per week
      - Common adverse reactions: injection site reaction, nausea, chest pain, hypertonia, diaphoresis
      - No recommended routine tests
  - Natalizumab (Tysabri): 300 mg IV every 4 weeks
    - Restricted distribution in the United States; call 1-800-456-2255 for more information.
    - MRI at baseline
    - Alemtuzumab (Lemtrada) 12 mg IV daily for 5 days, then 12 months later 12 mg IV for 3 days
    - Premedicate with corticosteroids (methylprednisolone 1,000 mg) first 3 days of each treatment. Also consider antihistamines, antipyretics; antiviral prophylaxis (for herpetic viral infections) beginning on the first

day of treatment and continue at least 2 months and until CD4+ lymphocyte count is ≥200/mm^3
  - Fingolimod (Gilenya): 0.5 mg PO daily
    - ECG at baseline
    - Serious adverse reactions: QT prolongation, AV block; 6-hour observation following first dose
  - Teriflunomide (Aubagio): 7 to 14 mg PO daily
    - Avoid pregnancy, teratogenic; pregnancy test at baseline
    - Use reliable contraception during Tx.
- Symptomatic therapies (5)[B]:
  - Ataxia: clonazepam, propranolol, ondansetron
  - Spasticity: baclofen, diazepam, tizanidine, dantrolene, cyclobenzaprine hydrochloride
  - Pain: NSAIDs, carbamazepine, gabapentin, phenytoin, amitriptyline, mexiletine
  - Bladder dysfunction: (urgency) propantheline bromide, oxybutynin, tolterodine tartrate; (retention) phenoxybenzamine, terazosin hydrochloride, bethanechol
  - Constipation: high-fiber diets, fluids, natural or other laxatives, stool softeners, bulk-producing agents, suppositories
  - Sexual dysfunction: tadalafil, sildenafil, vardenafil
  - Weakness/fatigue: dalfampridine, amantadine, methylphenidate
  - Tremors: clonazepam, β-blockers, primidone
  - Depression: fluoxetine, other SSRIs, tricyclic antidepressants, nontricyclic antidepressants

ADDITIONAL THERAPIES

- Cognitive behavioral therapy
- Physical and occupational therapy
- Water therapy: Swimming, in cool water, is typically well-tolerated.
- Strenuous physical activity appears to confer protective benefit and slow the disease progression in pediatric patients.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Omega-3s have immunomodulary properties.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Treat relapses with corticosteroids to minimize disease progression and duration of relapse. Maintain regular activity but avoid overwork and fatigue. Rest during periods of acute relapse (2)[B].

Patient Monitoring

Assessing the severity of neurologic impairment from MS can be done using the Kurtzke Expanded Disability Status Scale (EDSS): 0 indicates a normal neurologic exam and 10 indicates death due to MS. The EDDS uses a functional status (FS) score, covering the following: pyramidal symptoms, cerebellar, brainstem, sensory, bowel and bladder, visual/optic, and cerebral/mental functions. EDDS scoring system (9)[C]:

- 1.0—no disability, minimal signs in 1 FS
- 2.0—minimal disability in 1 FS
- 3.0—moderate disability in 1 FS or mild disability in 3 to 4 FS, but fully ambulatory
- 4.0—ambulatory without aid or rest for ~500 m
- 5.0—ambulatory without aid or rest for ~200 m
- 6.0—intermittent/constant unilateral assistance (cane, crutch, or brace) must be able to walk 100 m
- 7.0—unable to walk beyond 5 m even with aid; essentially restricted to wheelchair, wheels self and transfers alone; active in wheelchair for ~12 hr/day
- 8.0—essentially restricted to bed, chair, or wheelchair; may be out of bed most of the day; retains self-care functions, generally effective use of arms
- 9.0—helpless, bed-bound; but patient can communicate, eat
- 10.0—death due to MS

DIET

High fiber, bulk laxatives, fluids to prevent constipation

PATIENT EDUCATION

National Multiple Sclerosis Society: 1-800-344-4867 or

www.nationalmssociety.org/

PROGNOSIS

- Differs in each individual; depends on the form of MS, the individual's sex and age, the initial presentation of the disease, and the amount of disability
- Average life expectancy is 5 to 10 years less than unaffected people.
- Specific clinical features suggesting more favorable course: early onset, RRMS form, female sex, <2 relapses within first year of diagnosis, and minimal functional decline after 5 years (5).
- Mortality secondary to MS relapse is unusual; death more commonly associated with a complication of MS such as infection in a person with more disability.

COMPLICATIONS

Depression or emotional instability, paraplegia, chronic pain, sexual dysfunction, delirium, impaired vision (9)

CODES

ICD10

G35 Multiple sclerosis

CLINICAL PEARLS

- Immune-mediated inflammatory disease causing demyelination, neuronal loss, and scarring within the white matter of the CNS
- Charcot classical MS triad: nystagmus, intention tremor, and dysarthria
- Acute relapses are treated with steroids; disease-modifying medications are used for chronic treatment; currently, there is no treatment for promoting remyelination or neuronal repair.
- Based on limited clinical data, IVIG is not thought to be effective therapy for relapsing remitting MS (10).
- Autologous stem cell transplantation for MS shows promise, but more rigorous research is needed (11,12).

MUMPS

Frances Yung-tao Wu, MD

BASICS

An acute, generalized paramyxovirus infection typically presenting with unilateral or bilateral parotitis

DESCRIPTION

- Can be asymptomatic in 1/3 of nonimmune individuals and 60% of previously vaccinated cases
- Painful parotitis occurs in 95% of symptomatic mumps cases.
- Epidemics in late winter and spring. Transmission by respiratory secretions
- Incubation period is 14 to 24 days.
- System(s) affected: hematologic/lymphatic/immunologic, reproductive, skin, exocrine
- Synonym(s): epidemic parotitis; infectious parotitis

EPIDEMIOLOGY

- Predominant age: 85% of mumps cases occur before 15 years of age.
- Adult cases are typically more severe.
- Predominant sex: male = female
- Geriatric population: Most adults are immune.
- Acute epidemic mumps
  - Most cases occur in unvaccinated children 5 to 15 years of age.
  - Recent (2015 to 2016) U.S. outbreaks in college students Illinois/Iowa:
    - Another U.S. epidemic in 2009 to 2010 in New York/New Jersey: >1,500 cases
- Mumps is unusual in children <2 years of age, and most infants <1 year are immune.
  - Period of maximal communicability is 24 hours before to 72 hours after onset of parotitis.

Incidence

- 1,057 cases in the United States in 2015

- Occasional epidemic outbreaks in a given region

Prevalence

- 0.0064/100,000 persons in United States
- 90% of adults are seropositive even without history.

ETIOLOGY AND PATHOPHYSIOLOGY

Mumps virus replicates in glandular epithelium of parotid gland, pancreas, and testes, leading to interstitial edema and inflammation.

- Interstitial glandular hemorrhage may occur.
- Pressure caused by testicular edema against the tunica albuginea can lead to necrosis and loss of function.

RISK FACTORS

- Foreign travel: Many other nations do *not* vaccinate for mumps, including most of Africa and Asia.
- Crowded environments such as dormitories, barracks, or detention facilities increase risk of transmission.
- Immunity wanes after single-dose vaccination:
  - When receiving two doses, immunity drops from 95% to 86% after 9 years.
  - Genotypic variation from original vaccine strain may have a role in decreased vaccine efficacy (1).

GENERAL PREVENTION

- Vaccination
  - Two doses of live mumps vaccine or measles-mumps-rubella (MMR) vaccine are recommended, first at 12 to 15 months and second at 4 to 6 years of age.
  - 95% effective in clinical studies, but field trials show 68–95% efficacy, which may be below level for herd immunity to prevent spread.
  - Scandinavian data suggest prevention may require 95% first-dose and >80% second-dose adherence.
  - Adverse effects: most common is idiopathic thrombocytopenic purpura (ITP), with incidence of 3.3/100,000 doses
  - *No relationship between MMR vaccine and autism*
- Immunoglobulin (Ig) does not prevent mumps.

- Postexposure vaccination does not protect from recent exposure (2)[B].
- Isolate hospitalized patients for 5 days after onset.
- Isolate nonimmune individuals for 26 days after last case onset (social quarantine).
- In an epidemic situation, a 3rd dose of MMR may decrease the attack rate (3).

Pregnancy Considerations

- Live viral vaccines are typically contraindicated in pregnancy; however, vaccination of children should not be delayed due to a pregnant family member.
- Immunization of contacts protects against future (but not current) exposures.

DIAGNOSIS

HISTORY

- Parotid swelling peaks in 1 to 3 days; lasts 3 to 7 days
- Clinical diagnosis (swelling of one or both parotid glands):
  - Lasting ≥2 days
  - No other apparent cause
  - Meningitis without parotitis (rare; 1–10%)
- 1/3 of individuals with mumps may be asymptomatic.
- Rare prodrome of fever, neck ache, and malaise
- Sour foods cause pain in parotid gland region.
- Moderate fever, usually not >104°F (40°C):
  - High fever frequently is associated with complications.

PHYSICAL EXAM

- Painful parotid swelling (unilateral or bilateral) obscures angle of mandible and elevates earlobe
- Meningeal signs in 15%, encephalitis in 0.5%
- Rarely arthritis, orchitis, thyroiditis, mastitis, pancreatitis, oophoritis, myocarditis
- Rare maculopapular, erythematous rash
- Up to 50% of cases may be very mild.
- Redness at opening of Stensen duct but no pus

- Swelling in sternal area; rare but pathognomonic of mumps

DIFFERENTIAL DIAGNOSIS

- If not epidemic, other viruses are more common: parainfluenza parotitis, Epstein-Barr virus, coxsackievirus, adenovirus, parvovirus B19
- Suppurative parotitis: often associated with *Staphylococcus aureus* (presence of pus within Wharton duct when parotid is massaged essentially excludes diagnosis of mumps)
- Recurrent allergic parotitis
- Salivary calculus with intermittent swelling
- Lymphadenitis from any cause, including HIV infection
- Cytomegalovirus parotitis (immunocompromised patients)
- Mikulicz syndrome: chronic, painless parotid and lacrimal gland swelling of unknown cause that occurs in tuberculosis, sarcoidosis, lupus, leukemia, lymphosarcoma, and salivary gland tumors
- Sjögren syndrome, diabetes mellitus, uremia, malnutrition
- Drug-related parotid enlargement (iodides, guanethidine, phenothiazine)
- Other causes of the complications of mumps (meningoencephalitis, orchitis, oophoritis, pancreatitis, polyarthritis, nephritis, myocarditis, prostatitis)
- Mumps orchitis must be differentiated from testicular torsion and from chlamydial or bacterial orchitis. (Testicular sonogram can be useful.)

DIAGNOSTIC TESTS & INTERPRETATION

- Three special tests used to confirm an outbreak—if positive, report to health department (3)[A]
  - IgM titer (positive by day 5 in 100% of nonimmunized patients)
  - Swab of parotid duct or other affected salivary ducts for viral culture
  - Rise in IgG titer samples; order if patient previously immunized: first sample within 5 days of onset, and second, 2 weeks later.
- Other potential findings: elevated serum amylase; CSF leukocytosis, or leukopenia
- Testicular ultrasound may help differentiate mumps orchitis from testicular torsion.

Diagnostic Procedures/Other

If meningitis is present, lumbar puncture to exclude bacterial process. CSF pleocytosis, usually lymphocytes, is found in 65% of patients with parotitis.

Test Interpretation

Periductal edema and lymphocytic infiltration in affected glands on biopsy

TREATMENT

- No specific antiviral therapy, only supportive care (3)[A],(4)[C]
- Analgesics to relieve pain
- Avoid corticosteroids for mumps orchitis because they can reduce testosterone concentrations and increase testicular atrophy.
- IVIG only successful for certain autoimmune-based sequelae:
  - Postinfectious encephalitis
  - Guillain-Barré syndrome
  - ITP
- Interferon-α2b improved severe bilateral orchitis but did not decrease testicular atrophy in small studies (5)[B].

GENERAL MEASURES

- Rarely need to hospitalize patients with high fever, pancreatitis, or CNS symptoms for supportive care, steroids, or interferon. Use isolation precautions.
- Orchitis
  - Ice packs to scrotum can help to relieve pain.
  - Scrotal support with adhesive bridge while recumbent and/or athletic supporter while ambulatory

MEDICATION

First Line

- Analgesics and anti-inflammatory medications (acetaminophen, nonsteroidal anti-inflammatory drugs [NSAIDs]) may diminish pain and swelling in acute orchitis and arthritis mumps.
- May use acetaminophen for fever and/or pain
- Precautions: Avoid aspirin for pain in children as previously associated with

Reye syndrome.

Second Line

- Interferon-α2b (5)[B]
- Medicinal herbs and acupuncture have not shown benefit in randomized controlled trials.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Hospitalize only if CNS symptoms occur.
- Outpatient supportive care if no complications
- IV fluids if severe nausea or vomiting accompanies pancreatitis

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Mumps orchitis:

- Bed rest and local supportive clothing (e.g., two pairs of briefs) or adhesive-tape bridge
- Withhold from school until no longer contagious (9 days after onset of pain)

Patient Monitoring

Most cases will be mild. Monitor hydration status.

DIET

Liquid diet if unable to chew

PATIENT EDUCATION

Orchitis is common in older children but rarely results in sterility, even if bilateral.

PROGNOSIS

- Complete recovery is typical; immunity is lifelong.
- Transient sensorineural hearing loss in 4% of adults
- Recurrence after 2 weeks may be nonepidemic parotitis.

COMPLICATIONS

- May precede, accompany, or follow salivary gland involvement and may occur (rarely) without primary involvement of the parotid gland
- Orchitis is common (30%) in postpubertal boys:
  – It starts within 8 days of onset of parotitis.
  – Impaired fertility in 13%; absolute sterility is rare.
- Meningitis (1–10%) or encephalitis (0.1%) may present 5 to 10 days after first symptoms of illness. Aseptic meningitis is typically mild, but meningoencephalitis may lead to seizures, paralysis, hydrocephalus, or (in 2% of cases) death.
- Acute cerebellar ataxia has been reported after mumps infections; self-resolving in 2 to 3 weeks
- Oophoritis in 7% of postpubertal females; no decreased fertility
- Pancreatitis, usually mild
- Nephritis, thyroiditis, and arthralgias are rare.
- Myocarditis: usually mild but may depress ST segment; may be linked to endocardial fibroelastosis
- Deafness: 1/15,000 unilateral nerve deafness; may not be permanent
- Inflammation about the eye (keratouveitis) is rare.
- Dacryoadenitis, optic neuritis

Pediatric Considerations

- Orchitis is more common in adolescents.
- Young children are less likely to develop complications.
- Most complications occur in postpubertal group.
- Avoid aspirin use in children with viral symptoms.

Pregnancy Considerations

Disease may increase the rate of spontaneous pregnancy loss in 1st trimester. Perinatal mumps often has a benign course.

CODES

ICD10

- B26.9 Mumps without complication
- B26.1 Mumps meningitis
- B26.2 Mumps encephalitis

CLINICAL PEARLS

- Mumps is a clinical diagnosis based on swelling of ≥1 parotid glands for ≥2 days without other obvious cause. Confirmatory testing must be done in epidemic settings.
- Ultrasound is useful to distinguish testicular torsion from testicular pain related to mumps orchitis.
- A history of vaccination with MMR does not exclude mumps. The MMR vaccine is 68–95% effective after a series of two immunizations. Immunity commonly wanes over time.

MUSCULAR DYSTROPHY

Nimmy Thakolkaran, MD • George G.A. Pujalte, MD, FACSM

BASICS

- Primary inherited myopathies caused by dysfunctional proteins of muscle fibers and extracellular matrix
- Distribution of weakness, other associated symptoms, and disease prognosis depend on the specific gene affected and severity of the mutation.

DESCRIPTION

- Duchenne muscular dystrophy (DMD)
  - Highest incidence muscular dystrophy, X-linked inheritance, early onset, progressive
  - Patients are wheelchair-dependent prior to age 13 years.
- Becker muscular dystrophy (BMD)
  - Less severe phenotype than Duchenne, also caused by mutation in *DMD* gene; later onset and milder clinical course
  - Distinction from DMD is clinical: Patients are usually wheelchair-dependent after age 16 years.
  - Collectively referred to as dystrophinopathies
- Myotonic muscular dystrophy (MMD)
  - Myotonia (slow relaxation after muscle contraction), distal and facial weakness
  - Second most common inherited muscle disease.
- Facioscapulohumeral muscular dystrophy (FSHMD)
  - Facial and shoulder muscles most affected
  - Third most common inherited muscle disease.
- Limb-girdle muscular dystrophy (LGMD)
  - Proximal weakness and atrophy, variable prognosis with many different identified mutations
- Oculopharyngeal muscular dystrophy (OPMD)

  - Usually adult-onset, affects extraocular and pharyngeal muscles. Presents with ptosis and dysphagia
- Emery-Dreifuss muscular dystrophy (EDMD)
  - Triad of early development of joint contractures, slowly progressive muscle wasting, and cardiomyopathy. Can present as sudden death in apparently healthy young adults
- Congenital muscular dystrophies (CMD)
  - Heterogeneous group of autosomal recessive myopathic diseases presenting in infancy with generally poor prognosis
  - Includes Fukuyama CMD, Ullrich CMD, Walker-Warburg syndrome, muscle-eye-brain disease

EPIDEMIOLOGY

Incidence

- Duchenne: 1/3,600 male births (1)
- Myotonic dystrophy: 1/10,000 births
- Other muscular dystrophies vary widely by population but are generally rare.

ETIOLOGY AND PATHOPHYSIOLOGY

Mutations affect proteins connecting cytoskeleton to cell membrane and extracellular matrix, causing muscle fibers to become fragile and easily damaged; muscle weakness and atrophy result.

- DMD/BMD
  - Defective protein is dystrophin, product of the largest human gene, *DMD*; Duchenne phenotype results from mutations that cause profound loss of dystrophin, the protein involved in calcium transport in muscle cells and stabilizing fibers during contraction.
  - Becker phenotype results from less severe mutations in *DMD* gene; patients have low but detectable levels of functional dystrophin.
- MMD: Trinucleotide repeat expansion in the untranslated region of the gene *DMPK* on chromosome 19; encodes myotonin–protein kinase
- LGMD: mutations in genes encoding proteins associated with dystrophin: calpain-, dysferlin-, and fukutin-related proteins are affected most commonly.
- EDMD: Dysfunctional proteins are associated with the nuclear membrane in muscle fibers; emerin in X-linked form, lamin A/C in autosomal forms

- OPMD: Trinucleotide repeat expansion in *PABPN1* results in nuclear inclusions in muscle cells by hampering normal transport of mRNA from the nucleus.
- FSHMD: Deletion in untranslated region of chromosome 4; function of deleted genes is unclear, although the most accepted concept is that they likely affect the expression of multiple genes by epigenetic effects.

Genetics

- X-linked
  - Duchenne and Becker muscular dystrophies
  - Gene located at Xp21
    - 30% of affected males have a de novo mutation (mother is not a carrier).
    - 20% of female carriers have some manifestation of the mutation (usually mild muscle weakness or cardiomyopathy).
- Autosomal dominant
  - Generally later onset and less severe than diseases with recessive or X-linked inheritance
  - FSHMD, OPMD, some forms of LGMD and EDMD
  - Myotonic dystrophy
    - Trinucleotide repeat expansion with more severe phenotype in subsequent generations due to accumulation of repeats
- Autosomal recessive
  - Most types of CMD

GENERAL PREVENTION

Genetic counseling for carriers and prenatal diagnosis

COMMONLY ASSOCIATED CONDITIONS

- Decreased IQ: on average, 1 *SD* below the mean in DMD; speech and language delay
- Dilated cardiomyopathy and conduction abnormalities
  - Can be severe in EDMD
  - Can affect otherwise asymptomatic female carriers of DMD
  - Progressive scoliosis

DIAGNOSIS

HISTORY

- DMD: normal attainment of early motor milestones with subsequent abnormal gait and slowing gross motor development: clumsiness, waddling gait, frequent falls, difficulty running or climbing stairs
- BMD: progressive difficulty with ambulation and frequent falls in later childhood
- MMD: slurred speech, muscle wasting, difficulty with ambulation; often with family history
- LGMD: back pain, lordosis/inability to rise from a chair, climb stairs, and use arms overhead
- FSHMD: facial weakness, inability to close eyes completely
- EDMD: contractures of elbows and ankles, difficulty with ambulation in teenage years
- OPMD: ptosis and dysphagia; often with family history

PHYSICAL EXAM

- DMD/BMD
  - Proximal muscle weakness; Gower sign: use of arms to push upper body into standing posture from lying prone
  - Trendelenburg gait (hip waddling)
  - Hyporeflexia/areflexia
  - Winged scapulae and lordosis
  - Pseudohypertrophy of the calf (caused by replacement of muscle with fibroadipose tissue)
  - Contractures of lower extremity joints and elbows
- MMD
  - Characteristic facial appearance: narrow face, open triangular mouth, high-arched palate, concave temples, drooping eyelids, frontal balding in males
  - Myotonia: inability to relax muscles after contraction
  - Distal muscle weakness and wasting
- CMD
  - Arthrogryposis (multiple joint contractures); diffuse hypotonia and muscle

wasting in an infant

DIFFERENTIAL DIAGNOSIS

- Glycogen storage diseases and other metabolic myopathies
- Mitochondrial myopathies: MELAS (**M**itochondrial **E**ncephalopathy, **L**actic **A**cidosis, and **S**troke-like episodes), MERRF (**M**yoclonus with **E**pilepsy and **R**agged-**R**ed **F**ibers)
- Inflammatory myopathies: polymyositis, dermatomyositis, inclusion-body myositis
- Neuromuscular junction diseases: myasthenia gravis, Lambert-Eaton syndrome
- Motor neuron diseases: amyotrophic lateral sclerosis, spinal muscular atrophy
- Charcot-Marie-Tooth disease
- Friedreich ataxia

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Creatine kinase (CK): initial screening test if MD is suspected (2)[A]
- Elevated in DMD (10 to 100 times); elevated at birth, peaks at time of presentation, and falls during illness
- Initial detected lab abnormality may be elevated aspartate transaminase/alanine transaminase (AST/ALT) originating from muscle.
- Genetic testing/molecular diagnosis
  - For definitive diagnosis in patient with characteristic presentation and elevated CK
  - Deletion and duplication analysis (MLPA or CGH) will identify most patients; followed by genomic sequencing of *DMD* gene for point mutations (3)[A].
  - Genetic testing is available clinically for most other muscular dystrophies.

Diagnostic Procedures/Other

- Muscle biopsy: rarely performed in DMD (dystrophin protein absent); may be helpful in other cases (4)[A]
- Electromyography and nerve conduction studies are not necessary unless considering alternative diagnoses.

- ECG: abnormalities found in >90% of males and up to 10% of female carriers of DMD; Q waves in anterolateral leads, tall R waves in V1, shortened PR interval, arrhythmias, resting sinus tachycardia

Test Interpretation

- Heterogenic muscle fibers: atrophy and hypertrophy of fibers with proliferation of connective tissue in muscle
- Immunohistochemical staining for dystrophin protein
  - DMD: no detectable dystrophin in most fibers; occasional revertant fibers with normal dystrophin
  - BMD: highly variable staining for dystrophin throughout muscle

TREATMENT

Trials of agents that affect gene expression, such as antisense oligonucleotides, and small molecules that cause skipping of premature stop codons (ataluren) are ongoing; however, steroid treatment is the only clinically available therapy that affects disease progression.

GENERAL MEASURES

- Ambulation prolonged by knee-ankle-foot orthoses
- Serial casting to treat contractures
- Diagnose sleep apnea with polysomnography; treat with noninvasive ventilation.
- Adaptive devices to improve function
- Avoid overexertion and strenuous exercise.

MEDICATION

- Prednisone 0.75 mg/kg/day (4)[A]
  - Slows the decline in muscle function, progression to scoliosis, and degradation of pulmonary function; prolongs functional ambulation; prolongs lifespan; improved cardiac outcomes
  - Therapy should be initiated when there is no longer progress in motor skills, but prior to decline (2).
  - Monitor adverse effects.

    - Bisphosphonates should be considered for preventing loss of bone density; annual exam for cataracts; hypertension should be monitored; no NSAIDs due to risk of peptic ulcer disease (PUD); stress-dose steroids during surgeries and illnesses due to adrenal suppression.
    - Patients should be aware of immune suppression and notify emergency providers.
- Deflazacort (0.9 mg/kg) is an alternative oral steroid that is also considered first-line therapy in DMD; it acts on muscle regeneration and differentiation; not available in the United States (3)
- ACE inhibitors
  – Treatment of cardiomyopathy; may be used in conjunction with β-blockers

ISSUES FOR REFERRAL

- Refer to neuromuscular diseases center for definitive diagnosis and coordinated multidisciplinary care (4).
- Cardiology for management of cardiomyopathy
- Pulmonology for monitoring of pulmonary function and clearance regimen
- Physical medicine and rehabilitation for management of adaptive devices
- Nutrition/swallowing: for normal weight gain, attention for dysphagia
- Psychosocial: learning/behavior and coping assessment, social development (2)

ADDITIONAL THERAPIES

Novel medication: Ataluren interferes with premature stop codons, allowing expression of dystrophin protein. In DMD patients with nonsense mutation; FDA approved orphan drug designation (3)

SURGERY/OTHER PROCEDURES

- Spinal surgery for scoliosis—diminishes rate of deformity progression (5),(6) [A].
- Scapular fixation for scapular winging may be beneficial; also lacking clinical trials
- Consider surgical treatment of ankle/knee contractures.
- Surgical procedures should be performed at a center experienced in DMD; total IV anesthesia should be used.

ONGOING CARE

- Individualized education plan and developmental evaluation for school accommodations
- Maintenance of current influenza and pneumococcal vaccination status

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Electrocardiogram (ECG), echocardiogram, and consultation with a cardiologist at diagnosis and annually after age 10 years
  - Female carriers of DMD mutation should be monitored every 5 years.
- Annual spinal radiography for scoliosis
- Dual-energy x-ray absorptiometry (DEXA) scanning and serum marker testing for osteoporosis
- Pulmonary function testing twice yearly if no longer ambulatory
- Psychosocial: coping, emotional adjustment, depression

DIET

- Obesity is common due to steroid treatment and wheelchair confinement: Weight control can improve quality of life.
- Diet may be limited by dysphagia; swallow evaluation can determine appropriate foods; may require gastrostomy
- Calcium and vitamin D supplementation for patients on steroids; monitor vitamin D levels.

PATIENT EDUCATION

- Muscular Dystrophy Association: http://www.mda.org
- Parent Project Muscular Dystrophy: http://www.endduchenne.org

PROGNOSIS

- DMD/BMD
  - Progressive weakness, contractures, inability to walk
  - Kyphoscoliosis and progressive decline in respiratory vital capacity with recurrent pulmonary infections.
  - Significantly shortened lifespan (DMD: 16 ± 4 years; BMD: 42 ± 16 years). Respiratory failure cause of death in 90%; remaining due to myocardial

disease (heart failure and dysrhythmia) (5)

- Other types: slow progression and near-normal lifespan with functional limitations

COMPLICATIONS

- Cardiac arrhythmia, cardiomyopathy
- Dysphagia, gastroesophageal reflux disease (GERD), constipation
- Scoliosis, joint contractures
- Obstructive sleep apnea
- Malignant hyperthermia–like reaction to anesthesia
- Respiratory failure and early death

CODES

ICD10

- G71.0 Muscular dystrophy
- G71.11 Myotonic muscular dystrophy
- G71.2 Congenital myopathies

CLINICAL PEARLS

- Primary care providers should have a low threshold to obtain serum CK as a

screening test in the face of gross motor delay/muscular weakness, especially in boys.

- Steroids should be initiated in patients with DMD when gross motor function ceases to progress.
- High-quality care of patients requires a medical home; a multidisciplinary team of physicians, therapists, and other providers; and extensive patient and family support.

MYASTHENIA GRAVIS

Melody A. Jordahl-Iafrato, MD

BASICS

DESCRIPTION

Primary disorder of neuromuscular transmission characterized by fluctuating muscle weakness:

- Ocular myasthenia gravis (MG) (15%): weakness limited to eyelids and extraocular muscles
- Generalized MG (85%): commonly affects ocular as well as a variable combination of bulbar, proximal limb, and respiratory muscles
- 50% of patients who present with ocular symptoms develop generalized MG within 2 years.
- Onset may be sudden and severe, but it is typically mild and intermittent over many years, maximum severity reached within 3 years for 85%.
- System(s) affected: neurologic; hematologic; lymphatic; immunologic; musculoskeletal

EPIDEMIOLOGY

Occurs at any age but a bimodal distribution to the age of onset:

- Female predominance: 20 to 40 years
- Male predominance: 60 to 80 years

Incidence

Estimated annual incidence 2 to 21/1 million

Prevalence

In the United States, 200/1 million; increasing over the past 5 decades

Pediatric Considerations

A transient form of neonatal MG seen in 10–20% of infants born to mothers with MG. It occurs as a result of the transplacental passage of maternal antibodies that interfere with function of the neuromuscular junction; resolves in weeks to months.

ETIOLOGY AND PATHOPHYSIOLOGY

- Reduction in the function of acetylcholine receptors (AChR) at muscle endplates, resulting in insufficient neuromuscular transmission
- Antibody-mediated autoimmune disorder
- Antibodies are present in most cases of MG.
  - Seropositive/antiacetylcholine receptor (anti-AChR): a humoral, antibody-mediated, T-cell–dependent attack of the AChRs or receptor-associated proteins at the postsynaptic membrane of the neuromuscular junction. Found in 85% of generalized MG and 50% of ocular MG. Thymic abnormalities common (1)
  - Muscle-specific kinase (MuSK). 5% of generalized MG patients. Typically females. Is a severe form, respiratory and bulbar muscles involved. Thymic abnormalities are rare (1).
  - In remainder of seronegative, 12–50% with anti-LRP4, a molecule that forms a complex with MuSK, clinical phenotype not well defined (1)
  - Seronegative MG (SNMG): 5%; may have anti-AChR detectable by cell-based assay. Clinically similar to anti-AChR, thymic hyperplasia may be present (1).
- Also documented immediately after viral infections (measles, Epstein-Barr virus [EBV], HIV, and human T-lymphotropic virus [HTLV])

Genetics

- Congenital MG syndrome describes a collection of rare hereditary disorders. This condition is not immune-mediated but instead, results from the mutation of a component of the neuromuscular junction (autosomal recessive).
- Familial predisposition is seen in 5% of cases.

RISK FACTORS

- Familial MG
- D-penicillamine (drug-induced MG)
- Other autoimmune diseases

COMMONLY ASSOCIATED CONDITIONS

- Thymic hyperplasia (60–70%)
- Thymoma (10–15%)

- Autoimmune thyroid disease (3–8%)

DIAGNOSIS

Myasthenia Gravis Foundation of America Clinical Classification (2)[C]:

- Class I: any eye muscle weakness, possible ptosis, no other evidence of muscle weakness elsewhere
- Class II: eye muscle weakness of any severity; mild weakness of other muscles:
  - Class IIa: predominantly limb or axial muscles
  - Class IIb: predominantly bulbar and/or respiratory muscles
- Class III: eye muscle weakness of any severity; moderate weakness of other muscles:
  - Class IIIa: predominantly limb or axial muscles
  - Class IIIb: predominantly bulbar and/or respiratory muscles
- Class IV: eye muscle weakness of any severity; severe weakness of other muscles:
  - Class IVa: predominantly limb/axial muscles
  - Class IVb: predominantly bulbar and/or respiratory muscles (can also include feeding tube without intubation)
- Class V: intubation needed to maintain airway

HISTORY

The hallmark of MG is fatigability.

- Fluctuating weakness, often subtle, that worsens during the day and after prolonged use of affected muscles, may improve with rest
- Early symptoms are transient with asymptomatic periods lasting days or weeks.
- With progression, asymptomatic periods shorten, and symptoms fluctuate from mild to severe.
- >50% of patients present with ocular symptoms (ptosis and/or diplopia). Eventually, 90% of patients with MG develop ocular symptoms.
- Ptosis might be unilateral, bilateral, or shifting from eye to eye.
- 15% present with bulbar symptoms.

- <5% present with proximal limb weakness alone.

ALERT
Myasthenic crisis: respiratory muscle weakness producing respiratory insufficiency and pending respiratory failure

PHYSICAL EXAM

- Ptosis may worsen with propping of opposite eyelid (curtain sign) or sustained upward gaze.
- "Myasthenic sneer," in which the midlip rises but corners of mouth do not move.
- Muscle weakness is usually proximal and symmetric.
- Test for muscle fatigability by repetitive or prolonged use of individual muscles.
- Important to test and monitor respiratory function.

DIFFERENTIAL DIAGNOSIS

- Thyroid ophthalmopathy
- Oculopharyngeal muscular dystrophy
- Myotonic dystrophy
- Kearns-Sayre syndrome
- Chronic progressive external ophthalmoplegia
- Brainstem and motor cranial nerve lesions
- Botulism
- Motor neuron disease (e.g., amyotrophic lateral sclerosis [ALS])
- Lambert-Eaton myasthenic syndrome
- Drug-induced myasthenia
- Congenital myasthenic syndrome
- Dermatomyositis/polymyositis
- Neurosarcoidosis
- Tolosa-Hunt syndrome

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Anti-AChR antibody (74–85% are seropositive):
  - Generalized myasthenia: 75–85%

  - Ocular myasthenia: 50%
  - MG and thymoma: 98–100%
  - Poor correlation between antibody titer and disease severity (1)[C]
  - False-positive results in thymoma without MG, Lambert-Eaton myasthenic syndrome, small cell lung cancer, and rheumatoid arthritis treated with penicillamine
- Anti-MuSK antibody:
  - Used if MG is suspected, patient seronegative
  - Strong correlation between titer and disease severity (1)[C]
- LRP4 and clustered anti-AChR:
  - Used if MG suspected, patient seronegative
- Thyroid and other autoimmune testing antistriated muscle (anti-SM) antibody:
  - Present in 84% of patients with thymoma who are <40 years of age
  - Can be present without thymoma in patients >40 years of age
- Chest radiographs or CT scans may identify a thymoma.
- MRI of brain and orbits to rule out other causes of cranial nerve deficit

Diagnostic Procedures/Other

- Tensilon (Edrophonium) test:
  - Initial 2-mg IV dose, followed by another 2 mg every 60 seconds up to a maximum dose of 10 mg
  - A positive test shows improvement of strength within 30 seconds of administration.
  - Sensitivity 80–90% (3)[C]
  - Cardiac disease and bronchial asthma are relative contraindications, especially in elderly.
  - Atropine: 0.4 to 0.6 mg IV may rarely be required as antidote; must be available.
  - Can also do trial of other cholinesterase inhibitors (neostigmine or oral) and monitor response
- Ice pack test:
  - Ice pack applied to closed eyelid for 60 seconds, then removed; extent of ptosis immediately assessed.
  - Ice will decrease the ptosis induced by MG.
  - Sensitivity 80% in patients with prominent ptosis

- Electrophysiology testing:
  - Repetitive nerve stimulation (RNS):
    - Widely available, most frequently used
    - Moderately sensitive for both generalized MG (75%) and ocular MG (50%) (3)[C]
  - Single-fiber electromyogram (SFEMG):
    - Assesses temporal variability between two muscle fibers within same motor unit (jitter)
    - Sensitive (90–95%) but less specific
    - Technically difficult to perform; limited availability, use if suspected and negative RNS (3)[C]

Test Interpretation

- Lymphofollicular hyperplasia of thymic medulla occurs in 65% of patients with MG, thymoma in 15%.
- Immunofluorescence: IgG antibodies and complement on receptor membranes in seropositive patients

TREATMENT

GENERAL MEASURES

- Treatment based on age, gender, and disease severity and progression
- Three basic approaches: symptomatic, immunosuppressive, and supportive. Few should receive a single therapeutic modality.

MEDICATION

First Line

Symptomatic treatments (anticholinesterase agents)

- Pyridostigmine bromide (Mestinon):
  - *Most commonly prescribed because available in oral tablet*
  - Starting dose of 30 mg PO TID with food
  - Maximum dose: 120 mg q3–4h
  - Long-acting available, but effect not consistent
- Neostigmine methylsulfate (Prostigmin):

  - Starting dose of 0.5 mg SC or IM q3h
  - Titrate dosage to clinical need.
- Patients with anti-MuSK may not respond well to these meds.

Second Line

- Immunosuppressants: Oral corticosteroids are the first choice of drugs when immunosuppression is necessary.
  - Prednisone: Start as inpatient with a 60 mg/day PO; taper the dosage every 3 days; switch to alternate-day regimen within 2 weeks. Taper very slowly to establish the minimum dosage necessary to maintain remission (4)[B].
  - Cyclophosphamide: adults: 1 to 5 mg/kg/day PO; children: 2 to 8 mg/kg/day PO (5)[B]
  - Cyclosporine: adults: 5 mg/kg/day PO (nephrotoxicity and drug interactions) (5)[B]
  - Mycophenolate: 1 g PO or IV BID
  - Azathioprine: 100 to 200 mg/day PO (5)[B]
    - *Most frequently used for long-term immunomodulation*, similar efficacy to steroids and IVIG
    - Benefit may not be apparent for up to 18 months after initiation of therapy.
    - Prednisolone + azathioprine may be effective when used as a corticosteroid-sparing agent.
- Acute immunomodulating treatments:
  - Plasmapheresis: bulk removal of 2 to 3 L of plasma 3 times per week, repeated until rate of improvement plateaus (6)[B]
    - Improves weakness in nearly all and can last up to 3 months
  - Immunoglobulin: 2 g/kg IV over 2 to 5 days (5)[B]
  - *Plasmapheresis and immunoglobulin have comparable efficacy in treating moderate to severe MG* (6)[C].
  - Rapid onset of effect but short duration of action
  - Used for acute worsening of MG to improve strength prior to surgery, prevent acute exacerbations induced by corticosteroids, and as a chronic intermittent treatment to provide relief in refractory MG.
- Other immunosuppressant therapies:

- Tacrolimus
- Rituximab:
  - Seronegative MuSK-antibody positive MG patients may have better response to rituximab than conventional therapies.

ALERT

Use caution with drugs that can precipitate weakness: aminoglycosides, fluoroquinolones, β-blockers, calcium channel blockers, neuromuscular blockers, statins, diuretics, oral contraceptives, gabapentin, phenytoin, lithium, among others.

SURGERY/OTHER PROCEDURES

- Thymectomy recommended for patients with thymic abnormalities
- May be beneficial for patients without thymic abnormalities in those <60 years of age

Pediatric Considerations

- Infants with severe weakness from transient neonatal myasthenia may be treated with oral pyridostigmine; general support is necessary until the condition clears.
- Corticosteroids limited only to severe disease

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Management of pulmonary infections
- Myasthenic/cholinergic crises
- Plasmapheresis
- IV γ-globulin

ONGOING CARE

PATIENT EDUCATION

MG Foundation of America (MGFA): http://www.myasthenia.org/

PROGNOSIS

- Overall good but highly variable

- Myasthenic crisis associated with substantial morbidity and 4% mortality
- Seronegative patients are more likely to have purely ocular disease, and those with generalized SNMG have a better outcome after treatment.

COMPLICATIONS

Acute respiratory arrest; chronic respiratory insufficiency

CODES

ICD10

- G70.00 Myasthenia gravis without (acute) exacerbation
- G70.01 Myasthenia gravis with (acute) exacerbation
- P94.0 Transient neonatal myasthenia gravis

CLINICAL PEARLS

- An autoimmune disease, marked by abnormal fatigability and weakness of selected muscles, which is relieved by rest
- Anticholinesterase medication and a thymectomy lessen symptom severity.
- Steroid therapy, plasma exchange, or immunoglobulin can be used in severely affected patients.

MYELODYSPLASTIC SYNDROMES

Richard A. Larson, MD

BASICS

DESCRIPTION

Myelodysplastic syndromes (MDSs) constitute a heterogeneous group of acquired hematopoietic stem cell disorders characterized by cytologic dysplasia in the bone marrow and blood and by various combinations of anemia, neutropenia, and thrombocytopenia.

- The natural progression of disease evolves as cellular maturation becomes more arrested and blast cells accumulate. There is an overlap between arbitrary diagnostic subgroups (1)[C],(2)[A],(3)[C]. World Health Organization (WHO) classification
  - MDS with single lineage dysplasia (SLD)
  - Cytopenia with <5% blasts and <15% ring sideroblasts in marrow; <1% blasts in blood
  - MDS with multilineage dysplasia (MLD)
  - Marked trilineage dysplasia but with <5% blasts in marrow; no Auer rods; <1% blasts in blood
  - MDS with ring sideroblasts (MDS-RS)
  - <5% blasts in marrow; ≥15% of erythroid precursors are ring sideroblasts; <1% blasts in blood. Also known as acquired idiopathic sideroblastic anemia
  - MDS with isolated del(5q)
  - Typically, anemia with erythroid hyperplasia, increased megakaryocytes with hypolobated nuclei, and normal or increased platelets; <5% blasts in marrow; <1% blasts in blood. No Auer rods
  - MDS with excess blasts (EB)
  - MDS-EB-1: 5–9% blasts in marrow or 2–4% blasts in blood. No Auer rods
  - MDS-EB-2: 10–19% blasts in marrow or 5–19% blasts in blood or Auer rods
  - MDS, unclassifiable

  - Myeloid neoplasms with germ line predisposition
  - Chronic myelomonocytic leukemia (CMML) is now grouped with myelodysplastic/myeloproliferative disorders:
  - >1,000 monocytes/μL blood and >10% of all WBCs. <20% blasts in marrow and blood
  - MDS/MPN with ring sideroblasts and thrombocytosis
  - Anemia with >15% ring sideroblasts, <5% marrow blasts, <1% blood blasts; platelets >450,000/ μL. Often with mutation in *SF3B1*
  - Therapy-related MDS (t-MDS):
  - Typically seen 3 to 7 years after treatment with alkylating agents and/or radiotherapy. Evolves to AML over ~6 months. Classified by the WHO as therapy-related myeloid neoplasm
  - MDS-EB in transformation is now considered acute myeloid leukemia (AML, >20% blasts).
- System(s) affected: hematologic, lymphatic, immunologic
- Synonym(s): dysmyelopoietic syndrome; hemopoietic dysplasia; preleukemia; smoldering or subacute myeloid leukemia

Pediatric Considerations

Pediatric presentations of MDS

- Monosomy 7 syndrome
- Juvenile chronic myelogenous leukemia

EPIDEMIOLOGY

- Predominant age: median age, >65 years; uncommon in children and young adults
- Predominant sex: male = female

Incidence

Apparent increased incidence (1 to 2/100,000 per year) in recent years may be due to improved diagnosis; incidence increases markedly with older age.

Genetics

- Most are clonal neoplasms by cytogenetics, G6PD isoenzyme analysis, or restriction fragment length polymorphism analysis.
- Mutations in *RAS* oncogene

- Mutations in *RPS14* gene on chromosome 5q
- Mutations in *TET2*, *SF3B1*, *SRSF2*, *U2AF1*, *DNMT3A*, *ASXL1*

RISK FACTORS

- Primary MDS is associated with older age, occupational exposure to petroleum solvents (benzene, gasoline), and smoking.
- Secondary (therapy-related) MDS is associated with prior treatment with alkylating agents or radiotherapy.

COMMONLY ASSOCIATED CONDITIONS

- Anemia
- Neutropenia
- Thrombocytopenia
- Pancytopenia
- Opportunistic infections
- Bleeding, bruising
- Sweet syndrome (neutrophilic dermatosis)

DIAGNOSIS

HISTORY

- Fatigue
- Fever
- Easy bruising

PHYSICAL EXAM

- Anemia
  - Fatigue
  - Shortness of breath
  - Light-headedness
  - Angina
- Leukopenia
  - Fever
  - Infection
- Thrombocytopenia

  - Ecchymoses
  - Petechiae
  - Epistaxis
  - Purpura
- Splenomegaly (uncommon)
  - Mild to moderate enlargement may be encountered, particularly in CMMoL.
- Skin infiltrates
  - Sweet syndrome

DIFFERENTIAL DIAGNOSIS

- Other malignant disorders
  - Evolving AML or erythroleukemia
  - Chronic myeloproliferative neoplasm
  - Polycythemia vera
  - Myeloid metaplasia with myelofibrosis
  - Malignant lymphoma
  - Metastatic carcinoma
- Nonmalignant disorders
  - Aplastic anemia
  - Autoimmune disorders (Felty syndrome, lupus, hemolytic anemia)
  - Nutritional deficiencies (vitamin B_{12}, pyridoxine, copper, protein malnutrition)
  - Heavy metal intoxication (arsenic, lead)
  - Alcoholism
  - Chronic liver disease
  - Hypersplenism
  - Chronic inflammation
  - Recent cytotoxic therapy or irradiation
  - HIV infection
  - Paroxysmal nocturnal hemoglobinuria

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- CBC with differential and peripheral smear

- Reticulocyte count and serum erythropoietin level if anemia were present
- Review of the peripheral blood smear for the presence of dysplasia
- Lead, arsenic, ESR/CRP, hepatitis profile, HIV, B_{12} (4)[A]
- Liver/spleen scan or CT, although rarely necessary, may disclose occult splenomegaly or lymphadenopathy.
- Cytogenetics
  - At least 50% of patients with primary MDS and nearly all with t-MDS have clonal chromosomal abnormalities: +8, −7, del(5q), del(7q), del(20q), iso(17p), various others, and complex karyotypes.
  - Detection of clonal abnormality establishes a diagnosis of neoplasm and rules out a nutritional, toxic, or autoimmune disorder.
  - Cytogenetic analysis of metaphase cells from a bone marrow aspiration provides more information than fluorescence in situ hybridization analysis on blood cells.
- Granulocyte function tests: abnormal in 50% (decreased myeloperoxidase activity, phagocytosis, chemotaxis, and adhesion)
- Platelet function tests: impaired aggregation
- Marrow colony assays in vitro
  - Results are variable and correlate poorly with clinical course.
  - Poor clonal growth may suggest more rapid evolution to AML.
- Immunophenotyping
  - Nonspecific myeloid markers are present.
  - Occasionally, evidence can be found for concomitant lymphoproliferative disorder.
  - Loss of CD59 expression suggests paroxysmal nocturnal hemoglobinuria (PNH).

Follow-Up Tests & Special Considerations

- Anemia: often macrocytic; occasional poikilocytosis, anisocytosis; variable reticulocytosis
- Granulocytopenia: hypogranular or agranular neutrophils with poorly condensed chromatin; Pelger-Huet anomaly with hyposegmented nuclei
- Thrombocytopenia: occasionally giant platelets or hypogranular platelets
- Fetal hemoglobin may be elevated.
- Flow cytometry to detect loss of CD59 on RBCs, CD16 on granulocytes, and

CD14 on monocytes; typical of PNH
- Direct antiglobulin (Coombs) test
- Paraprotein: present in some
- Erythropoietin: usually normally elevated given the degree of anemia unless renal failure is present
- Increased serum and tissue iron (ferritin), especially if anemia has been long-standing
- Serum copper level

Diagnostic Procedures/Other
- Review peripheral blood smear.
- Bone marrow aspiration, biopsy, and cytogenetics
- Myeloid gene mutation array

Test Interpretation
- Ineffective hematopoiesis with dysplasia in one or more cell lineages dominates the bone marrow picture in MDS.
- Marrow cellularity usually is normal or increased for the patient's age but may be hypoplastic in ~10%.
- Reticulin fibrosis usually is minimal except in t-MDS and acute MDS with sclerosis.
- Myeloblasts may be clustered in the intertrabecular spaces with abnormal localization of immature precursors.

TREATMENT

GENERAL MEASURES
- Immunize for pneumococcal pneumonia, pertussis, influenza, and hepatitis B.
- RBC transfusions to alleviate symptoms
- Platelet transfusions only for bleeding or before surgery; reduce alloimmunization
- Early use of antibiotics for fever, even while culture results are pending, due to quantitative and qualitative granulocyte disorder
- Iron chelation therapy to reduce iron overload from chronic transfusions

MEDICATION

First Line

- Epoetin alfa or darbepoetin can increase hemoglobin levels in MDS patients who have low serum erythropoietin levels at baseline (5)[C].
- Only azacitidine, decitabine, and lenalidomide have been approved by the FDA for MDS.
- Azacitidine and decitabine have been proven in randomized controlled trials to be more effective for these heterogeneous disorders than only supportive care, with antibiotics, and transfusions.
- Vitamins, iron, corticosteroids, androgens, or thyroid hormone are rarely helpful, unless evidence of a specific deficiency exists.
- Clinical trials show azacitidine, 75 mg/m^2/day SC for 7 days and repeated every 28 days, decreases RBC transfusion requirements, yields longer times to AML or death, and improves quality of life.
- Decitabine was approved with a continuous IV schedule over 72 hours that usually requires hospitalization. More commonly, it is given at 20 mg/m^2 IV over 1 hour daily for 5 days as an outpatient, repeated every 4 weeks.
- Lenalidomide, 10 mg PO daily for 21 days every 4 weeks, has yielded complete remission in patients with MDS and del(5q). It is less effective in patients with MDS without del(5q) (6)[B].
- Intensive chemotherapy
  - Younger patients with MDS may benefit from AML chemotherapy, especially if Auer rods are present, but toxicity may be severe for older patients.
  - Remission durations are variable (median, ~1 year).
- Allogeneic hematopoietic stem cell transplantation:
  - Recommended for younger patients with HLA-matched donors to eradicate the malignant clone and resupply normal hematopoietic stem cells (7)[A]
- Aminocaproic acid (epsilon-aminocaproic acid) or tranexamic acid may benefit patients with chronic, severe thrombocytopenia and bleeding.
- Contraindications: Cytotoxicity of chemotherapy may increase the risk of bleeding and infection and the need for transfusion support.
- Precautions: Aspirin, salicylates, and NSAIDs should be avoided.

Second Line

- Danazol or prednisone may be of benefit for concomitant autoimmune thrombocytopenia.
- Investigational agents
  - Low doses of cytarabine, tretinoin (all-trans retinoic acid), 13-cis retinoic acid, arsenic trioxide, histone/protein deacetylase inhibitors, interferon, cyclosporine, antithymocyte globulin, filgrastim, and interleukin-3

ISSUES FOR REFERRAL

- Refer younger adults for allogeneic hematopoietic cell transplantation.
- Refer patients with symptoms or transfusion requirements for clinical trials.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Usually outpatient, except when necessary to hospitalize for the treatment of infection, blood transfusions, or intensive chemotherapy

Patient Monitoring

- At least monthly during supportive care
- More frequently if receiving treatment

DIET

Reduce alcohol use and iron intake (unless patient is iron deficient).

PATIENT EDUCATION

- Stop smoking.
- Seek early medical attention for fever, bleeding, or symptoms of anemia.
- Advise about the risks of chronic transfusion therapy.

PROGNOSIS

- Median survival for RA and RARS is 5 years, but it may extend much longer (8)[B].
- RA with del(5q) syndrome is favorable.
- Median survival for RAEB, RCMD, and CMMoL is ~1 year; 50% of patients evolve to AML and the other 50% die of infection or bleeding.

COMPLICATIONS

- Infection
- Bleeding
- Complications of anemia and transfusions

CODES

ICD10

- D46.9 Myelodysplastic syndrome, unspecified
- D46.4 Refractory anemia, unspecified
- D46.B Refract cytopenia w multilin dysplasia and ring sideroblasts

CLINICAL PEARLS

- MDS constitutes a heterogeneous group of acquired, hematopoietic stem cell disorders characterized by cytologic dysplasia in the bone marrow and blood and by various combinations of anemia, neutropenia, and thrombocytopenia.
- The natural progression of this malignant disease evolves as cellular maturation becomes more arrested and blast cells accumulate.

MYELOPROLIFERATIVE NEOPLASMS

Tarsheen K. Sethi, MBBS • Sanjay Mohan, MD, MSCI

BASICS

DESCRIPTION

- Myeloproliferative neoplasms (MPNs) are a group of clonal disorders that share a common cell of origin in the pluripotent hematopoietic stem cell.
- MPNs are characterized by proliferation of cells of myeloid lineage—granulocytic, erythroid, megakaryocytic or mast cell. They share common clinical features including risk of thrombosis, spleen and/or liver enlargement and constitutional symptoms related to a hypermetabolic state.
- The "classic" MPNs include chronic myelogenous leukemia (CML), polycythemia vera (PV), essential thrombocythemia (ET), and primary myelofibrosis (PMF). World Health Organization (WHO) MPN classification also includes chronic neutrophilic leukemia, chronic eosinophilic leukemia not otherwise specified (CEL-NOS), systemic mastocytosis, and MPN unclassifiable.
- This topic focuses on the classic MPNs.
- CML is characterized by the presence of Philadelphia-chromosome (reciprocal translocation between chromosomes 9 and 22 resulting in a *BCR-ABL* fusion gene). This fusion gene mediates the uninhibited proliferation of myeloid precursor stem cells predominantly resulting in granulocytosis and excess granulocyte precursors.
- The following three MPNs are characterized by varying degree of presence of *JAK2* V617F mutation and are negative for *BCR-ABL* fusion gene.
  - PMF: JAK2 in about 50%; MPN characterized by marrow fibrosis, extramedullary hematopoiesis, and splenomegaly
  - ET: JAK2 in about 50%; MPN characterized by a clonal proliferation of megakaryocytes, leading to thrombocytosis
  - PV: JAK2 in 95%; MPN characterized by trilineage growth of hematopoietic stem cells with erythroid precursors predominating, leading to erythrocytosis

EPIDEMIOLOGY

Incidence

- CML: 0.6 to 2.0/100,000/year; median age at diagnosis 66 years; male > female (1.6:1)
- PMF: 0.2 to 0.5/100,000/year; median age at diagnosis 65 years; male = female
- ET: 0.6 to 2.5/100,000/year; median age at diagnosis 60 years, second peak in younger patients at ~30 years; female > male (2:1)
- PV: 1 to 2/100,000/year; male > female (1.3:1)

ETIOLOGY AND PATHOPHYSIOLOGY

- *CML: BCR-ABL1* gene leads to increased and unrestrained activity of the ABL tyrosine kinase resulting in an unchecked activation of downstream signaling pathways which have an antiapoptotic effect on the hematopoietic cells.
- PMF: Progenitor hematopoietic stem cells undergo a clonal proliferation independent of growth factors likely due to activation of downstream intracellular pathways. The fibroblasts are nonclonal, and the increased fibrosis is driven by growth factors released by hematopoietic cells especially megakaryocytes.
- ET: Thrombopoietin-induced megakaryocyte proliferation is uncontrolled due to a combination of increased sensitivity to thrombopoietin and decreased feedback regulation of the thrombopoietin levels by platelets allowing the platelet mass to expand.
- PV: Gain-of-function mutation (*JAK2*) leads to increased erythrocyte production due to a downstream activation of proteins involved in cell proliferation and resistance to apoptosis. The *JAK2* tyrosine kinase is downstream of the erythropoietin receptor and thus its constitutive activation makes the hematopoietic progenitor cell independent of erythropoietin.

Genetics

- Philadelphia chromosome (*BCR-ABL1* gene): translocation and fusion of the *BCR* gene on chromosome 22 and the *ABL* gene on chromosome 9; seen in all patients with CML
- *JAK2* mutations: point mutations in the tyrosine kinase domain of *JAK2*,

causing a substitution of phenylalanine for valine at position 617 (*JAK2V617F*); leading to unrestrained *JAK2* activation with a deactivation of typical feedback mechanism. Seen in >95% of PV cases; 50% of ET and PMF cases.

- CALR mutation: Calreticulin (CALR) is an endoplasmic reticulum chaperone protein directing proper folding of proteins. This mutation may be seen in up to a third of patients of ET and PMF. These patients are seen to have a higher platelet count but lower risk of thrombosis.
- Myeloproliferative leukemia virus (*MPL*) gene: Mutations found in 5–10% of patients with PMF and in 3–5% of those with ET. This encodes the thrombopoietin receptor *MPL*.
- *JAK2*, CALR, and *MPL* mutations are mutually exclusive and together account for 85% of cases of ET and PMF.

RISK FACTORS

- Rare familial cases have been reported.
- CML: exposure to ionizing radiation

COMMONLY ASSOCIATED CONDITIONS

- Progression to acute myeloid leukemia; most common with CML
- Thrombosis/hemorrhage

DIAGNOSIS

HISTORY

- Many MPN cases are found incidentally on routine blood work.
- CML: Most patients are asymptomatic at time of diagnosis.
  - Fatigue, malaise, weight loss, excessive perspiration, abdominal fullness, early satiety, bleeding episodes
- PMF: Symptoms depend on the degree of anemia and splenomegaly.
  - Fatigue, shortness of breath, early satiety, constitutional symptoms, cachexia, Budd-Chiari syndrome, splenic infarcts, osteosclerosis resulting in bone pains
- ET: characterized by thrombotic and hemorrhagic events
  - Thrombotic events (deep vein thrombosis, pulmonary embolism, Budd-

Chiari syndrome), microvascular occlusive events (digital ischemia, erythromelalgia), major/minor hemorrhagic events; headaches, dizziness, syncope, tingling, visual changes, transient ischemic attacks

- PV: Symptoms are due to level of erythrocytosis and the resultant increased blood viscosity.
  - Erythromelalgia, pruritus after hot baths, headaches, tinnitus, paresthesias, gout attacks

PHYSICAL EXAM

- CML: splenomegaly, hepatomegaly
- PMF: splenomegaly seen in nearly all patients, hepatomegaly, pallor
- ET: possible petechiae, purpura, ecchymosis; splenomegaly
- PV: cyanotic blush (lips, nose, ears, distal extremities), increased blood pressure, splenomegaly, epistaxis, ecchymosis

DIFFERENTIAL DIAGNOSIS

- CML: leukemoid reaction (elevated LAP), juvenile myelomonocytic leukemia, chronic myelomonocytic leukemia (CMML), chronic eosinophilic leukemia, chronic neutrophilic leukemia
- PMF: other MPNs, lymphoma, hairy cell leukemia; secondary myelofibrosis (malignant or nonmalignant)
- ET: reactive thrombocytosis, CML, PV, PMF, and myelodysplastic syndromes
- PV: hypoxic states (e.g., chronic obstructive pulmonary disease [COPD], anemia), renal cell carcinoma, Wilms tumor, hepatoma, polycystic kidney disease, exogenous androgens

DIAGNOSTIC TESTS & INTERPRETATION

- CML: White blood cell count >10,000 × 10^9/L with differential showing increased mature and immature neutrophils and an increased percentage of myelocytes, metamyelocytes, and band forms; neutrophils have decreased leukocyte alkaline phosphatase; platelet count >600,000 × 10^9/L and a normochromic, normocytic anemia. Basophilia is common.
- PMF (1)[A] (WHO criteria): Diagnosis requires meeting all three major criteria and two or more minor criteria:
  - *Major criteria*: (i) megakaryocyte proliferation and atypia accompanied by

either reticulin or collagen fibrosis; (ii) not meeting WHO criteria for CML, PV, MDS, or other myeloid neoplasm; (iii) demonstration of *JAK2V617F* or other clonal marker or absence of marker with no evidence of secondary marrow fibrosis
  - *Minor criteria*: (i) leukoerythroblastosis, (ii) increased serum lactate dehydrogenase level, (iii) anemia, and (iv) palpable splenomegaly
- ET (1)[A] (WHO criteria): Diagnosis requires meeting all four major criteria:
  - *Major criteria*: (i) thrombocytosis with persistent platelet level ≥450 × 10^9/L; (ii) megakaryocyte proliferation with large and mature morphology; (iii) not meeting the WHO criteria for CML, PV, PMF, MDS, or other myeloid neoplasm; and (iv) demonstration of *JAK2V617F* or other clonal marker or absence of clonal marker with no evidence of reactive thrombocytosis
- PV (1)[A] (WHO criteria): Diagnosis requires either both major criteria and one minor criterion or the first major criterion and two of the minor criteria:
  - *Major criteria*: (i) hemoglobin >18.5 g/dL in men, >16.5 g/dL in women or other evidence of increased red cell volume and (ii) presence of *JAK2V617F* or other functionally similar mutation (e.g., *JAK2* exon 12 mutation) (1)[B]
  - *Minor criteria*: (i) bone marrow biopsy showing hypercellularity for age with trilineage myeloproliferation, (ii) low serum erythropoietin level, (iii) endogenous erythroid colony formation in vitro

Initial Tests (lab, imaging)

If clinical suspicion of MPN, obtain a CBC and peripheral blood smear; if suggestive, obtain bone marrow biopsy.

- PMF: radiographic osteosclerosis in 25–66%

Diagnostic Procedures/Other

- CML: Diagnosis with identification of Philadelphia chromosome: Fluorescence in situ hybridization is more sensitive than karyotyping and is routinely used. Polymerase chain reaction (P210) is done at baseline to help monitor response to tyrosine kinase inhibitors (TKIs).
  - Bone marrow biopsy: increased cellularity and increased myeloid to erythroid ratio

- PMF, ET, and PV: genotypic analysis and bone marrow biopsy as described in earlier WHO criteria; “dry tap” is common in PMF.
- Risk stratification
  - CML: three phases of CML
    - (i) Chronic phase (85% patients at diagnosis; <5% blast counts); (ii) accelerated phase (poorly controlled splenomegaly regardless of treatment, 10–19% blast counts, worsening anemia, basophil ≥20%); (iii) blast crisis (resembles acute myeloid or lymphoid leukemia, >20% blast counts)
  - PMF: International Prognostic Scoring System (IPSS) at diagnosis and Dynamic IPSS (DIPSS-plus) throughout disease
    - IPSS: age >65 years, constitutional symptoms, hemoglobin <10 g/dL, leukocyte count >25 × 10^9, circulating blasts >1%
      - Low risk = 0 of above; intermediate-1 risk = 1 of above; intermediate-2 risk = 2 of above; high risk = ≥3 of above
    - DIPSS-plus: same 5 risk factors in the IPSS + the need for red cell transfusion, platelets <100 × 10^9/L and unfavorable karyotype
      - Low risk = 0 of above; intermediate-1 risk = 1 of above; intermediate-2 risk = 2 to 3 of above; high risk = ≥4 of above
  - ET: low risk = age <40 years, no prior thromboembolic events, no cardiovascular risk factors, platelet count <1,500 × 10^9/L; intermediate risk = age 40 to 59 years, presence of cardiovascular risk factors, platelet count <1,500 × 10^9/L; high risk = age ≥60 years and/or prior thromboembolic or hemorrhagic episode and/or platelet count >1,500 × 10^9/L
  - PV: low risk = age <60 years, no history of thrombosis/cardiovascular risk factors; intermediate risk = platelets >1,000 × 10^9/L and cardiovascular risk factors; high risk = age >60 years or a history of thrombosis

TREATMENT

GENERAL MEASURES

Low-dose aspirin for ET and PV

MEDICATION

First Line

- CML
  - Chronic phase: imatinib mesylate (Gleevec): 400 mg/day, a TKI. Dasatinib and nilotinib are also approved for use in the first line (1).
  - Accelerated or blast phase: Increase imatinib to 800 mg/day or switch to 2nd- or 3rd-generation TKIs like nilotinib and dasatinib.
  - While awaiting confirmation of diagnosis, hydroxyurea can be used to lower the WBC count.
- PMF: Main goal is symptomatic relief:
  - Low risk: symptom-directed therapy
  - Intermediate and high risk: Consider allogeneic SCT.
  - *JAK2* inhibitor ruxolitinib is approved for intermediate or high-risk myelofibrosis. It is also approved for post-PV and post-ET myelofibrosis (2).
  - Supportive treatment
    - Anemia: transfusions, erythropoiesis-stimulating agents, androgens, danazol, thalidomide, or lenalidomide
    - Splenomegaly: ruxolitinib, hydroxyurea, splenectomy, or IV cladribine for refractory cases
    - Thrombosis: hydroxyurea and low-dose aspirin
- ET low and intermediate risk: “Watch and wait” + low-dose aspirin if microvascular disturbances are present and no contraindications; high risk: hydroxyurea 15 mg/kg/day in divided doses to reduce platelet count to <450 × 10^9/L(2). Anagrelide is an additional cytoreductive option.
- PV
  - Low and intermediate risk: phlebotomy with goal hematocrit <45 and low-dose aspirin
  - High risk (or those who do not tolerate phlebotomy): hydroxyurea 500 to 1,000 mg/day (2). Ruxolitinib if poor response to or intolerance of hydroxyurea.

Second Line

- CML: Only curable treatment is aSCT; reserved for accelerated/blast phase due to high rates of morbidity and mortality with aSCT

  - 2nd-generation TKIs: dasatinib, nilotinib, and bosutinib; increasing evidence for improved, deeper responses with these medication resulting in use of 2nd-generation TKIs for first-line therapy. Ponatinib is a 3rd-generation TKI that has activity in cases of TKI resistance due to a T315I mutation for which all the other available TKIs are ineffective.
- PMF: Only curable treatment is allogeneic SCT; reserved for intermediate or high-risk patients.
  - If unresponsive to hydroxyurea, use pegylated interferon-α; tolerance may be an issue.
- ET: If resistant/intolerant to hydroxyurea, use anagrelide.
  - If resistant/intolerant to hydroxyurea or anagrelide, pregnant or age <40 years: Use interferon-α.
- PV: if resistant or intolerant to hydroxyurea, can use ruxolitinib

ISSUES FOR REFERRAL

Patients with MPNs are usually referred to hematology/oncology.

SURGERY/OTHER PROCEDURES

May require splenectomy/palliative radiation for foci of extramedullary hematopoiesis

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Severe cachexia; renal failure and hepatomegaly secondary to extramedullary hematopoiesis; massive splenomegaly requiring treatment; severe thrombotic/hemorrhagic episodes; anemia; tumor lysis syndrome
- Optimal hydration to prevent tumor lysis syndrome

ONGOING CARE

PROGNOSIS

- CML: 10-year survival rate ~80% from time of diagnosis; 85% will die in blast crisis; 12- to 18-month median survival for accelerated phase; 3- to 6-month median survival for blast phase
- PMF: worst prognosis of the MPNs; drug therapy does not modify disease

course but treats the symptoms; median survival for IPSS low risk = 135 months, intermediate-1 risk = 95 months; intermediate-2 risk = 48 months; high risk = 27 months
- PV: median survival often >10 years
- ET: near-normal life expectancy

COMPLICATIONS

- CML: blast crisis, transformation to acute leukemia, gout, or nephropathy due to hyperuricemia
- PMF: 10% develop acute myeloid leukemia; anemia, massive hepatosplenomegaly, thrombohemorrhagic events, osteosclerosis, secondary gout, splenic infarcts, paraspinal/epidural extramedullary hematopoiesis.
- ET: <10% develop post-ET myelofibrosis, 2% develop acute myeloid leukemia; thrombohemorrhagic events
- PV: 15–20% develop post-PV myelofibrosis, 5% develop leukemia; erythromelalgia, pruritus, secondary gout, headaches, vascular occlusive events

CODES

ICD10

- D47.1 Chronic myeloproliferative disease
- C92.10 Chronic myeloid leukemia, BCR/ABL-positive, not having achieved remission
- D45 Polycythemia vera

CLINICAL PEARLS

- MPNs are a group of clonal disorders that share a common cell of origin in the pluripotent hematopoietic stem cell.
- MPNs are characterized by proliferation of cells of myeloid lineage—granulocytic, erythroid, megakaryocytic or mast cell. They share common clinical features including risk of thrombosis, spleen and/or liver enlargement and constitutional symptoms related to a hypermetabolic state.
- Splenectomy as an option for symptom and cytopenia control is associated with high risk of postsplenectomy mortality and complications including thrombosis.

NARCOLEPSY

Jesse A. Morse, MD, MBA • Naureen Rafiq, MD

BASICS

DESCRIPTION

- Disorder characterized by excessive daytime sleepiness (EDS) often associated with cataplexy (sudden bilateral weakness of skeletal muscles) and other rapid eye movement (REM) sleep phenomena, such as sleep paralysis and hypnagogic hallucinations (e.g., vivid auditory or visual perceptions without an external stimulus that occur as one is falling asleep).
- Frequently overlooked disorder, averaging 5 to 15 years from onset of symptoms prior to diagnosis (1)
- Usually feel refreshed after a full night's sleep or a brief nap, but their sleepiness returns 1 to 2 hours later, especially when they are sedentary (1)
- System affected: nervous

EPIDEMIOLOGY

Incidence

- Onset usually 10 to 20 years old, average age = 24 years (2)
- Bimodal distribution peak at 15 and 35 years of age
- Predominant sex: male > female (1.6:1)
- Incidence: 1/2,000 people (1)

Prevalence

- Narcolepsy type 1 (with cataplexy): 25 to 50/100,000 people
- Narcolepsy type 2 (without cataplexy): 20 to 34/100,000 people
- Western countries: 20 to 60/100,000 (2)
- Highest in Japan, lowest in Israel (2)

ETIOLOGY AND PATHOPHYSIOLOGY

- Narcolepsy type 1 is a neurodegenerative disorder resulting from selective loss of neurons containing hypocretin (orexin) in the lateral hypothalamus; may be autoimmune (associated with influenza A, H1N1 vaccine, and

Streptococcus pyogenes) (1)
- Orexin-A neurons also regulate metabolism, feeding, reward and autonomic tone; weight gain and depression can result from dysfunction of this neuronal pathway (1).
- 90–95% of patients with narcolepsy type 1 have low orexin-A in CSF (1).
- People with narcolepsy type 2 do not have cataplexy and have normal orexin-A levels (1).
- The cause of narcolepsy type 2 is not well established.
- Possible involvement of immune system and environmental influences; onset is often in late spring. (1)
- Could also be called syndrome of hypocretin deficiency (2)

Genetics

- Usually sporadic but increased incidence in families with positive history: 1–2% in first-degree relative of index case (10 to 40 times the general population) (1)
- Twin concordance is 25–31% (suggests environmental contribution).
- 98% of patients with narcolepsy type 1 have human leukocyte antigen (HLA) DQB1*0602; 50% of patients with narcolepsy type 2 express this antigen. HLA DQB1*0602 is present in 12–30% of the general population (1).
- Presence of DQB1*0602 gene increased risk of narcolepsy by a factor of 200 (1).
- Autosomal-recessive inheritance pattern
- 12% of Asians, 25% of Whites, and 38% of African Americans are gene carriers.

RISK FACTORS

- Obesity
- Head trauma
- CNS infectious disease
- Anesthesia
- Psychological stress
- Family history
- Recent influenza A, streptococcal infection, or H1N1 vaccine

COMMONLY ASSOCIATED CONDITIONS

Obstructive sleep apnea (OSA) (up to 25%), obesity, anxiety

DIAGNOSIS

HISTORY

- Classic tetrad of EDS, cataplexy, sleep paralysis, and hypnagogic hallucinations (four most common symptoms): Only 10–20% of patients have all four symptoms.
- Clinical diagnosis confirmed with overnight polysomnography (PSG) followed by a multiple sleep latency test (MSLT) the next day (1)
- Three general forms
  - Narcolepsy type 1: 40%
  - Narcolepsy type 2: 60%
  - Secondary narcolepsy due to a medical condition (e.g., Parkinson disease with sleep disturbance, myotonic dystrophy, CNS tumors, Prader-Willi syndrome, Niemann-Pick disease type C)
- EDS and sleep attacks (cardinal symptom)
  - Primary symptom and required for diagnosis
  - Instantaneous, irresistible REM sleep
  - First and most disabling symptom
  - Tendency to take naps lasting 5 to 10 minutes
  - Episodes last minutes and rarely more than an hour.
  - 1 to 8 naps/day but normal 24-hour sleep duration
  - Fall asleep for nap within 8 minutes, whereas healthy people take 15 minutes or more (1)
  - REM sleep during at least 2 daytime naps (1)
  - Associated with dreaming
  - Nap restores wakefulness for several hours.
  - More likely in a monotonous, warm environment, after a large meal, or with strong emotions
- Cataplexy: auxiliary symptom (60%; cardinal symptom)
  - Occurs almost exclusively in type 1 (1)
  - Pathognomonic if present

  - Sudden bilateral weakness of skeletal muscles
  - Provocation by sudden strong emotions, often positive emotions, but negative is possible too (1)
  - Consciousness and memory are not impaired.
  - Short duration (seconds to minutes)
  - Can be limited to a particular muscle group (e.g., jaw droop with inability to speak; arm, neck, or leg weakness; respiratory and eye muscles not affected); usually starts with head then spread to limbs
  - Status cataplecticus is a rare, prolonged episode of cataplexy (lasting hours) that is more likely in children or on withdrawal of drugs.
- Sleep paralysis: auxiliary symptom (25–50%)
  - When falling asleep or on awakening, the patient wants to but cannot move; this can end abruptly when the patient is touched or spoken to.
  - Brain wakes from sleep while body remains paralyzed in REM sleep.
  - Lasts seconds to minutes
  - Patients are aware of events around them but cannot open eyes or move.
  - Can be preceded by hallucinatory phenomena
  - 50% of the normal population have had at least one of these episodes (thus, this symptom is nonspecific).
- Hypnagogic hallucinations: auxiliary symptom (30–60%)
  - Vivid, frightening visual, auditory or tactile illusions or hallucinations at onset of sleep
  - Dreamlike experiences that occur during awakening (hypnopompic hallucinations) or suddenly at sleep onset (hypnagogic) (1)
  - Characteristic hallucinations include being attacked by animals or feeling that someone else is in the room (1).
- Disturbed nocturnal sleep (66%)
  - Normal total sleep with decreased sleep efficiency
  - More frequent transitions from wakefulness to sleep
  - Retrograde amnesic and automatic behavior lasting minutes to hours
  - Increased periodic leg movements (50%)
  - Depression (18–37%)
  - Automatic behavior: activity without memory of the event
  - Panic attacks and social phobias (20%)

PHYSICAL EXAM

- A complete exam is useful to rule out other causes of hypersomnia.
- If cataplexy is witnessed, examiner will be unable to elicit deep tendon reflexes.

DIFFERENTIAL DIAGNOSIS

EDS is present in 4% of the general population, although most individuals are not narcoleptic. Possible etiologies include the following:

- Sleep apnea syndromes (40–50% of those with excessive somnolence); increased incidence in narcolepsy, up to 26% prevalence
- Epileptic seizures and syncope
- Idiopathic hypersomnia (5–10% of those with excessive somnolence)
- Psychiatric (depression, substance abuse/withdrawal)
- Sleep-related movement disorders (restless leg syndrome, periodic limb movements of sleep)
- Iatrogenic secondary to medication (benzodiazepines; opioids; antihistamines; β-blockers; and some antipsychotics, antidepressants, and anticonvulsants)
- Poor sleep hygiene and habits leading to sleep deficit
- Circadian rhythm disorders (jet lag, shift work, delayed or advanced sleep phase disorders)
- Seizures
- Niemann-Pick type C
- Hypersomnia related to a medical condition, such as Parkinson disease
- Kleine-Levin syndrome (recurrent hypersomnia that lasts days to weeks and recurs months later)
- Menstrual-associated hypersomnia

Pediatric Considerations

Narcolepsy is rare before the age of 5 years. EDS is more often attributable to OSA, poor sleep hygiene, and the increased sleep requirements early in life. Recommended amount of sleep decreases with age: newborns 16 to 18 hr/day; preschool-aged children 11 to 12 hr/day; school-aged children and teens 10 hr/day; adults 7 to 8 hr/day. Children can gain excessive weight, from 20 to 40 lb (1).

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Epworth Sleepiness Scale: Score ranges from 0 to 24, and >10 is suggestive of a sleep disorder rather than generalized fatigue; helpful for detecting response to medications (1)
- Stanford Sleepiness Scale: Patients select one of seven statements that best describe energy level, concentration, and sleepiness. Statements 4 to 7 may indicate excessive sleepiness.
- Nighttime PSG: Monitoring of patients in a sleep laboratory will usually document fragmented sleep with a normal amount of REM sleep but rapid-onset REM (within 15 minutes of sleep onset) and decreased sleep efficiency (3)[A]. The PSG is useful to rule out other causes of EDS, including sleep apnea syndromes and nocturnal myoclonus.
- MSLT: begins ≥90 minutes after nighttime test (3)[A]
  - Cornerstone in diagnosis of narcolepsy (2)
  - The patient is monitored during four to five 20-minute naps taken at 2-hour intervals; rapidity of sleep onset and type of sleep pattern are documented. The supportive test includes mean sleep latency (time to fall asleep) of ≤8 minutes and ≥2 sleep-onset REM periods.
  - Sensitivity 77%; specificity 97%; positive predictive value 73%
- Maintenance of Wakefulness Test (MWT): used to assess ability to remain awake to determine restrictions (e.g., driving), assess treatment response. Not usually performed during the initial evaluation
- CSF hypocretin measurements:
  - Over 90% of confirmed patients with narcolepsy had undetectable hypocretin-1 levels (2).

Follow-Up Tests & Special Considerations

- HLA typing for DQB1 in ambiguous cases
- Low CSF hypocretin-1 level: 99% specificity, 87% sensitivity in patients with cataplexy; useful in children when unable to do an MSLT

Diagnostic Procedures/Other

- Narcolepsy type 1 (3)[C]
  - Excessive daytime sleepiness daily for ≥3 months

- One of the following:
  - Cataplexy with sleep latency ≤8 minutes with ≥2 sleep-onset REM periods within 15 minutes of the onset of sleep (SOREMP)
  - Low CSF hypocretin-1 level <110 pg/mL or < 1/3 of mean values in normal subjects
- Narcolepsy type 2 (3)[C]
  - All above without the cataplexy and low hypocretin-1
- Diagnosis of exclusion

TREATMENT

GENERAL MEASURES

- None of the currently available medications enables people with narcolepsy to consistently maintain a fully normal state of alertness.
- Drug therapy should be supplemented by various behavioral strategies: Avoid shift work, heavy meals, and caffeine later in the day.
- Well-timed 20-minute naps may be helpful.
- Avoid sedating drugs and alcohol.
- Use safety precautions, particularly when driving. People with untreated narcoleptic symptoms are involved in automobile accidents roughly 10 times more frequently than the general population. However, accident rates are at normal levels among patients who have received appropriate medication therapy.

MEDICATION

First Line

- EDS
  - Modafinil (Provigil) (4)[A]:
    - Structurally distinct from amphetamines
    - 200 to 400 mg/day divided BID; start with 100 mg/day and increase over 3 to 4 days; maximum of 300 mg/dose, 400 mg/day 3
    - Reduces reuptake of dopamine (1)
    - First-line treatment: 60% effective and 20% partially effective
    - Half-life of 14 hours, can dose daily

    - Fewest adverse effects (headache, GI upset, increased metabolism of oral contraceptives) with less rebound hypersomnia and does not affect BP; tolerance limited
    - No decrease in cataplexy
  - Armodafinil (Nuvigil):
    - Enantiomeric form of modafinil with slightly longer half-life of 15 hours
    - 150 to 250 mg every morning
- Cataplexy:
  - Sodium oxybate (Xyrem):
    - 2.5 to 9 g; may take 3 months for full response
    - Preferred treatment for narcolepsy with cataplexy and disturbed nocturnal sleep
    - Give 1/2 dose once in bed and 1/2 dose 2 to 4 hours later.
    - Date rape drug; abuse potential (4)[A]
    - Can use with modafinil in severe cases
    - May worsen sleep-disordered breathing in patients with OSA
    - Can lead to coma with overdose (1)
    - Expensive with short half-life
    - Only used for moderate-to-severe cataplexy (1)
  - Tricyclic antidepressants
    - Protriptyline: 5 to 60 mg/day
    - Clomipramine: 10 to 150 mg/day
    - High side effect profile: dry mouth, sedation, urinary retention, impotence
  - Serotonin-norepinephrine reuptake inhibitors
    - Venlafaxine: 37.5 to 75 mg BID
    - Fluoxetine: 20 to 80 mg/day
    - Work by suppressing REM sleep
  - The patient may develop a tolerance to the anticataplectic drugs and can have rebound cataplexy when a drug is withdrawn.
  - Although often used, quality evidence is lacking to demonstrate improvement in cataplexy symptoms from antidepressants.
- Auxiliary symptoms (e.g., hypnagogic hallucination, sleep paralysis) require treatment less often than EDS and cataplexy, but anticataplectics are useful when symptoms are problematic.

Second Line

- EDS
  - Amphetamines
    - Methylphenidate (Ritalin): initial dose 10 to 60 mg/day divided BID or TID; maximum dose 60 mg/day (4)[B], short-acting, most potent amphetamine available; can be used in combination with modafinil and armodafinil.
    - Dextroamphetamine: initial dose 10 mg/day; can increase by 10 mg weekly to a maximum dose 60 mg/day divided BID or TID (4)[B]
    - Contraindicated in patients with HTN
    - Adverse reactions: headaches, irritability, hypertension (HTN), psychosis, anorexia, habituation, rebound hypersomnia
    - If the patient develops a tolerance to stimulants, switch drugs rather than increase dose, there is little cross-tolerance.
- Cataplexy
  - Selegiline: selective MAO-B inhibitor
    - Anticataplectic effective for EDS; 20 to 40 mg/day divided morning and noon (4)[B]
    - Doses >20 mg require a low-tyramine diet because the drug begins to lose selectivity.

ISSUES FOR REFERRAL

- Unresponsive to primary medications
- Patient support groups can be very beneficial.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Frequent BP checks and regular follow-ups (approximately every 6 months) are recommended.

DIET

Selegiline: Doses >20 mg require a low-tyramine diet because the drug begins to

lose selectivity.

PATIENT EDUCATION

- Narcolepsy information from the National Institute of Neurological Disorders and Stroke at www.ninds.nih.gov/disorders/narcolepsy/narcolepsy.htm
- Narcolepsy Network, Inc., North Kingstown, RI 02852; www.narcolepsynetwork.org

PROGNOSIS

Narcolepsy is a lifelong disease. Symptoms can worsen with aging. In women, symptoms can improve after menopause.

CODES

ICD10

- G47.429 Narcolepsy in conditions classified elsewhere w/o cataplexy
- G47.411 Narcolepsy with cataplexy
- G47.419 Narcolepsy without cataplexy

CLINICAL PEARLS

- Narcolepsy is a frequently missed disorder, with an average of 15 years of symptoms before a definitive diagnosis is made.
- The classic tetrad of symptoms includes EDS, cataplexy, sleep paralysis, and hypnagogic hallucinations, but only cataplexy is pathognomonic for the

disorder.

- The International Classification of Sleep Disorders has specific diagnostic criteria for narcolepsy.
- Medications are helpful but not curative.

NASAL POLYPS

Katherine Holmes, MD • Daniel Young Kim, MD

BASICS

- Chronic inflammatory lesion of nasal mucosa
- Appearance of edematous pedunculated mass in the nasal cavity or within the paranasal sinus
- Often causes symptoms of blockage, discharge, or loss of smell
- Most commonly bilateral; suspect tumor, such as inverted papilloma, if unilateral.
- Estimated to be ~1–4% in adults
- Much rarer in children: ~0.1%
- Increases with age
- Predominant sex: female > male (2:1)
- Asthma is present in 65% of patients; 25% of patients have undiagnosed asthma.
- No clearly delineated pathway; research has demonstrated separate TH1- and TH2-driven pathways (1)[B].
- Development of condition remains unclear; multiple inflammatory and infectious pathways resulting from chronic rhinosinusitis is most common.

GENERAL PREVENTION

Use of intranasal corticosteroids after polyp removal surgery has shown effectiveness against recurrence.

COMMONLY ASSOCIATED CONDITIONS

- Bronchial asthma
- Aspirin hypersensitivity
- Allergic rhinitis
- Cigarette smoking promotes eosinophilic inflammation.
- Chronic sinusitis
- Allergic fungal sinusitis
- Aspirin sensitivity

- Cystic fibrosis
- Primary ciliary dyskinesia (Kartagener syndrome)
- Laryngopharyngeal reflux

DIAGNOSIS

- Two or more symptoms, one of which is either nasal blockage/obstruction/congestion OR nasal discharge (2)
- Nasal obstruction/restricted nasal airflow: persistent mouth breathing
- Nasal discharge:
  - Anterior discharge—rhinorrhea
  - Postnasal drip
- Reduction/loss of smell
- Dull headaches
- Facial pain/pressure
- Symptoms of acute, recurrent, or chronic rhinosinusitis
- Anterior rhinoscopy looking for a pale translucent mass of tissue
  - Most commonly from lateral wall of middle meatus
  - Otoscope with nasal speculum or even otologic speculum is typically used.
- Flexible/rigid endoscopy is required to assess the nasal cavity fully.
  - Endoscopy is the gold standard for diagnosis.
  - Topical anesthesia nasal spray should be used prior to the endoscopy if patient is awake.
- Tympanic membrane examination for eustachian tube dysfunction secondary to large posterior nasal polyps
- Examine the posterior pharynx via oral cavity for large posterior polyps.
- Antrochoanal polyp
- Benign or malignant tumor:
  - Papilloma
  - Intranasal glioma
  - Encephalocele
  - Rhabdomyosarcoma
  - Mycetoma
- Allergy testing (3)[B]:

- Skin prick test
- ImmunoCAP testing
- Radioallergosorbent test (RAST)

- Testing for cystic fibrosis in children with multiple benign polyps: sweat test: often requires repeat tests (3)[B]
- CT scanning (3)[B]:
  - May be helpful to corroborate history and endoscopic findings
  - Unable to differentiate polyp from other soft tissue masses
- MRI (3)[B]:
  - May aid in unilateral polyposis if concern for neoplasia, mycetoma, or encephalocele

Histologic exam to exclude malignancy if unilateral polyp

- Diagnosis is made by the combination of rhinoscopy, endoscopy, and CT scanning.
- CT reveals extent of disease and is necessary to formulate a plan for surgical intervention (3)[B].
- Ciliated pseudostratified columnar epithelium: with areas of transitional or squamous epithelium
- Chronic infiltration of inflammatory cells
- Eosinophils are the predominant cells in most patients.

TREATMENT

- Intranasal corticosteroid use has been demonstrated to reduce polyp size and recurrence, as well as improvement in nasal congestion based on controlled studies (1)[A].
- Treat for a minimum of 12 weeks; minimal systemic absorption, side effects rare—minor nose bleeding is most common (1)[A].
  - Budesonide 256 μg/day
  - Beclomethasone dipropionate 320 μg/day
  - Fluticasone propionate 400 μg/day
  - Mometasone furoate 200 μg BID
  - For children, mometasone furoate is preferred:
    - 100 μg BID ages 6 to 12 years

    - 200 μg BID for ages 12 to 17 years
- Oral systemic corticosteroids: less definitive benefit; more systemic adverse effects; use with caution in patients with diabetes mellitus, hypertension, or peptic ulcer disease (1)[A].
- Prednisolone
  - Weight-based dosing burst with taper
- Perioperative use oral prednisone 30 mg daily 5 to 7 days prior to surgery (1) [A]
  - Decrease nasal mucosa inflammation
  - Improves surgical field
  - Shorter surgical time
  - Improves postop results
  - Weight-based dosing burst with taper

ISSUES FOR REFERRAL

Patients with severe obstruction symptoms should be referred for surgery (2).

ADDITIONAL THERAPIES

Antileukotrienes: clinical improvement without aspirin hypersensitivity (1)[A], (3)[B]:

- Aspirin desensitization may have a role in reducing recurrence of nasal polyposis.
- Anti-interleukin-5 immunomodulators: may benefit those with T_H2 eosinophilic disease process
- Oral antibiotics: Doxycycline for 3 to 4 weeks or oral macrolide for 12 weeks is an option for disease unresponsive to steroids alone with mixed results of therapy (4)[A].
- Indicated for patients with four or more episodes in 1 year of acute rhinosinusitis refractory to medical therapy (2)
  - Disease must be documented endoscopically or on CT during symptomatic period prior to surgical intervention.
- Most surgeries are approached endonasally.
  - Endoscopic sinus surgery has become the mainstay of treatment.
  - The external (Caldwell-Luc) approach is used for more difficult cases but carries higher risk of complications.

- Functional endonasal sinus surgery has slightly lower revision rate than intranasal polypectomy. Both modalities provide effective symptom relief.
- Postoperative use of nasal corticosteroids delay the recurrence of nasal polyps and hence the timing of revision surgery (1,5)[A].
- Postoperative use of steroid-releasing stents to prevent polyp recurrence by decreasing mucosal inflammation (1,5)[A]
- Intrapolyp steroid injection may be considered in cases refractory to other interventions but has risk of visual loss.

ONGOING CARE

- Acute/chronic sinus infection
- Heterotropic bone formation within the sinus cavity
- Recurrence:
  - Of patients, 5–10% with severe disease
  - Twice as likely in those with asthma

CODES

ICD10

- J33.9 Nasal polyp, unspecified
- J33.0 Polyp of nasal cavity
- J33.8 Other polyp of sinus

CLINICAL PEARLS

- Intranasal corticosteroid use has been demonstrated to reduce polyp size and recurrence, as well as to improve nasal congestion.
- Asthma is a common concomitant diagnosis and is often previously

undiagnosed.

- Aggressive medical and surgical treatment improves asthma outcomes.
- Treat for a minimum of 12 weeks.
- Allergy testing can be helpful.
- Nasal polyposis associated with asthma and aspirin hypersensitivity known as Samter triad or aspirin-exacerbated respiratory disease (AERD)
- Patients with severe obstruction should be referred for surgery.
- Unilateral nasal polyp needs malignancy workup (MRI).

NEPHROTIC SYNDROME

Hanadi Abou Dargham, MD • Nandhini Veeraraghavan, MD, CAQSM, FAAFP • Ravindra Bollu, MD

BASICS

DESCRIPTION

- A clinical syndrome of proteinuria (>3.5 g/1.73 m^2/24 hr), hypoalbuminemia (<3 g/dL), hyperlipidemia, peripheral edema, with risk for thrombotic disease
- Includes both primary and secondary forms
- Associated with many types of kidney disease

EPIDEMIOLOGY

Based on definitive diagnosis

- Diabetic nephropathy: most common cause of secondary nephrotic syndrome (1)
- Minimal change disease (MCD)
  - Most common cause of nephrotic syndrome in children <10 years (90%)
  - Peaks at 2 to 8 years of age
  - Associated with drugs (mainly NSAIDs) or lymphoma in adults
- Amyloidosis: 7–14% of idiopathic nephrotic syndrome—two renal types primary (AL) and secondary (AA)
- Lupus nephropathy (LN): Adult women are affected about 10 times more often than men.
- Focal segmental glomerulosclerosis (FSGS)
  - 35% of nephrotic syndrome in adults
  - Most common primary nephrotic syndrome in African Americans
  - Has both primary (idiopathic) and secondary forms (associated with HIV, morbid obesity, reflux nephropathy, previous glomerular injury)
- Membranous nephropathy
  - Most common cause of primary nephrotic syndrome in adults
  - May be primary or secondary associated with malignancy, Hep B, autoimmune diseases, thyroiditis, and certain drugs

- Membranoproliferative glomerulonephritis (MPGN)
  - May be primary or secondary
  - May present in the setting of a systemic viral or rheumatic illness.

ETIOLOGY AND PATHOPHYSIOLOGY

- Increased glomerular permeability to protein macromolecules, especially albumin
- Podocytes injury is the most common finding in diseases that cause primary nephrotic syndrome.
- Edema results primarily from renal salt retention, with arterial underfilling from decreased plasma oncotic pressure playing an additional role.
- Hyperlipidemia is thought to be a consequence of increased hepatic synthesis resulting from low oncotic pressure and urinary loss of regulatory proteins.
- The hypercoagulable state that can occur in some nephrotic states is likely due to loss of antithrombin III in urine.
- Primary renal disease:
  - MCD
  - FSGS
  - MPGN
  - IgA nephropathy
- Secondary renal disease (associated primary renal disease shown in parentheses):
  - Diabetic nephropathy
  - Amyloidosis
  - LN
  - FSGS
  - Infections (MPGN)
  - Cancer (MCD or MPGN)
  - Drugs (MCD or MPGN)

Genetics

Genetic factors are likely to play a role in susceptibility to the various nephrotic syndromes, although these have not been sufficiently defined to be useful clinically.

RISK FACTORS

- Drug addiction (e.g., heroin [FSGS])
- Hepatitis B and C, HIV, other infections
- Immunosuppression
- Nephrotoxic drugs
- Vesicoureteral reflux (FSGS)
- Cancer (usually MPGN, may be MCD)
- Chronic analgesic use/abuse (NSAIDs)
- Preeclampsia
- Diabetes mellitus

GENERAL PREVENTION

In general, there are few preventive measures, including avoidance of known causative medications including NSAIDs, gold, penicillamine, and captopril; avoidance of heroin abuse and tight glycemic control

DIAGNOSIS

HISTORY

- Inquire about signs or symptoms of systemic disease: joint complaint, rash, edema, infectious complaint, fevers, anorexia, oliguria, foamy urine, acute flank pain, and hematuria.
- Obtain a recent drug history for medications that may be causative, especially NSAIDs.
- Assess for risk factors.

PHYSICAL EXAM

A complete physical exam may discover clues to systemic disease as a potential cause and/or may suggest the severity of disease.

- Fluid retention: abdominal distention, abdominal fluid shift, extremity edema, puffy eyelids, scrotal swelling, weight gain, shortness of breath. Pericardial rub and decreased breath sounds with pleural effusions may develop.
- Hypertension
- Orthostatic hypotension

ALERT

The potential for thromboembolic disease leading to pulmonary embolism is one of the most life-threatening aspects of a patient who is actively nephrotic.

DIFFERENTIAL DIAGNOSIS

- Edema and proteinuria: See "Etiology and Pathophysiology."
- Edema alone: Other diseases to rule out in patients who have edema without proteinuria include congestive heart failure, cirrhosis, hypothyroidism, nutritional hypoalbuminemia, protein-losing enteropathy.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Confirm proteinuria if present: by urine dipstick initially, and then quantitate by 24-hour urine or spot urine protein-to-creatinine ratio.
- Rule out urine infection with urine culture.
- Full blood count and coagulation screen
- Renal function tests: BUN, creatinine with estimated glomerular filtration rate (GFR)
- Glucose to rule out overt diabetes
- Consider blood cultures to rule out a postinfectious process.
- Lipid panel
- Liver function tests to exclude liver disease or infection
- Look for autoimmune disease.
  - Antinuclear antibody and/or antidouble-stranded DNA positivity suggest lupus.
  - Complement levels (C3/C4 and total hemolytic complement): A low C3 may suggest a postinfectious or membranoproliferative process, whereas both low C3 and C4 point to lupus.
- Serum protein electrophoresis/urine immune electrophoresis to rule in a paraproteinemia
- Hepatitis B and C screen
- Measurement of cryoglobulins
- HIV and syphilis serology
- Urinalysis to evaluate for the presence of cellular casts
- Renal US to verify the presence of 2 kidneys of normal shape and size

- Chest x-ray to detect presence of pleural effusion or infection
- If thrombosis is suspected:
  - Doppler US of the legs
  - MRI or venography for renal vein thrombosis
  - Ventilation/perfusion nuclear medicine lung scan and/or CT angiography may be required to rule out pulmonary embolism.

Diagnostic Procedures/Other

Renal biopsy is standard in determining the underlying cause of nephrotic syndrome.

- Rarely done in children with first episode of nephrotic syndrome, as MCD is common and empiric steroid therapy is the standard of care.
- Required to confirm the clinical diagnosis in adults and assist with making a treatment plan (1)
- Contraindications to renal biopsy include: small kidneys, renal tumor or bilateral renal cysts, active infection, severe malignant hypertension, hydronephrosis, bleeding diathesis, uncooperative patient

Test Interpretation

- Light microscopy
  - May see nothing (e.g., MCD)
  - Sclerosis (e.g., FSGS or diabetic nodules in diabetes)
  - Diffuse hypercellularity suggests a proliferative disease such as IgA nephropathy, LN, or postinfectious glomerulonephritis (GN).
- Immunofluorescence: Mesangial IgA suggests IgA nephropathy, Henoch-Schönlein; other staining patterns are specific for other disease processes.
- Electron microscopy: The location of immunoglobulin deposits is useful in pointing to a particular diagnosis.

TREATMENT

MEDICATION

First Line

- Edema: salt restriction and salt-wasting diuretics (loop and thiazide diuretics)

(2)[A]:

- Salt restriction to <2 g sodium per day
- Restrict fluid intake to <1.5 L/day if hyponatremic.
- Target weight loss of 0.5 to 1 kg/day (1 to 2 lb/day)

- Edema should be corrected slowly to avoid acute hypovolemia, and diuretic dose should be increased in comparison to the general population.
- Hyperlipidemia:
  - Is reversed with resolution of the disease
  - The role of dietary modification is unproven yet.
- Statins have been shown to improve endothelial function (2)[A] and may decrease proteinuria (3)[A], but effect on GFR and preservation of renal function is small. The major role for statin use is in cardiovascular risk reduction.
- ACE inhibitors or angiotensin II receptor blockers are thought to reduce proteinuria, hyperlipidemia, thrombotic tendencies, progression of renal failure, and to control hypertension, if present (4)[A].
- For steroid-responsive disease (MCD and FSGS), steroids dosed in consultation with nephrologist.

Second Line

- Many of the nephrotic diseases will require escalation in therapy above steroids. These include rapidly relapsing forms, as well as MPGN, LN, and IgA nephropathy. Bolus steroids and other immunosuppressives are required in this circumstance (cyclophosphamide, mycophenolate mofetil, chlorambucil, cyclosporine) (5)[A].
- Rituximab, combined with steroids or other immunosuppressive agents, has demonstrated early promise in the treatment of refractory nephrotic syndrome (6)[B].
- Randomized controlled data have been insufficient to determine which patients require prophylactic anticoagulation (7)[A]. Common practice is to anticoagulate with heparin and then warfarin in patients who have persistent nephrotic-range proteinuria. This decision is made based on the patient's history of edema, hypoalbuminemia, thromboembolism, or immobility.
- Hypocalcemia from vitamin D loss should be treated with oral vitamin D.

ISSUES FOR REFERRAL

Consultation with a nephrologist is often required to assist with renal biopsy to confirm diagnosis and to assist with management of edema. Cytotoxic medications may be called for, depending on the disease process, and this may best be handled by a nephrologist.

ADDITIONAL THERAPIES

Ambulation or range-of-motion exercises to lower risk of deep vein thrombosis (DVT)

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Admission criteria/initial stabilization: respiratory distress, sepsis/severe infection, thrombosis, renal failure, hypertensive urgency/emergency, or other complications
- Discharge criteria: Hemodynamically stable patients without complications may be managed as outpatients.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Frequent monitoring is required for relapse, disease progression, and for detecting signs of toxicity of medical management.
- Reevaluate for azotemia, urine protein, hypertension, edema, loss of renal function, cholesterol, and weight.

DIET

- Normal protein (1 g/kg/day)
- Low fat (cholesterol)
- Reduced sodium (<2 g/day)
- Supplemental multivitamins and minerals, especially vitamin D and iron
- Fluid restriction if hyponatremic

PATIENT EDUCATION

- Printed material for patients: National Kidney Foundation, 30 E. 33rd Street, Suite 1100, New York, NY 10016; 800-622-9010
  - Childhood nephrotic syndrome
  - Diabetes and kidney disease
  - Focal glomerulosclerosis
- Web site: National Institutes of Health: nephrotic syndrome

PROGNOSIS

Nephrotic syndrome in children (MCD) is typically self-limited and carries a good prognosis. In the adult, the prognosis is variable. Complete remission is expected if the basic disease is treatable (infection, malignancy, drug-induced); otherwise, a relapsing and remitting course is possible, with progression to dialysis seen in more aggressive forms (diabetic glomerulosclerosis).

COMPLICATIONS

- Thromboembolism:
  - Deep vein, renal vein, or central venous thrombosis may occur.
  - The risk appears to be greater the lower the serum albumin.
  - Pulmonary embolism is a known complication.
- Pleural effusion
- Symptomatic hypovolemia
- Ascites
- Hyperlipidemia, cardiovascular disease
- Acute renal failure, progressive renal failure
- Protein malnutrition/muscle wasting
- Infection secondary to low serum IgG concentrations, reduced complement activity, and depressed T-cell function: peritonitis, pneumonia, or cellulitis
- Loss of vitamin D (vitamin D–binding protein loss in urine) leading to bone disease
- Proximal tubular dysfunction resulting in glucosuria, aminoaciduria, phosphaturia, bicarbonaturia, and vitamin D deficiency

Amyloidosis; Diabetes Mellitus, Type 1; Diabetes Mellitus, Type 2; Glomerulonephritis, Acute; HIV/AIDS; Lupus Erythematosus, Discoid; Multiple Myeloma; Renal Failure, Acute

CODES

ICD10

- N04.9 Nephrotic syndrome with unspecified morphologic changes
- N04.1 Nephrotic syndrome w focal and segmental glomerular lesions
- N04.2 Nephrotic syndrome w diffuse membranous glomerulonephritis

CLINICAL PEARLS

- Nephrotic syndrome is a clinical syndrome of >3.5 g/day proteinuria, hypoalbuminemia, hyperlipidemia, and edema often associated with diabetes and NSAIDs use.
- Pediatric nephrotic syndrome typically carries a good prognosis and is more easily treated with steroids, although recurrences are common.
- Nondiabetic adults with nephrotic syndrome will require a renal biopsy to determine cause.
- Have a high index of suspicion for symptoms that may represent an embolic event in patients with nephrotic syndrome.

NEUROFIBROMATOSIS TYPE 1

Rayna Goldstein, MD • Michele Roberts, MD, PhD

BASICS

DESCRIPTION

- Neurofibromatosis types 1 (NF1) and 2 (NF2) are neurocutaneous syndromes (phakomatoses). Although they share a name, they are distinct and unrelated conditions with genes on different chromosomes.
  - NF2 is a rare condition that causes bilateral vestibular schwannomas.
  - NF1 is a multisystem disorder that may affect any organ. It is the most common of the phakomatoses.
- System(s) affected: musculoskeletal, nervous, skin/exocrine, cardiovascular, neuroophthalmologic
- Synonym(s): von Recklinghausen disease, formerly peripheral NF

EPIDEMIOLOGY

Incidence

- Predominant sex for NF1: male = female
- Birth incidence NF1: 1:2,500 to 3,000

Prevalence

1:3,000 to 1:4,000

ETIOLOGY AND PATHOPHYSIOLOGY

- Neurofibromin is a guanosine triphosphatase–activating protein that acts as a tumor suppressor by downregulating a cellular protooncogene, *p21-ras*, which enhances cell growth and proliferation.
- Neurofibromata are benign tumors composed of Schwann cells, fibroblasts, mast cells, and vascular components that develop along nerves.
- The two-hit hypothesis has been invoked to explain malignant transformation in *NF1*.

Genetics

- Online Mendelian Inheritance in Man 162200

- Caused by a mutation in the *NF1* gene on chromosome 17q11.2; autosomal dominant inheritance; protein product is called *neurofibromin*.
- 50% of cases are due to de novo mutations, mostly paternal; likelihood increases with paternal age
- Prenatal diagnosis is possible if mutation is known.
- Penetrance is nearly 100%; expressivity is highly variable, even within a family.
- Gene is large, with a variety of mutations causing NF1. Molecular technology can detect 95% of clinically important *NF1* mutations, but clinical diagnosis frequently can be made in childhood.
- ~5% of individuals with NF1 have a large deletion of the entire *NF1* gene (or nearly so); they usually have a more severe phenotype.
- *Segmental NF* is limited to a single body region and is caused by mosaicism for the *NF1* mutation.

RISK FACTORS

- Having an affected first-degree relative is a diagnostic criterion for NF1, although relatives may be unaware of their condition.
- Affected individuals with a positive family history, as well as those with a new mutation, have a 50% risk of transmitting NF1 to each of their offspring; 1 in 12 will be severely affected.
- Individuals with segmental NF1 may have gonadal mosaicism and may be at risk for transmission of the mutated gene.

COMMONLY ASSOCIATED CONDITIONS

Congenital heart disease, pulmonary stenosis, hypertension, renal artery stenosis

DIAGNOSIS

- NF1 can be diagnosed by routine exam by age 4 years, with attention to skin stigmata; diagnostic criteria include ≥2 of the following (1):
  - ≥6 café au lait (light brown) macules, ≥5 mm in prepubertal individuals or ≥15 mm in adults
  - ≥2 neurofibromata of any type or 1 plexiform (noncircumscribed) neurofibroma

  - Axillary or inguinal freckling
  - ≥2 Lisch nodules (benign iris hamartomas, asymptomatic)
  - Optic glioma by MRI
  - Characteristic osseous lesions: sphenoid dysplasia, long-bone cortical thinning, ribbon ribs, angular scoliosis
  - First-degree relative with NF1 by above criteria
- Prenatal diagnosis is possible with known mutation or by linkage testing (with positive family history), although not predictive of clinical course.

HISTORY

- Family history of a first-degree relative with NF1
- Manifestations generally are not visible at birth, although plexiform neurofibromata usually are congenital and tibial bowing is congenital.
- In addition to cutaneous lesions, NF1 may present with painful neurofibromata, pathologic fractures, or headaches secondary to hypertension caused by pheochromocytomas.
- Optic gliomata may present as involuntary eye movement, squinting, loss of vision, or as diencephalic syndrome.

PHYSICAL EXAM

- Skin
  - Café au lait macules develop during the first 3 years of childhood and are usually the presenting feature of NF1. Evenly pigmented, irregularly shaped (coast-of-California), light brown macules present in 97% of patients with NF1; many unaffected individuals have one to three such macules.
  - Neurofibromata: can be cutaneous, subcutaneous, or plexiform and may be soft or firm; buttonhole invagination is pathognomonic. Cutaneous neurofibromata usually begin to appear during late childhood or adolescence.
  - Plexiform neurofibromata are present in up to 50% of individuals with NF1
    - Usually congenital; may be subtle in infancy
    - Freckling or hypertrichosis may be present over plexiform neurofibromata; may affect underlying structures or cause focal hyperplasia
    - Many are internal, not obvious on exam.

    - Most grow slowly over many years but can have rapid growth, especially in early childhood.
  - Evaluate for new lesions and progression of pre-existing ones. Rapidly growing cutaneous lesions should be evaluated thoroughly.
  - Axillary freckling (Crowe sign) or inguinal freckling (91%)
- Ophthalmologic
  - Lisch nodules (benign iris hamartomas) in 30%: well-defined, dome-shaped, gelatinous hamartomatous lesions projecting from the iris, varying from clear yellow to brown
  - Essentially unique to NF, Lisch nodules are asymptomatic; significant only for diagnosis.
  - Pallor or atrophy of optic disc, bulging of orbit, loss of vision may be signs of optic glioma.
- Skeletal
  - Scoliosis and vertebral angulation
  - Localized bone hypertrophy, especially of the face
  - Limb abnormalities:
    - Pseudoarthrosis of the tibia
    - Tibial dysplasia (anterolateral bowing of the tibia) is congenital, if present.
    - Nonossifying fibromas of the long bones in adolescents and adults are uncommon but can increase risk of fracture.
- Pay particular attention to neurologic examination or new focal pain.
- Measure BP yearly. Hypertension is more common in patients with NF1 and could be secondary to renal artery stenosis, aortic stenosis, pheochromocytoma.
- Evaluate neurodevelopmental progress in children. Learning disabilities occur in 50–75%.

DIFFERENTIAL DIAGNOSIS

Familial café au lait spots (autosomal dominant, no other NF1 features), Legius syndrome, constitutional mismatch repair deficiency syndrome (CMMRD), NF2, Watson syndrome, LEOPARD syndrome, McCune-Albright syndrome, neurocutaneous melanosis, proteus syndrome, lipomatosis, Jaffe–Campanacci syndrome

Geriatric Considerations

In NF1, cutaneous lesions and tumors increase in size and number with age.

Pediatric Considerations

- Children who have inherited the *NF1* gene of an affected parent usually are identified by age 1 year, but external stigmata may be subtle. If there are no stigmata by age 2 years, NF is unlikely, but the child should be reexamined within the next few years. Definite diagnosis can be made by age 4 years using National Institute of Health (NIH) criteria (1).
- Young children with multiple café au lait spots, but no other stigmata after careful physical and ophthalmologic evaluation, should be followed clinically as if they have NF1 (2).
- Molecular confirmation may be appropriate, especially with atypical presentation (3).

DIAGNOSTIC TESTS & INTERPRETATION

- DNA sequence and deletion/duplication analysis of the *NF1* gene can identify mutations in ~96% of those with a clinical diagnosis.
- Molecular genetic testing is available, although often not necessary for diagnosis. Diagnostic laboratory information: https://www.genetests.org/
- Confirmatory genetic testing is appropriate in those who are suspected of having NF1 but do not fulfill diagnostic criteria or for prenatal diagnosis or preimplantation genetic diagnosis (PGD) (4).

Initial Tests (lab, imaging)

- Characteristic radiographic findings: sphenoid dysplasia, long bone cortical thinning, ribbon ribs, and angular scoliosis. Screening radiographs of the knees in adolescents is controversial. CT can demonstrate bony changes.
- MRI findings of the orbits, brain, or spine (86%). Routine head MRI scanning in asymptomatic individuals with NF1 is controversial. Optic gliomata (seen on MRI, 11–15%) may lead to blindness. Although areas of increased T_2 signal intensity (unidentified bright objects) are common on brain MRI, they are not diagnostic of NF1 and likely are of no clinical significance.
- The NIH Consensus Development Conference does not recommend routine neuroimaging as a means of establishing a diagnosis, although modification of

diagnostic criteria is discussed (1)[C].

Diagnostic Procedures/Other

- Ophthalmologic evaluation, including slit-lamp exam of the irides; visual field testing to evaluate optic gliomata
- Neuropsychological testing: Intelligence usually normal but may have significant deficits in language, visuospatial skills, and neuromotor skills.

TREATMENT

MEDICATION

First Line

There are no specific therapeutic agents approved; individual aspects are treated as they arise (e.g., anticonvulsants for seizures, medications for ADHD, management of blood pressure).

Second Line

- In case studies, Sirolimus, a mammalian target of rapamycin [mTOR] inhibitor, did not shrink nonprogressive plexiform neurofibromas, but did relieve pain and retard progression of inoperable plexiform neurofibromas (5) [C].
- Multiple clinical trials for NF1 are recruiting patients (see https://www.clinicaltrials.gov/).

ISSUES FOR REFERRAL

- Patients with more than minimal manifestations of NF1: Refer to a multidisciplinary NF clinic.
- Referral for psychosocial issues of family and affected individuals
- Educational intervention for children with learning disabilities or ADHD (40%)
- Early referral to orthopedics for congenital tibial bowing

ADDITIONAL THERAPIES

- Occupational therapy for children with NF1 who present with fine motor difficulties

- There is no evidence supporting laser therapy for café au lait spots.
- The Children's Tumor Foundation (CTF) has established the NF Clinical Trials Consortium and the CTF NF Clinic Network to facilitate future clinical trials and help identify best practices (6).

SURGERY/OTHER PROCEDURES

Surgical treatment for severe scoliosis, plexiform neurofibromata, or malignancy

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

NF1 health supervision 2008 guidelines:

- Infancy to 1 year (7)[C]
  - Growth and development: mild short stature, macrocephaly (increased brain volume); aqueductal stenosis/obstructive hydrocephalus, hydrocephalus
  - Check for focal neurologic signs or asymmetric neurologic exam.
  - Skeletal abnormalities, especially spine and legs
  - Neurodevelopmental progress
- 1 to 5 years (7)[C]
  - Café au lait spots and axillary freckling have no clinical significance.
  - Annual ophthalmologic exam
  - Brain MRI for visual changes, persistent headaches, seizures, marked increase in head size, plexiform neurofibroma of the head
  - Assess speech and language: hypernasal speech due to velopharyngeal insufficiency and delayed expressive language development.
  - Developmental evaluation of learning and motor abilities; may benefit from speech/language and/or motor therapy, and special education
  - Monitor BP annually.
- 5 to 13 years (7)[C]
  - Evaluate for skin tumors causing disfigurement and obtain consultation if surgery is desired to improve appearance or function.
  - Evaluate for premature or delayed puberty. If sexual precocity is noted, evaluate for an optic glioma or hypothalamic lesion. Review the effects of puberty on NF.

  - Evaluate for learning disabilities and ADHD.
  - Evaluate social adjustment, development, and school placement.
  - Monitor ophthalmologic status yearly until age 8 years; complete eye exam every 2 years.
  - Monitor BP annually.
  - Refer patient to a clinical psychologist or child psychiatrist for problems with self-esteem.
  - Discuss growth of neurofibromata during adolescence and pregnancy.
  - Counsel parents about discussing diagnosis with child.
- 13 to 21 years (7)[C]
  - Examine the adolescent for abnormal pubertal development.
  - Thorough skin examination for plexiform neurofibromata and a complete neurologic exam for findings suggestive of deep plexiform neurofibromata; seek surgical consultation for signs of pressure on deep structures.
  - Continue to monitor BP yearly.
  - Continue ophthalmologic examination every 2 years until age 18 years.
  - Discuss genetics of NF1 or refer for genetic counseling.
  - Discuss sexuality, contraception, and reproductive options.
  - Discuss effects of pregnancy on NF1, if appropriate. Neurofibromata may enlarge and new tumors may develop during pregnancy.
  - Review prenatal diagnosis or refer the patient to a geneticist.

PATIENT EDUCATION

- Genetic counseling and patient education regarding future complications about family planning
- Support groups are important: http://www.ctf.org/.

PROGNOSIS

Variable; most patients have a mild expression of NF1 and lead normal lives.

COMPLICATIONS

- Disfigurement: Skin neurofibromata develop primarily on exposed areas. The number tends to increase with puberty or pregnancy.
- Scoliosis: 10–30% (most cases mild); bowing of long bones, 2%; osteopenia and osteoporosis

- A large head is common but rarely associated with hydrocephalus.
- Increased risk of malignancy: malignant peripheral nerve sheath tumor (MPNST) (5–10%) usually in adults (1), especially within the field of previous radiotherapy for plexiform neurofibroma
- CNS tumors (5–15%), especially optic pathway glioma (most common CNS tumor), most often asymptomatic, but if symptomatic, usually presents before age 6 years. Symptomatic lesions are usually stable or only slowly progressive.
- High relative risk (RR) for some uncommon malignancies
- Increased risk for pheochromocytoma, rhabdomyosarcoma, leukemia, Wilms tumor
- Relative risk for cancer of the esophagus (3.3), stomach (2.8), colon (2.0), liver (3.8), lung (3.0), bone (19.6), thyroid (4.9), malignant melanoma (3.6), non-Hodgkin lymphoma (3.3), chronic myeloid leukemia (6.7), female breast (2.3), and ovary (3.7)
- Learning disability: ∼50%; may be associated with ADHD; mental retardation in 4–8%
- GI neurofibromata may cause GI disturbances.
- Seizures: 6–7%
- Hypertension is a frequent finding in adults and may occur during childhood.
- Disorders of puberty

Pregnancy Considerations

Increased risk of perinatal complications, stillbirth, intrauterine growth constriction; risk of cord compression, and outlet obstruction by pelvic neurofibromata

CODES

ICD10

Q85.01 Neurofibromatosis, type 1

CLINICAL PEARLS

- Marked clinical variability. External stigmata may be subtle or absent in young children. Minimally affected children may become severely affected adults.
- A single café au lait spot is of no concern in a child, but having ≥6 is a diagnostic criterion for NF1.

NEUROPATHIC PAIN

Janet Grotticelli, DO, MBA, CHSE

BASICS

DESCRIPTION

- Defined as pain caused by a lesion or disease that leads to an abnormal and dysfunctional somatosensory system (1)
- A complex state that arises from abnormal neural activity secondary to disease, injury, or dysfunction of the peripheral or central nervous system
- Can exist without ongoing disease
- Can arise from damage to the nerve pathways at any point from the terminals of the peripheral nociceptors to the cortical neurons in the brain
- May be triggered by direct nerve injury, infection, metabolic dysfunction, autoimmune disease, neoplasm, drugs, radiation, and neurovascular disorders
- May reflect abnormal central nervous system activity rather than a manifestation of any underlying pathology itself (i.e., phantom limb pain, complex regional pain syndrome [CRPS])

EPIDEMIOLOGY

Incidence

Data is challenging due to the diversity of related clinical entities.

- Includes various chronic conditions that together, affect up to 8% of the population (2)

Prevalence

- Approximately 20% of people with cancer have cancer-related neuropathic pain as a result of either the disease or its treatment (3).
- The lifetime incidence of herpes zoster (shingles) is ~25%. Studies in the United States and Netherlands found 2.6% and 10%, respectively, will develop chronic postherpetic neuralgia (3).
- 33 million people infected with HIV across the world; ~35% have neuropathic pain (3)
- Up to 50% of people with diabetes have some form of neuropathy.

ETIOLOGY AND PATHOPHYSIOLOGY

- Positive symptoms due to changes in peripheral nerves, loss of inhibitory mechanisms in CNS, and central sensitization
- Negative symptoms (sensory deficits) reflecting neural damage
- Associated with a predisposing factor
- Risk factors:
  - Demyelinating disorders (multiple sclerosis, Guillain-Barré)
  - Neoplasm (primary/metastatic)
  - Neurovascular (central poststroke syndrome, diabetes, trigeminal neuralgia)
  - Autoimmune disease (Sjögren syndrome, polyarteritis nodosa)
  - Structural disease (herniated disc disease) (4)

RISK FACTORS

- General risk factors include older age, female gender, physical inactivity, and manual occupation.
- There is growing evidence of genetic factors.
- Includes factors that increase the risk of underlying conditions, as well as those that increase the risk of pain when these conditions are present:
  - Diabetes
  - Herpes zoster
  - Trigeminal neuralgia
  - HIV
  - Lyme disease
  - Cancer and chemotherapy
  - Stroke
  - Multiple sclerosis
  - Trauma
  - Surgery
  - Limb amputation
  - Nutritional deficiencies
  - Medications

COMMONLY ASSOCIATED CONDITIONS

- Depression/anxiety
- Insomnia

- Drug dependence

DIAGNOSIS

The diagnosis is based primarily on history (e.g., underlying disorder and distinct pain qualities) and the findings on physical examination (e.g., pattern of sensory disturbance); however, several tests may sometimes be helpful (2,5)[A].

HISTORY

- Careful history that includes:
  - Onset and duration of symptoms: this is a chronic condition, location, intensity, character, temporal profile, and possible exacerbating factors. Concomitant symptoms should also be questioned. Past medical and surgical history, psychosocial history, and functional history (i.e., the impact of symptoms on level of mobility, activities of daily living, relation with others, sleep, and mood) are also important.
  - Sensory descriptors: numbness, weakness, reduced sensation to touch, pinprick, temperature, or vibration; decreased proprioception
- Pain is often described as burning, shock-like, tingling (2,4)[A]
- No single feature is diagnostic (1).

PHYSICAL EXAM

- Positive signs/symptoms (2,6)[A]
  - Hypoesthesia (abnormally reduced sensation of a tactile stimulus) to touch or cold
  - Hypoalgesia (abnormally reduced pain sensation to a noxious stimulus)
  - Hyperalgesia: (abnormally increased pain sensation to a noxious stimulus) to pinprick, blunt pressure, heat, or cold
  - Allodynia: (pain sensation to a nonnoxious stimulus) for example, pain evoked by light touch, clothing, bed sheets
- Motor signs and symptoms: may include hypotonia, tremor, dystonia, ataxia, hypo-/hyperreflexia, or motor neglect. Motor symptoms include weakness, fatigability, decreased range of motion, joint stiffness, and spontaneous muscle spasm (4)[A].
- Sensory examination

  - Light touch, pinprick, vibration sense, and proprioception may be diminished or absent in the involved nerve territory.
  - Sensory disturbance may aberrantly extend beyond a discrete nerve territory.
- Skin examination
  - Alterations in temperature, color, sweating, and hair growth suggestive of CRPS
  - Residual dermatomal scars consistent with previous herpes zoster (shingles) infection
  - Characteristic skin changes consistent with diabetes mellitus

DIFFERENTIAL DIAGNOSIS

- Nociceptive pain: induced by transmission impulses along peripheral nociceptors usually due to tissue damage
- Differentiate by clinical signs and symptoms, mechanisms and therapeutic management

DIAGNOSTIC TESTS & INTERPRETATION

For definite diagnosis, the abnormal sensory findings are confirmed to the innervation territory of the lesioned nervous system structure AND diagnostic test(s) confirming a nervous system lesion or disease that could explain neuropathic pain (1)[A].

Initial Tests (lab, imaging)

None specifically for neuropathic pain but can rule in or out a cause of symptoms

- Neuroimaging based on affected area
- Blood and cerebrospinal fluid samples
  - Structural tests:
    - Skin biopsy analyses
    - Sural nerve biopsy
    - Structural imaging tests
- Serum B_{12}
- 25-hydroxyvitamin D
- Thyroid-stimulating hormone (TSH)

- Rapid plasma reagin (RPR) or Venereal Disease Research Laboratory (VDRL) test
- Fasting glucose, creatinine Lyme serology

Follow-Up Tests & Special Considerations

- Nerve conduction study (NCS): the standard electrodiagnostic tool for assessing peripheral nerve fiber function (2)[A]
- Electromyography (2)[A]
- Evoked potentials (2)[A]
- Quantitative Sensory Testing (2)[A]
- Thermography (2)[A]
- CSF samples (2)[A]

TREATMENT

GENERAL MEASURES

- Generally resistant to acetaminophen or NSAIDs
- Learn ways to relax body and mind.

MEDICATION

- The efficacy of systemic drug treatments is generally not dependent on the etiology of the underlying disorder (2,7).
- Combined therapy (polypharmacy) may be more effective.
- Treatment needs to be individualized

First Line

- Calcium channel alpha-2-delta ligands
  - Gabapentin (2,8)[A]
    - Dosing: 1,200 to 3,600 mg in three divided doses
    - Precautions: Reduce dosages in renal insufficiency.
    - Common side effects: sedation, dizziness, peripheral edema, weight gain
  - Pregabalin (2,8)[A]
    - Used for the treatment of PDN, spinal cord injury, PHN, fibromyalgia (3)[A]
    - Dosing: 300 to 600 mg in two doses

- Precautions: Reduce dosages in renal insufficiency.
- Common side effects: sedation, dizziness, peripheral edema, weight gain

- Tricyclic antidepressants (2,8)[A]
  - Nortriptyline, desipramine, amitriptyline, clomipramine, imipramine
    - Dosing: Start at 10 to 25 mg at bedtime, then increase by 10 to 25 mg every 4 to 7 days up to 150 mg/day to efficacy and side effects.
    - Precautions: cardiac disease, glaucoma, prostatic adenoma, seizure, tramadol use
    - Geriatric considerations: patients (dose ≤75 mg daily)
    - Common side effects: somnolence, anticholinergic effects, weight gain
- Serotonin-norepinephrine reuptake inhibitors (SNRIs) (2,8)[A]
  - Duloxetine
    - Dosing: 30 mg once daily/60 mg twice daily. Effective doses 60 to 120 mg daily
    - Precautions: hepatic disorder, tramadol use, hypertension
    - Common side effects: nausea
  - Venlafaxine
    - Dosage: 37.5 mg once or twice daily/225 mg daily. Effective doses 150 to 225 mg daily
    - Precautions: cardiac disease, hypertension; tramadol use
    - Common side effects: nausea, hypertension at high dosages
- Topical lidocaine (first line for elderly, frail patients only)
  - Lidocaine, 5% plasters (2,8)[A]
    - Dosage: 1 to 3 patches/3 patches for 12 hours to cover the painful area
    - Precautions: none
    - Common side effects: local erythema, itch, rash
  - Carbamazepine (9)[A]

Second Line

- Topical treatments (2)[A]
  - Lidocaine patches
    - (See “Topical lidocaine”)
  - Capsaicin high-concentration patches (8%)
    - Dosage: 1 to 4 patches to cover the painful area, repeat every 3 months;

30 minutes application to feet, 60 minutes application to remainder of body; avoid use on face.
    - Precautions: caution in progressive neuropathy
    - Common side effects: pain, erythema, itching, rare hypertension (initial increase in pain)
- Tramadol (2)[A]
  - Dosage: 50 mg once or twice daily/400 mg daily as long-acting drug. Increase by 50 to 100 mg every 3 to 7 days.
  - Precautions: history of substance abuse, suicide risk
  - Geriatric considerations: use of antidepressant in elderly patients
  - Common side effects: nausea, vomiting, constipation, dizziness, somnolence

Third Line

- Opioids (2)[A]
  - Morphine, oxycodone
    - Dosage: 10 to 15 mg morphine every 4 hours or as needed (equianalgesic doses for other opioids)/up to 300 mg morphine has been used
    - Precautions: history of substance abuse, suicide risk, risk of misuse on long-term use
  - Botulinum toxin type A
    - Dosage: 50 to 300 units subcutaneously to the painful area; repeat every 3 months
    - Precautions: infection of area
    - Common side effects: pain at injection site

ISSUES FOR REFERRAL

Referral to pain clinic if refractory to initial treatment or additional therapies below are warranted.

ADDITIONAL THERAPIES

- Cannabinoids (dronabinol and nabilone): The appropriateness of medical marijuana for a patient should be comprehensive assessments that revolve around risk–benefit discussion (8,10).
- Neural stimulation (11)

- Spinal cord stimulation (SCS): Pain that is continuous and unchanging responds best. The most common indication is failed back surgery syndrome with leg pain. Less common indications are peripheral nerve injury, CRPS, and painful peripheral neuropathy (11).
- Dorsal root ganglion stimulation to treat challenging pain syndromes that do not respond to conventional SCS (11).
- Peripheral nerve stimulation (PNS): Indications include pain in the distribution of an accessible peripheral nerve. The most common nerves treated are the supraorbital, infraorbital, greater occipital, ulnar, median, suprascapular, intercostal, ilioinguinal, iliohypogastric, genitofemoral, lateral femoral cutaneous, saphenous, sciatic, posterior tibial, superficial peroneal, and sural nerves (11).
- Intrathecal drug delivery considered invasive and labor intensive; may be used when other conservative therapies fail (11)
- Transcutaneous electrical nerve stimulation is widely used; evidence is poor in supporting the efficacy (11).
- Osteopathic manipulative treatment should be offered to all patients. Myofascial trigger point release can be an effective primary technique. Indirect or passive myofascial techniques may be used to address all regions of tissue texture change (12).
- Hypnosis can reduce pain and anxiety related to the pain.
- Acupuncture

SURGERY/OTHER PROCEDURES

Nerve destructive procedures haven't shown effectiveness and may cause additional insult/injury (an exception is treatment of terminal cancer) (11).

- Sympathectomy dorsal root entry zone lesion (dorsal rhizotomy)
- Lateral cordotomy
- Trigeminal nerve ganglion ablation (13)[A]

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Multidisciplinary team

- Periodic evaluation to rule out other treatable conditions (2)

Patient Monitoring

- Pain management requires ongoing evaluation, patient education, and reassurance.
- Patient compliance and adequacy of analgesic drug titrations should be continually evaluated and documented.

PROGNOSIS

Chronic course of pain symptoms often requires management with numerous medications and adjunctive therapies.

COMPLICATIONS

Long-term disability and drug addiction are possible.

CODES

ICD10

- M79.2 Neuralgia and neuritis, unspecified
- E10.40 Type 1 diabetes mellitus with diabetic neuropathy, unsp
- E11.40 Type 2 diabetes mellitus with diabetic neuropathy, unsp

CLINICAL PEARLS

- Neuropathic pain is a chronic pain syndrome, affecting between 2% and 8% of people with a major impact on quality of life.
- The ongoing challenge for clinicians (and patients) is being able to determine which treatment is most likely to work for any one individual.
- The first line of treatment is pharmacologic and may be more beneficial with additional therapies.
- Generally resistant to acetaminophen or NSAIDs

NEUROPATHY, PERIPHERAL

Amy Chen, MD, PhD • David N. Herrmann, MBBCh

BASICS

DESCRIPTION

- Peripheral neuropathy (PN) is a functional or structural disorder of the peripheral nervous system (PNS).
- PN affects any combination of motor, sensory, or autonomic nerves.
- The motor PNS comprises spinal cord motor neurons, their nerve roots that combine to form plexus, and branches that form individual nerves innervating skeletal muscles. Peripheral motor involvement causes muscle atrophy, weakness, cramps, and fasciculations.
- The sensory PNS consists of sensory organs, which transmit touch, vibration, and position sensation in large-diameter myelinated fibers; pain and temperature in small-diameter, lightly myelinated and unmyelinated C fibers to the dorsal root ganglia. Sensory signals are relayed to the central nervous system (CNS) for integration. Disorders of sensory nerves produce negative phenomena (loss of sensibility, lack of balance) or heightened phenomena (tingling or pain). Large sensory fiber dysfunction impairs touch and vibration sensation, whereas small fiber sensory neuropathy (SFN) affects pin and thermal sensation and causes neuropathic pain.
- The autonomic nervous system (ANS) includes the sympathetic and parasympathetic systems. ANS dysfunction causes cardiovascular, gastrointestinal, and sudomotor symptoms.
- The PNS can be affected from the cell body (sensory ganglionopathy or motor neuronopathy), root (radiculopathy), or plexus (plexopathy) to the nerve (demyelinating or axonal neuropathy).

EPIDEMIOLOGY

Prevalence

Approximately 2.4% of general population, or 8% of people >55 years old, are affected by distal symmetric PN, the most common form of PN.

ETIOLOGY AND PATHOPHYSIOLOGY

- PN can be acquired or hereditary.
- The most common cause of acquired PN is diabetes.
- Other categories of acquired PN with illustrative examples are the following:
  - Vascular: ischemia, vasculitis
  - Infectious: HIV, hepatitis C, cryoglobulinemia, Lyme disease
  - Traumatic: compression, crush, or transection
  - Autoimmune: rheumatoid arthritis, Sjögren, postinfectious Guillain-Barré syndrome (GBS), chronic inflammatory demyelinating polyneuropathy (CIDP)
  - Metabolic: diabetes, renal failure, hypothyroidism, vitamin B_{12} deficiency, celiac disease
  - Iatrogenic/toxic: chemotherapy, platinum, taxanes, metronidazole, colchicine, infliximab, alcoholism
  - Idiopathic: 30% of PN
  - Neoplastic/paraneoplastic: paraproteinemia, Waldenstrom macroglobulinemia, multiple myeloma, amyloidosis, neurofibromatosis
- PN occurs due to demyelination or axonal degeneration.
- Demyelination results from Schwann cell dysfunction, mutations in myelin protein genes, or direct damage to myelin sheaths.
- Axonal degeneration occurs when injury/dysfunction occurs at the cell body or axon.

Genetics

- Approximately 50% of undiagnosed PN is hereditary.
- Currently, there are over 70 known genetic causes of hereditary PN.
- Charcot-Marie-Tooth (CMT) neuropathies: the most common hereditary PN
  - *CMT1A* (duplication of the *PMP22* gene) is the most common CMT.
  - A *PMP22* deletion causes hereditary neuropathy with liability to pressure palsy (HNPP)

RISK FACTORS

Systemic disorders predispose to PN.

GENERAL PREVENTION

- Healthy nutrition and avoidance of alcoholism and of pressure at nerve entrapment sites
- Surveillance for glucose dysmetabolism and tight glycemic control may prevent diabetic PN.

DIAGNOSIS

HISTORY

- A detailed inquiry for symptoms of sensory, motor, or autonomic dysfunction:
  - Numbness, tingling, prickling, burning pain, a “tightly wrapped” sensation, and an “unsteady gait”
  - Distal weakness manifests as foot drop (tripping, foot slapping) or difficulty with grip; proximal weakness (e.g., difficulty arising from a chair) is less common.
  - Orthostatic dizziness, abnormal sweating, constipation, or voiding difficulties
- Symptom onset:
  - Acute: Consider infection (e.g., Lyme disease), postinfectious dysimmune process (e.g., GBS), ischemia (e.g., vasculitis), toxin, or trauma.
  - Subacute: Consider metabolic, neoplastic, paraneoplastic, or dysimmune processes.
  - Chronic: Consider dysimmune process (CIDP), idiopathic, or hereditary.
- Progression: stable or indolent; slowly or rapidly progressive; monophasic or relapsing or remitting
- Anatomic pattern: focal, multifocal, diffuse

PHYSICAL EXAM

- Based on exam, a functional (*sensory*: small-fiber vs. large-fiber vs. mixed, *sensorimotor*, *motor*, *autonomic*) and anatomic pattern of PN (*distal symmetric*, *multifocal*, or *focal*) should be established.
- Cognition preserved in isolated PN.
- Cranial nerves may be involved with focal or multifocal PN (e.g., bifacial weakness may occur with GBS, Lyme disease, sarcoidosis, among other causes).

- Stocking/glove sensory loss is typical of distal symmetric sensory PN (e.g., diabetes).
- Isolated reduced pin or thermal sensation or allodynia suggests a pure SFN.
- Reduced vibration and joint position sense suggests large-fiber sensory neuropathy; when severe, a Romberg sign is present, and gait is wide-based or ataxic.
- Distal muscle atrophy and weaknesses of toe extension and finger abduction are often present with distal symmetric axonal PN.
- In acquired demyelinating PN (e.g., GBS or CIDP), weakness is commonly both proximal and distal.
- Deep tendon reflexes may be reduced or absent, distally at the ankles in large-fiber axonal PN, or diffusely in demyelinating PN.
- High arched or flat feet or hammer toes suggest hereditary PN.

ALERT

- Hemibody deficits or sensory loss below a spinal cord level suggest a CNS process.
- Hyperreflexia and spasticity are upper motor neuron signs not seen with isolated PN.

DIFFERENTIAL DIAGNOSIS

The following categories of PN can be identified (differential diagnosis [DDx] listed when applicable):

- Pure sensory neuropathy
  - DDx: SFN, sensory ganglionopathy, polyradiculopathy
- Distal symmetric sensorimotor axonal PN
  - Most common type of PN
  - DDx: distal acquired demyelinating symmetric PN (DADS)
- Motor predominant PN
  - DDx: motor neuron disease, polyradiculopathy, immune-mediated multifocal motor neuropathy (MMN)
- Mononeuropathy
  - Most likely due to compression, entrapment, or trauma
  - DDx: monoradiculopathy
- Mononeuropathy multiplex

- DDx: plexopathy, polyradiculopathy

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Nerve conduction studies and electromyography (NCS/EMG)
  - Best performed by physicians with specialty training in electrodiagnostic medicine
  - Delineate axonal versus demyelinating, anatomic pattern, chronicity, and severity of PN.
- Blood tests
  - CBC, BUN, creatinine, fasting glucose, HgA1C, vitamin B_{12}, serum protein electrophoresis, and immunofixation
- Specialized skin biopsy
  - In clinically suspected SFN if NCS/EMG is normal
  - Analysis of lower limb epidermal nerve fiber density (ENFD) (1)[A]
- Autonomic tests
  - Not routinely done but useful to characterize autonomic PN
- Neuroimaging
  - Generally not indicated in evaluation of PN but useful in evaluation of brachial plexopathies, radiculopathies, or where findings are attributable to the CNS

Follow-Up Tests & Special Considerations

- Additional blood tests are done based on the medical history, the PN type, and NCS/EMG findings.
- Genetic testing for diagnosis of hereditary PN should be ordered by neurologists with expertise in PN.
- Screen patients with distal symmetric PN for unhealthy alcohol use with CAGE-AID or AUDIT-C.

ALERT

Ordering of laboratory batteries (e.g., peripheral nerve antibody panels) without careful consideration of the clinical and NCS/EMG features should be avoided.

Diagnostic Procedures/Other

- Nerve biopsy (sural or superficial peroneal nerve): useful if vasculitis, amyloidosis, granulomatous disorders, or neoplastic infiltration is suspected; rarely helpful in late-onset chronic, slowly progressive distal symmetric PN
- Lumbar puncture
  - Cytoalbuminologic dissociation in GBS or CIDP
  - Infection, inflammation, or neoplasia in polyradiculopathies

Test Interpretation

- Demyelinating PN: disproportionate slowing of conduction velocities or prolonged distal latencies on NCS
- Axonal PN: reduced amplitude in sensory or motor responses, with relatively preserved conduction velocities on NCS
- Reduced ENFD on distal leg skin biopsies is supportive of SFN.

TREATMENT

GENERAL MEASURES

- Targeted treatment for underlying systemic conditions:
  - Glycemic control, thyroid hormone supplementation, vitamin supplementation, antimicrobial therapy (e.g., Lyme disease, HIV), glucocorticoids for sarcoidosis, and cytotoxic therapy for vasculitis
- Immunotherapy for dysimmune PN
  - Intravenous immunoglobulin (IVIG): within the first 2 weeks of GBS to hasten recovery (2)[A]; as a first-line alternative to corticosteroids for treatment of CIDP (3)[A]; and for prevention of secondary axonal loss in MMN (4)[A]
    - Loading dose 2 g/kg body weight divided into 2 to 5 days; maintenance regimen variable for CIDP and MMN
    - Adverse effects (AE): headache, fever, hypertension, and rarely pulmonary embolism
  - Plasma exchange: first agent shown to improve functional outcome for patients with GBS (5)[A]; short-term benefit in CIDP (5)[A]
    - AE: catheter complication, hypotension, and others
  - Corticosteroids: a first-line option in treatment of CIDP (5)[C]; oral or

pulsed IV regimen can induce remission

- Treatment of autonomic symptoms
  - Compression stockings, hydration, midodrine, and fludrocortisone for orthostatic hypotension
  - Pyridostigmine for immune-mediated dysautonomia (off-label)

MEDICATION

First Line

- Treatment of neuropathic pain: evidence of efficacy derived from clinical trials in diabetic painful neuropathy (DPN), postherpetic neuralgia (PHN), or trigeminal neuralgia:
  - Pregabalin: for DPN and PHN
  - Duloxetine: for DPN
  - Venlafaxine: (off-label) for DPN
  - Gabapentin: for PHN, (off-label) for DPN
  - Tricyclic antidepressants: (off-label) for DPN
  - Carbamazepine: for trigeminal neuralgia

Second Line

- Lidocaine patch: for PHN
- Capsaicin 8% patch: for PHN

Third Line

- Tapentadol: for DPN
- Tramadol: (off-label) for DPN

ISSUES FOR REFERRAL

- Rapidly progressive symptoms, suspected demyelinating PN, or hereditary PN should be referred to a neurologist with expertise in neuromuscular disorders.
- Patients with vasculitic PN should be referred to rheumatology.
- Patients with progressive painful PN, dysautonomia, and/or cardiomyopathy should be evaluated for transthyretin (TTR)-related familial amyloidosis.
- Patients with paraproteinemia should have a skeletal bone survey and be referred to hematology.
- Patients with imbalance, ataxia, or falls should be referred to physical therapy for gait and balance training.

ADDITIONAL THERAPIES

- Combination therapy (e.g., gabapentin with TCA or venlafaxine or tramadol) can be more effective than monotherapy for neuropathic pain.
- Long-acting opiates can be considered for refractory neuropathic pain.
- Additional immunosuppressant agents (e.g., cyclophosphamide) may be used in refractory chronic dysimmune PN.

ALERT

Opiates have significant side effects and may cause rebound headaches, tolerance, and dependence.

SURGERY/OTHER PROCEDURES

- Decompressive surgery for entrapment neuropathy (e.g., carpal tunnel syndrome)
- Foot and ankle surgery to improve symptoms or function in hereditary PN
- Radiation, surgery, or bone marrow transplantation for plasmacytoma or osteosclerotic myeloma or POEMS syndrome
- Liver transplantation for amyloidotic PN

COMPLEMENTARY & ALTERNATIVE MEDICINE

Low-intensity transcutaneous electrical nerve stimulation (TENS), acupuncture, meditation

ALERT

Vitamin B_6 supplementation may cause peripheral neurotoxicity and should be avoided except for a deficiency state.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Patients with suspected GBS should be admitted for diagnosis, monitoring (30–60% may develop cardiovascular or respiratory failure), and for acute treatment.
- Elective intubation may be required in GBS when forced vital capacity is <15 mL/kg body weight.
- Other rapidly progressive undiagnosed PNs that impair independent ambulation may require admission.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Physical therapy and gait assistive devices as needed
- Flu vaccination should be avoided in the first year following GBS.

PROGNOSIS

- Late-onset idiopathic distal symmetric axonal PNs are indolent.
- 80% of GBS have a near complete or good recovery. 80% of CIDP have moderate or good response with treatment but can be relapsing.

CODES

ICD10

- G62.9 Polyneuropathy, unspecified

- G60.9 Hereditary and idiopathic neuropathy, unspecified
- G60.8 Other hereditary and idiopathic neuropathies

CLINICAL PEARLS

- There are many causes of PN. Diagnosis is made by history and physical exam, targeted laboratory testing, NCS/EMG, skin biopsy, or ANS testing.
- Consider hereditary neuropathy if patient has an early age of PN symptom onset, family history of PN, or foot deformity.
- GBS is monophasic and progresses for up to 4 weeks; CIDP progresses beyond 8 weeks, and if untreated, usually has a progressive course.

NICOTINE ADDICTION

Kamala M. Nyamathi, MD • Benjamin N. Schneider, MD

BASICS

DESCRIPTION

The constellation of compulsive use of nicotine product including lack of control over using, withdrawal symptoms, and/or continued use despite knowledge of or experiencing adverse consequences.

EPIDEMIOLOGY

Incidence

The following % of the U.S. population using nicotine in the last 1 month: Cigarettes age over 18 years: 21–28%, under 18 years: 5%, smokeless tobacco age over 18 years: 3–6%, under 18 years: 2% (1)

Prevalence

Approximately 40 million people in the United States ≥18 years of age are current tobacco users. In the past year, 58.7 million smoked cigarettes, 13.3 million smoked cigars, 2.1 million smoked pipes, and 8.6 million used smokeless tobacco (1).

Pediatric Considerations

Nicotine use is common and under recognized in this population. In 2013, 15% of U.S. high school students reported smoking in the past 30 days, with increasing rates of e-cigarette and hookah use. About 80% of these individuals will continue smoking into adulthood (1).

ETIOLOGY AND PATHOPHYSIOLOGY

- Similar to other addictive drugs, nicotine affects neural pathways that control reward and pleasure.
- Nicotinic acetylcholine receptors (nAChRs) play a major role via neurotransmitter interactions of glutamate, GABA, dopamine, serotonin, acetylcholine, and norepinephrine.
- Nicotine induces euphoria, assists information processing, reduces anxiety,

and mitigates fatigue.
- Polymorphisms in neuronal nAChR genes are associated with increased susceptibility to dependence.
- Specific genes associated with nicotine dependence have been linked with decreased CYP2B86 activity (an enzyme that breaks down nicotine). Patients with this genetic link are 1.5 times more likely to fail treatment.

RISK FACTORS

- Mental illness (depression, posttraumatic stress disorder, bipolar disorder, and schizophrenia)
- Low socioeconomic status
- Low educational status
- Early first-hand nicotine experience
- Concurrent substance abuse
- Home and peer influence

GENERAL PREVENTION

- The U.S. Preventive Services Task Force (USPSTF) strongly recommends (2) [A]:
  - Screening all adults for tobacco use and provide cessation interventions for those who screen positive
  - Screening all pregnant women for tobacco use and provide pregnancy-tailored counseling to those who screen positive (2)
- The USPSTF recommends that clinicians provide interventions, including education or brief counseling to prevent initiation of tobacco use among school-aged children and adolescents (2)[B].

Pregnancy Considerations

- Carbon monoxide and nicotine interfere with fetal oxygen supply, resulting in decreased birth weights and possible intrauterine growth restriction.
- Maternal smoking adversely affects fetal lung development, with lifelong decreases in pulmonary function and increased risk of asthma.
- Smoking is associated with increased risk for spontaneous abortion, sudden infant death syndrome, learning and behavioral problems and obesity.

DIAGNOSIS

HISTORY

- Identify types, amount, and duration of nicotine products used.
- Review previous attempts to quit (methods used and duration of cessation).

PHYSICAL EXAM

- Pulmonary exam: wheezing, decreased breath sounds, prolonged expiration, distant heart sounds
- Cardiovascular exam
- Oral mucosal exam
- Clubbing

DIAGNOSTIC TESTS & INTERPRETATION

- Low dose CT: recommended by American College of Chest Physicians for people age 55 to 75 years with a history of 30+ pack years of tobacco use; those currently smoking or who have quit within the past 15 years (unless they have life limiting comorbidities).
- Spirometry: not recommended for routine screening, only perform if COPD is suspected.
- Chest x-ray: not recommended for routine screening

TREATMENT

COUNSELING (2)[A]

- Advice from providers improves quit rate (number needed to treat [NNT] 75).
- Providing brief, simple advice increases the likelihood of sustained cessation at 12 months.
- More intensive advice (i.e., motivational interviewing) may result in higher rates of quitting.
- Providing follow-up support may increase quit rates.
- Brief strategies to help the patient willing to quit tobacco use—the “5 As” (3) [A]
  - Ask patient if he or she uses nicotine.

  - Advise him or her to quit.
  - Assess willingness to make a quit attempt.
  - Assist those willing to make a quit attempt.
  - Arrange for follow-up contact to prevent relapse.
- Enhancing motivation to quit: the "5 Rs" (3)[A]
  - Relevance: Encourage patient to indicate why quitting is personally relevant.
  - Risks: Ask patient to identify potential negative consequences of use.
  - Rewards: Ask patient to identify potential benefits of cessation.
  - Roadblocks: Ask patient to identify barriers or impediments to quitting and provide treatment (e.g., problem-solving counseling or medication) that could address barriers.
  - Repetition: This motivational intervention should be repeated each visit.
- Users should be given a choice of methods to quit.
- Quit rates are equivalent for tapering use vs abrupt cessation. Patient preference should dictate plan.

MEDICATION

- Seven FDA-approved medications exist: nicotine replacement therapy (NRT), both long acting (i.e., patch) and short acting (i.e., gum, inhaler, lozenge, nasal spray) types, and non-NRT meds, bupropion SR and varenicline.
- With few exceptions, the choice of a first-line medication depends on patient preference.
- Combination NRT: All forms of NRT increase quit rate 50–70% (4)[A]. Combining long-acting and short-acting NRTs is more effective than using any single method alone. Heavier users may need higher doses. Starting NRT before planned quit date may increase success.
- Nicotine replacement (Gum: Pregnancy Category C all other formulations are pregnancy Category D).
  - Patch: for >10 cigarettes/day, start with 21 mg patch/day for 6 weeks, then 14 mg patch/day for 2 weeks, then 7 mg patch/day for 2 weeks; for <10 cigarettes/day, start with 14 mg patch/day for 6 weeks, then 7 mg patch/day for 2 weeks. Extending use of the patch beyond 8 to 10 weeks may improve abstinence rates.

  - Gum: for >25 cigarettes/day, use 4 mg gum q1–2h for 6 weeks; for <25 cigarettes/day, use 2 mg gum q1–2h for 6 weeks; decrease dosing by q1–2h for 3 weeks; chew then tuck between cheek and gingiva once nicotine flavor is released, repeat up to 30 minutes, then discard.
  - Nicotine lozenge (Commit): for patients who smoke their first cigarette within 30 minutes of waking, 4 mg lozenge PO q1–2h for 6 weeks; first cigarette >30 minutes after waking, 2 mg lozenge PO q1–2h for 6 weeks; decrease dosing by q1–2h for 3 weeks.
  - Nicotine nasal: Start 1 to 2 sprays (0.5 mg/spray) each nostril q1hr for 8 weeks, then taper; max 10 sprays/hr and 80 sprays/day
  - Nicotine inhaler: 6 to 16 cartridges inhaled (4 mg/cartridge) per day for 6 to 12 weeks, then taper. Incorporates the behavioral and sensory aspects of smoking
- Varenicline a nicotinic acetylcholine partial agonist (pregnancy category C). Contraindications: known history of skin reactions or hypersensitivity.

ALERT

Associated neuropsychiatric symptoms including depression, suicidal ideation/attempts in patients with and without preexisting psych conditions—recommend close monitoring. Longer term therapy (up to 24 weeks) may delay or prevent relapse:

- Starter pack: 0.5 mg/day for 3 days, 0.5 mg BID for 4 days, 1 mg/day starting day 7
- Maintenance pack 1 mg BID continue 12 weeks total; if successful in quitting, may continue for another 12 weeks
- Varenicline+bupropion is not more effective than either agent alone and confers increased side effects.
- Varenicline+nicotine replacement is more effective at 6 months than varenicline alone (NNT 6).
- Bupropion SR is an atypical antidepressant and norepinephrine-dopamine reuptake inhibitor (pregnancy Category C). Contraindications: history of seizure, stroke, brain injury, brain tumors, anorexia/bulimia, recent use of MAOI (within 14 days).
  - Start 1 week before target quit date due to time needed to reach steady state.

  - Use 150 mg/day for 3 days, then 150 mg BID for 7 to 12 weeks.
- Nortriptyline a tricyclic antidepressant (pregnancy Category D). Contraindications: narrow-angle glaucoma, heart disease (CAD, heart block, long QT).
  - Start 25 mg/day, gradually increase to target of 75 to 100 mg/day and continue for 12 weeks.
  - Set quit date 2 to 4 weeks after initiation.
- E-cigarette a battery-operated device that delivers nicotine with various flavorings and other chemicals as vapor. Insufficient evidence exists regarding this product's safety and efficacy. There is low quality evidence that suggests e-cigarettes can help patients cut down on the total number of cigarettes smoked. Other research demonstrates poor efficacy of abstinence with long-term follow up. The long-term safety of these devices has not been established (5).

ISSUES FOR REFERRAL

- Individuals receiving support from significant others are more likely to quit.
- Group programs double cessation rates compared to self-help materials alone.

Pregnancy Considerations

- Smoking is associated with intrauterine growth restriction, placenta previa, abruptio placentae, decreased maternal thyroid function, preterm premature rupture of membranes, low birth weight, perinatal mortality, and ectopic pregnancy.
- Tobacco cessation prior to 15 weeks' gestation provides the greatest benefit for both the woman and fetus, but quitting any time is beneficial.
- ACOG recommends that pregnant women be offered behavioral therapy and education as first-line treatment and that NRT and medications be reserved for patients in need of additional assistance.

ALERT

NRT is metabolized faster in pregnant women, which may lead to a higher dose requirement.

Pediatric Considerations

- There are currently no FDA approved pharmacologic treatments for children.

- AAP recommends using NRT only for patients with moderate to severe substance use disorder.
- Behavioral therapy (including CBT) is recommended as first line treatment.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Acupuncture: no consistent evidence of efficacy
- Hypnotherapy: no consistent evidence of efficacy

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Programs to stop nicotine use that begin during hospitalization and include follow-up support after discharge are effective.
- Programs are effective for all hospitalized users, regardless of admission diagnosis (6)[A].
- Consider NRT for all inpatients who use nicotine to decrease withdrawal symptoms (6)[A].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Patients motivated to quit smoking and who have initiated therapy should follow up after 1 to 2 weeks to monitor response and side effects.
- Monitor for signs of nicotine withdrawal syndrome and start medication-assisted treatment or adjust dosage:
  - Increased appetite/weight gain (4 to 5 kg over 10 years)
  - Dysphoric, depressed mood, or anhedonia
  - Insomnia
  - Irritability, frustration, or anger
  - Anxiety
  - Difficulty concentrating
  - Restlessness

PATIENT EDUCATION

- http://smokefree.gov
- http://women.smokefree.gov/

- http://teen.smokefree.gov
- http://www.nicotine-anonymous.org
- http://quitnet.meyouhealth.com
- 1-877-44U-QUIT (1-877-448-7848)

PROGNOSIS

- Roughly 50% of all smokers will die from a tobacco-related illness.
- Former smokers have a 50% reduction in risk of CAD 1 year after quitting, a 50% reduction in head and neck cancers by 2 to 5 years, and a 50% reduction in mortality from lung cancer by 10 years. The risk of stroke is reduced to that of nonsmokers 2 to 5 years after quitting.
- >85% of those who try to quit on their own relapse, most within 1 week
- Approximately 50–60% of women who quit smoking in pregnancy returned to smoking by 1-year postpartum.

COMPLICATIONS

- Chronic obstructive pulmonary disease (COPD) (emphysema and chronic bronchitis)
- Cancers (lung, oral/pharyngeal, kidney, bladder, cervical, anal)
- Atherosclerotic disease
- Periodontal disease
- Osteoporosis and hip fracture (in women)
- Peptic ulcer disease

CODES

ICD10

- F17.200 Nicotine dependence, unspecified, uncomplicated
- F17.201 Nicotine dependence, unspecified, in remission
- F17.203 Nicotine dependence unspecified, with withdrawal

CLINICAL PEARLS

- Nicotine dependence is a chronic disease and will often require repeated interventions and multiple cessation attempts.
- Consider NRT for all hospitalized patients who smoke to decrease withdrawal

symptoms.

- Treatments, including but not limited to medications, can significantly increase the rate of long-term abstinence.
- No single type of NRT/medication is best; thus, the choice should be based on patient preference and risk factors for side effects.

NONALCOHOLIC FATTY LIVER DISEASE (NAFLD)

Jill T. Wei, MD • Daniel T. Lee, MD, MA

BASICS

- A spectrum of fatty liver diseases not due to excess alcohol consumption ranging from nonalcoholic fatty liver (NAFL), to nonalcoholic steatohepatitis (NASH), to cirrhosis with hepatocyte injury with/without fibrosis
- Leading cause of chronic liver disease; implicated in up to 90% of patients with asymptomatic, mild aminotransferase elevation not caused by alcohol, viral hepatitis, or medications

DESCRIPTION

- NAFL (1)
  - Reversible condition in which large vacuoles of triglyceride fat accumulate in hepatocytes
  - Liver biopsy: fatty deposits in >30% of cells, no hepatocyte ballooning, no necrosis, no fibrosis
  - Alanine aminotransferase/aspartate aminotransferase (ALT/AST) enzymes usually normal but may be elevated, rarely >3 to 4 times ULN
  - Minimal risk of progressing to cirrhosis or liver failure
  - Synonym: steatosis
- NASH: progressive form of NAFL (1)
  - Liver biopsy: fatty deposits in >50% of cells with ballooning, acute/chronic inflammation, ± fibrosis
  - ALT and AST elevated, generally <3 to 4 times ULN
  - May progress to cirrhosis, liver failure, and rarely hepatocellular cancer; 30% with NASH may progress to fibrosis over 5 years.
- NASH cirrhosis (1)
  - Presence of cirrhosis with current or previous histologic evidence of steatosis or steatohepatitis

EPIDEMIOLOGY

- NAFLD: most common chronic liver disease globally; usually benign, asymptomatic
- Predicted to become the most frequent indication for liver transplantation by 2030 (2)
- NASH may be symptomatic with progressive inflammation and fibrosis.
  - Predominant age: 40s to 50s; can occur in children
  - Predominant sex: male > female (slight)

Incidence

Estimates vary widely from 31 to 86 cases of NAFLD per 10,000 person-years to 29/100,000 person-years (1).

Prevalence

- United States estimate: 30–40% (3)
- Worldwide: 6–33%, median 20% (1)
- Present in 58–74% of obese persons (BMI >30) and 90% of morbidly obese persons (BMI >39) (1)
- Among individuals with T2DM, rate of 69–87%; in patients with dyslipidemia, rate of 50% (1)

ETIOLOGY AND PATHOPHYSIOLOGY

Primary mechanism is *insulin resistance*, which leads to increased lipolysis, triglyceride synthesis, and increased hepatic uptake of fatty acids.

- NAFLD: excessive triglyceride accumulation in the liver and an impaired ability to remove fatty acids
- NASH: “2-hit” hypothesis: (i) macrovesicular steatosis due to increased hepatic lipid synthesis, reduced transfer of lipids, and increased insulin resistance with hepatic oxidative stress and (ii) mitochondrial damage leading to impaired restoration of ADT stores, lipid peroxidation, and resultant inflammatory injury (1)
- Other possible mechanism is lipotoxicity. Free-fatty acid metabolites cause endoplasmic reticular stress, hepatocyte apoptosis, necrosis, and inflammation. Hepatocellular injury triggers fibrogenesis and inflammation, hastening disease progression (3).

Genetics

Largely unknown: Some familial clustering and increased heritability. NAFL: more first-degree relatives with cirrhosis than matched controls; NASH: 18% with affected first-degree relative. Carriers of hemochromatosis gene are more likely to be affected. Patatin-like phospholipase domain-containing 3 (PNPLA3) I148M polymorphism may play a role in NAFLD, hypertriglyceridemia and insulin resistance (1,2).

RISK FACTORS

- Obesity (BMI >30), visceral obesity (waist circumference >102 cm for men or >88 cm for women), hypertension, dyslipidemia, high serum triglycerides and low serum high-density lipoprotein (HDL) levels, metabolic syndrome
- Type 2 diabetes, cardiovascular disease, and chronic kidney disease (2)
- Possible associations with hypothyroidism, hypopituitarism, hypogonadism, obstructive sleep apnea, pancreatoduodenal resection, osteoporosis, psoriasis, and polycystic ovary syndrome (2)
- Increasing age associated with increased prevalence, severity, advanced fibrosis, and mortality
- High fructose intake linked to intestinal dysbiosis and metabolic stress (4)
- Protein–calorie malnutrition; total parenteral nutrition (TPN) >6 weeks
- Severe weight loss (starvation, bariatric surgery)
- Organic solvent exposure (e.g., chlorinated hydrocarbons, toluene); vinyl chloride; hypoglycin A
- Gene for hemochromatosis/other conditions with increased iron stores
- Smoking
- Drugs: tetracycline, glucocorticoids, tamoxifen, methotrexate, valproic acid, fialuridine, many chemotherapy regimens, and nucleoside analogues

Pregnancy Considerations

Acute fatty liver of pregnancy: Rare but serious complication in 3rd trimester. 50% of cases are associated with preeclampsia.

- Symptoms: nausea, vomiting, headache, fatigue, right upper quadrant or epigastric gain, jaundice
- Elevated ALT and AST >300 IU/L but usually <1,000 IU/L; elevated bilirubin
- Liver biopsy confirms diagnosis (do not delay treatment for biopsy).
- Early recognition and prompt delivery is key.

- Recurrence is rare.

Pediatric Considerations

- Increasing prevalence of NAFLD among children parallels rise in pediatric obesity.
- Reports of NAFLD as early as age 2 years and NASH-related cirrhosis as early as age 8 years
- Treat with intensive lifestyle modification. Vitamin E may be of possible benefit.
- Reye syndrome: fatty liver syndrome with encephalopathy usually following viral illness
  - Vomiting with dehydration
  - Confusion, progressive CNS damage
  - Hepatomegaly with extensive fatty vacuolization
  - Hypoglycemia
- Etiology unknown; viral URIs and drugs (especially salicylates) have been implicated.
- Mortality rate: 50%
- Treat with mannitol, IV glucose, and FFP.

GENERAL PREVENTION

- Avoid excess alcohol: ≤3 standard drinks/day (men); ≤2 standard drinks/day (women)
- Maintain appropriate BMI.
- Prevention and optimal management of diabetes
- Avoid hepatotoxic medications.
- HAV and HBV vaccination if not immune
- Pneumococcal and annual influenza vaccinations

COMMONLY ASSOCIATED CONDITIONS

Central obesity; HTN; type 2 diabetes; insulin resistance; hyerlipidemia; preeclampsia in pregnancy; CVD; hypothyroidism; hypogonadism; OSA (2)

DIAGNOSIS

- Routine screening not recommended
- Consider NAFLD in patients with asymptomatic aminotransferase elevations (1)[A].
- Can occur with normal AST/ALT levels (1)[A]
- NAFLD has no distinguishing historical/lab features to distinguish from other chronic liver disorders.
- Index of suspicion is higher with risk factors such as metabolic syndrome, insulin resistance, or obesity.
- May present as cryptogenic cirrhosis
- Noninvasive biomarkers of steatosis/fibrosis are not sufficiently reliable. There is currently no validated test available.
- Liver biopsy is the definitive diagnostic test but should only be considered if results will change management.

HISTORY

- Typically asymptomatic
- Possible fatigue and/or abdominal fullness
- Vague right upper quadrant pain
- History of medications, alcohol use, family history

PHYSICAL EXAM

Most common signs (all are infrequent)

- Liver tenderness
- Mild to marked hepatomegaly
- Splenomegaly
- In advanced cases: cutaneous stigmata of chronic liver disease or portal hypertension, for example, palmar erythema, spider angiomata, ascites

DIFFERENTIAL DIAGNOSIS

- Viral hepatitis
- Alcoholic fatty liver
- Drug- or toxin-induced hepatitis
- Metabolic liver disease
- Autoimmune hepatitis
- Celiac disease

- Muscle disease, if nonhepatic cause of elevated enzymes are possible

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (labs, imaging)

- Both ALT and AST may be elevated.
  - Nonalcoholic, usually ALT:AST >1
  - If alcohol-induced, usually AST:ALT ≥2
  - Nonspecific enzyme abnormalities may exist or may be normal with advanced cirrhosis (1).
- Level of enzyme elevation does NOT correlate with degree of fibrosis (1).
- Serum ferritin (1.5 times normal), alkaline phosphatase (2 to 3 times normal), and total/direct bilirubin often elevated (1).
- Severity and chronicity are characterized by defects in ability to produce plasma proteins (serum albumin, PT) and thrombocytopenia (1).
- Lipids abnormalities are common and include elevated cholesterol, low-density lipoprotein (LDL), and triglyceride and decreased HDL (1).
- Biomarkers of inflammation, increased oxidative stress, or hepatocyte apoptosis such as leptin, adiponectin, CRP, serum caspase, and cytokeratin 18 may help differentiate NASH from NAFLD (1)[B].
- Serologic studies to exclude other etiologies of liver disease (celiac, α-1-antitrypsin, iron, copper, HepA IgG, HepB SAg, HepC SAb, anti-smooth muscle antibody, ANA, serum gammaglobulin (1)[B]
- Ultrasound (US) is first-line imaging modality for assessing liver chemistry abnormalities: fatty liver is hyperechoic on US. MRI/CT may also be used (1) [B].
- Liver-derived microparticles released in response to free-fatty acid induced lipotoxicity and volatile organic compounds (VOCs) in exhaled breath (5)[C].

Follow-Up Tests & Special Considerations

- Imaging modalities help noninvasively quantify fibrosis by estimating liver stiffness (5)[B]; (i) vibration-controlled transient elastography (VCTE) or FibroScan, (ii) acoustic radiation force impulse (ARFI), (iii) magnetic resonance elastography (MRE)
- No imaging modality has been found to accurately distinguish and diagnosis simple steatosis from steatohepatitis (6)[B].

Diagnostic Procedures/Other

- Liver biopsy is the gold standard for diagnosis—must have likelihood of changing management (1)[B].
- NAFLD fibrosis score age (>50 years), BMI (>30), platelet count, albumin, and AST/ALT ratio identifies patients at risk of developing fibrosis/cirrhosis (7)[B].

Test Interpretation

- Liver biopsy is the gold standard for prognosis (1).
- In NASH, steatosis, ballooning, and lobular inflammation are minimal criteria for diagnosis. Other common findings include mild to moderate portal inflammation, acidophil bodies, perisinusoidal zone 3 fibrosis, megamitochondria, and Mallory-Denk bodies (hyaline) in hepatocytes (1).
- Staging is based largely on the extent of fibrosis (1).

TREATMENT

- Sustained weight loss (3–5% body weight) through lifestyle modification is most successful treatment (1,7)[A]. Weight loss for those who are overweight or obese is the only therapy that has good evidence of benefits and safety.
- Foregut bariatric surgery not yet proven to specifically treat NASH (1)[B]
- Aerobic exercise 3 to 5 times per week for 20 to 45 minutes with reduced calorie intake/diet modifications (1)[B]
- Tight control of diabetes (1,7)[B]
- Treatment of metabolic syndrome—hypertension, dyslipidemia, and obesity (1,7)[B]
- Limit alcohol consumption (<21 drinks/week for men and <14 drinks/week for women) (7)[A].
- Avoid hepatotoxic medications (1)[B].

MEDICATION

- Currently no effective medication treatment (1,7)[A]
- Several promising agents include the following:
  - Thiazolidinediones (pioglitazone) (1)[B]

- Vitamin E 400 to 800 IU daily, though long-term safety concerns at high doses (1,5)[B,C] for dosing
- Other drugs studied in small studies (1,7)[B,C]
  - Statins (excluded with AST and AST >1.5 times ULN)
  - Gemfibrozil; omega-3 fatty acids
  - Angiotensin receptor blockers; probiotics
  - Obeticholic acid (bile acid derivative)
  - Ursodeoxycholic acid

ISSUES FOR REFERRAL

Patients with persistent AST/ALT elevations 2 to 3 times ULN or fibrosis on biopsy benefit from hepatology consult (1)[A].

SURGERY/OTHER PROCEDURES

Bariatric procedures: NAFLD is not a contraindication in otherwise eligible obese patients. There is a lack of data to definitively assess benefits and harms of surgery in treating patients with NASH (1)[B].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Annual monitoring of LFTs (1,7)[B]
- Consider surveillance with US or CT scan to evaluate disease progression (7)[B]. Improvements provide motivation for lifestyle changes.
- Routine liver biopsy is not recommended but may be repeated 5 years after baseline biopsy if progression of fibrosis is suspected (1,7)[B].
- Hepatic fibrosis staging is the strongest predictor for all-cause and disease-specific mortality in patients with histologically confirmed NAFLD (2)[B].

DIET

Low in saturated and trans fat; low in simple carbohydrates; avoid excessive alcohol (protective or worsening effect of light/moderate consumption inconclusive).

PATIENT EDUCATION

Extensive counseling on sustained lifestyle changes in nutrition, exercise, and alcohol use.

PROGNOSIS

Within the spectrum of NALFD, only NASH has been shown to be progressive, potentially leading to cirrhosis, hepatocellular carcinoma, cholangiocarcinoma, and/or liver failure:

- Cirrhosis develops in up to 15–20% of patients. Approximately 2–3% of patients with cirrhosis will develop HCC each year (3).
- Transplantation is effective, but NASH may recur after transplantation due to ongoing risk factors.

COMPLICATIONS

Progressive disease may lead to decompensated cirrhosis and portal hypertension with complications such as ascites, encephalopathy, bleeding varices, and hepatorenal or hepatopulmonary syndromes.

CODES

ICD10

K76.0 Fatty (change of) liver, not elsewhere classified

CLINICAL PEARLS

- NAFLD is a major cause of liver disease. Spectrum ranges from NAFL to NASH, advanced fibrosis, and cirrhosis.
- NAFLD is the most common chronic liver disease in children; there has been a parallel rise in childhood obesity and NAFLD.
- Lifestyle changes with targeted weight loss are the cornerstones of therapy for NAFLD.
- NAFLD is a common cause of asymptomatic mild serum aminotransferase elevation.

NONFATAL DROWNING

Joseph L. Steele, APA-C • Natasha J. Pyzocha, DO

BASICS

DESCRIPTION

- Survival at least temporarily after suffocation by submersion in a liquid medium or rescue from drowning at any time; drowning defined as respiratory impairment from submersion/immersion in liquid (1)
- System(s) affected: cardiovascular, nervous, pulmonary, renal
- Synonym(s): submersion injury; according to the Utstein guidelines terms such as “near-drowning,” “secondary drowning,” and “wet drowning” should not be used.

EPIDEMIOLOGY

Incidence

- From 2005 to 2014, an average of 3,536 fatal unintentional drownings in the United States (2).
- Three age-related peaks: toddlers and young children (1 to 5 years), adolescents and young adults (15 to 25 years), and the elderly
- 80% of people who die from drowning are male (2).
- Greater incidence in minorities; African Americans age 5 to 19 years old are affected at 5.5 times the Caucasian rate (2).

Prevalence

- Most common injury-related cause of death for children 1 to 4 in the United States (3)
- For every child age <15 years who dies from drowning, five more children are seen in the emergency room for nonfatal submersion injuries.

ALERT

Proper water supervision and safety techniques are critical in avoiding morbidity and mortality from drowning.

ETIOLOGY AND PATHOPHYSIOLOGY

Hypoxemia via aspiration and/or reflex laryngospasm causing cerebral hypoxia and multisystem organ involvement

- 10–20% of victims drown without aspiration; likely due to prolonged laryngospasm, previously termed “dry lungs.”
- Bathtub and bucket drowning in children <1 year of age
- Swimming pool drowning in children and young adults
- Motor vehicle accidents (e.g., automobile submerged in water)
- Head trauma while swimming or diving
- Suicide
- Pulmonary: morbidity primarily as a result of hypoxia. Aspiration also causes dilution of surfactant with decreased gas transfer across alveoli, atelectasis, development of intrapulmonary right-to-left shunting; acute respiratory distress syndrome (ARDS); obstruction due to laryngospasm and bronchospasm
- Cardiac: hypoxic-ischemic injury and arrhythmia (primary or secondary)
- Renal: acute tubular necrosis from hypoxemia, shock, hemoglobinuria, myoglobinuria
- Neurologic: hypoxic-ischemic brain injury with damage especially to the hippocampus, insular cortex, and basal ganglia; cerebral edema
- Coagulation: hemolysis and coagulopathy

RISK FACTORS

- Risk-taking behavior
- Inadequate physical barriers surrounding pools
- Alcohol ingestion
- Male sex
- Low socioeconomic status
- Use of illicit drugs
- Seizure disorder
- Inability to swim
- Hyperventilation prior to underwater swimming
- Boating mishaps and trauma during water sports, particularly when not wearing a life jacket
- Scuba diving
- Inadequate adult supervision of children

- Concomitant stroke or myocardial infarction (MI)
- Hypothermia
- Cardiac arrhythmias: familial long QT and polymorphic ventricular tachycardia (VT)
- Residence within sunbelt states
- African Americans
- Lack of instruction regarding swimming and supervision

GENERAL PREVENTION

- Periodic education/reinforcement of supervision with an emphasis on drowning prevention for caretakers of young children
- Consistent practice of proper adult supervision of children
- Knowledge of water safety guidelines
- Mandatory physical barriers surrounding pools
- Pool alarms
- Fences higher than 54 inches (137 cm) for home pools (four-sided)
- Avoidance of alcohol or recreational drugs around water
- Swimming instruction at an early age
- Cardiopulmonary resuscitation (CPR) instruction for pool owners and parents
- Boating safety knowledge
- Personal flotation device (e.g., preserver, if necessary)

Pediatric Considerations

Children should never be left alone near water. Young children can drown in very small amounts of water, such as in bathtubs, buckets, and toilets.

COMMONLY ASSOCIATED CONDITIONS

- Trauma
- Seizure disorder
- Alcohol or illicit drug use
- Hypothermia
- Concomitant stroke or MI
- Cardiac arrhythmias: familial long QT and familial polymorphic VT
- Hyperventilation

DIAGNOSIS

HISTORY

The Utstein approach to the evaluation of drowning victims standardizes reporting data and provides guidance for the history, physical exam, and appropriate management.

- Gender, age, birthdate, event date
- Time call received and emergency medical services (EMS) starts resuscitation.
- Precipitating event
- Location of drowning
- Duration of submersion
- Loss of consciousness
- Period of apnea
- Artificial ventilation/CPR performed
- History of associated trauma
- Approximate water temperature (hypothermia)
- Recent use of alcohol or drugs
- Known seizure disorder, cardiac disease, syncopal event

PHYSICAL EXAM

- Airway status and degree of respiratory effort and/or distress
- Pulse: absent, weak, or normal
- Vital signs, including pulse oximetry
- Glasgow Coma Scale (GCS)
- Wheezing
- Evidence of trauma

DIFFERENTIAL DIAGNOSIS

Syncopal event, head trauma, arrhythmia, seizure, MI, stroke, alcohol or other substance overdose, nonaccidental trauma

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

May be unnecessary if initial GCS and pulse oximetry are normal and remain that way for 6 to 8 hours

- CBC with differential
- Arterial blood gases (ABGs): hypoxia, hypercarbia, acidosis
- Electrolytes: hypokalemia, hyponatremia, hypernatremia
- Blood glucose: may be low if the cause of near-drowning; increased levels may impair neurologic recovery after ischemic brain injury.
- BUN, creatinine: acute tubular necrosis
- ECG, cardiac monitoring, and serial troponin: MI
- Creatine kinase (CK) and urine myoglobin: rhabdomyolysis
- Coagulation studies: coagulopathy
- Urinalysis/urine drug screen
- Blood alcohol level
- A chest x-ray (CXR) may be unnecessary for patients with all of the following:
  - Normal initial GCS and pulse oximetry
  - No evidence of respiratory distress
  - No change after 6 to 8 hours of observation
- For others, a CXR may show evidence of aspiration, atelectasis, pneumothorax, or ARDS.
- Head CT and/or C-spine imaging as needed for associated trauma

Follow-Up Tests & Special Considerations

- Patients with an initial GCS of 15 and pulse oximetry >95% should be observed for 6 to 8 hours in the emergency department (ED).
- CXR findings may be minimal or absent on early imaging.

Diagnostic Procedures/Other

- Continuous cardiac monitoring
- Continuous pulse oximetry
- Continuous core temperature monitoring if hypothermic
- ECG
- Central venous pressure (CVP) monitoring for critically ill patients with hypotension refractory to IV fluids
- Electroencephalogram (EEG) if suspect seizure as cause

TREATMENT

Early resuscitation and reversal of hypoxemia optimizes outcome.

GENERAL MEASURES

- Prehospital
  - Never approach a struggling victim alone.
  - Initially evaluate as per Basic Life Support (BLS) and Advanced Cardiovascular Life Support (ACLS) (4).
  - Rescue breathing may be helpful while the victim is in the water and not able to be immediately removed from the water, but chest compressions in the water may not be effective and may even harm the rescuer and the victim (4)[C].
  - Remove the victim from the water and begin effective resuscitation as quickly as possible (5).
  - Early CPR that emphasizes effective chest compressions and rapid defibrillation as indicated
  - Start CPR if pulse is not definitely felt within 10 seconds, even in the hypothermic victim whose heart rate may be severely bradycardic (4)[C].
  - Routine cervical collar use and spinal precautions are not needed unless a high suspicion for trauma exists (5)[C].
  - Supplemental oxygen and early intubation with mechanical ventilation, as needed (1)[A]
  - Rapid crystalloid infusion if hypotension not corrected by oxygenation (1) [A]
  - If patient is breathing on his or her own and does not need spinal precautions, consider placing in the right lateral decubitus position to prevent aspiration of vomit or gastric contents (1).
- ED
  - Oxygen, as needed, to maintain saturation between 92% and 96%, ensuring chest rise (1)
  - Continuous positive airway pressure (CPAP), bilevel positive airway pressure (BiPAP), or intubation if supplemental O_2 alone is unsuccessful
  - If intubation is indicated, employ lung-protective vent settings (lower end-

inspiratory airway pressures, lower tidal volumes of 6 mL/kg, higher positive end-expiratory pressures of 6 to 12 cm H_2O) to avoid lung barotrauma (4)[A].

- Indications for intubation
  - Neurologic deterioration
  - Inability to protect the airway
  - Inability to maintain oxygen saturation >90% or PaO_2 >60 mm Hg on high-flow supplemental oxygen
  - $PaCO_2$ >50 mm Hg
- Remove wet clothing and initiate rewarming.
- Core temperature reading for possible hypothermia
- Rewarming with minimally invasive core rewarming such as warm IV fluids, warm/humidified oxygen, and external rewarming
- Active core rewarming reserved for refractory cases and only when extracorporeal blood warming is unavailable, depending on physician comfort level, due to major complications that can develop including core temperature after drop, rewarming acidosis, and rewarming shock

MEDICATION

First Line

- High-flow oxygen, as needed (1)[A]
- For bronchospasm: aerosolized bronchodilator (3)[C]: albuterol (Proventil, Ventolin), 3 mL of 0.083% solution or 0.5 mL of 0.5% solution diluted in 3 mL of saline
- Pressors, as needed, for hypotension refractory to IV fluid resuscitation
- Prophylactic antibiotics are not recommended (1)[B].

Second Line

For pneumonia: antibiotics based on sputum or endotracheal lavage culture (1)[A]

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- All symptomatic patients
- Patients with abnormalities in vital signs, mental status, oxygenation, CXR, or

laboratory analysis
- Continuous cardiac monitoring
- Continuous pulse oximetry monitoring
- Frequent monitoring of vital signs and clinical reassessment
- Careful monitoring of neurologic status
- Induced hypothermia with core temp maintained between 32°C and 34°C for 24 hours may be neuroprotective (1).
- Patients can be discharged from the ED after 6 to 8 hours of observation if the following criteria are met:
  - GCS = 15
  - Normal CXR, if indicated
  - Lack of clinical evidence of respiratory difficulty
  - Normal lung exam
  - Normal vital signs
  - Oxygen saturation ≥95% on room air (5)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Appropriate follow-up with primary care provider, orthopedic, neurologic, cardiac, pulmonary, and additional specialists as indicated

Patient Monitoring

- Continuous cardiac monitoring
- Continuous pulse oximetry monitoring
- Frequent monitoring of vital signs and clinical reassessment
- Careful monitoring of neurologic status
- ABG monitoring, as indicated
- A pulmonary artery catheter may be needed for hemodynamic monitoring in unstable patients (3)[C].
- Intracranial pressure monitoring in selected patients (3)[C]
- Serum electrolyte determinations

DIET

NPO until mental status normalizes

PATIENT EDUCATION

Reemphasize preventive measures on discharge from hospital. Educate parents regarding supervision and preventive practices.

PROGNOSIS

- 75% of drowning victims survive; 6% of these with residual neurologic deficits
- Patients with an initial GCS ≥13 and an oxygen saturation ≥95% have a low risk of complications and an excellent chance for a full recovery.
- Patients who are comatose or receiving CPR at the time of presentation as well as those who have dilated and fixed pupils and no spontaneous respiratory activity have a more guarded and often poor prognosis, often secondary to neurologic sequelae.
- Neurogenic pulmonary edema may occur within 48 hours of initial presentation.

COMPLICATIONS

- Early
  - Bronchospasm
  - Vomiting/aspiration
  - Hypoglycemia
  - Hypothermia
  - Seizure
  - Hypovolemia
  - Electrolyte abnormalities
  - Arrhythmia from hypoxia or hypothermia (rarely from electrolyte imbalance)
  - Hypotension
- Late
  - ARDS
  - Anoxic encephalopathy
  - Pneumonia
  - Lung abscess/empyema
  - Renal failure
  - Coagulopathy

- Sepsis
- Barotrauma
- Seizure

CODES

ICD10

- T75.1XXA Unsp effects of drowning and nonfatal submersion, init
- T75.1XXD Unsp effects of drowning and nonfatal submersion, subs
- T75.1XXS Unsp effects of drowning and nonfatal submersion, sequel

CLINICAL PEARLS

- The single most important treatment for near-drowning victims is prompt reversal of the hypoxic state. This should form the cornerstone for all other treatment modalities. Without oxygenation, other treatment is futile.
- Focus water safety counseling on prevention measures targeting epidemiologic concerns that combine physical, behavioral, medical, and

community areas of interest for greatest effect (4).

- Family physicians and pediatricians should review water safety tips and guidelines with parents and children at yearly visits. Encourage pool owners and parents with young children to become CPR certified. Prevention of drowning can save many lives each year.
- Despite successful resuscitation, patients are at risk for ARDS due to delayed pulmonary edema that may start hours after their submersion incident. For this reason, careful monitoring of every resuscitated patient is essential.
- Patients requiring intubation should be treated with lung-protective vent settings to prevent barotrauma.
- Patients with an initial GCS ≥13 and an oxygen saturation ≥95% have a low risk of complications and an excellent chance for a full recovery.

OBESITY

Kimberly Bombaci, MD

BASICS

DESCRIPTION

- Excess adipose tissue, typically quantified in adults by body mass index (BMI), ([kg]/ [m^2]), ≥30 kg/m^2.
- Obesity is associated with negative health outcomes. Abdominal obesity increases the risk of morbidity and mortality.
- System(s) affected: endocrine/metabolic, cardiac, respiratory, gastrointestinal, musculoskeletal, dermatologic, mental health
- Synonym(s): overweight; adiposity

Geriatric Considerations

Underweight BMI (≤18) is also associated with an increased risk of mortality.

EPIDEMIOLOGY

- Predominant age: Incidence rises in the early 20s.
- Predominant sex: female > male

Prevalence

- 35% of U.S. adults are obese (1,2).
- 40% of men and 25% of women are overweight.

Pediatric Considerations

- Pediatric obesity is defined as a BMI ≥95th percentile, by age and sex specific WHO or CDC growth curves.
- Obesity during adolescence and young adulthood is strongly associated with obesity in adulthood.

ETIOLOGY AND PATHOPHYSIOLOGY

- Obesity is caused by an imbalance between food intake, absorption, and energy expenditure.
- Underlying organic causes include psychiatric disturbances, hypothyroidism,

hypothalamic disorders, insulinoma, and Cushing syndrome.
- Medications that contribute to obesity include corticosteroids, neuroleptics (particularly atypical antipsychotics), and antidepressants.

Genetics

- Genetic syndromes such as Prader-Willi and Bardet-Biedl are found in a minority of people with obesity.
- Multiple genes are implicated in obesity.

RISK FACTORS

- Parental obesity
- Sedentary lifestyle
- Consumption of calorie-dense food
- Low socioeconomic status
- >2 hr/day of television viewing

GENERAL PREVENTION

- Encourage at least 1 hour of daily exercise, limited television viewing, and moderation in portion size.
- Avoid calorie-dense and nutrient-poor foods such as sugar-sweetened beverages and processed foods.

DIAGNOSIS

HISTORY

- Diet and exercise habits
- Prior attempts at weight loss
- Reported readiness to change lifestyle
- Social support and resources
- Comorbidities: diabetes mellitus type 2, hypertension, hyperlipidemia, sleep apnea
- Psychiatric history
- Symptoms suggesting hypothyroidism, Cushing syndrome, and genetic syndromes

PHYSICAL EXAM

- Elevated BMI:
  - Overweight: BMI = 25 to 29.9 kg/m^2
  - Obese: BMI 30 to 39.9 kg/m^2
  - Morbid obesity: BMI ≥40 kg/m^2
- Abdominal circumference:
  - Measure at the level of the umbilicus. Elevated:
    - Male: >40 inches (102 cm)
    - Female: >35 inches (88 cm)

DIAGNOSTIC TESTS & INTERPRETATION

- Screen for underlying physiologic causes as well as associated comorbid conditions.
- Labs should be done while fasting (nonfasting labs within normal limits are considered adequate).
- Glucose, total insulin, hemoglobin A1C, lipids
- Thyroid function tests
- LFTs (fatty liver)

TREATMENT

GENERAL MEASURES

- Assess:
  - Motivation to lose weight
  - Patient-specific goals of therapy
  - Need for intensive counseling to enhance adherence with diet, exercise, and behavior modification recommendations
- Goal is to achieve and sustain loss of at least 10% of body weight.
- Track nutritional intake and physical activity habits.
- Use of commercial weight loss programs (e.g., Weight Watchers) can be more effective than “standard of care” counseling (3)[B].
- Behavior therapy and cognitive-behavioral methods result in modest weight loss and are most effective when combined with dietary and exercise treatments.

MEDICATION

- Include diet, exercise, and behavior therapy for all patients without comorbid conditions who are considering pharmacologic treatment.
- NIH guidelines suggest at least 6 months nonpharmacologic treatment.
- Consider medication for unsatisfactory weight loss in those with:
  - BMI ≥30
  - BMI ≥27 combined with associated risk factors (e.g., coronary artery disease, diabetes, sleep apnea, hypertension, hyperlipidemia)
- Relapse common after medications are discontinued.
- Treat comorbidities (such as diabetes and hyperlipidemia).

First Line

- When compared to placebo, medications have been associated with at least 5% weight loss at 52 weeks (4)[B]. Orlistat (Xenical) is a lipase inhibitor that decreases the absorption of dietary fat. Dose: 120 mg PO TID with meals containing fat; omit dose if meal is skipped or does not contain fat. Patients must avoid taking fat-soluble vitamin supplements within 2 hours of taking orlistat. The FDA has approved orlistat (Alli) 60 mg PO TID to be sold over the counter as a weight loss aid. Adverse effects mainly GI (cramps, flatus, fecal incontinence)
- Contraindications
  - Orlistat: chronic malabsorption syndromes, cholestasis, pregnancy

Second Line

- Appetite suppressants recommended for short-term treatment (≤6 months) (5) [A]
- Only beneficial in patients who exercise and eat reduced calorie diet
  - Naltrexone/bupropion (Contrave): 8 mg naltrexone/90 mg bupropion per tablet; slow titration up to 2 tablets PO BID by week 4; contraindicated if uncontrolled HTN, seizure disorder, chronic opioid use, pregnancy
  - Liraglutide (Saxenda): 1.203 mg SC once daily; GLP-1 agonist recently approved for obesity; discontinue if weight loss is <4% after 16 weeks.
  - Topiramate: Initiate with 25 mg BID and increase by 50 mg/week up to 100 mg PO BID; not FDA-approved for the treatment of obesity; tolerance is a concern (paresthesias, somnolence, difficulty concentrating).

- Schedule IV drugs:
  - Lorcaserin (Belviq) 10 mg PO BID (D/C if weight loss is <5% after 12 weeks); works as serotonin agonist; avoid in those with CrCl <30 mL/min; contraindicated in pregnancy; avoid use with other serotonergic drugs.
  - Phentermine: 15, 30, 37.5 mg PO every morning; discontinue if tolerance or no response after 4 weeks; contraindicated if history of CV disease, hyperthyroidism, history of substance abuse, pregnancy
  - Phentermine/topiramate (3.75 to 23 mg, 7.5 to 46 mg, 11.25 to 69 mg, 15 to 92 mg); initiate 3.75 to 23 mg PO once daily; requires enrollment into Risk Evaluation and Mitigation Strategy (REMS); women of childbearing age require negative pregnancy test prior to initiation and monthly thereafter.
  - Diethylpropion: 25 mg PO before meals TID; discontinue if no response after 4 weeks; contraindicated if severe HTN, hyperthyroidism, history of substance abuse

Pregnancy Considerations

During pregnancy, obese women should gain fewer pounds than recommended for nonobese women.

SURGERY/OTHER PROCEDURES

Consider bariatric surgery if patients meet criteria.

- Requires complex presurgical evaluation, surgery, and follow-up in a skilled treatment center.
- Surgical procedures include biliopancreatic diversion, Roux-en-Y gastric bypass, sleeve gastrectomy, adjustable gastric banding, vagal blocking therapy (Maestro Rechargeable system), and gastric aspiration (AspireAssist).
- Surgical treatment is the most effective long-term weight-loss treatment available for morbidly obese patients, but there is insufficient evidence on long-term outcomes (6)[A].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Physical activity is an integral part of any weight loss program, yet physical

activity alone rarely results in significant weight loss.
- Combination of weight training and aerobic activity is preferred over aerobic activity alone.

Patient Monitoring

Long-term routine follow-up may prevent relapse after weight loss or further weight gain.

DIET

- Long-term studies suggest net calorie reduction (500 to 1,000 kcal/day) and ease of use are more important than the composition of the particular diet for long-term results:
  - A reduction of 500 kcal/day can result in ~1 lb (0.45 kg) weight loss per week.
  - Portion-control is essential.
- Very low-calorie diet (400 to 800 kcal/day)
  - Can result in more rapid weight loss than higher calorie diets but is less effective in the long term
  - Complications include dehydration, orthostatic hypotension, fatigue, muscle cramps, constipation, headache, and cold intolerance.
  - Relapse common if diet discontinued.
  - Contraindications: recent myocardial infarction or cerebrovascular accident, renal disease, cancer, pregnancy, insulin-dependent diabetes mellitus, and some psychiatric disturbances

PATIENT EDUCATION

- Healthy diet and physical activity patterns
- Focus on behaviors (not numbers)
- Recommended Web site:
  - www.nal.usda.gov/fnic/foodcomp/search for the FDA nutritional content in common foods

PROGNOSIS

- Lowest mortality associated with a BMI of 22
- Long-term maintenance of weight loss is difficult.
- Patient motivation is associated with successful weight loss (7).

COMPLICATIONS

- Cardiovascular disease
- Stroke (in men)
- Thromboembolism
- Heart failure
- Hypertension
- Hypoventilation and sleep apnea syndromes
- Higher death rates from cancer: colon, breast, prostate, endometrial, gallbladder, liver, kidney
- Diabetes mellitus
- Skin changes
- Hyperlipidemia
- Gallbladder disease
- Osteoarthritis
- Gout
- Poor self-esteem
- Discrimination
- Increased sick leave

CODES

ICD10

- E66.9 Obesity, unspecified
- E66.3 Overweight
- R63.5 Abnormal weight gain

CLINICAL PEARLS

- A majority of American adults are overweight or obese.
- Modification in dietary and physical activity patterns remain the cornerstone of therapy for obesity. Consider bariatric surgery in patients with a BMI >40 who have failed more conservative treatment, particularly if there are associated risk factors.
- Medication may be indicated when nonpharmacologic treatment for 6 months has been ineffective and the patient has a BMI >30 or a BMI >27 with associated risk factors.

OBSESSIVE-COMPULSIVE DISORDER (OCD)

Amar Kapur, DO, CPT, MC, USA

BASICS

DESCRIPTION

- A psychiatric condition classified as an anxiety disorder characterized by pathologic obsessions (recurrent intrusive thoughts, ideas, or images) and compulsions (repetitive, ritualistic behaviors or mental acts) causing significant patient distress
- Not to be confused with obsessive-compulsive personality disorder

EPIDEMIOLOGY

Incidence

- Predominant age: mean age of onset 22 to 36 years
  - Male = female (males present at younger age)
  - Child/adolescent onset in 33% of cases 1/3 of cases present by age 15 years
  - 85% of cases present at <35 years of age
  - Diagnosis rarely made at >50 years of age
- Predominant gender: female > males but males more commonly affected in childhood

Pediatric Considerations

Insidious onset; consider brain insult in acute presentation of childhood obsessive-compulsive disorder (OCD).

Geriatric Considerations

Consider neurologic disorders in new-onset OCD in the elderly.

Prevalence

- 2.3% lifetime in adults
- 1–2.3% prevalence in children/adolescents (1)

ETIOLOGY AND PATHOPHYSIOLOGY

- Exact pathophysiology is unknown.

- Dysregulation of serotonergic pathways
- Dysregulation of corticostriatal-thalamic-cortico (CSTC) pathway
- Exact etiology unknown
- Genetic and environmental factors
- Pediatric autoimmune disorder associated with streptococcal infections

Genetics

- Greater concordance in monozygotic twins
- Positive family history: prevalence rates of 7–15% in first-degree relatives of children/adolescents with OCD

RISK FACTORS

- Exact cause of OCD is not fully elucidated.
- Combination of biologic and environmental factors likely involved the following:
  - Link between low serotonin levels and development of OCD
  - Link between brain insult and development of OCD (i.e., encephalitis, pediatric streptococcal infection, or head injury)

GENERAL PREVENTION

- OCD cannot be prevented.
- Early diagnosis and treatment can decrease patient's distress and impairment.

COMMONLY ASSOCIATED CONDITIONS

- Major depressive disorder
- Panic disorder
- Phobia/social phobia
- Tourette syndrome/tic syndromes and other movement disorders
- Substance abuse
- Eating disorder/body dysmorphic disorder

DIAGNOSIS

HISTORY

- Patient presents with either obsessions or compulsions, which cause marked

distress, are time-consuming (>1 hr/day) and cause significant occupational/social impairment.

- Four criteria support diagnosis of obsessions:
  - Patients are aware that they are thinking the obsessive thoughts; thoughts are not imposed from outside (as in thought insertion).
  - Thoughts are not just excessive worrying about real-life problems.
  - Recurrent thoughts are persistent, intrusive, and inappropriate, causing significant anxiety and distress.
  - Attempts to suppress intrusive thoughts are made with some other thought/activity.
- Two criteria support a diagnosis of compulsions:
  - The response to an obsession is to perform repetitive behaviors (e.g., hand washing) or mental acts (e.g., counting silently) rigidly.
  - Although done to reduce stress, the responses are either not realistically connected with the obsession or they are excessive.
  - In children, check for precedent streptococcal infection.

PHYSICAL EXAM

- Dermatologic problems caused by excessive hand washing may be observed.
- Hair loss caused by compulsive pulling/twisting of the hair (trichotillomania) may be observed.

DIFFERENTIAL DIAGNOSIS

- Obsessive-compulsive personality disorder
  - In personality disorder, traits are ego-syntonic and include perfectionism and preoccupation with detail, trivia, or procedure and regulation. Patients tend to be rigid, moralistic, and stingy. These traits are often rewarded in the patient's job as desirable.
- Impulse-control disorders: compulsive gambling, sex, or substance abuse: The compulsive behavior is not in response to obsessive thoughts, and the patient derives pleasure from the activity.
- Major depressive disorder
- Eating disorder
- Tics (in tic disorder) and stereotyped movements
- Schizophrenia: Patient perceives thought to be true and coming from an

external source.

- Generalized anxiety disorder, phobic disorders, separation anxiety: similar response on heightened anxiety, but presence of obsessions and rituals signifies OCD diagnosis
- Anxiety disorder due to a general medical condition: Obsessions/compulsions are assessed to be a direct physiologic consequence of a general medical condition.

DIAGNOSTIC TESTS & INTERPRETATION

According to *DSM-5*, diagnostic criteria for OCD are the following (2)[C]:

- Presence of obsessions, compulsions, or both
- Obsessions are defined by:
  - Recurrent or persistent thoughts, urges, or images that are experienced at some time during the disturbance, as intrusive and unwanted, and that in most individuals cause marked anxiety or distress
  - The individual attempts to ignore or suppress such thoughts, urges, or images or to neutralize them with some other thought or actions (i.e., by performing compulsion).
- Compulsions are defined by the following:
  - Repetitive behavior (e.g., hand washing, ordering, checking) or mental acts (e.g., praying, counting, repeating words silently) that the individual feels driven to perform in response to an obsession or according to rules that must be applied rigidly.
  - The behavior or mental acts are aimed at preventing or reducing anxiety or distress or preventing some dreaded event or situation. However, these behavior or mental acts are not connected in a realistic way with what they are designed to neutralize or prevent or are clearly excessive.
- The obsessions or compulsions are time-consuming (e.g., **take >1 hr/day**) or cause clinically significant distress or impairment in social, occupational, or other important areas of functioning.
- The obsessive-compulsive symptoms are not attributable to the physiologic effects of a substance (e.g., a drug of abuse, a medication, or other medical condition).
- The disturbance is not better explained by the symptoms of another mental disorder (e.g., excessive worries, as in generalized anxiety disorder,

preoccupation with appearance, as in body dysmorphic disorder or skin picking).

- Specify if:
  - With good or fair insight: The individual recognizes the OCD beliefs are definitely or probably not true or that they may or may not be true.
  - With poor insight: The individual thinks that OCD beliefs are probably true.
  - With absent insight/delusional beliefs: The individual is completely convinced that OCD beliefs are true.
- Specify if:
  - Tic related: The individual has a current or past history of tic disorder.

Diagnostic Procedures/Other

- Yale-Brown Obsessive-Compulsive Scale (Y-BOCS) or CY-BOCS for children (1)[C]
- Maudsley Obsessive-Compulsive Inventory (MOCI) (3)[C]

Test Interpretation

- Compulsions are designed to relieve the anxiety of obsessions; they are not inherently enjoyable (ego-dynastic) and do not result in completion of a task.
- Common obsessive themes
  - Harm (i.e., being responsible for an accident)
  - Doubt (i.e., whether doors/windows are locked or the iron is turned off)
  - Blasphemous thoughts (i.e., in a devoutly religious person)
  - Contamination, dirt, or disease
  - Symmetry/orderliness
- Common rituals or compulsions
  - Hand washing, cleaning
  - Checking
  - Counting
  - Hoarding
  - Ordering, arranging
  - Repeating
- Neither obsessions nor compulsions are related to another mental disorder (i.e., thoughts of food and presence of eating disorder).
- 80–90% of patients with OCD have obsessions and compulsions.

- 10–19% of patients with OCD are pure obsessional.

TREATMENT

GENERAL MEASURES

- Cognitive-behavioral therapy (CBT) is recommended as first-line treatment (1)[A].
- Five phases of treatment for CBT:
  - Family and individual psychoeducation
  - Cognitive training
  - Mapping OCD
  - Graded exposure and response training
  - Relapse prevention and generalization training
- Combined medications and CBT is most effective (1,2)[A].
- Brain modulation available for severe OCD includes electroconvulsive therapy and transcranial magnetic stimulation in small groups of patients.

MEDICATION

First Line

- Adequate trial at least 10 to 12 weeks
- Doses may exceed typical doses for depression.
- Optimal duration for pediatrics unknown but recommended minimum of maintenance treatment: 6 months
- Varying degrees of efficacy between agents (1)
- SSRIs recommended first-line agents (1,4,5)[A]
  - Fluoxetine (Prozac)
    - Adults: 20 mg/day; increase by 10 to 20 mg every 4 to 6 weeks until response; range: 20 to 80 mg/day
    - Children (7 to 17 years of age): 10 mg/day; increase 4 to 6 weeks until response; range: 20 to 60 mg/day
- Sertraline (Zoloft)
  - Adults: 50 mg/day; increase by 50 mg every 4 to 7 days until response; range: 50 to 200 mg/day; may divide if above 100 mg/day
  - Children (6 to 17 years of age): 25 mg/day; increase by 25 mg every 7 days

until response; range: 50 to 200 mg/day

- Paroxetine (Paxil)
  - Adults: 20 mg/day; increase by 10 mg every 4 to 7 days until response; range: 40 to 60 mg/day
  - Children: Safety and effectiveness in patients <18 years have not been established.
- Fluvoxamine (Luvox)
  - Adult: 100 mg/day; increase by 50 mg every 4 to 7 days until response; range: 200 to 300 mg/day
  - Children (8 to 17 years of age): 25 mg/day; increase by 25 mg every 4 to 7 days until response; range: 50 to 200 mg/day
- Absolute SSRI contraindications
  - Hypersensitivity to SSRIs
  - Concomitant use within 14 days of monoamine oxidase inhibitor (MAOI)
- Relative SSRI contraindications
  - Severe liver impairment
  - Seizure disorders (lower seizure threshold)
- Precautions
  - Watch for suicidal behavior/worsening depression during first few months of therapy/after dosage changes with antidepressants, particularly in children, adolescents, and young adults.
  - Long half-life of fluoxetine (>7 days) may be troublesome if patient has an adverse reaction.
  - May cause drowsiness and dizziness when therapy was initiated; warn patients about driving and heavy equipment hazards.

Pregnancy Considerations

All SSRIs are pregnancy Category C, except paroxetine, which is Category D.

Second Line

- Try switching to another SSRI.
- 40–60% of patients will remain refractory to SSRI
- Tricyclic acid (TCA), clomipramine (Anafranil)
  - Adults: 25 mg/day; increase gradually over 2 weeks to 100 mg/day, then to 250 mg/day (max dose) over next several weeks, as tolerated.

- Children (10 to 17 years of age): 25 mg/day; titrate as needed and tolerated up to 3 mg/kg/day or 200 mg/day (whichever is less).
- Absolute clomipramine contraindications
  - Within 6 months of a myocardial infarction (MI)
  - Hypersensitivity to clomipramine or other TCA
  - Concomitant use within 14 days of a MAOI
  - 3rd-degree atrioventricular (AV) block
- Relative clomipramine contraindications
  - Narrow-angle glaucoma (increased intraocular pressure)
  - Prostatic hypertrophy (urinary retention)
  - 1st- or 2nd-degree AV block, bundle-branch block, and congestive heart failure (proarrhythmic effect)
  - Pregnancy Category C
- Precautions
  - Dangerous in overdose
  - Pretreatment ECG for patients >40 years of age
  - Watch for suicidal behavior/worsening depression during first few months of therapy or after dosage changes with antidepressants, particularly in children, adolescents, and young adults.
  - May cause drowsiness and dizziness when therapy is initiated; warn patients about driving and heavy equipment hazards.

ISSUES FOR REFERRAL

- Psychiatric referral for CBT (in vivo exposure and prevention of compulsions)
- Psychiatric evaluation if obsessions and compulsions significantly interfere with patient's functioning in social, occupational, or educational situations

ADDITIONAL THERAPIES

Dopamine receptor antagonists (antipsychotic agents) alone are not effective in treatment of OCD. They can be used as augmentation to SSRI therapy for treatment-resistant OCD; they also can worsen OCD symptoms (4)[C]. Some evidence show that addition of quetiapine or risperidone to antidepressants will increase efficacy; data with olanzapine too limited to draw conclusions (4)[A].

- Risperidone (Risperdal): initial dose: 0.5 mg/day; target dose: 0.5 to 2 mg/day
- Quetiapine (Seroquel): initial dose: 25 mg/day; target dose: 600 mg/day

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Y-BCOS or MOCI surveys to track progress

Patient Monitoring

Monitor for decrease in obsessions and time spent performing compulsions.

DIET

No dietary modifications/restrictions recommended

PATIENT EDUCATION

- Importance of medication adherence
- Importance of psychotherapy (CBT)
- International OCD Foundation, Boston, MA 617973-5801:https://iocdf.org/
- Obsessive Compulsive Anonymous, New Hyde Park, NY: http://obsessivecompulsiveanonymous.org

PROGNOSIS

- Chronic waxing and waning course in most patients:
  - 24–33% fluctuating course
  - 11–14% phasic periods of remission
  - 54–61% chronic progressive course
- Early onset a poor predictor

COMPLICATIONS

- Depression in 1/3 patients with OCD
- Avoidant behavior (phobic avoidance)
  - Children may drop out of education.
  - Adults may become homebound.
- Anxiety and panic-like episodes associated with obsessions

CODES

ICD10

- F42 Obsessive-compulsive disorder
- F63.9 Impulse disorder, unspecified
- F63.3 Trichotillomania

CLINICAL PEARLS

- CBT is the initial treatment of choice for mild OCD.
- CBT plus an SSRI or an SSRI alone is the treatment choice for more severe OCD.
- The majority of patients with OCD respond to first SSRI treatment.
- Improvement in symptoms, however, is often incomplete, ranging from 25%

to 60%.

OCULAR CHEMICAL BURNS

Robert J. Hyde, MD, MA

BASICS

DESCRIPTION

- Chemical exposure to the eye can result in rapid, devastating, and permanent damage and is one of the true emergencies in ophthalmology.
- Separate alkaline from acid chemical exposure.
  - Alkali burns: more severe. Alkaline compounds are lipophilic, penetrating rapidly into eye tissue; saponification of cells leads to necrosis and may produce injury to lids, conjunctiva, cornea, sclera, iris, and lens (cataracts).
  - Acid burns: Acid usually does not damage internal structures because its associated anion causes protein denaturation, creating a barrier to further acid penetration (hydrofluoric acid is an exception to this rule; see below). Injury is often limited to lids, conjunctiva, and cornea.
- System(s) affected: nervous, skin/exocrine
- Synonym(s): chemical ocular injuries

EPIDEMIOLOGY

- Predominant age: can occur at any age, peak from 20 to 40 years of age
- Predominant sex: male > female

Incidence

- Estimated 300/100,000 per year
- Alkali burns twice as common as acid burns

ETIOLOGY AND PATHOPHYSIOLOGY

- Acidic compounds
  - Anion leads to protein denaturing and protective barrier formation by coagulation necrosis forming an eschar. This more superficial mechanism of injury tends to have prominent scarring that may lead to vision loss:
    - Hydrofluoric acid is an exception. In its nonionized form, it behaves like an alkaline substance, capable of penetrating the corneal stroma and

leading to extensive anterior segment lesions. When ionized, it may combine with intracellular calcium and magnesium to form insoluble complexes, leading to potassium ion movements and cell death. Once systemically absorbed, severe hypocalcemia can occur.

- Alkaline compounds
  - Lipophilic compounds that penetrate into deep structures on disassociation into cations and hydroxide
  - Hydroxide causes saponification of fatty acids in cell membranes, leading to cell death.
  - Cation causes hydration of glycosaminoglycans, leading to corneal opacification and hydration of collagen, resulting in rapid shortening and thickening of collagen fibrils that leads to an acute elevation in intraocular pressure secondary to shrinking and contraction of the cornea and sclera.
  - Long-term elevation in intraocular pressure may occur from accumulation of inflammatory debris within the trabecular meshwork.
  - Penetration into deep structures may also affect perfusing vessels, leading to ischemia of affected area.

Sources of Alkaline and Acidic Compounds

Alkaline Compounds	**Typical Sources**
Calcium hydroxide (lime)	Cement, whitewash
Sodium hydroxide (lye)	Drain cleaner, airbags
Potassium hydroxide (lye)	Drain cleaner
Ammonia	Cleaning agents
Ammonium hydroxide	Fertilizers
Acidic Compounds	**Typical Sources**
Sulfuric acid	Car batteries
Sulfurous acid	Bleach
Hydrochloric acid	Chem labs, swimming pools
Acetic acid	Vinegar
Hydrofluoric acid	Glass polish

RISK FACTORS

- Construction work (plaster, cement, whitewash)
- Use of cleaning agents (drain cleaners, ammonia)
- Automobile battery explosions (sulfuric acid)

- Industrial work, including work in industrial chemical laboratories
- Alcoholism
- Any risk factor for assault (~10% of injuries due to deliberate assault)

GENERAL PREVENTION

Safety glasses to safeguard eyes

COMMONLY ASSOCIATED CONDITIONS

Facial (including eyelids) cutaneous chemical or thermal burns

DIAGNOSIS

HISTORY

- Most often, complaints of pain, photophobia, blurred vision, and a foreign body sensation
- In alkali burns, can have initial pain that later diminishes
- Mild burns: pain and blurred vision
- Moderate to severe burns: severe pain and markedly reduced vision

PHYSICAL EXAM

- Acidic compound may present with a ground-glass appearance secondary to superficial scar formation.
- Alkaline compounds may present with corneal opacification secondary to glycosaminoglycan hydration; however, severe acid burns may also present with this finding.
- Mild burns
  - Blurry vision
  - Eyelid skin erythema and edema
  - Corneal epithelial defects or superficial punctate keratitis
  - Conjunctival chemosis, hyperemia, and hemorrhages without perilimbal ischemia
  - Mild anterior chamber reaction
- Moderate to severe burns
  - Reduced vision
  - 2nd- and 3rd-degree burns of eyelid skin

  - Corneal edema and opacification
  - Corneal epithelial defects
  - Marked conjunctival chemosis and perilimbal blanching
  - Moderate anterior chamber reaction
  - Increased intraocular pressure
  - Local necrotic retinopathy

DIFFERENTIAL DIAGNOSIS

- Thermal burns
- Ocular cicatricial pemphigoid
- Other causes of corneal opacification
- Ultraviolet radiation keratitis

DIAGNOSTIC TESTS & INTERPRETATION

Not necessary unless suspicion of intraocular or orbital foreign body is present. In this case, CT should be used and MRI is contraindicated.

Diagnostic Procedures/Other

- Measure pH of tear film with litmus paper or electronic probe:
  - Irrigating fluid with nonneutral pH (e.g., normal saline has pH of 4.5) may alter results.
- Careful slit-lamp exam, fundus ophthalmoscopy, tonometry, and measurement of visual acuity
- Full extent of damage from alkali burns may not be apparent until 48 to 72 hours after exposure.

Test Interpretation

- Corneal epithelial defects or superficial punctate keratitis, edema, opacification
- Conjunctival chemosis, hyperemia, and hemorrhages
- Perilimbal ischemia
- Anterior chamber reaction
- Increased intraocular pressure

TREATMENT

Copious irrigation and removal of corneal or conjunctival foreign bodies are always the initial treatment (1,2)[A]:

- Passively open patient's eyelid and have patient look in all directions while irrigating.
- Be sure to remove all reservoirs of chemical from the eyes.
- Continue irrigation until the tear film and superior/inferior cul-de-sac is of neutral pH (7 ± 0.1) and pH is stable (1)[C]:
  - Severe burns should be irrigated for at least 15 minutes to as much as 2 to 4 hours; this irrigation should not be interrupted during transportation to hospital (1)[C].
  - Irrigation via Morgan lens (polymethylmethacrylate scleral lens) is a good way to achieve continuous irrigation over a prolonged period of time.
  - It is impossible to overirrigate.
- Initial pH testing should be done on both eyes even if the patient claims to only have unilateral ocular pain/irritation so that a contralateral injury is not neglected.
- Use whatever nontoxic fluid is available for irrigation on scene. In hospital, sterile water, normal saline, normal saline with bicarbonate, balanced salt solution (BSS), or lactated Ringer solution may be used:
- A topical anesthetic can be used to provide patient comfort (e.g., proparacaine, tetracaine).
- Sweep the conjunctival fornices every 12 to 24 hours to prevent adhesions (1)[C].
- Eye patching may relieve pain but has not been shown to improve outcomes (3)[C].

MEDICATION

First Line

- Further treatment (depending on severity and associated conditions)
  - Topical prophylactic antibiotics: any broad-spectrum agent (e.g., bacitracin–polymyxin B ointment q2–4h, ciprofloxacin drops q2–4h)
    - Some experts suggest that systemic tetracycline 250 mg PO q6h and especially derivatives such as doxycycline 100 mg PO BID may be beneficial to encourage healing of persistent corneal epithelial defects by

inhibiting metalloproteinases (4)[C].

- Tear substitutes: carboxymethylcellulose (Refresh Plus) drops q4h
  - Most beneficial in those with impaired tear production (elderly patients)
- Cycloplegics for photophobia and/or uveitis: cyclopentolate 1% TID or scopolamine 1/4% BID (1)[C]
- Antiglaucoma for elevated intraocular pressure: latanoprost (Xalatan) 0.005% q24h, timolol (Timoptic) 0.5% BID, *or* levobunolol (Betagan) 0.5% BID, *and/or* acetazolamide (Diamox) 125 to 250 mg PO q6h, *or* methazolamide (Neptazane) 25 to 50 mg PO BID (1)[C]
- Corticosteroids for intraocular inflammation: prednisolone (Pred-Forte) 1% or equivalent q1–4h for 7 to 10 days; if severe, prednisone 20 to 60 mg PO daily for 5 to 7 days. Taper rapidly if epithelium is intact by this time (1)[C]:
  - Use of corticosteroids >10 days may do harm by inhibiting repair and cause corneoscleral melt (5)[C].
- Vitamin C (ascorbic acid) 500 mg PO QID and topical 10% ascorbate solution in artificial tears reduces the incidence of corneal thinning and ulceration (1)[C].
- Acetylcysteine (Mucomyst) 10–20% topically q4h to promote wound healing (1)[C]

- Precautions
  - Timolol and levobunolol: history of heart failure (HF) or chronic obstructive pulmonary disease (COPD)
  - Acetazolamide and methazolamide: history of nephrolithiasis or metabolic acidosis
  - Mannitol: history of HF or renal failure
  - Scopolamine: history of urinary retention
  - Topical corticosteroids must be used with caution in the presence of damaged corneal epithelium because iatrogenic infection can occur. Daily follow-up or consultation with an ophthalmologist is recommended.

SURGERY/OTHER PROCEDURES

- Goal of subacute treatment is restoration of the normal ocular surface anatomy, control of glaucoma, and restoration of corneal clarity.
- Surgical options include the following:

- Débridement of necrotic tissue
- Conjunctival/tenon advancement (tenoplasty) to restore vascularity in severe burns
- Tissue adhesive (e.g., isobutyl cyanoacrylate) for impending or actual corneal perforation of
  - Tectonic keratoplasty for acute perforation >1 mm
- Limbal autograft transplantation for epithelial stem cell restoration
- Amniotic membrane transplantation (5)[C] or umbilical cord serum drops to promote epithelial regeneration (5)[C]
- Conjunctival or mucosal membrane transplant to restore ocular surface in severe injury
- Lamellar or penetrating keratoplasty for tectonic stabilization or visual rehabilitation

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Based on ophthalmologic consultation and concomitant burn injuries

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Depending on severity of ocular injury
  - From daily to weekly visits initially
- May be inpatient
- If on mannitol or prednisone, consider frequent serum electrolytes.

PATIENT EDUCATION

- Safety glasses
- Need for immediate ocular irrigation with any available water following chemical exposure to the eyes

PROGNOSIS

- Depends on severity of initial injury: Increased limbal involvement in clock hours and greater percentage of conjunctival involvement correlate with

poorer prognosis (Dua classification system).

- For mildly injured eyes, complete recovery is the norm.
- For severely injured eyes, permanent loss of vision is not uncommon.

COMPLICATIONS

- Orbital compartment syndrome
- Persistent epitheliopathy
- Fibrovascular pannus
- Corneal ulcer/perforation
- Corneal scarring
- Progressive symblepharon
- Neurotrophic keratitis
- Lid malposition secondary to cicatricial ectropion and entropion
- Glaucoma
- Cataract
- Hypotony
- Phthisis bulbi
- Blindness

Burns

CODES

ICD10

- T26.50XA Corrosion of unsp eyelid and periocular area, init encntr
- T26.60XA Corrosion of cornea and conjunctival sac, unsp eye, init
- S05.00XA Inj conjunctiva and corneal abrasion w/o fb, unsp eye, init

CLINICAL PEARLS

- Prompt irrigation of all chemical burns, even prior to arrival to the emergency department, is essential to ensure best outcomes. It is impossible to overirrigate.
- All patients with chemical injuries to their eyes should have urgent ophthalmology consultation and/or referral.

ONYCHOMYCOSIS

Lauren M. Simon, MD, MPH, FAAFP, FACSM

BASICS

DESCRIPTION

- Fungal infection of fingernails/toenails
- Caused mostly by dermatophytes but also yeasts and nondermatophyte molds
- Toenails are more commonly affected than fingernails.
- System(s) affected: skin, exocrine
- Synonym(s): tinea unguium; ringworm of the nail

EPIDEMIOLOGY

Prevalence

- Occurs in 2–10% of general population
- Predominant age: 20% in adults >60 years of age
- Rare before puberty
- Prevalence 15–40% in persons with human immunodeficiency infection (1)

ETIOLOGY AND PATHOPHYSIOLOGY

- Dermatophytes: *Trichophyton* (*Trichophyton rubrum* most common), *Epidermophyton*, *Microsporum*
- Yeasts: *Candida albicans* (most common), *Candida parapsilosis*, *Candida tropicalis*, *Candida krusei*
- Molds: *Scopulariopsis brevicaulis*, *Hendersonula toruloidea*, *Aspergillus sp.*, *Alternaria tenuis*, *Cephalosporium*, *Scytalidium hyalinum*
- Dermatophytes cause 90% of toenail and most of fingernail onychomycoses.
- Fingernail onychomycosis is more often caused by yeasts, especially *Candida*.
- Dermatophytes can invade normal keratin, whereas nondermatophyte molds invade altered keratin (dystrophic/injured nails).

RISK FACTORS

- Older age
- Tinea pedis

- Occlusive footwear
- Cancer/diabetes/psoriasis
- Peripheral vascular disease
- Cohabitation with others with onychomycosis
- Immunodeficiency
- Communal swimming pools
- Smoking
- Peripheral vascular disease
- History of nail trauma
- Autosomal dominant genetic predisposition

COMMONLY ASSOCIATED CONDITIONS

- Immunodeficiency/chronic metabolic disease (e.g., diabetes)
- Tinea pedis/manuum

DIAGNOSIS

PHYSICAL EXAM

- Dermatophytes: commonly preceded by dermatophyte infection at another site; 80% involve toenails, especially hallux; simultaneous infection of fingernails and toenails is rare. Five clinical forms occur.
  - Distal/lateral subungual onychomycosis (most common): mainly due to *T. rubrum*. Spreads from distal/lateral margins to nail bed to nail plate; subungual hyperkeratosis; onycholysis; nail dystrophy; discoloration—yellow-white or brown-black, yellow streaking laterally; can progress proximally, *bois vermoulu* ("worm-eaten wood"); onychomadesis
  - Proximal subungual onychomycosis (rare <1% of cases): hands/feet; leukonychia—begins at proximal part of nail plate, appearing to occur from the proximal underside of the nail (or direct invasion of the nail plate from above); spreads to nail plate and lunula; seen with immunosuppressive conditions
  - Superficial (formerly known as superficial white onychomycosis) about 10% of cases: hallux is preferentially affected; infection of outer surface of nail plate; opaque white spots on nail plate eventually merge to involve

entire surface of the nail. Most commonly due to *Trichophyton mentagrophytes*
  - Endonyx onychomycosis involves interior of nail plate, sparing nail bed. Nail develops milky white appearance with indentations. Subungual hyperkeratosis is absent.
  - Totally dystrophic onychomycosis causes complete destruction of nail plate by fungus, resulting in thickened and ridged nail bed covered with keratotic debris.
- Candidal
  - Hands, 70%, especially for the dominant hand
  - Middle finger is most common.
  - Pain is mild, unless secondarily infected.
  - Increases on prolonged contact with water
  - Primarily affects tissue surrounding nail
  - Begins with cuticle detachment
  - White or white-yellow nail discoloration
  - Secondary ungual changes: convex, irregular, striated nail plate with dull, rough surface
  - Onycholysis, especially on hands
  - Distal subungual onychomycosis may occur.
  - Primary involvement of the nail plate is uncommon (thin, crumbly, opaque, brownish nail plate deformed by transverse grooves).
  - Periungual edema/erythema may occur (club-shaped, bulbous fingertips).
- Molds (nondermatophyte)
  - More common in those >60 years of age
  - More common in nails of hallux
  - Resembles distal and lateral onychomycosis

Pediatric Considerations

- Candidal infection presents more commonly as superficial onychomycosis.
- The U.S. Food and Drug Administration (FDA) has not approved any systemic antifungal agents for treatment of onychomycosis in children. Efficacy and safety profiles in children for some systemic antifungals are similar to those previously reported in adults (2).

DIFFERENTIAL DIAGNOSIS

- Psoriasis (most common alternate diagnosis)
- Traumatic dystrophy
- Lichen planus
- Onychogryphosis (“ram’s horn nails”)
- Eczematous conditions
- Hypothyroidism
- Drugs and chemicals
- Yellow nail syndrome
- Neoplasms (0.7–3.5%) of all melanoma cases are subungual. In a brownish yellow nail, if dark pigment extends into periungual skin fold, consider subungual melanoma.

DIAGNOSTIC TESTS & INTERPRETATION

- Accurate diagnosis requires both laboratory and clinical evidence.
- About 50% of nail dystrophy seen on visual inspection is not fungal in origin, so laboratory assessment improves diagnostic accuracy.
- If onychomycosis is suspected clinically and initial diagnostic laboratory tests are negative, the tests should be repeated.
- A nail plate biopsy or partial/full removal of nail with culture is needed to diagnose proximal subungual onychomycosis.

Initial Tests (lab, imaging)

- Direct microscopy with potassium hydroxide (KOH) preparation (1)[C]
  - Clean nail with 70% isopropyl alcohol.
  - Using sterile clippers, remove diseased, discolored nail plate.
  - Collect debris from stratum corneum of most proximal area (beneath nail or crumbling nail itself) with 1-mm curette/scalpel.
  - Place sample on microscope slide with drop of 5–10% KOH. View after 5 minutes.
  - Gentle heat applied to slide can enhance keratin breakdown.
  - High sensitivity if >2 preparations were examined
  - Look for hyphae, pseudohyphae, or spores.
- Cultures: False-negative finding in 30% (secondary to loss of dermatophyte viability; improved by immediate culture on Sabouraud cell culture medium);

results may take 3 to 6 weeks.

- In office dermatophyte test, medium culture indicates dermatophyte growth with yellow-to-red color change of the medium; results in 3 to 7 days; limited studies.
- Histologic examination of nail clippings/nail plate punch biopsy: proximal lesions; stain both with periodic acid–Schiff (PAS) stain (1)[C].
- KOH-treated nail clipping stained with PAS: significantly higher rates of detection of onychomycosis as compared with standard methods of KOH preparation and fungal culture (3)[C]
- Polymerase chain reaction (PCR) increases sensitivity of detection of dermatophytes in nail specimen, results available within 3 days can be used as complementary to direct microscope exam and fungal culture; not widely available.
- Fluorescence microscopy can be used as a rapid screening tool for identification of fungi in nail specimens.
- Commercial laboratories may use KOH with calcofluor white stain to improve view of fungal elements in fluorescent microscopy.
- Discontinue all topical medication for at least 1 week before obtaining a sample.

Test Interpretation

Pathogens within the nail keratin

TREATMENT

GENERAL MEASURES

- Avoid factors that promote fungal growth (i.e., heat, moisture, occlusion, tight-fitting shoes).
- Treat underlying disease risk factors.
- Treat secondary infections.

MEDICATION

Pregnancy Considerations

Oral antifungals and ciclopirox are pregnancy Category B (terbinafine,

ciclopirox) or C (itraconazole, fluconazole, and griseofulvin). Griseofulvin is not advised in pregnancy due to risks of teratogenicity and conjoined twins. Ideally postpone treatment of onychomycosis until after pregnancy.

First Line

- Oral antifungals are preferred due to higher rates of cure but have systemic adverse effects and many drug–drug interactions.
- Terbinafine: 250 mg/day PO for 6 weeks for fingernails and 12 weeks for toenails; most effective in cure and prevention of relapse compared with other antifungals and with itraconazole pulse in meta-analysis for toenail onychomycosis I (4)[A]
- Itraconazole pulse: 200 mg PO BID for 1 week, then 3 weeks off, repeat for two cycles for fingernails and three to four cycles for toenails; does not need to monitor liver function tests (LFTs) with pulse dosing
- Itraconazole continuous: 200 mg/day PO for 6 weeks for fingernails and 12 weeks for toenails (less effective than itraconazole pulse for dermatophytes, more effective than terbinafine for *Candida* and molds)

Second Line

- Fluconazole pulse: 150 to 300 mg PO weekly for 6 months (lower cure rate); not FDA-approved for onychomycosis
- Griseofulvin: 500 to 1,000 mg/day PO for up to 18 months (lower cure rate, continue until the diseased nail is replaced)
- Posaconazole: 100, 200, or 400 mg once daily for 24 weeks; 400 mg once daily for 12 weeks; higher cost
- Topical agents: Use limited to disease not involving the lunula (proximal nail plate). Topical therapy does not cause systemic toxicity but is less effective than oral therapy. Head-to-head comparison of efficacy of available agents is generally not available.
- Ciclopirox: 8% nail lacquer (available generically): Apply once daily to affected nails (if without lunula involvement) for up to 48 weeks; remove lacquer with alcohol every 7 days, then file away loose nail material and trim nails (low-cure rate, avoids systemic adverse effects, less cost-effective). Application after PO treatment may reduce recurrences. Systematic review >60% failure rate after 48 weeks of use (5)[A],(6)

- Tavaborole 5% solution, a topical oxaborole antifungal is indicated for onychomycosis of the toenails due to *Trichophyton rubrum* or *Trichophyton mentagrophytes*. Complete or almost-complete cure 15–18% after 48 weeks (NNT compared to vehicle approx 7)
- Efinaconazole solution 10% (7). Complete or almost-complete cure after 48 weeks in range of 15–18% (NNT compared to vehicle 7 to 10)
- Contraindications for oral antifungals
  - Hepatic disease
  - Pregnancy (see "Pregnancy Considerations")
  - Current/history of congestive heart failure (CHF) (itraconazole)
  - Ventricular dysfunction (itraconazole)
  - Porphyria (griseofulvin)
- Precautions/adverse effects
  - Oral antifungals
    - Hepatotoxicity/neutropenia
    - Hypersensitivity
    - Photosensitivity, lupus-like symptoms, proteinuria (griseofulvin)
    - Chronic kidney disease (avoid terbinafine for patients with creatine clearance [CrCl] <50 mL/min, decrease fluconazole dose)
    - CHF, peripheral edema, pulmonary edema (itraconazole)
    - Rhinitis (itraconazole)
- Ciclopirox: rash, nail disorders; avoid contact with skin except along nail edge; caution with broken skin or vascular compromise
- Oral agents: numerous significant drug–drug interactions. Need to check each medication:
  - Terbinafine (inhibits cytochrome P450 2D6 isozyme [CYP2D6]): for example, β-blockers, monoamine oxidase inhibitors (MAOIs), SSRIs, tricyclic antidepressants (TCAs), warfarin, oxycodone
  - Itraconazole, fluconazole (inhibit CYP3A4): for example, antiarrhythmics, benzodiazepines, ergot alkaloids, 3-hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) reductase inhibitors, calcium channel blockers, corticosteroids, hydrochlorothiazide, hypoglycemics, oral contraceptives (OCPs), warfarin, zolpidem
  - Griseofulvin: for example, OCPs, salicylates, warfarin

SURGERY/OTHER PROCEDURES

- Nail débridement to remove infected keratin (efficacy not well studied): Use for few nails involved or if not, for candidate of systemic therapy.
  - Mechanical: Soften with occlusive dressing with 40% urea gel; detach from nail bed with tweezers, file with abrasive stone or curette.
  - Chemical: Protect peripheral tissue with adhesive strips; apply ointment of 30% salicylic acid, 40% urea, or 50% potassium iodide under occlusive dressing.
  - Débridement may be combined with topical antifungal therapy.
  - Surgical avulsion if few nails are involved; for pain control.
- Laser treatment has shown some positive results but limited efficacy data (7).
- Photodynamic therapy using topical photosensitizing agents and irradiation with appropriate light source some success for treatment of superficial nail infections; limited data.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- *Melaleuca alternifolia* (tea tree oil) Cochrane review found no evidence of benefit (5).
- Vicks VapoRub application to nails daily for 48 weeks has been found safe, but efficacy is uncertain.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Formation of a new fingernail takes 4 to 6 months, and a new toenail takes 12 to 18 months.
- Cure defined as:
  - Clinical cure, 100% absence of clinical signs, and/or
  - Mycotic cure, negative mycology with ≥1 of the following clinical signs:
    - Distal subungual hyperkeratosis/onycholysis leaving <10% of the nail plate affected
    - Nail plate thickening that does not improve with treatment because of comorbid condition

Patient Monitoring

- Topical agents: Slow response is expected; visits every 6 to 12 weeks.
- Terbinafine, griseofulvin: baseline, and as needed, LFTs and CBC
- Itraconazole continuous: baseline, and as needed, LFTs

PATIENT EDUCATION

- Advise patient to:
  - Keep affected area clean and dry.
  - Avoid rubber/other occlusive, tight-fitting footwear.
  - Wear absorbent cotton socks.
  - Launder clothing and towels frequently in hot water.
  - Avoid sharing nail implements or use on both normal and abnormal nails.
- Cure of all toenails may not be attainable.
- Nails may not appear normal after cure.

PROGNOSIS

- Complete clinical cure in 25–50% (higher mycologic cure rates) with oral therapy
- Recurrence is 10–50% (relapse/reinfection).
- Poor prognostic factors
  - Areas of nail involvement >50%
  - Significant proximal/lateral disease
  - Subungual hyperkeratosis >2 mm
  - White/yellow or orange/brown streaks in the nail (includes dermatophytoma)
  - Total dystrophic onychomycosis (with matrix involvement)
  - Nonresponsive organisms (e.g., *Scytalidium* mold)
  - Patients with immunosuppression
  - Diminished peripheral circulation

COMPLICATIONS

- Secondary infections with progression to soft tissue infection/osteomyelitis
- Toenail discomfort/pain that can limit physical mobility or activity
- Anxiety, negative self-image

CODES

ICD10

- B35.1 Tinea unguium
- B37.2 Candidiasis of skin and nail

CLINICAL PEARLS

- Psoriasis and chronic nail trauma are commonly mistaken for fungal infection.
- Diagnosis should be based on both clinical and mycologic laboratory evidence.

OPTIC NEURITIS

Olga Cerón, MD • Pablo Hernandez Itriago, MD, MHCM, FAAFP

BASICS

DESCRIPTION

- Inflammation of the optic nerve (cranial nerve II)
- Most common form is acute demyelinating optic neuritis (ON), but other causes include infectious disease and systemic autoimmune disorders.
- Optic disc may be normal in appearance at onset (retrobulbar ON, 67%) or swollen (papillitis, 33%).
- Key features:
  - Abrupt visual loss (typically monocular)
  - Periorbital pain with eye movement (90%)
  - Pain in the distribution of the first division of the trigeminal nerve
  - Dyschromatopsia: color vision deficits
  - Relative afferent pupillary defect (RAPD)
- Usually unilateral in adults; bilateral disease is more common in children.
- Presenting complaint in 25% of patients with multiple sclerosis (MS)
- In children, headaches are common.
- System(s) affected: nervous
- Synonym(s): papillitis; demyelinating optic neuropathy; retrobulbar ON

EPIDEMIOLOGY

Incidence

- 1 to 5/100,000 cases per year
- More common in northern latitudes
- More common in whites than in other races
- Predominant age: 18 to 45 years; mean age 30 years
- Predominant sex: female > male (3:1)

ETIOLOGY AND PATHOPHYSIOLOGY

- In both MS-associated and isolated monosymptomatic ON, the cause is presumed to be a demyelinating autoimmune reaction.
- Possible mechanisms of inflammation in immune-mediated ON are the cross-reaction of viral epitopes and host epitopes and the persistence of a virus in CNS glial cells.
- Neuromyelitis optica (NMO) IgG autoantibody, which targets the water channel aquaporin-4
- Primarily idiopathic
- MS
- Viral infections: measles, mumps, varicella-zoster, coxsackievirus, adenovirus, hepatitis A and B, HIV, herpes simplex virus, cytomegalovirus
- Nonviral infections: syphilis, tuberculosis, meningococcus, cryptococcosis, cysticercosis, bacterial sinusitis, streptococcus B, *Bartonella*, typhoid fever, Lyme disease, fungus
- Systemic inflammatory disease: sarcoidosis, systemic lupus erythematosus, vasculitis
- Local inflammatory disease: intraocular or contiguous with the orbit, sinus, or meninges
- Toxic: lead, methanol, arsenic, radiation
- Vascular lesions affecting the optic nerve
- Posterior uveitis (i.e., birdshot retinochoroidopathy, toxoplasmosis, toxocariasis)
- Tumors
- Medications: ethambutol, chloroquine, isoniazid, chronic high-dose chloramphenicol, tumor necrosis factor α-antagonist, infliximab (Remicade), adalimumab (Humira), etanercept (Enbrel)

COMMONLY ASSOCIATED CONDITIONS

- MS (common): ON is associated with an increased risk of MS.
- Other demyelinating diseases: Guillain-Barré syndrome, Devic NMO, multifocal demyelinating neuropathy, acute disseminated encephalomyelitis

DIAGNOSIS

HISTORY

- Decreased visual acuity, deteriorating in hours to days, usually reaching lowest level after 1 week
- Usually unilateral but can also be bilateral
- Brow ache, globe tenderness, deep orbital pain exacerbated by eye movement (92%)
- Retro-orbital pain may precede visual loss.
- Desaturation of color vision (dull or faded colors), especially red tones
- Apparent dimness of light intensities
- Impairment of depth perception (80%); worse with moving objects (Pulfrich phenomenon)
- Transient increase in visual symptoms with increased body temperature and exercise (Uhthoff phenomenon)
- May present with a recent flulike viral syndrome
- Detailed history and review of systems, looking for a history of demyelinating, infectious, or systemic inflammatory disease

PHYSICAL EXAM

Complete general exam, full neurologic exam, and ophthalmologic exam looking for the following:

- Decreased visual acuity and color perception
- Central, cecocentral, arcuate, or altitudinal visual field deficits
- Papillitis: swollen disc ± peripapillary flame-shape hemorrhage or often normal disc exam
- Temporal disc pallor seen later at 4 to 6 weeks (1)[A]
- RAPD (Marcus-Gunn pupil): The pupil of the affected eye dilates with a swinging light test unless disease is bilateral.

DIFFERENTIAL DIAGNOSIS

- Demyelinating disease, especially MS
- Infectious/systemic inflammatory disease
- Neuroretinitis: virus, toxoplasmosis, *Bartonella*
- Toxic or nutritional optic neuropathy
- Acute papilledema (bilateral disc edema)
- Compression:

  - Orbital tumor/abscess compressing the optic nerve
  - Intracranial tumor/abscess compressing the afferent visual pathway
  - Orbital pseudotumor
  - Carotid–ophthalmic artery aneurysm
- Temporal arteritis or other vasculitides
- Trauma or radiation
- NMO (Devic disease)
- Anterior ischemic optic neuropathy
- Leber hereditary optic neuropathy
- Kjer-type autosomal dominant optic atrophy
- Severe systemic hypertension
- Diabetic papillopathy

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- In typical presentations, ESR is standard, but other labs are unnecessary. Antinuclear antibodies (ANAs), angiotensin-converting enzyme level, fluorescent treponemal antibody absorption (FTA-ABS), and chest radiograph have been shown to have no value in typical cases (1)[A].
- In atypical presentations, including absence of pain, a very swollen optic nerve, >30 days without recovery, or retinal exudates, labs may be indicated to rule out underlying disorders:
  - CBC
  - ANA test
  - Rapid plasma reagin test
  - FTA-ABS test
- MRI of brain and orbits: thin cuts (2 to 3 mm) gadolinium-enhanced and fat-suppression images to look for Dawson fingers of MS (periventricular white matter lesions oriented perpendicular to the ventricles) and also to look for enhancement of the optic nerve
- CT scan of chest to rule out sarcoidosis if clinical suspicion is high
- Ocular coherence tomography (OCT) of the retinal nerve fiber layer (RNFL); a noninvasive imaging technique of the optic nerve. May serve as a diagnostic tool to quantify thickness of the nerve fiber layer objectively and, thus,

monitor structural change (axonal loss) of the optic nerve in the course of the disease.

Follow-Up Tests & Special Considerations

- Visual field test (Humphrey 30–2) to evaluate for visual field loss: diffuse and central visual loss more predominant in the affected eye at baseline (2)[A]
- OCT of the optic nerve RNFL to detect and monitor axonal loss in the anterior visual pathways
- Low-contrast visual acuity (as a measure of disease progression)
- A novel blood test called *NMO-IgG* checks for antibodies for NMO.

Diagnostic Procedures/Other

- In atypical cases, including bilateral deficits, young age, or suspicion of infectious etiology, lumbar puncture (LP) with neurology consultation is indicated.
- LP for suspected MS is a physician-dependent decision. Some studies indicate that it may not add value to MRI for MS detection (1)[A], but no consensus on the subject exists.

TREATMENT

Most persons with ON recover spontaneously.

MEDICATION

First Line

- IV methylprednisolone has been shown to speed up the rate of visual recovery but without significant long-term benefit; consider for patients who require fast recovery (i.e., monocular patients or those whose occupation requires high-level visual acuity). For significant vision loss, parenteral corticosteroids may be considered on an individualized basis: optic neuritis treatment trial (ONTT):
  - Observation and corticosteroid treatment are both acceptable courses of action.
  - High-dose IV methylprednisolone (250 mg q6h for 3 days) followed by oral corticosteroids (1 mg/kg/day PO for 11 days, taper over 1 to 2 weeks) (3)

[A]

- Others use IV Solu-Medrol infusion (1 g in 250 mL D_5 1/2 normal saline infused over 1 hour daily for 3 to 5 days):
  - No evidence of long-term benefit (1)[A]
  - May decrease recovery time (3)[A]
  - May decrease risk of MS at 2 years but not 5 years (3)[A]
- Give antiulcer medications with steroids.

Second Line

- Disease-modifying agents, such as interferon-β1a (IFN-β1a; Avonex, Rebif) and IFN-β1b (Betaseron), are used to prevent or delay the development of MS in people with ON who have ≥2 brain lesions evident on MRI.
  - These medications have been proposed for use in patients with one episode of ON (clinically isolated syndrome) at high risk of developing MS (1+ lesion on brain MRI).
- Decisions should be made individually with neurology consultation.

ALERT

Never use **oral** prednisone **alone** as the primary treatment because this *may increase the risk for recurrent ON* (3)[A].

Pediatric Considerations

- No systematic study defining high-dose corticosteroids in children with ON have been conducted.
  - Consensus recommends: 3 to 5 days of IV methylprednisolone (4 to 30 mg/kg per day), followed by a 2- to 4-week taper of oral steroids (4)[C]
- Optic disc swelling and bilateral disease are more common in children as is severe loss of visual acuity (20/200 or worse).
- Consider infectious and postinfectious causes of optic nerve impairment.

ISSUES FOR REFERRAL

Referral to a neurologist and/or ophthalmologist

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Monthly follow-up to monitor visual changes and steroid side effects

PATIENT EDUCATION

- Provide reassurance about recovery of vision.
- If the disease is believed to be secondary to demyelinating disease, patient should be informed of the risk of developing MS.
- For patient education materials favorably reviewed on this topic, contact:
  - National Eye Institute, Information Officer, Department of Health and Human Services, 9000 Rockville Pike, Bethesda, MD 20892, 301-496-5248
  - North American Neuro-Ophthalmology Society (NANOS), 5841 Cedar Lake Road, Suite 204, Minneapolis, MN 55416, 952-646-2037, Fax: 952-545-6073, http://www.nanosweb.org/i4a/pages/index.cfm?pageid=3280

PROGNOSIS

- Orbital pain usually resolves within 1 week.
- Visual acuity
  - Rapid spontaneous improvement at 2 to 3 weeks and continues for several months (may be faster with IV corticosteroids)
  - Often returns to normal or near-normal levels (20/40 or better) within 1 year (90–95%), even after near blindness
- Other visual disturbances (e.g., contrast sensitivity, stereopsis) often persist after acuity returns to normal.
- Recurrence risk of 35% within 10 years: 14% affected eye, 12% contralateral, 9% bilateral; recurrence is higher in MS patients (48%).
- ON is associated with an increased risk of developing MS; 35% risk at 7 years, 58% at 15 years (5)[A]
  - Brain MRI helps to predict risk:
    - 0 lesions: 16%
    - 1 to 2 lesions: 37%
    - 3+ lesions: 51%

Poor prognostic factors:

- Absence of pain
- Low initial visual acuity

- Involvement of intracanalicular optic nerve

Children with bilateral visual loss have a better prognosis than adults.

COMPLICATIONS

Permanent loss of vision

SEE ALSO

Multiple Sclerosis

CODES

ICD10

- H46.9 Unspecified optic neuritis
- H46.00 Optic papillitis, unspecified eye
- H46.10 Retrobulbar neuritis, unspecified eye

CLINICAL PEARLS

- MRI is the procedure of choice for determining relative risk and possible therapy for MS prevention.
- The ONTT showed that high-dose IV methylprednisolone followed by oral prednisone accelerated visual recovery but did not improve the 6-month or 1-year visual outcome compared with placebo, whereas treatment with oral prednisone alone did not improve the outcome and was associated with an increased rate of recurrence of ON (1,2)[A],(6)[B],(7)[C].

OSGOOD-SCHLATTER DISEASE (TIBIAL APOPHYSITIS)

David P. Sealy, MD • Robert J. Tiller, MD, FAAFP

BASICS

DESCRIPTION

- Osgood-Schlatter Disease (OSD) is a syndrome associated with traction apophysitis and patellar tendinosis that is most common in adolescent boys and girls.
  - Patients present with pain and swelling of the anterior tibial tubercle
- System(s) affected: musculoskeletal
- Synonym: Tibial tubercle apophysitis

EPIDEMIOLOGY

Incidence

Incidence in girls increasing with increased participation in organized youth sports; still more common in boys

Prevalence

- A common apophysitis in childhood and adolescence affecting athletes (21%) and nonathletes (4.5%) (1)[B]
- Approximately 10% remain symptomatic as adults (2)[C].
- 10% of all adolescent knee pain is due to OSD.

ETIOLOGY AND PATHOPHYSIOLOGY

Traction apophysitis of the tibial tubercle due to repetitive strain on the secondary ossification center of the tibial tuberosity, concurrent patellar tendinosis, and disruption of the proximal tibial apophysis

- Basic etiology unknown, exacerbated by exercise
  - Jumping and pivoting sports place highest strain on the tibial tubercle. Repetitive trauma is the most likely inciting factor.
- Possible association with tight hip flexors and tight quadriceps; increased quadriceps strength in adolescence relative to hamstring strength

- Early sports specialization increases the risk for OSD 4-fold (3)[B].

RISK FACTORS

- Affects children and adolescents most commonly from the ages of 8 to 18 years
  - Girls 8 to 14 years
  - Boys 10 to 18 years
- OSD is slightly more common in boys.
- Rapid skeletal growth
- Participation in repetitive-jumping sports and sports with heavy quadriceps activity (football, volleyball, basketball, hockey, soccer, skating, gymnastics)
- Ballet (2-fold risk compared with nonathletes)
- Potential increased risk of OSD in adolescents with ADD/ADHD (4)[C]

GENERAL PREVENTION

- Avoid sports with heavy quadriceps loading (especially deceleration activities—eccentric loading).
- Patients may compete if pain is minimal.
- Increase hamstring and quadriceps flexibility.

COMMONLY ASSOCIATED CONDITIONS

- Shortened (tight) rectus femoris found in 75% with OSD
- Possible association with ADD/ADHD; adolescents with ADD/ADHD are at risk for other musculoskeletal injuries.
- Sinding-Larsen-Johansson apophysitis

DIAGNOSIS

HISTORY

- Unilateral or bilateral (30%) pain of the tibial tuberosity
- Pain exacerbated by exercise, especially jumping and landing after jumping
- Pain upon kneeling on the affected side(s)
- Antalgic or straight-legged gait

PHYSICAL EXAM

- Knee pain with squatting or crouching

- Absence of effusion or condyle tenderness
- Tibial tuberosity swelling and tenderness
- Pain increased with resisted knee extension or kneeling
- Erythema over tibial tuberosity
- Functional testing: Single-leg squat (SLS) and standing broad jump reproduce pain (3)[C].

DIFFERENTIAL DIAGNOSIS

- Stress fracture of the proximal tibia
- Pes anserinus bursitis
- Quadriceps tendon avulsion
- Patellofemoral stress syndrome
- Chondromalacia patellae (retropatellar pain)
- Proximal tibial neoplasm
- Osteomyelitis of the proximal tibia
- Tibial plateau fracture
- Sinding-Larsen-Johansson syndrome (patellar apophysitis)—pain over inferior patellar tendon
- Patellar fracture
- Infrapatellar bursitis
- Patellar tendinitis—pain over inferior patellar tendon and inferior pole of patella

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Generally a clinical diagnosis. No tests are indicated unless other diagnoses are under consideration.
- Radiographic imaging of the proximal tibia and knee may show heterotopic calcification in the patellar tendon:
  - X-rays are rarely diagnostic, but appearance of a separate fragment at the tibial tuberosity identifies candidates for potential surgical intervention.
  - Calcified thickening of the tibial tuberosity with irregular ossification at tendon insertion on the tibial tubercle (5)[B]

Diagnostic Procedures/Other

- Bone scan may show increased uptake in the area of the tibial tuberosity:
  - Increased uptake in apophysis is normal in children, but with OSD, there *may be more uptake on the opposite side*.
- Ultrasound is an excellent alternative, showing thickening of the distal patellar tendon and infrapatellar bursa effusion.
- MRI shows fragmentation of the tibial tubercle and bone edema.

Test Interpretation

Biopsy is not necessary but would show osteolysis and fragmentation of the tibial tubercle.

TREATMENT

GENERAL MEASURES

- Frequent ice applications 2 to 3 times per day for 15 to 20 minutes
- Rest and activity modification—avoid activities that increase pain and/or swelling.
- Physical therapy helps with hamstring and quadriceps strengthening and stretching.
- Open- and closed-chain eccentric quadriceps strengthening
- Avoid aggressive stretching if pain is significant to avoid risk of tibial tubercle avulsion (1)[B].
- Consult orthopedic surgery for tibial tuberosity fracture or complete avulsion.
- Electrical stimulation and iontophoresis may be beneficial (1)[B].
- Patients with marked pronation may benefit from orthotics.
- A single study showed benefit from an infrapatellar strap and many experts recommend the use of a knee brace with an H- or U-shaped buttress (1)[C].

MEDICATION

First Line

- Any analgesic may be considered.
- NSAIDs may help control pain.
- Opioids are not recommended as first line.

Second Line

- More potent analgesics, such as opioids, may be considered for short-term use in extreme situations.
- Corticosteroid injections are not recommended.
- Hypertonic glucose and/or Xylocaine injections have shown recent benefit (6) [C].

ISSUES FOR REFERRAL

When conservative therapy is unsuccessful, consider surgical referral.

SURGERY/OTHER PROCEDURES

- Débridement of a thickened, cosmetically unsatisfactory tibial tubercle (rare) or removal of mobile heterotopic bone
- Surgical excision of a painful tibial tubercle is rarely needed (<5%) and may be successfully done with bursoscopy instead of an open procedure (5)[C].
- Recent report of successful pain elimination in OSD with percutaneous screw fixation of the tibial tuberosity (2)[C]
- 75% return to normal sport activity and 89% are not restricted from competition due to recurrent pain.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Athletes may return to play if pain is controlled.
- Presence of pain does not preclude competition.

Patient Monitoring

With worsening of symptoms only

PATIENT EDUCATION

- Avoid jumping sports or reduce activities that increase pain and swelling.
- Assure family that symptoms and findings will diminish with time and rest.
- Patients can safely play sports with mild pain.
- Quadriceps stretching and strengthening are important.

PROGNOSIS

- Except in rare cases, this is a self-limiting illness that resolves within 2 years

of full skeletal maturation.

- 10% of patients with OSD as adolescents will have symptoms in adulthood. Up to 60% of adults with prior OSD report occasional symptoms and pain with kneeling.
- Most patients with OSD have residual “knots” of tibial tubercles that never completely resolve.

COMPLICATIONS

- Rarely, a heavily fragmented and inflamed tibial ossicle will avulse and require surgery.
- Rare complications in adulthood include pseudoarthrosis of the tibial tubercle, genu recurvatum, patella alta, and ossicle fragmentation possibly leading to osteoarthritis of the knee.

CODES

ICD10

- M92.50 Juvenile osteochondrosis of tibia and fibula, unsp leg
- M92.51 Juvenile osteochondrosis of tibia and fibula, right leg
- M92.52 Juvenile osteochondrosis of tibia and fibula, left leg

CLINICAL PEARLS

- Infrapatellar pain in an adolescent athlete undergoing a rapid growth spurt is OSD, patellar tendinosis, or Sinding-Larsen-Johansson syndrome.
- Always consider lumbar disc disease, osteogenic sarcoma, or hip pathology in the differential diagnosis of OSD.
- OSD is generally self-limited. Athletes should modify activity based on pain. Mild pain is not a contraindication to athletic participation.
- Treatment focuses on strengthening and stretching of the hamstrings and quadriceps.
- 10% of adolescents with OSD will be symptomatic as adults.

OSTEOARTHRITIS

Patrick Wakefield Joyner, MD, MS

BASICS

DESCRIPTION

- Progressive loss of articular cartilage with reactive changes at joint margins and in subchondral bone
- Primary osteoarthritis (OA)
  - Idiopathic: categorized by clinical features (localized, generalized, erosive)
- Secondary OA
  - Posttraumatic
  - Childhood anatomic abnormalities (e.g., congenital hip dysplasia, slipped capital femoral epiphysis [SCFE], Legg-Calvé-Perthes disease)
  - Inheritable metabolic disorders (e.g., Wilson disease, alkaptonuria, hemochromatosis)
  - Neuropathic arthropathy (Charcot joints)
  - Hemophilic arthropathy
  - Endocrinopathies: acromegalic arthropathy, hyperparathyroidism, hypothyroidism
  - Paget disease
  - Noninfectious inflammatory arthritis (e.g., rheumatoid arthritis [RA], spondyloarthropathies)
  - Gout, calcium pyrophosphate deposition disease (pseudogout)
  - Septic or tuberculous arthritis
  - Femoral acetabular impingement (FAI)
- System(s) affected: musculoskeletal
- Synonym(s): osteoarthrosis; degenerative joint disease (DJD)

EPIDEMIOLOGY

- Symptomatic OA is most common in patients >40 years of age.
- Leading cause of disability in patients >65 years old
- Predominant sex: male = female
- 90% of hip OA is primary.

- Hip OA is more common in whites.

Prevalence

- ~60 million patients
- Increases with age; radiographic evidence of OA is present in many patients >65 years old.
- Moderate to severe hip OA in 3–6% of whites; <1% in East Indians, blacks, Chinese, and Native Americans

ETIOLOGY AND PATHOPHYSIOLOGY

- Failure of chondrocytes to maintain the balance between degradation and synthesis of extracellular collagen matrix. Collagen loss results in alteration of proteoglycan matrix and increased susceptibility to degenerative change.
- Biomechanical, biochemical, inflammatory, and immunologic factors contribute to cartilage loss. Attempts at repair most commonly manifest as osteophyte formation.

Genetics

- Up to 65% of OA may have a genetic component.
- The heritability of end-stage hip OA is up to 27%.
- Twin studies in women show 50% (hip, knee) to 65% (hip) heritability rates of OA.

RISK FACTORS

- Increasing age: >50 years
- Age as a risk factor is greatest for hip and knee OA.
- Hand OA is most common in postmenopausal women.
- Obesity (weight-bearing joints)
- Small critical shoulder angle (<30°) can predispose to shoulder OA.
- Trauma, infection, or inflammatory arthritis
- Female gender (knee and hand)

DIAGNOSIS

HISTORY

- Distinguish OA from other types of arthritis by:

  - Absence of systemic findings
  - Minimal articular inflammation
  - Distribution of involved joints (e.g., distal and proximal interphalangeal joints)
- OA characterized by slowly developing joint pain. Pain often described as aching or burning in nature. Anecdotally, many patients describe pain changes with alterations in weather conditions.
- Transient stiffness (especially after awakening in morning and after sitting) that tends to lessen 10 to 15 minutes after joint movement
- OA more commonly affects hands, spine, and large weight-bearing joints (hip, knee).

PHYSICAL EXAM

- Joint bony enlargement (Heberden nodes of distal interphalangeal joints; Bouchard nodes of proximal interphalangeal joints)
- Decreased range of motion of affected joints
- Mechanical symptoms (clicking, locking) may be present, especially in knees with degenerative meniscal injury.
- Crepitation is a late sign.
- Local pain and stiffness with OA of spine. Radicular pain (if compression of nerve roots)
- Changes in joint alignment (genu varum [bow-legs] and genu valgum [knock-knees])

DIFFERENTIAL DIAGNOSIS

- Crystalline arthropathies (gout; pseudogout): inflammatory arthritides (RA); spondyloarthropathies (reactive arthritis; psoriatic arthritis); septic arthritis
- Fibromyalgia; avascular necrosis; Lyme disease

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Routine chemistries are not helpful in diagnosis.
- X-rays are usually normal early in disease process.
- As OA progresses, plain films show:
  - Narrowed, asymmetric joint space

  - Osteophyte formation
  - Subchondral bony sclerosis
  - Subchondral cyst formation
- Erosions may occur on surface of distal and proximal interphalangeal joints (erosive OA).

Follow-Up Tests & Special Considerations

- May be useful in monitoring treatment with NSAIDs (renal insufficiency and GI bleeding)
- In secondary OA, underlying disorder may have abnormal lab results (e.g., hemochromatosis [abnormal iron studies]).

Diagnostic Procedures/Other

Joint aspiration

- May help to distinguish OA from chronic inflammatory arthritis
- OA: cell count usually <500 cells/mm^3, predominantly mononuclear
- Inflammatory: cell count usually >2,000 cells/mm^3, predominantly neutrophils
- Birefringent crystals in gout (−) and pseudogout (+)

Test Interpretation

- Macroscopic patchy cartilage damage and bony hypertrophy
- Histologic phases:
  - Extracellular matrix edema and cartilage microfissures
  - Subchondral fissuring and pitting
  - Erosion and formation of osteocartilaginous loose bodies
- Subchondral bone trabecular microfractures and sclerosis with osteophyte formation
- Degradation secondary to release of proteolytic and collagenolytic enzymes, prostaglandins, and associated immune response

TREATMENT

GENERAL MEASURES

- Weight management

- Heat (in the morning and prior to activity) or cold (in the afternoon or after activity) applications for symptomatic relief
- Physical therapy to maintain or regain joint motion and muscle strength
  - Quadriceps-strengthening exercises relieve knee pain and disability.
- Muscle strengthening improves pain in general.
- Transition to non–weight-bearing exercises (i.e., elliptical, stationary bike, swimming.
- Exercise must be maintained; benefits are lost 6 months after exercise cessation.
- Protect joints from overuse; ambulatory aides are beneficial (e.g., cane, crutches, walker) as is proper fitting footwear.
- Bracing, joint supports, or insoles in patients with biomechanical instability:
  - Bracing is more beneficial in patients with unicompartmental disease of the knee.
- For knee OA in particular, **nonpharmacologic modalities are strongly recommended**: aerobic, aquatic, and/or resistance exercise and weight loss.
- Nonpharmacologic modalities that are conditionally recommended for knee OA include medial wedge insoles for valgus knee OA, subtalar strapped lateral insoles for varus knee OA, medially directed patellar taping, manual therapy, walking aids, thermal agents, tai chi, self-management programs, and psychosocial intervention.

MEDICATION

First Line

- Manage pain and inflammation:
  - Acetaminophen up to 1,000 mg TID–QID: effective for pain relief in OA of knee and hip
  - Topical NSAID gels, creams have short-term (<4 weeks) benefits. Topical NSAIDs should be a core treatment for knee and hand OA.
  - If acetaminophen or topical NSAIDs are insufficient, consider an oral NSAID/COX-2 inhibitor. Use the lowest effective dose for the shortest time possible. Use is associated with renal insufficiency, hypertension, edema, and GI bleeding.
  - May use nonacetylated salicylates (e.g., salsalate, choline-magnesium

salicylate) or low-dose ibuprofen ≤1,600 mg/day
  - Topical NSAIDs and capsaicin as alternatives to oral analgesic/anti-inflammatory medications in knee OA
- NSAID contraindications:

ALERT
http://www.health.harvard.edu/blog/fda-strengthens-warning-that-nsaids-increase-heart-attack-and-stroke-risk-201507138138

  - All PO NSAIDs/COX-2 inhibitors have analgesic effects of a similar magnitude but vary in their potential GI and cardiorenal toxicity.
  - NSAIDs should be avoided in patients with renal disease, CHF, HTN, active peptic ulcer disease, and previous hypersensitivity to an NSAID or aspirin (asthma, nasal polyps, hypotension, urticaria/angioedema).
  - Combination of NSAIDs and full-strength aspirin (325 mg) is contraindicated due to risk of adverse reactions.
  - In patients at high cardiovascular risk: Combination of a nonselective NSAID and low-dose aspirin (81 mg) is recommended.
  - Oral or parenteral corticosteroids are contraindicated.
- Precautions:
  - If PO NSAID/COX-2 inhibitor use is necessary for a patient aged >65 years or a patient <65 years with increased GI-bleeding risk factors, proton-pump inhibitors are recommended.
  - Significant possible interactions:
    - NSAIDs reduce effectiveness of ACE inhibitors and diuretics.
    - Aspirin and NSAIDs (except COX-2 inhibitors) may increase effects of anticoagulants.
    - Salicylates reduce effectiveness of spironolactone (Aldactone) and uricosurics.
    - Corticosteroids and some antacids increase salicylate excretion, whereas ascorbic acid and ammonium chloride reduce salicylate excretion and may cause toxicity.

Pregnancy Considerations

- ASA and NSAIDs have reported fetal risk during 1st and 3rd trimesters of pregnancy.

- Compatible with breastfeeding

Second Line

- Topical capsaicin is an adjunct therapy for knee and hand OA; may cause local burning
- Topical NSAIDs (e.g., diclofenac gel) can lower gastric and renal risks associated with oral NSAIDs.
- Rubefacients (e.g., oil of wintergreen) are not recommended.
- Physical therapy: Core strengthening for hip OA and knee muscle strengthening for knee OA decrease joint reactive forces on the affected joint and can relieve pain.
- Bracing; medial and lateral unloader braces are effective; long leg alignment x-rays can help determine the appropriate brace (1).

Third Line

- Intra-articular corticosteroid injections can be used for acute flares and for patients failing first- and second-line treatments. Minimize injections (<2/joint/year).
- The use of viscosupplementation injections for OA remains controversial. There is no clear evidence for benefit from hyaluronic acid (HA) injections.
- Platelet-rich plasma (PRP) is more effective than HA injections for early-stage knee OA (2).
- PRP injections appear to be more effective for early OA when done in a series of three (3).
- Glenohumeral joint OA managed with HA injections and corticosteroid injection has similar outcomes (4).
- TENS is effective for pain relief in large-joint OA.
- Ultrasound improves injection accuracy.

ADDITIONAL THERAPIES

Address psychosocial factors (i.e., self-efficacy, coping skills). Screen for and appropriately treat anxiety and depression. Improve social support.

SURGERY/OTHER PROCEDURES

- Total knee arthroplasty (TKA) may be necessary after patient has failed all forms of conservative management.

- Knee arthroscopy is not routinely recommended for the treatment of osteoarthritis in the absence of clear mechanical symptoms (i.e., locking, clicking, etc.).

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Nutritional supplements (glucosamine and chondroitin sulfate) may benefit some patients and have low toxicity. There is lack of standardized outcome assessments. Trial results using glucosamine and chondroitin have been mixed. If no response is apparent within 6 months, treatment should be discontinued.
- TENS, yoga, and acupuncture have shown benefit.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Regularly assess joint range of motion and functional status.
- Monitor for GI blood loss, cardiac, renal, and mental status in older patients on NSAIDs or aspirin.
- Periodic CBC, renal function tests, stool for occult blood in patients on chronic NSAID therapy

PATIENT EDUCATION

- American College of Rheumatology: http://www.rheumatology.org/public/factsheets/index.asp?aud=pat
- Arthritis Foundation: http://www.arthritis.org

PROGNOSIS

- Progressive disease: early in course, pain relieved by rest; later, pain may persist at rest and at night.
- Joint effusions and enlargement may occur (especially in knees) as disease progresses.
- Osteophyte (spur) formation, especially at joint margins
- Advanced stage with full-thickness loss of cartilage at which point joint replacement is a consideration

COMPLICATIONS

- Leading cause of musculoskeletal pain and disability
- Decompensated CHF, GI bleeding, decreased renal function on chronic NSAID or aspirin therapy

CODES

ICD10

- M19.90 Unspecified osteoarthritis, unspecified site
- M19.91 Primary osteoarthritis, unspecified site
- M19.93 Secondary osteoarthritis, unspecified site

CLINICAL PEARLS

- Patients with OA typically have morning stiffness lasting for <15 minutes.
- OA most commonly affects the hips, knees, and hands (PIP and DIP joints).
- Intra-articular steroid injections should be limited to no more than 2 per joint per year (if used at all).
- Consider PRP for early-stage knee OA.
- American Academy of Orthopaedic Surgeons (AAOS) recommends against the use of HA injections for OA.
- Long-term therapy should be based on individual patient goals and expectations, particularly regarding pain management and activity level.

OSTEOMYELITIS

Tricia Elaine VanWagner, MD

BASICS

DESCRIPTION

- An acute or chronic infection and inflammation of the bone; can occur as a result of hematogenous seeding, contiguous spread of infection, or direct inoculation into intact bone (trauma or surgery)
- Two major classification systems:
  - Lew and Waldvogel classification
    - Classified according to duration (acute or chronic) and the mechanism of infection (hematogenous, contiguous)
  - Cierny-Mader classification
    - Based on the portion of bone affected, the physiologic status of the host, and other risk factors
    - Stage 1: medullary bone (typically monomicrobial)
    - Stage 2: bony surface (deep soft tissue infection or ulcer)
    - Stage 3: advance local infection (polymicrobial); often associated with open fracture or infected orthopedic hardware
    - Stage 4: Extensive disease (multiple tissue layers) requires combination medical and surgical therapy.
    - Class A host: otherwise normal
    - Class B host: immunocompromised
    - Class C host: Treatment risk outweighs benefit.
- Special situations
  - Vertebral osteomyelitis
    - Acute, subacute, or chronic
    - May result from hematogenous seeding, direct inoculation, or contiguous spread
    - Back pain is most common initial symptom.
    - Lumbar spine is most commonly involved, followed by thoracic spine.
  - Infections of prosthetic joints

    - Obtaining specific diagnosis and targeted therapy quicker (easy access)
    - X-ray, then 3-phase bone scan, as MRI/CT is limited use in this circumstance
    - Treat with combination of antibiotics, including rifampin.
  - Posttraumatic infections
    - Depends on type of fracture, level of contamination, and severity of tissue injury
    - Tibia is the most commonly involved.
- System(s) affected: musculoskeletal

EPIDEMIOLOGY

- Predominant age: more common in older adults
- Predominant sex: male > female
- Hematogenous osteomyelitis
  - Adults (most >50 years of age): vertebral
  - Children: long bones
- Contiguous osteomyelitis: related to trauma and surgery in younger adults and decubitus ulcers and infected total joint arthroplasties in older adults

Incidence

Generally low; normal bone is resistant to infection.

Prevalence

Up to 66% of diabetics with foot ulcers

ETIOLOGY AND PATHOPHYSIOLOGY

- Infection is caused by biofilm bacteria (protects bacteria from antimicrobial agents and host immune responses).
- Acute: suppurative infection of bone with edema and vascular compromise leading to sequestra
- Chronic: presence of necrotic bone or sequestra or recurrence of previous infection
- Hematogenous osteomyelitis (typically monomicrobial)
  - *Staphylococcus aureus* (most common)
  - Coagulase-negative staphylococci and aerobic gram-negative bacteria
  - *Salmonella* sp. (sickle cell disease)

  - *Mycobacterium tuberculosis* and fungi (rare) in endemic areas or in immunocompromised hosts
- Contiguous focus osteomyelitis (commonly polymicrobial)
  - Diabetes or vascular insufficiency
    - Coagulase-positive and coagulase-negative staphylococci
    - Streptococci, gram-negative bacilli, anaerobes (*Peptostreptococcus* sp.)
  - Prosthetic device
    - Coagulase-negative staphylococci and *S. aureus*

RISK FACTORS

- Diabetes mellitus
- Recent trauma/surgery
- Foreign body (e.g., prosthetic implant)
- Neuropathy and vascular insufficiency
- Immunosuppression
- Sickle cell disease
- Injection drug use
- Previous osteomyelitis

GENERAL PREVENTION

- Antibiotic prophylaxis
  - Clean bone surgery
    - Administer IV antibiotics within an hour of skin incision and continue no longer than 24 hours after the procedure.
  - Closed fractures
    - Cefazolin, cefuroxime, clindamycin (β-lactam allergy), or vancomycin (β-lactam allergy or MRSA infection)
  - Open fractures
    - In patients who can receive antibiotics within 3 hours of injury with prompt operative treatment, 1st-generation cephalosporins are preferred (clindamycin or vancomycin if allergy exists). Add aminoglycoside if type III fracture and penicillin for anaerobic coverage if farm injury or possible bowel contamination.
- All diabetic patients should have an annual foot examination.

COMMONLY ASSOCIATED CONDITIONS

See "Risk Factors."

DIAGNOSIS

HISTORY

- Fever, chills, lethargy (particularly in children)
- Pain, swelling, erythema in affected area
- Hematogenous osteomyelitis
  - Elicit a history of conditions predisposing to bacteremia (diabetes, renal insufficiency, invasive procedures, IV drug use)
- Contiguous osteomyelitis and vascular insufficiency
  - Recent trauma/surgery within 1 to 2 months
  - Presence of prosthetic device
  - History of diabetes
- Chronic osteomyelitis
  - History of acute osteomyelitis

PHYSICAL EXAM

- Fever
- Restriction of movement of the involved extremity or refusal to bear weight
- Pain or tenderness in the infected area
- Signs of localized inflammation
- Motor and sensory deficits (vertebral infection)
- Visible defect: probe to bone
- Ulcer >2-cm wide and >2-cm deep increases likelihood in diabetic foot ulcers.
- In patients with diabetes, classic signs and symptoms of infection may be masked due to vascular disease and neuropathy.

DIFFERENTIAL DIAGNOSIS

- Systemic infection from other source
- Aseptic bone infarction
- Localized inflammation or infection of overlying skin and soft tissues (e.g., gout)
- Brodie abscess (subacute osteomyelitis)

- Neuropathic joint disease (Charcot foot)
- Fractures/trauma
- Tumor

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

Labs

- WBC is not reliable (can be normal with infection).
- CRP is usually elevated but nonspecific.
- ESR is high in most cases:
  - ESR >70 mm/hr increases likelihood.
- Antimicrobial agents given prior to culture may alter culture results.
- Disorders that may alter lab results: immunosuppression (including diabetes), chronic inflammatory disease, other/adjacent sites of infection (1)[C]
- Routine radiography is first-line imaging: Classic triad for osteomyelitis is demineralization, periosteal reaction, and bone destruction:
  - Bone destruction is not apparent on plain films until after 10 to 21 days of infection.
  - Bone must undergo 30–50% destruction before damage is evident on films.
  - Bone scan is typically first test after plain x-ray in setting of joint prosthesis.
- Radionuclide scanning (e.g., technetium, indium, or gallium) is useful when diagnosis is ambiguous or extent of disease is in question but is limited by low sensitivity and specificity.
- MRI
  - Best for visualization of septic arthritis, spinal infection, and diabetic foot infections (1)[C]
  - T1-weighted image: low signal intensity
  - T2-weighted image: high signal intensity
  - MRI with gadolinium: sensitivity and specificity range from 60–100% to 50–90%, respectively
  - MRI is not helpful in assessing the response to therapy due to persistence of bony edema.
- CT

  - Better than standard radiography in fragments and sequestration, but inferior to MRI in soft tissue and bone marrow assessment
  - Helps define soft tissues and identify sequestra

Follow-Up Tests & Special Considerations

- A persistently elevated CRP (4 to 6 weeks) can be associated with persistent osteomyelitis.
- Patients receiving prolonged antimicrobial therapy should be monitored with:
  - Weekly CBC
  - Liver and kidney function tests

Diagnostic Procedures/Other

- Cultures
  - Definitive diagnosis is made by blood culture (hematogenous) or by needle aspiration/bone biopsy, with identification of the microorganism by culture and sensitivity or histology.
  - Patients with positive blood cultures and with radiographic evidence of osteomyelitis may not need bone culture.
  - Wound swabs and sinus tract cultures correlate well with the presence of *S. aureus* in deep cultures.
- Image-guided bone biopsy for vertebral osteomyelitis (unless positive blood culture and positive radiographic evidence)

Test Interpretation

Inflammatory process of bone with pyogenic bacteria, necrosis

TREATMENT

GENERAL MEASURES

- Adequate nutrition
- Smoking cessation
- Control diabetes

MEDICATION

- Direct empiric therapy toward probable organism and tailor once culture results are available.

- Optimal antimicrobial concentration at infection site is essential (consider vascular perfusion to site).
- Antibiotic dosing altered for renal function
- Duration of therapy 4 to 6 weeks for acute osteomyelitis and generally >8 weeks for chronic osteomyelitis or MRSA infection
- In children, early transition from IV to oral therapy, (after 3 to 4 days if responding well) followed by oral therapy for 3 weeks may be as effective as longer courses for uncomplicated acute osteomyelitis (2)[B].

First Line

- *S. aureus* or coagulase-negative staphylococci
  - MSSA: *β*-lactam at high dose (nafcillin or oxacillin 2 g IV q4h) *or* cefazolin 2 g IV q8h
  - MRSA: vancomycin 15 mg/kg IV q8–12h (use q8h interval if CrCl >70 mL/min) with target trough of 15 to 20 *μ*g/mL
- *Streptococcus* sp.
  - Ceftriaxone 2 g IV q24h or cefazolin 2 g IV q8h
- *Enterobacter sp.*
  - Fluoroquinolone (levofloxacin 750 mg IV/PO q24h) *or* ceftriaxone 2 g IV q24h
- *Pseudomonas aeruginosa*
  - Ciprofloxacin 750 mg PO BID or levofloxacin 750 mg PO q24h
- Anaerobes
  - Clindamycin 600 mg IV q8h (300 to 450 mg PO q6–8h)

Second Line

- *S. aureus*
  - MSSA: fluoroquinolone plus rifampin (levofloxacin 750 mg IV/PO q24h plus rifampin 300 mg PO q12h *or* 600 mg PO q24h)
  - MRSA: linezolid 600 mg PO/IV q12h *or* daptomycin 6 mg/kg IV q24h
- *Streptococcus sp.*
  - Penicillin G 4 million U q4–6h
- *Enterobacter* sp. (quinolone-resistant, including extended-spectrum *β*-lactamase–producing *Escherichia coli*)
  - Carbapenem (imipenem/cilastatin) 500 mg IV q6h

- *P. aeruginosa*
  - Cefepime or ceftazidime 2 g IV q8h (consider adding aminoglycoside)
- Anaerobes
  - Metronidazole 500 mg IV/PO q6–8h

ADDITIONAL THERAPIES

- Hyperbaric oxygen therapy may be a useful adjunct.
- Negative pressure wound therapy is a possible adjunctive treatment.

SURGERY/OTHER PROCEDURES

Surgical drainage, dead space management, adequate soft tissue coverage, restoration of blood supply, and removal of necrotic tissues improve cure rates.

Pediatric Considerations

Medullary osteomyelitis (stage 1) in children may be treated without surgical intervention (2)[B].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Correct electrolyte imbalances, hyperglycemia, azotemia, and acidosis; control pain.
- Bed rest and immobilization of the involved bone and/or joint
- Discharge criteria clinical and laboratory evidence of resolving infection and appropriate outpatient therapy

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Blood levels of antimicrobial agents, ESR, CRP, and repeat plain radiography as clinical course dictates

PATIENT EDUCATION

Diabetic glycemic control and foot care

PROGNOSIS

- Superficial and medullary osteomyelitis treated with antimicrobial and surgical therapy have a response rate of 90–100%.
- Up to 36% recurrence rate in diabetics
- Increased mortality after amputation

COMPLICATIONS

- Abscess formation
- Bacteremia
- Fracture/nonunion
- Loosening of prosthetic implant
- Postoperative infection
- Sinus tract formation can be associated with neoplasms, especially in presence of long-standing infection.

CODES

ICD10

- M86.9 Osteomyelitis, unspecified
- M86.00 Acute hematogenous osteomyelitis, unspecified site
- M86.10 Other acute osteomyelitis, unspecified site

CLINICAL PEARLS

- Hematogenous osteomyelitis is usually monomicrobial, whereas osteomyelitis due to contiguous spread or direct inoculation is usually polymicrobial.
- Acute osteomyelitis typically presents with gradual onset of pain.
- Treatment of osteomyelitis often requires both surgical débridement and at least 6 weeks of antimicrobial therapy.

OSTEOPOROSIS AND OSTEOPENIA

Andrew J. McBride, MD • Rahul Kapur, MD

BASICS

DESCRIPTION

A skeletal disease characterized by low bone mass, deterioration of bone tissue, and disruption of bone architecture that leads to compromised bone strength and an increased risk of fracture

EPIDEMIOLOGY

- Most common bone disease in humans
- Predominant age: elderly >60 years of age
- Predominant sex: female > male (80%/20%)

Incidence

There is poor data on incidence of osteoporosis and osteopenia. However, there is an estimated 2 million fractures yearly attributed to osteoporosis.

Prevalence

- >10.2 million Americans have osteoporosis.
- >43.4 million Americans have osteopenia.
- Women >50 years of age: osteoporosis 15.4% and osteopenia 51.4%
- Men >50 years of age: osteoporosis 4.3% and osteopenia 35.2%
- One in three women will experience an osteoporotic fracture, as will one in five men.

ETIOLOGY AND PATHOPHYSIOLOGY

- Imbalance between bone resorption and bone formation
- Aging
- Hypoestrogenemia

Genetics

- Familial predisposition
- More common in Caucasians and Asians than in African Americans and

Hispanics

RISK FACTORS

- Nonmodifiable
  - Advanced age (>65 years)
  - Female gender and menopause
  - Caucasian or Asian
  - Family history of osteoporosis
  - History of atraumatic fracture
- Modifiable
  - Low body weight (58 kg or body mass index [BMI] <21)
  - Calcium/vitamin D deficiency
  - Inadequate physical activity
  - Cigarette smoking
  - Excessive alcohol intake (>3 drinks/day)
  - Medications: See "Commonly Associated Conditions."

GENERAL PREVENTION

The aim in the prevention and treatment of osteoporosis is to prevent fracture:

- Regularly perform weight-bearing exercise.
- Consume a diet that includes adequate calcium (1,000 mg/day for men aged 50 to 70 years; 1,200 mg/day for women aged 51+ years and men 70+ years) and vitamin D (800 to 1,000 IU/day).
- The USPSTF has concluded that vitamin D supplementation is effective in preventing falls in community-dwelling adults aged 65 years or older who are at increased risk for falls (1)[B].
- Evidence is insufficient to assess the balance of the benefits and harms of daily supplementation with >400 IU of vitamin D_3 and >1,000 mg of calcium for the primary prevention of fractures in noninstitutionalized postmenopausal women (1)[B].
- USPSTF recommends against daily supplementation with 400 IU or less of vitamin D_3 and 1,000 mg or less of calcium for the primary prevention of fractures in noninstitutionalized postmenopausal women (1)[B].
- Avoid smoking.
- Limit alcohol consumption (<3 drinks/day).

- Fall prevention (vitamin D supplementation, home safety assessment, correction of visual impairment)
- Screen (USPSTF recommendations):
  - All women ≥65 years of age (1)[B]
  - Women >50 years of age with ≤10-year fracture risk (using the WHO's Fracture Risk Assessment [FRAX] Tool) >9.3%
  - The current evidence is insufficient to recommend screening for osteoporosis in men; however, the National Osteoporosis Foundation recommends screening men age >70 years, especially if at increased risk.

COMMONLY ASSOCIATED CONDITIONS

- Malabsorption syndromes: gastrectomy, inflammatory bowel disease, celiac disease
- Hypoestrogenism: menopause, hypogonadism, eating disorders, female athlete triad
- Endocrinopathies: hyperparathyroidism, hyperthyroidism, hypercortisolism, diabetes mellitus
- Hematologic disorders: hemophilia, sickle cell disease, multiple myeloma, thalassemia, hemochromatosis
- Other disorders: multiple sclerosis, end stage renal disease, rheumatoid arthritis, lupus, chronic obstructive pulmonary disease (COPD), HIV/AIDS
- Medications: antiepileptics, aromatase inhibitors (raloxifene), chronic corticosteroids (>5 mg prednisone or equivalent for >3 months), medroxyprogesterone acetate, heparin, SSRI, thyroid hormone (in supraphysiologic doses), PPI

DIAGNOSIS

HISTORY

- Review modifiable and nonmodifiable risk factors.
- Online risk factor assessment tools are available:
  - FRAX: http://www.shef.ac.uk/FRAX/
- Assess for any commonly associated conditions.

PHYSICAL EXAM

- Thoracic kyphosis, poor balance, deconditioning
- Historical height loss >1.5 cm (difference between current height and peak height at age 20 years)
- Prospective height loss >2 cm (difference between current height and previously documented height)

DIFFERENTIAL DIAGNOSIS

- Multiple myeloma/other neoplasms
- Osteomalacia
- Type I collagen mutations
- Osteogenesis imperfecta

DIAGNOSTIC TESTS & INTERPRETATION

Dual-energy x-ray absorptiometry (DEXA) of the lumbar spine/hip is considered the gold standard for the diagnosis of osteoporosis.

Initial Tests (lab, imaging)

Consider in screening for secondary osteoporosis:

- Serum 25-hydroxyvitamin D and parathyroid hormone
- CBC
- Serum chemistry, including calcium, phosphorus, magnesium, total protein, albumin, liver enzymes, creatinine, alkaline phosphatase, and thyroid-stimulating hormone
- Urinalysis (24-hour collection) for calcium, sodium, and creatinine (to identify calcium malabsorption of hypercalciuria)
- DEXA of the lumbar spine/hip is the gold standard for measuring bone mineral density (BMD).
- A BMD at the hip or lumbar spine that is ≤2.5 standard deviations (SDs) below the mean BMD of a young-adult reference population is diagnostic of osteoporosis.
- A minimum of 2 years may be needed to reliably measure a change in BMD.
- BMD is expressed in terms of T-scores and *Z*-scores:
  - T-score is the number of SDs a patient's BMD deviates from the mean for young, normal (age 25 to 40 years) control individuals of the same sex.
  - WHO defines normal BMD as a T-score ≥−1, osteopenia as a T-score

between −1 and −2.5, and osteoporosis as a T-score ≤−2.5.
  - WHO thresholds can be used for postmenopausal women and men >50 years of age.
  - The *Z*-score is a comparison of the patient's BMD with an age-matched population.
  - A *Z*-score <−2 should prompt evaluation for causes of secondary osteoporosis.
- Quantitative ultrasound densitometry does not measure BMD directly but may be used clinically in predicting fractures in postmenopausal women and in men >65 years (2).
- Plain radiographs lack sensitivity to diagnose osteoporosis, but an abnormality (e.g., widened intervertebral spaces, rib fractures, vertebral compression fractures) should prompt evaluation.

Follow-Up Tests & Special Considerations

Further labs depending on initial evaluation, *Z*-score −2.5, or lower or young age.

- Iron and ferritin (hemochromatosis)
- Testosterone levels (hypogonadism in men)
- Serum protein electrophoresis and free κ and λ light chains (multiple myeloma)
- Urinary-free cortisol (Cushing disease)
- Tissue transglutaminase antibodies (celiac disease)
- Markers of bone resorption (urine *N*-telopeptides of type 1 collagen, serum C-telopeptides of type 1 collagen, serum *N*-terminal propeptide of type 1 procollagen): no prospective studies supporting use in osteoporosis diagnosis and management; potential role for identifying patients at high risk for fracture and monitoring response to therapy

Diagnostic Procedures/Other

Bone biopsy may be recommended for patients with bone disease and renal failure to establish the correct diagnosis as it can assess the degree of mineralization and microarchitecture and specific bone loss mechanisms.

Test Interpretation

- In osteoporosis, can see reduced skeletal mass; trabecular bone thinned or lost

more than cortical bone
- Can assess osteoclast and osteoblast relative activity
- Can rule out other metabolic bone diseases
- Can assess if bone marrow is normal or atrophic

TREATMENT

- Criteria for patients who benefit from Treatment for their Osteoporosis includes:
  - All patients with a T-score ≤−2.5 with no risk factors
  - All postmenopausal women who have had an osteoporotic vertebral/hip fracture
  - All postmenopausal women who have BMD values consistent with osteoporosis (T-score ≤2.5) at the lumbar spine, femoral neck, or total hip region
  - Postmenopausal women with T-scores from −1.0 to −2.5 and a 10-year risk, based on FRAX calculator, of an osteoporotic fracture (spine, hip, shoulder, and wrist) of at least 20% or hip of at least 3%
  - Treat men >50 years of age who present with a hip or vertebral fracture or a T-score <−2.5 after appropriate evaluation; however, evidence for the effectiveness of treatment of osteoporosis in men is limited.
    - For Osteopenia, treatment should ONLY focus on risk lowering: Weight bearing Exercise, A diet high in Calcium, Vitamin D supplementation, limiting alcohol and smoking cessation

MEDICATION

Calcium 1,200 mg/day and vitamin D 800 IU/day

First Line

- Bisphosphonates
  - Alendronate 10 mg PO daily or 70 mg PO weekly
  - Risedronate 5 mg PO daily, 35 mg PO weekly, 75 mg PO twice monthly, or 150 mg PO monthly
  - Ibandronate 150 mg PO once monthly or 3 mg IV every 3 months
  - Zoledronic acid 5 mg IV yearly

- These drugs become incorporated into skeletal tissue, where they inhibit the resorption of bone by osteoclasts (3,4).
- Alendronate, Risedronate, and zoledronic acid reduce the incidence of vertebral and nonvertebral fractures, while ibandronate reduces vertebral fracture only.
- Zoledronic acid appeared to be the most effective in preventing vertebral and nonvertebral fracture in a 2016 meta-analysis (5).
- The side effects are similar for all bisphosphonates and include gastrointestinal problems such as difficulty swallowing and inflammation of the esophagus and stomach.
- Osteonecrosis of the jaw has been associated with bisphosphonates, particularly in patients with cancer who receive high doses (6).
- There is a possible risk of midfemur fractures in patients receiving bisphosphonates for more than 5 years (7).
- Avoid oral bisphosphonates in patients with
  - Delayed esophageal emptying
  - Inability to stand/sit upright for at least 30 to 60 minutes after taking the bisphosphonates
  - Hypocalcemia (correct prior to initiating therapy)
  - Severe renal impairment (creatine clearance [CrCl] ≤30 to 35 mL/min for alendronate, risedronate, and ibandronate and ≤35 mL/min for zoledronic acid)

Second Line

- Raloxifene 60 mg PO daily
  - Selective estrogen receptor modulator with positive effects on BMD and vertebral fracture risk but no stimulatory action on breasts/uterus
  - Nonvertebral or hip fracture efficacy has not been demonstrated; increases risk of thromboembolism
  - Additional side effects include menopausal symptoms (hot flashes and night sweats).
- Teriparatide 20 mg SC daily
  - Recombinant formulation of PTH
  - Works anabolically to stimulate the growth of bone through osteoblastic activation

  - Studies have shown a reduction in the incidence of vertebral fractures by 65% and nonvertebral fractures by 53%.
  - No data exist on its safety and efficacy after >2 years of use (8).
- Denosumab: 60 mg SQ every 6 months
  - Human monoclonal antibody receptor activator of nuclear factor kappa-B ligand (RANKL) receptor
  - Inhibits osteoclast formation
- Estrogen 0.625 mg PO daily (with progesterone if patient has a uterus): effective in prevention and treatment of osteoporosis (34% reduction in hip and vertebral fractures after 5 years of use), but the risks (e.g., increased rates of myocardial infarction, stroke, breast cancer, pulmonary embolus, and deep vein thrombosis) must be weighed against the benefits
- Strontium 2 g PO daily
  - Appears to inhibit bone resorption and increase bone formation
  - Available for use in Europe
- Calcitonin
  - PTH antagonist that reduces osteoclastic activity, therefore decreasing bone turnover
  - FDA approved for treatment of osteoporosis in women who are at least 5 years postmenopausal when alternative treatments are not suitable
  - Calcitonin reduces vertebral fracture occurrence in those with prior vertebral.
  - Has been associated with an increased risk for malignancy

ISSUES FOR REFERRAL

Endocrinology for recurrent bone loss/fracture

ADDITIONAL THERAPIES

- Weight-bearing exercise 30 minutes 3 times per week
- Smoking cessation
- Physical therapy to help with muscle strengthening

SURGERY/OTHER PROCEDURES

Options for patients with painful vertebral compression fractures failing medical treatment:

- Vertebroplasty: Orthopedic cement is injected into the compressed vertebral body.
- Kyphoplasty: A balloon is expanded within the compressed vertebral body to reconstruct volume of vertebrae. Cement is injected into the space.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Isoflavones not better than placebo for fracture risk
- Beneficial effect of Chinese herbal medicines in improving BMD is still uncertain.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Inpatient care for pain control of acute back pain secondary to new vertebral fractures and for acute treatment of femoral and pelvic fractures
- Rehabilitation, nursing home, or home care may be needed following hospitalization for fractures.

 ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Weight-bearing exercises, such as walking, jogging, stair climbing, and tai chi, have been shown to decrease falls and fracture risk.
- Yearly height measurement is essential to determination of osteoporosis treatment efficacy. Patients who lose >2 cm in height should have repeat vertebral imaging to determine if any new vertebral fractures have occurred (2).
- While there is no consensus, most recommendations suggest BMD testing by DEXA scanning retesting 2 years after starting bisphosphonate therapy.
- For many women, 3 to 5 years of treatment with a bisphosphonate is as good as 10 years of treatment.
- A comprehensive risk assessment should be performed after 3 to 5 years of treatment. Those at high risk for vertebral fracture or with very low BMD may benefit by continuing treatment beyond 5 years.

- Physicians prescribing bisphosphonates should advise patients of the small risk of osteonecrosis and encourage dental examinations (2).

DIET

- Diet to maintain normal body weight
- Calcium and vitamin D (see "General Prevention")

PATIENT EDUCATION

National Osteoporosis Foundation: http://nof.org/

PROGNOSIS

- With treatment, 80% of patients stabilize skeletal manifestations, increase bone mass and mobility, and have reduced pain.
- 15% of vertebral and 20–40% of hip fractures may lead to chronic care and/or premature death.

COMPLICATIONS

Severe, disabling pain and recurrent fractures

CODES

ICD10

- M85.80 Other specified disorders of bone density and structure, unspecified site
- M81.0 Age-related osteoporosis w/o current pathological fracture
- M80.00XA Age-rel osteopor w current path fracture, unsp site, init

CLINICAL PEARLS

- Regular weight-bearing exercise from adolescence onward is recommended for prevention.
- Screen all women ≥65 years of age with DEXA scans.
- Premenopausal women with osteoporosis should be screened for secondary causes, such as malabsorption syndromes, hyperparathyroidism, hyperthyroidism, and medication sensitivity.
- Evaluate and treat all patients presenting with fractures from minimal trauma.
- Bisphosphonates are first line for treatment of osteoporosis in most patients.
- For Osteopenia, treat with weight bearing exercise, diet high in calcium, Vitamin D, limiting alcohol and smoking cessation
- If the patient is not responding to treatment, consider screening for a secondary, treatable cause of osteoporosis.

OTITIS EXTERNA

Douglas S. Parks, MD

BASICS

DESCRIPTION

Inflammation of the external auditory canal:

- Acute diffuse otitis externa: the most common form; an infectious process; usually bacterial; occasionally fungal (10%)
- Acute circumscribed otitis externa: synonymous with furuncle; associated with infection of the hair follicle, a superficial cellulitic form of otitis externa
- Chronic otitis externa: same as acute diffuse but of longer duration (>6 weeks)
- Eczematous otitis externa: may accompany typical atopic eczema or other primary skin conditions
- Necrotizing malignant otitis externa: an infection that extends into the deeper tissues adjacent to the canal; may include osteomyelitis and cellulitis; rare in children
- System(s) affected: skin/exocrine
- Synonym(s): swimmer's ear

EPIDEMIOLOGY

Incidence

- Unknown; higher in the summer months and in warm, wet climates
- Predominant age: all ages
- Predominant sex: male = female

Prevalence

- Acute, chronic, and eczematous: common
- Necrotizing: uncommon

ETIOLOGY AND PATHOPHYSIOLOGY

- Acute diffuse otitis externa
  - Traumatized external canal (e.g., from use of cotton swab)
  - Bacterial infection (90%): *Pseudomonas* (67%), *Staphylococcus*,

Streptococcus, gram-negative rods
  - Fungal infection (10%): *Aspergillus* (90%), *Candida*, *Phycomycetes*, *Rhizopus*, *Actinomyces*, *Penicillium*
- Chronic otitis externa: bacterial infection: *Pseudomonas*
- Eczematous otitis externa (associated with primary skin disorder)
  - Eczema
  - Seborrhea
  - Psoriasis
  - Neurodermatitis
  - Contact dermatitis
  - Purulent otitis media
  - Sensitivity to topical medications
- Necrotizing otitis externa
  - Invasive bacterial infection: *Pseudomonas*, increasing incidence of methicillin-resistant *Staphylococcus aureus* (MRSA)
  - Associated with immunosuppression

RISK FACTORS

- Acute and chronic otitis externa
  - Traumatization of external canal
  - Swimming
  - Hot, humid weather
  - Hearing aid use
- Eczematous: primary skin disorder
- Necrotizing otitis externa in adults
  - Advanced age
  - Diabetes mellitus (DM)
  - Debilitating disease
  - AIDS
  - Immunosuppression
- Necrotizing otitis externa in children (rare)
  - Leukopenia
  - Malnutrition
  - DM
  - Diabetes insipidus

GENERAL PREVENTION

- Avoid prolonged exposure to moisture.
- Use preventive antiseptics (acidifying solutions with 2% acetic acid [white vinegar] diluted 50/50 with water or isopropyl alcohol, or 2% acetic acid with aluminum acetate [less irritating]) after swimming and bathing.
- Treat predisposing skin conditions.
- Eliminate self-inflicted trauma to canal with cotton swabs and other foreign objects.
- Diagnose and treat underlying systemic conditions.
- Use ear plugs when swimming.

DIAGNOSIS

HISTORY

Variable-length history of itching, plugging of ear, ear pain, and discharge from ear

PHYSICAL EXAM

- Ear canal: red, containing purulent discharge and debris
- Pain on manipulation of the pinnae
- Possible periauricular adenitis
- Possible eczema of pinna
- Cranial nerve (VII, IX to XII) involvement (extremely rare)

DIFFERENTIAL DIAGNOSIS

- Idiopathic ear pain
- Otitis media with perforation
- Hearing loss
- Cranial nerve (VII, IX to XII) palsy with necrotizing otitis externa
- Wisdom tooth eruption
- Basal cell or squamous cell carcinoma

DIAGNOSTIC TESTS & INTERPRETATION

- Gram stain and culture of canal discharge (occasionally helpful)
- Antibiotic pretreatment may affect results.

- Radiologic evaluation of deep tissues in necrotizing otitis externa with high-resolution CT scan, MRI, gallium scan, and bone scan

Test Interpretation

- Acute and chronic otitis externa: desquamation of superficial epithelium of external canal with infection
- Eczematous otitis externa: pathologic findings consistent with primary skin disorder; secondary infection on occasion
- Necrotizing otitis externa: vasculitis, thrombosis, and necrosis of involved tissues; osteomyelitis

TREATMENT

Outpatient treatment, except for resistant cases and necrotizing otitis externa

GENERAL MEASURES

- Cleaning the external canal may facilitate recovery.
- Analgesics as appropriate for pain
- Antipruritic and antihistamines (eczematous form)
- Ear wick (Pope) for nearly occluded ear canal

MEDICATION

- Trial data is of generally poor quality and may not be fully relevant to primary care settings (1)[A].
- Resistance is an increasing problem. *Pseudomonas* is the most common bacteria, and it is more susceptible to fluoroquinolones such as ciprofloxacin or ofloxacin, whereas *Staphylococcus* is equally susceptible to both fluoroquinolones and polymyxin B combinations (2)[B]. If a patient has recurring episodes or is not improved in 2 weeks, change the class of antibacterial and consider cultures and sensitivities.
- There is evidence that using of a topical antibiotic with a corticosteroid shortens time to symptom resolution, although there is no evidence that it increases overall cure rate. There is not enough evidence to demonstrate that any antibiotic regimen is clearly superior to any other (3)[B].
- Oral antibiotics are indicated only if there is associated otitis media. Oral

antibiotics alone are not effective and markedly increase the risk of progressing to chronic otitis externa.

- Analgesics as needed; narcotics may be necessary. Recurrent otitis externa may be prevented by applying equal parts white vinegar and isopropyl alcohol (over-the-counter [OTC] rubbing alcohol) to external auditory canals after bathing and swimming.

First Line

- Acute bacterial and chronic otitis externa
  - Ciprofloxacin 0.3% and dexamethasone 0.1% suspension (expensive as brand): 4 drops BID for 7 days or ofloxacin: 0.3% solution (inexpensive generic) 10 drops once a day for 7 days (1)[A]. Less ototoxicity and reported antibiotic resistance (4)[A].
  - Neomycin/polymyxin B/hydrocortisone (Cortisporin, generics): 5 drops QID. If the tympanic membrane is ruptured, use the suspension; otherwise, the solution may be used; may be ototoxic and resistance-developing in *Staphylococcus* and *Streptococcus* sp. (5)[B]; not expensive
  - Acetic acid 2% with hydrocortisone 1%: 3 to 5 drops q4–6h for 7 days; may cause minor local stinging. An inexpensive generic. This is as effective as neomycin–polymyxin B (6)[B]. It may take up to 2 days longer to achieve resolution of symptoms (3)[A]. A wick may be helpful in severe cases by keeping the canal open and keeping antibiotic solution in contact with infected skin.
- Fungal otitis externa
  - Topical therapy, antiyeast for *Candida* or yeast: 2% acetic acid 3 to 4 drops QID; clotrimazole 1% solution; itraconazole oral
  - Parenteral antifungal therapy: amphotericin B
  - Patients with Ramsay-Hunt syndrome: acyclovir IV
- Eczematous otitis externa: topical therapy
  - Acetic acid 2% in aluminum acetate
  - Aluminum acetate (5%; Burow solution)
  - Steroid cream, lotion, ointment (e.g., triamcinolone 0.1% solution)
  - Antibacterial, if superinfected
- Necrotizing otitis externa

- Parenteral antibiotics: antistaphylococcal and antipseudomonal
- 4 to 6 weeks of therapy
- Fluoroquinolones PO for 2 to 4 weeks

Second Line

- Acute bacterial and chronic otitis externa
  - Betamethasone 0.05% solution may be as effective as a polymyxin B combination without the risk of ototoxicity or antibiotic resistance. However, the data are not very robust, and more study is needed (3)[A].
- Azole antifungals for fungal otitis externa

ISSUES FOR REFERRAL

Resistant cases or those requiring surgical intervention

SURGERY/OTHER PROCEDURES

For necrotizing otitis externa or furuncle

COMPLEMENTARY & ALTERNATIVE MEDICINE

- OTC white vinegar; 3 drops in affected ear for minor case
- Tea tree oil in various concentrations has been used as an antiseptic. Ototoxicity has been reported in animal studies at very high doses.
- Grapefruit seed extract in various concentrations has been described as useful in the lay literature.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Admission criteria/initial stabilization: necrotizing otitis media requiring parenteral antipseudomonal antibiotics
- Discharge criteria: resolution of infection

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

No restrictions

Patient Monitoring

- Acute otitis externa
  - 48 hours after therapy instituted to assess improvement
  - At the end of treatment
- Chronic otitis externa
  - Every 2 to 3 weeks for repeated cleansing of canal
  - May require alterations in topical medication, including antibiotics and steroids
- Necrotizing otitis externa
  - Daily monitoring in hospital for extension of infection
  - Baseline auditory and vestibular testing at beginning and end of therapy

DIET

No restrictions

PROGNOSIS

- Acute otitis externa: rapid response to therapy with total resolution
- Chronic otitis externa: With repeated cleansing and antibiotic therapy, most cases will resolve. Occasionally, surgical intervention is required for resistant cases.
- Eczematous otitis externa: Resolution will occur with control of the primary skin condition.
- Necrotizing otitis externa: usually can be managed with débridement and antipseudomonal antibiotics; recurrence rate is 100% when treatment is inadequate. Surgical intervention may be necessary in resistant cases or if there is cranial nerve involvement. Mortality rate is significant, probably secondary to the underlying disease.

COMPLICATIONS

- Mainly a problem with necrotizing otitis externa; may spread to infect contiguous bone and CNS structures
- Acute otitis externa may spread to pinna, causing chondritis.

Algorithm: Ear Pain

CODES

ICD10

- H60.90 Unspecified otitis externa, unspecified ear
- H60.339 Swimmer’s ear, unspecified ear

- H60.509 Unsp acute noninfective otitis externa, unspecified ear

CLINICAL PEARLS

- Acute diffuse otitis externa is the most common form: bacterial (90%), occasionally fungal (10%).
- Acute circumscribed otitis externa is associated with infection of a hair follicle.
- Chronic otitis externa is the same as acute diffuse but of longer duration (>6 weeks).
- Eczematous otitis externa may accompany typical atopic eczema or other primary skin conditions.
- Necrotizing malignant otitis externa is an infection that extends into the deeper tissues adjacent to the canal. It may include osteomyelitis and cellulitis; it is rare in children.

OTITIS MEDIA

Paul George, MD, MHPE

BASICS

DESCRIPTION

- Inflammation of the middle ear; usually accompanied by fluid collection
- Acute otitis media (AOM): inflammation of the middle ear. Rapid onset; cause may be infectious, either viral (AOM-v) or bacterial (AOM-b), but there is also a sterile etiology (AOM-s).
- Recurrent AOM: ≥3 episodes in 6 months or ≥4 episodes in 1 year with ≥1 in the past 6 months
- Otitis media with effusion (OME): fluid in the middle ear without signs or symptoms of infection
- Chronic otitis media with or without cholesteatoma
- System(s) affected: nervous, ENT
- Synonym(s): secretory or serous otitis media

EPIDEMIOLOGY

Incidence

- AOM
  - Predominant age: 6 to 24 months; declines >7 years; rare in adults
  - Predominant gender: male > female
  - By age 7 years, 93% of children have had ≥1 episodes of AOM; 39% have had ≥6.
  - Placement of tympanostomy tubes is second only to circumcision as the most frequent surgical procedure in infants.
  - Increased incidence in the fall and winter
- OME
  - By age 4 years, 90% of children have had at least one episode.

Prevalence

- Most common infection for which antibacterial agents are prescribed in the United States

- Diagnosed 5 million times per year in the United States

ETIOLOGY AND PATHOPHYSIOLOGY

- AOM-b (bacterial): usually, a preceding viral upper respiratory infection (URI) produces eustachian tube dysfunction
  - *Streptococcus pneumoniae*: 20–35%, *Haemophilus influenzae*: 20–30%, *Moraxella* (*B.*) *catarrhalis*: 15%, group A streptococci: 3%, *Staphylococcus aureus*: 12% produce β-lactamases that hydrolyze amoxicillin and some cephalosporins.
- AOM-v (viral): 15–44% of AOM infections are caused primarily by viruses (e.g., respiratory syncytial virus, parainfluenza, influenza, enteroviruses, adenovirus, human metapneumovirus, and parechovirus).
- AOM-s (sterile/nonpathogens): 25–30%
- OME: Eustachian tube dysfunction; allergic causes are rarely substantiated.

Genetics

- Strong genetic component in twin studies for recurrent and prolonged AOM
- May be influenced by skull configuration or immunologic defects

RISK FACTORS

- Age
- Bottlefeeding while supine
- Routine daycare attendance
- Frequent pacifier use after 6 months of age
- Environmental smoke exposure
- Male gender
- Absence of breastfeeding
- Low socioeconomic status
- Family history of recurrent otitis
- AOM before age 1 year is a risk for recurrent AOM.
- Presence of siblings in the household
- Underlying ENT disease (e.g., cleft palate, Down syndrome, allergic rhinitis)

GENERAL PREVENTION

- Pneumococcal vaccine (PCV)-7 immunization reduces the number of cases of AOM by about 6–28% (however, evidence shows that this is offset by an

increase in AOM caused by other bacteria). The effect of the introduction of the PCV-13 vaccine on the incidence of AOM has yet to be studied (1,2)[B].

- Influenza vaccine reduces AOM.
- Breastfeeding for ≥6 months is protective.
- Avoiding supine bottlefeeding, passive smoke, and pacifiers >6 months may be helpful.
- Secondary prevention: Adenoidectomy and adenotonsillectomy for recurrent AOM has limited short-term efficacy and is associated with its own adverse risks.
- Vitamin D supplementation (1,000 U/day to maintain vitamin D levels >30) may be helpful in reducing recurrent AOM (3)[B], but further trials are needed.

COMMONLY ASSOCIATED CONDITIONS

URI

DIAGNOSIS

HISTORY

- AOM: acute history, signs, and symptoms of middle ear inflammation and effusion
  - Earache
  - Preceding or accompanying URI symptoms
  - Decreased hearing
- In adults, earache without fever or hearing loss may be the only presenting feature.

ALERT

- AOM in infants and toddlers:
  - May cause few symptoms in the first few months of life
  - Irritability may be the only symptom.
- OME: usually asymptomatic
  - Decreased hearing

PHYSICAL EXAM

- Infectious AOM:
  - Fever (not required for diagnosis)
  - Decreased eardrum mobility (with pneumatic otoscopy)
  - Moderate to severe bulging of tympanic membrane
  - Otorrhea
  - Redness alone is not a reliable sign.
- OME:
  - Eardrum often dull but not bulging
  - Decreased eardrum mobility (pneumatic otoscopy)
  - Presence of air-fluid level
  - Weber test is positive to affected ear for an ear with effusion.

DIFFERENTIAL DIAGNOSIS

- Tympanosclerosis
- Trauma
- Referred pain from the jaw, teeth, or throat
- TMJ in adults
- Otitis externa
- Otitis-conjunctivitis syndrome
- Temporal arteritis in adults

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

WBC count may be higher in bacterial AOM than in sterile AOM, but this is almost never useful.

Diagnostic Procedures/Other

- To document the presence of middle ear fluid, pneumatic otoscopy can be supplemented with tympanometry and acoustic reflex measurement.
- Hearing testing is recommended when hearing loss persists for ≥3 months or at any time suspecting language delay, significant hearing loss, or learning problems.
- Language testing should be performed for children with hearing loss.
- Tympanocentesis for microbiologic diagnosis is recommended for treatment failures; may be followed by myringotomy

TREATMENT

- Significant disagreement exists about the usefulness of antibiotic treatment for this often self-resolving condition. Studies suggest that ~15 children need to be treated with antibiotics to prevent one case of persisting AOM pain at 1 to 2 weeks; the number needed to treat to cause harm (primarily diarrhea) is 8 to 10 (2)[B].
- If antibiotics are not used, 81% of patients >2 years of age are better in 1 week versus 94% if antibiotics are used.
- Delay of antibiotics found a modest increase in mastoiditis from 2/100,000 to 4/100,000.
- American Academy of Pediatrics/American Academy of Family Physicians (AAP/AAFP) guidelines recommend the following for observation versus antibacterial therapy, although these guidelines are not rigorously evidence based (2)[B]:
  - <6 months of age: no recommendation (2004 guidelines suggest treatment with antibiotic therapy to any child diagnosed with otitis media <6 months of age)
  - >6 months: Antibacterial therapy is recommended when the diagnosis with severe otitis media (i.e., moderate to severe otalgia or fever ≥39°C in the previous 24 hours) or otorrhea or bilateral otitis media between 6 months and 2 years of age.
  - Observation is an option with nonsevere otitis media.
- OME: Watchful waiting for 3 months per AAP/AFPP guidelines for those not at risk (see "Complications"). Of these cases, 25–90% will recover spontaneously over this period; no benefit of antihistamines or decongestants or systemic steroids (4)[A], nor significant net benefit for antibiotics (5)[A]

GENERAL MEASURES

- Assess pain.
- Although unusual in adults, the treatment is the same.
- Acetaminophen, ibuprofen, benzocaine drops (additional but brief benefit over acetaminophen)

MEDICATION

First Line

- AOM: AAP/AAFP consensus guideline recommends amoxicillin, 80 to 90 mg/kg/day in 2 divided doses (6)[A] OR
- Amoxicillin-clavulanate 90 mg/kg/day of amoxicillin, with 6.4 mg/kg/day of clavulanate in 2 divided doses; recommended in children who have taken amoxicillin in the previous 30 days and those with concurrent conjunctivitis or history of AOM unresponsive to amoxicillin
- Treatment duration: 10-day course for children <2 years; 7-day course for children 2 to 5 years; 5- to 7-day course for children 6 years and older
- If penicillin allergic:
  - Non–type 1 hypersensitivity reaction: cefdinir, 14 mg/kg/day in 1 to 2 doses; cefpodoxime, 10 mg/kg/day BID; or cefuroxime 30 mg/kg/day BID
  - Type 1 hypersensitivity to penicillin: azithromycin (10 mg/kg/day [max dose 500 mg/day] as a single dose on day 1 and 5 mg/kg/day [max dose 250 mg/day] for days 2 to 5)
- A single dose of parenteral ceftriaxone (50 mg/kg) is as effective as a full course of antibiotics in uncomplicated AOM.
- A single dose of azithromycin has been approved by the FDA, but studies did not include otitis-prone children or have criteria for AOM diagnosis.
- Consider treatment of children between ages 6 months and 2 years with antibiotics to reduce duration of symptoms (7)[A].
- OME: See "General Measures"; no benefit to treatment. Medications promote transitory resolution in 10–15%, but the effect is short-lived.

Second Line

- Alternative antibiotics are indicated for the following AOM patients:
  - Persistent symptoms after 48 to 72 hours of amoxicillin
  - AOM within 1 month of amoxicillin therapy
  - Severe earache
  - Age <6 months with high fever
  - Immunocompromised
    - Amoxicillin-clavulanate, 90 mg/kg to 6.4 mg/kg/day, divided BID
    - Ceftriaxone, 50 mg/kg IM or IV q24h for 3 consecutive days can be reserved for those who are too sick to take oral medications or who

unsuccessfully took amoxicillin-clavulanate. Neither erythromycin-sulfisoxazole nor trimethoprim-sulfamethoxazole should be used as a second-line agent in treatment failures.

- Recurrent AOM: Antibiotic prophylaxis for recurrent AOM (>3 distinct, well-documented episodes in 6 months) is not recommended.

SURGERY/OTHER PROCEDURES

- Recurrent AOM: Consider referral for surgery if ≥3 episodes of well-documented AOM within 6 months, ≥4 episodes within 12 months with ≥1 episode in previous 6 months, or AOM episodes occur while on chemoprophylaxis.
- Tympanostomy tubes may be effective in selective patients, particularly children age <2 years with recurrent AOM (8)[A].
- Adenoidectomy has limited or no effect.
- Adenotonsillectomy reduced the rate of AOM by 0.7 episode per child only in the 1st year after surgery and had a 15% complications rate.
- OME: Referral for surgery for tympanostomy should be individualized. It can be considered if >4 to 6 months of bilateral OME and/or >6 months of unilateral OME and/or hearing loss >25 dB or for high-risk individuals at any time.
- Tympanostomy tubes may reduce recurrence of AOM minimally, but it does not lower the risk of hearing loss (9)[A].
- Adenoidectomy is indicated in specific cases; tonsillectomy or myringotomy is never indicated.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- It is unclear whether alternative and homeopathic therapies are effective for AOM, including mixed evidence about the effectiveness of zinc supplementation of reducing AOM.
- Xylitol, probiotics, herbal ear drops, and homeopathic interventions may be beneficial in reducing pain duration, antibiotic use, and bacterial resistance.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Outpatient, except if surgery is indicated, or for AOM in febrile infants age <2

months or children requiring ceftriaxone who also require monitoring for 24 hours

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patients with otitis media who do not respond within 48 to 72 hours should be reevaluated:

- If therapy was delayed and diagnosis is confirmed, start therapy with high-dose amoxicillin.
- If therapy was initiated, consider changing the antibiotic; options are limited because macrolides have limited benefit against *Haemophilus influenzae* over amoxicillin, and most oral cephalosporins have no improved outcomes.

Patient Monitoring

- AOM: Up to 40% may have persistent middle ear effusion at 1 month, with 10–25% at 3 months.
- OME: Repeat otoscopic or tympanometric exams at 3 months, as indicated, as long as OME persists or sooner if there are red flags (see earlier discussion).

PROGNOSIS

- See "General Measures."
- Recurrent AOM and OME: Usually subsides in school-aged children; few have complications.

COMPLICATIONS

- AOM: Serious complications are rare: tympanic membrane perforation/otorrhea, acute mastoiditis, facial nerve paralysis, otitic hydrocephalus, meningitis, hearing impairment.
- OME: Speech and language disabilities may occur. Hearing loss is not caused by OME, but in children who are at risk for speech, language, or learning problems (e.g., autism spectrum, syndromes, craniofacial disorders, developmental delay, and children already with speech/language delay), it could lead to further problems because they are less tolerant of a hearing impairment.

- Recurrent AOM and OME: atrophy and scarring of eardrum, chronic perforation and otorrhea, cholesteatoma, permanent hearing loss, chronic mastoiditis, other intracranial suppurative complications

SEE ALSO

Algorithm: Ear Pain

CODES

ICD10

- H66.90 Otitis media, unspecified, unspecified ear
- H66.40 Suppurative otitis media, unspecified, unspecified ear
- H65.199 Other acute nonsuppurative otitis media, unspecified ear

CLINICAL PEARLS

- Pneumatic otoscopy is the single most specific and clinically useful test for diagnosis.
- Consider a delay of antibiotics for 24 to 48 hours in uncomplicated presentations (>6 months of age) who do not have severe illness or otorrhea.
- First-line treatment is amoxicillin, 80 to 90 mg/kg/day for 10 days for children age <2 years; consider a 5- to 7-day course in >2 years of age.
- Erythema and effusion can persist for weeks.
- Antibiotics, antihistamines, and steroids are not indicated for OME.
- OME rarely develops in adults. Persistent unilateral effusion should be investigated to rule out neoplasm, particularly if there is a cranial nerve palsy.

OTITIS MEDIA WITH EFFUSION

Hobart Lee, MD, FAAFP

BASICS

DESCRIPTION

- Also called serous otitis media, secretory otitis media, nonsuppurative otitis media, “ear fluid,” or “glue ear”
- Otitis media with effusion (OME) is defined as the presence of fluid in the middle ear in the absence of acute signs or symptoms of infection.
- More commonly, a pediatric disease
- May occur spontaneously from poor eustachian tube function or as an inflammatory response after acute otitis media

EPIDEMIOLOGY

Incidence

Approximately 90% of children have OME before school age, mostly between the ages of 6 months and 4 years.

Prevalence

- Approximately 2.2 million new cases annually in the United States
- Less prevalent in adults and is usually associated with an underlying disorder

ETIOLOGY AND PATHOPHYSIOLOGY

- Chronic inflammatory condition where an underlying stimulus causes an inflammatory reaction with increased mucin production creating a functional blockage of the eustachian tube and thick accumulation of mucin-rich middle ear effusion
- Young children are more prone to OME due to shorter and more horizontal eustachian tubes, which become more vertical around 7 years of age.
- Biofilms, anatomic variations, and acute otitis media (AOM) caused by viruses or bacteria have been implicated as stimuli causing OME. The common pathogens causing AOM include nontypeable *Haemophilus influenzae*, *Streptococcus pneumoniae*, and *Moraxella catarrhalis*.

- In adults, OME is often associated with paranasal sinus disease (66%), smoking-induced nasopharyngeal lymphoid hyperplasia and adult onset adenoidal hypertrophy (19%), or head and neck tumors (4.8%).

RISK FACTORS

- Risk factors include a family history of OME, early daycare, exposure to cigarette smoke, bottlefeeding, and low socioeconomic status (1).
- Eustachian tube dysfunction may be a predisposing factor, although the evidence is unclear (2).
- Gastroesophageal reflux is associated with OME (2).

GENERAL PREVENTION

OME is generally not preventable, although lowering smoke exposure, breastfeeding, and avoiding daycare centers at an early age may decrease the risk.

DIAGNOSIS

HISTORY

- OME is transient and asymptomatic in many pediatric patients.
- Most common reported symptom is hearing loss (2). There may be mild discomfort present in the ear, fullness, or “popping.”
- Infants may have ear rubbing, excessive irritability, sleep problems, or failure to respond appropriately to voices or sounds.
- Clinical features may include “a history of hearing difficulties, poor attention, behavioral problems, delayed speech and language development, clumsiness, and poor balance” (2).
- There may be a history of recent or recurrent episodes of acute otitis media or a recent upper respiratory tract infection (2).

PHYSICAL EXAM

- Cloudy tympanic membrane (TM) with distinctly impaired mobility. Air-fluid level or bubble may be visible in the middle ear (1,2).
- Color may be abnormal (yellow, amber, or blue), and the TM may be retracted or concave (2).

- Distinct redness of the tympanic membrane may be present in approximately 5% of OME cases (1).
- Clinical signs and symptoms of acute illness should be absent in patients with OME (1).

DIFFERENTIAL DIAGNOSIS

- Acute otitis media
- Bullous myringitis
- Tympanosclerosis (may cause decreased/absent motion of the TM)
- Sensorineural hearing loss

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other

- The primary standard to make the diagnosis is pneumatic otoscopy, which demonstrates reduced/absent mobility of the TM secondary to fluid in the middle ear. Pneumatic otoscopy has 94% sensitivity and 80% specificity for diagnosing OME. Accuracy of diagnosis with an experienced examiner is between 70% and 79% (1)[C].
- Myringotomy is the gold standard but is not practical for clinical use (2)[C].
- Tympanometry may also be used to support or exclude the diagnosis in infants >4 months old, especially when the presence of middle ear effusion is difficult to determine (1)[C].
- Acoustic reflectometry (64% specificity and 80% sensitivity) may be considered instead of tympanometry (3)[B].
- Audiogram may show mild conductive hearing loss (2)[C].
- Hearing tests are recommended for OME lasting >3 months (1)[C].
- Language testing is recommended for children with abnormal hearing tests (1)[C].

TREATMENT

- OME improves or resolves without medical intervention in most patients within 3 months, especially if secondary to AOM (1)[C].
- Current guidelines support a 3-month period of observation with optional serial exams, tympanometry, and language assessment during that wait time

(1,2)[C].

- Adults found to have OME should be screened for an underlying disorder and treated accordingly (2)[C].

MEDICATION

- The 2016 AAOHNS/AAFP/AAP guideline and a 2012 Cochrane review recommend against routine use of antibiotics in treatment of OME. No long-term benefits of antibiotics have been proven, and often, prescribed antibiotics have adverse side effects such as diarrhea, vomiting, rashes, and allergic reactions (1)[C],(4)[A].
- The 2016 AAOHNS/AAFP/AAP and a 2006 Cochrane review found that antihistamines and decongestants have no benefit over placebo in the treatment of OME with possible adverse side effects such as insomnia, hyperactivity, and drowsiness (4)[A],(5)[C].
- The 2016 AAOHNS/AAFP/AAP guideline recommends against administering oral or intranasal corticosteroids. No long-term benefit was shown and adverse side effects such as weight gain and behavioral changes are possible (5)[C].
- In adults, eustachian tube dysfunction secondary to allergic rhinitis or recent upper respiratory infection can be the cause of OME. It is unknown whether decongestants, antihistamines, or nasal steroids improve outcomes in adults.

ISSUES FOR REFERRAL

The following are indications for referral to a surgeon for evaluation of tympanostomy tube placement (6)[C]:

- Chronic bilateral OME (≥3 months) with hearing difficulty
- Chronic OME with symptoms (e.g., vestibular problems, poor school performance, behavioral issues, ear discomfort, or reduced quality of life)
- At-risk children (speech, language, or learning problems due to baseline sensory, physical, cognitive, or behavioral factors) with chronic OME or type B (flat) tympanogram

ADDITIONAL THERAPIES

- Hearing aids may be an acceptable alternative to surgery (2)[C].
- Autoinflation, which refers to the process of opening the eustachian tube by

raising intranasal pressure (e.g., by forced exhalation with closed mouth and nose) may be beneficial in improving patients' tympanogram or audiometry and quality of life scores (6)[A].

SURGERY/OTHER PROCEDURES

- Tympanostomy tubes are recommended as initial surgery. Risks include purulent otorrhea, myringosclerosis, retraction pockets, and persistent tympanic membrane perforations (1,2,5)[C].
- Adenoidectomy with myringotomy has similar efficacy to tympanostomy tubes in children >4 years of age but with added surgical and anesthetic risks (1)[C].
- Adenoidectomy should not be performed in children with persistent OME alone unless there is a distinct indication for the procedure for another problem (e.g., adenoiditis/chronic sinusitis/nasal obstruction) (1,5)[C].
- Adenoidectomy (and concurrent tube placement) may be considered when repeat surgery for OME is necessary (e.g., when effusion recurs after tubes have fallen out or are removed). In these cases, adenoidectomy has been shown to decrease the need for future procedures for OME (1,2)[C].
- Tonsillectomy or myringotomy alone is not recommended for treatment (1)[C].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Children who are at risk for developmental difficulties should be evaluated for OME at the time of diagnosis and at 12 to 18 months (if initial diagnosis occurred younger than 12 months). At risk conditions include permanent hearing loss independent of OME, suspected or confirmed speech and language delay, autism spectrum disorder or other pervasive developmental disorder, Down syndrome or other craniofacial disorder, blindness or other uncorrectable visual impairment, cleft palate, unspecified developmental delay (5)[C].
- For patients diagnosed with OME, reevaluation and repeat hearing tests

should be performed every 3 to 6 months until the effusion has resolved or until the child develops an indication for surgical referral (1)[C].

PROGNOSIS

Approximately 50% of children >3 years of age have OME resolution within 3 months.

COMPLICATIONS

- The most significant complication of OME is permanent hearing loss, leading to possible language, speech, and developmental delays.
- Underventilation of the middle ear can cause a cholesteatoma (1)[C].

CODES

ICD10

- H65.90 Unspecified nonsuppurative otitis media, unspecified ear
- H65.00 Acute serous otitis media, unspecified ear
- H65.20 Chronic serous otitis media, unspecified ear

CLINICAL PEARLS

- OME is defined as the presence of a middle ear effusion in the absence of acute signs of infection.
- In children, OME most often arises following an acute otitis media. In adults, it often occurs in association with eustachian tube dysfunction.
- The primary standard for diagnosis is pneumatic otoscopy.
- There is no benefit to the routine use of antibiotics, antihistamines, decongestants, or corticosteroids for the treatment of OME in children.

- Management includes watchful waiting and surgery (when indicated); which strategy is chosen depends on many factors, including the risk/presence of any associated speech, language, or learning delays, and on the severity of any associated hearing loss.

OVARIAN CANCER

Celeste E. Straight, MD • Susan Zweizig, MD

BASICS

There are >22,000 new cases of ovarian cancer annually, and approximately 15,000 women will die of their disease, making this the most lethal of gynecologic cancers. This accounts for 2.4% of all cancer deaths nationally.

DESCRIPTION

Malignancy that arises from the epithelium (90%), stroma, or germ cells of the ovary as well as tumors metastatic to the ovary

Histologic types include the following:

- Epithelial
  - Serous (tubal epithelium)
  - Mucinous (cervical and GI mucinous epithelium)
  - Endometrioid (endometrial epithelium)
  - Clear cell (mesonephroid)
  - Brenner (transitional cell epithelium)
  - Carcinosarcoma
- Stromal
  - Granulosa cell tumor
  - Theca cell tumor
  - Sertoli–Leydig cell tumors
  - Gynandroblastoma
  - Lipid cell tumor
- Germ cell
  - Teratoma (immature)
  - Dysgerminoma
  - Embryonal carcinoma
  - Gonadoblastoma
  - Endodermal sinus tumor
  - Embryonal carcinoma
  - Choriocarcinoma

- Metastatic disease from the following:
  - Breast
  - Endometrium
  - Lymphoma
  - GI tract (Krukenberg tumor)
  - Primary peritoneal
- System(s) affected: GI; reproductive; endocrine; metabolic

EPIDEMIOLOGY

Incidence

- 22,280 new cases/year in the United States; 14,240 deaths/year
- Leading cause of gynecologic cancer death in women; mortality from ovarian cancer has decreased only slightly during the past 4 decades (1)[A].
- 75% diagnosed at advanced stage
- Predominant age
  - Epithelial: mid-50s
  - Germ cell malignancies: usually observed in patients <20 years of age

Prevalence

Lifetime risk for general population: 1 in 70 women develop ovarian cancer.

ETIOLOGY AND PATHOPHYSIOLOGY

- Malignant transformation of the ovarian epithelium from repeated trauma during ovulation may lead to this change. Many of these cancers originate in the distal fallopian tube.
- Most ovarian cancer (75%) presents as advanced disease. Metastatic disease may develop at the same time as the primary tumor (1).

Genetics

- Hereditary breast/ovarian cancer syndrome: early-onset breast or ovarian cancer, autosomal dominant transmission, usually associated with *BRCA-1* or *BRCA-2* mutation
- Lynch II syndrome: autosomal dominant inheritance; increased risk for colorectal, endometrial, stomach, small bowel, breast, pancreas, and ovarian cancers; defect in mismatch repair genes

RISK FACTORS

- 90% of ovarian cancer is sporadic and not inherited, but family history is the most significant risk factor. Multiple relatives with breast or ovarian cancer increases risk: Refer these patients for genetic counseling. Individuals in families with familial cancer syndromes have 20–60% risk of developing ovarian cancer.
- Nulligravidity (or infertility), early menarche, late menopause, endometriosis
- Environmental (talc, smoking, obesity)

GENERAL PREVENTION

For epithelial cancer, frequency of ovulation appears to be important. The following factors are protective (1)[A]:

- Use of oral contraceptives: 5 years of use decreases risk by 20%; 15 years by 50%
  - The progestin component of oral contraceptive preparations (OCPs) may protect against ovarian cancer by regulating apoptosis of the ovarian epithelium (2)[A].
- Multiparity
- Breastfeeding
- Tubal ligation or hysterectomy
- Recent studies have shown no clear association exists between ovarian cancer and use of ovulation-induction agents such as clomiphene, but more long-term studies are necessary.
- NSAIDs and acetaminophen use have been shown to reduce risk of ovarian cancer.
- Recommendations for high-risk (family history of a hereditary ovarian cancer syndrome) population
  - Women should undergo pelvic examinations, CA-125 level measurement, and transvaginal US every 6 to 12 months beginning at age 25 to 35 years.
  - Women with family histories of ovarian cancer or premenopausal breast cancer should be referred for genetic counseling.
  - Prophylactic oophorectomy is advised for mutation carriers after childbearing is completed or by age 35 years.
    - Risk of primary peritoneal carcinoma remains 1% after prophylactic

oophorectomy.

- Screening: No effective screening exists for ovarian cancer (1)[A].
  - Routine use of CA-125 and transvaginal US for screening in women of average risk is discouraged. Annual pelvic examinations are recommended, particularly in postmenopausal women. An adnexal mass in a premenarchal female or a palpable adnexa in a postmenopausal female warrants further evaluation.

COMMONLY ASSOCIATED CONDITIONS

- Ascites
- Pleural effusion
- Decrease of serum albumin
- Breast carcinoma
- Bowel obstruction
- Carcinomatosis

DIAGNOSIS

HISTORY

- Bloating
- Early satiety, anorexia, dyspepsia
- Sense of abdominal fullness, increased abdominal size
- Abdominopelvic pain or cramping
- Urinary frequency or urgency in absence of infection
- Fatigue
- Dyspareunia
- Weight loss
- Severe pain secondary to ovarian rupture or torsion; most frequent in germ cell tumors
- Precocious puberty (choriocarcinoma, embryonal carcinoma) (3)[B]

PHYSICAL EXAM

- Ascites
- Cul-de-sac and/or pelvic nodularity
- Pelvic mass

- Pleural effusion
- Omental mass
- Cachexia
- Adenopathy
- Hirsutism in androgen-secreting germ cell tumors

DIFFERENTIAL DIAGNOSIS

- GI, fallopian, or endometrial malignancies
- Irritable bowel syndrome
- Colitis
- Hepatic failure with ascites
- Diverticulitis
- Pelvic kidney
- Tubo-ovarian abscess or hydrosalpinx
- Uterine fibroids
- Endometriomas
- Physiologic cysts
- Benign or borderline neoplasms

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Obtain with confirmed or suspected disease.
- CA-125 (not specific for ovarian cancer)
- Liver function tests (LFTs) to rule out hepatic disease
- CBC
- Urinalysis
- Serum albumin
- Carcinoembryonic antigen (CEA) if GI primary suspected
- If nonepithelial tumor suspected: chorionic gonadotropin (β-hCG [dysgerminoma, choriocarcinoma, embryonal carcinoma]), α-fetoprotein (endodermal sinus tumor, embryonal carcinoma), lactate dehydrogenase (LDH [dysgerminoma]), or inhibin (granulosa cell tumor)
- Pelvic US
- CXR
- Abdominopelvic CT scan with contrast material

Follow-Up Tests & Special Considerations

Disorders that may alter lab results: CA-125 may be elevated from gynecologic causes (e.g., menses, pregnancy, endometriosis, peritonitis, myomas, pelvic inflammatory disease) and with ascites, pleural effusion, congestive heart failure (CHF), pancreatitis, systemic lupus erythematosus (SLE), or liver disease.

- Patients with ovarian cancer need current mammography.
- Barium enema or colonoscopy if a colon primary is suspected

Diagnostic Procedures/Other

- Endometrial biopsy if abnormal bleeding present
- Surgery is necessary for definitive diagnosis.
- Paracentesis or thoracentesis if patient with symptomatic ascites and not an operative candidate

Test Interpretation

Epithelial ovarian cancer commonly involves the peritoneal surfaces of the abdomen and pelvis, especially the cul-de-sac, paracolic gutters, and diaphragmatic surfaces.

TREATMENT

MEDICATION

First Line

- After surgery, most patients will require chemotherapy or adjuvant therapy. Stage 1a, grade 1, and most stage 1b, grade 1, tumors do not require adjuvant therapy. Patients with clear cell carcinomas, grade 3 tumors, or tumors staged 1c or worse do require adjuvant therapy. Patients should be encouraged to participate in clinical trials whenever possible.
- Paclitaxel (Taxol) or docetaxel are recommended in combination with platinum-based therapy (carboplatin or cisplatin) as the first-line treatment of epithelial ovarian cancer.
- Intraperitoneal (IP) chemotherapy in combination with IV chemotherapy improves survival in advanced ovarian cancer. IP chemotherapy is associated with more toxicity (4)[A].

- Germ cell cancers: bleomycin, etoposide, and platinum agent
- Contraindications: poor functional status, excessive toxicity, hypersensitivity
- Precautions: All regimens cause bone marrow suppression. Cisplatin is associated with ototoxicity, renal toxicity, and peripheral neuropathy. Taxol can cause neutropenia and neuropathy.
- Antiemetics: ondansetron (Zofran), dronabinol (Marinol), metoclopramide (Reglan), prochlorperazine (Compazine), promethazine (Phenergan)

Second Line

- Liposomal doxorubicin
- Carboplatin/gemcitabine
- Topotecan
- Etoposide
- Bevacizumab
- Cyclophosphamide
- Tamoxifen may be used in recurrent disease when chemotherapy is not appropriate (5)[A].

ADDITIONAL THERAPIES

Some patients with advanced disease and poor functional status and/or extreme tumor burden are managed with preoperative chemotherapy (neoadjuvant treatment) followed by interval cytoreductive surgery. These patients receive more chemotherapy after tumor debulking.

SURGERY/OTHER PROCEDURES

- Surgical exploration with staging and debulking is critical. Maximal cytoreduction of tumor burden enhances effectiveness of adjuvant therapy and is associated with longer survival.
- For epithelial malignancies, careful staging, tumor excision/debulking includes the following:
  - Cytologic evaluation of peritoneal fluid (or washings from peritoneal lavage)
  - Bilateral salpingo-oophorectomy with hysterectomy and tumor reductive surgery
  - Excision of omentum

  - Inspection and palpation of peritoneal surfaces
  - Cytologic smear of right hemidiaphragmatic surface
  - Biopsy of adhesions or any suspicious areas
  - Biopsy of paracolic recesses, pelvic sidewalls, posterior cul-de-sac, and bladder peritoneum
  - Pelvic and para-aortic lymph node biopsies
- Germ cell cancers (less likely to be bilateral): salpingo-oophorectomy (unilateral if only one ovary involved) in young patient

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Physical exam every 3 months for the first 2 years after diagnosis; every 6 months until 5 years and then annually thereafter
- If CA-125 elevated at diagnosis, follow levels after treatment to detect recurrence (is often elevated 2 to 5 months before clinical detection of relapse).
- Germ cell/sex-cord stromal cancer: physical exam and tumor markers every 3 months for the first 2 years after diagnosis
  - Tumor markers for sex-cord stromal cancers should be checked every 6 months for 10 years, as recurrences can occur remote from initial diagnosis.
- CT scan of chest, abdomen, and pelvis and/or PET scan when recurrence suspected
- Screening with CXR, MRI, CT, or PET not recommended; insufficient data to support (6)[B]

PROGNOSIS

- Recurrence rates
  - Early-stage disease: 25%
  - Advanced disease: >80%
- 5-year survival rates for ovarian cancer based on International Federation of Gynecology and Obstetrics (FIGO) data
- For most recent FIGO staging criteria, see “References” (7)[A].

Stage I	a 90%	b 86%	c 83%
Stage II	a 78%	b 73%	—
Stage III	a 47%	b 42%	c 33%
Stage IV	19%	—	—

COMPLICATIONS

- Pleural effusion
- Pseudomyxoma peritonei
- Ascites
- Toxicity of chemotherapy
- Bowel obstruction
- Malnutrition
- Electrolyte disturbances
- Fistula formation

CODES

ICD10

- C56.9 Malignant neoplasm of unspecified ovary
- C56.1 Malignant neoplasm of right ovary
- C56.2 Malignant neoplasm of left ovary

CLINICAL PEARLS

- Family history of ovarian cancer or early-onset breast cancer is the most significant risk factor for the development of ovarian cancer, yet the vast majority of cases remain sporadic.
- The diagnosis of ovarian cancer should be suspected in women with persistent bloating, upper abdominal discomfort, or GI symptoms of unknown etiology.
- Surgery is the mainstay of diagnosis and treatment for ovarian cancer. Many patients benefit from adjuvant chemotherapy.
- The prognosis of advanced ovarian cancer is poor and requires close follow-up by physical exam, tumor markers, and imaging when indicated.

OVARIAN CYST, RUPTURED

Heather O'Connor Greer, MD • Patricia Beauzile, MD

BASICS

- Ovarian cysts are frequent in reproductive-aged women.
- Most ovarian cysts are benign physiologic follicles created by the ovary at the time of ovulation.
- Ovarian cysts can cause symptoms when they become enlarged and exert a mass effect on surrounding structures, or when they rupture and the cyst contents cause irritation of the peritoneum or nearby pelvic organs.
- Patients with a symptomatic ruptured cyst will usually complain of acute onset unilateral lower abdominal pain.
- Evaluation of the patient should include exclusion of ectopic pregnancy, ovarian torsion, and nongynecologic sources of acute unilateral lower abdominal pain.
- Once the diagnosis of a ruptured cyst is confirmed, most patients can be managed conservatively as outpatients with adequate pain control. Surgical intervention is rarely indicated.

DESCRIPTION

A suspected ruptured ovarian cyst should be treated as an unknown adnexal mass (mass of the ovary, fallopian tube, and surrounding tissue) until proven otherwise.

EPIDEMIOLOGY

- The actual incidence of ovarian cysts is difficult to calculate as many ruptured cysts are asymptomatic or found incidentally.
- Ovarian cysts can be seen on transvaginal ultrasounds in nearly all premenopausal women and in up to 18% of postmenopausal women. The vast majority of these cysts are benign or functional.
- Most ruptured ovarian cysts are self-limiting, and expectant management with pain control is usually sufficient.
- About 13% of ovarian masses in reproductive-aged women are malignant, as

opposed to 45% in postmenopausal women.

RISK FACTORS

As benign physiologic cysts are a result of ovulation; medications or conditions associated with increased ovulation increase risk of cyst rupture. Examples include:

- Ovulation induction agents (i.e., Clomid, aromatase inhibitors, GnRH agonists)
- Tamoxifen increases the risk of ovarian cysts in reproductive-aged women.
- Rare risk factors for increased ovarian cyst formation include fibrous dysplasia/McCune-Albright syndrome.

GENERAL PREVENTION

Ovulation suppression with combined oral contraceptives is the mainstay therapy for prevention of recurrent ovarian cysts.

DIAGNOSIS

- When a ruptured ovarian cyst is suspected, a pregnancy test should be performed to rule out an ectopic pregnancy.
- Ultrasound imaging is standard for determining whether or not a patient with a ruptured cyst can be managed conservatively, or immediate intervention is indicated. Hemoperitoneum or hemodynamic instability is an indication for emergent intervention (1)[B].
- Sonographic imaging can also determine the characteristics of the cysts and can aid in separating malignant versus benign etiologies.
- Additionally, ultrasound is useful in confirming normal Doppler flow to affected ovary.

HISTORY

- A general past medical and surgical history should be reviewed.
- Specific questions that should be addressed if you suspect a ruptured cyst include:
  - Onset and characteristics of pain
  - Pain associated with sexual intercourse or strenuous activity

  - Date of last menstrual period
  - Vaginal bleeding
  - Nausea or vomiting
  - Shoulder pain
- Symptoms of circulatory collapse, including palpitation, shortness of breath, sensation of being hot or clammy, dizziness
- Additional information that will guide diagnosis should include patient age, symptom onset, particularly in relation to menstrual cycle, anatomic location, and imaging studies.

ALERT

Patients with bleeding diathesis or undergoing anticoagulation therapy may experience significant bleeding from hemorrhagic cysts.

PHYSICAL EXAM

- Vital signs are usually normal unless significant blood loss has occurred.
- Rupture characterized by significant blood loss may be present in the form of pallor, pale mucosal membranes, and tachycardia.
- Patient will have significant tenderness to palpation or an acute abdomen if the peritoneum is irritated or inflamed.
- On some occasions, a palpable adnexal mass can be felt on bimanual exam. Care should be taken not to cause further injury with a forceful exam.

DIFFERENTIAL DIAGNOSIS

Should include all causes of acute abdominal pain, both gynecologic and nongynecologic

ALERT

- Ectopic pregnancy should always be excluded with a negative pregnancy test.
- Benign nongynecologic causes of acute lower abdominal pain include:
  - Appendicitis
  - Diverticulitis
  - Infections of the urinary tract
  - Renal colic
- Malignant nongynecologic causes of acute lower abdominal pain can be

attributed to neoplastic processes of the lower GI tract.

- Benign gynecologic etiologies include:
  - Functional ovarian cysts
  - Ovarian torsion
  - Ectopic pregnancy
  - Tubo-ovarian abscess
  - Teratomas
  - Fibroids
  - Endometrioma
  - Cystadenoma (mucinous or serous)
  - Hydrosalpinx
- Malignant gynecologic etiologies can usually be attributed to the various gynecologic cancers of the reproductive tract.

DIAGNOSTIC TESTS & INTERPRETATION

- Urinalysis, STD testing, and a complete blood count should be obtained to evaluate for infectious causes, PID, or symptomatic renal stones. There are no laboratory tests that can definitively diagnose ovarian cyst rupture (2)[C].
- A type and screen is indicated if surgical intervention is planned or blood products are being considered.
- Transvaginal ultrasound is helpful in determining the presence of an ovarian mass, its characteristics, and the presence of intraperitoneal fluid (1)[A].
- CT, MRI, or PET imaging are not indicated for initial evaluation; however, these modalities are useful if malignancy is suspected (1)[A].

TREATMENT

GENERAL MEASURES

- Cyst rupture in a stable healthy patient can be managed conservatively with analgesia, bleeding and symptoms precautions, and outpatient follow-up (1)[A].
- For many patients, pain associated with a ruptured cyst will be transient and self-limiting.
- Scheduled NSAIDs or oral narcotics can be prescribed depending on pain

severity.

- Unstable patients with hemodynamic compromise or patients with significant intraperitoneal fluid should be resuscitated, and laparoscopy or a laparotomy should be considered. Surgical exploration should also be considered if there is a concern for malignancy.

ISSUES FOR REFERRAL

- OB-GYN
  - Consider referral to an obstetrician if an adnexal mass is diagnosed during pregnancy. Such masses have a low risk of malignancy or acute complication for the pregnancy.
- GYNECOLOGIC ONCOLOGY
  - Referral to a gynecologic oncologist should be considered for complex adnexal masses with an elevated CA125 and associated symptoms concerning for malignancy such as ascites, early satiety, pleural effusion, enlarging abdominal mass, or bowel obstruction.
- GENERAL SURGERY
  - Acute lower abdominal pain that is nongynecologic and suspicious for bowel involvement should be referred to general surgery or a gastroenterologist.

SURGERY/OTHER PROCEDURES

- Although the need for surgical intervention is rare, it is usually of an emergent nature.
- In most cases, laparoscopy will be sufficient to evaluate intra-abdominal bleeding. The decision to proceed with cystectomy or oophorectomy should be made intraoperatively after a thorough evaluation of the intra-abdominal environment has been completed.
- The advantages of a laparoscopic approach include a shorter length of stay, and most patients can be discharged home the same day. Postoperative recovery time as well as patient satisfaction is significantly improved with a minimally invasive approach.
- Laparotomy should be performed in cases of critical hemodynamic instability or lack of laparoscopically trained surgeons. If there is concern for malignancy or metastases, laparotomy may be the preferred method of

surgery.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Patients who require inpatient management should be managed with serial abdominal exams, analgesia, and intravenous resuscitation as indicated by their initial presentation.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Follow up for patients managed conservatively should be scheduled 1 to 2 weeks from the initial onset of symptoms. Patients should present sooner for new or worsening symptoms.
- Patients with complete resolution of symptoms within a few days can follow-up as needed. However, these patients should be counseled on ovarian cysts and options for prevention.
- Patient in whom surgical intervention was indicated, postop follow-up should be scheduled 2 weeks from the date of surgery.
- Patients in whom an ovarian cyst was diagnosed incidentally should follow-up based on the size of their cyst.
- Simple cysts up to 10 cm in diameter on ultrasound findings are almost always benign and may safely be followed without intervention in pre- and postmenopausal patients. These patients should also be referred to a gynecologist (3)[B].

Pregnancy Considerations

Adnexal masses in pregnancy have a low risk of malignancy or acute complications to the pregnancy, so in most cases, they can be managed expectantly (1)[C].

PATIENT EDUCATION

Reassurance of the benign nature of most ovarian cysts is an important cornerstone of patient education.

CODES

ICD10

- N83.20 Unspecified ovarian cysts
- N83.0 Follicular cyst of ovary
- N83.1 Corpus luteum cyst

CLINICAL PEARLS

- Functional ovarian cysts are very common in reproductive-age women and are usually self-limiting.
- Always exclude ectopic pregnancy.
- Management of symptomatic ruptured cysts is usually accomplished with outpatient pain control with follow-up.
- In cases where the patient with a ruptured cyst is unstable or presents with signs of an acute abdomen, surgical intervention is indicated.

PALLIATIVE CARE

Erika Oleson, DO, MS

BASICS

Palliative care is a specialty that focuses on preventing and alleviating suffering of patients (and their families) living with life-limiting illness at any stage of that illness.

DESCRIPTION

- Palliative care's principal aim is to prevent and alleviate suffering—whether physical (pain, breathlessness, nausea, etc.), emotional, social, or spiritual regardless of underlying diagnosis.
- The goal of palliative care is to improve or maintain quality of life of both patient and family despite serious illness.
- Palliative care is available for patients with serious, life-limiting illness, at any stage of their disease, with or without concurrent curative care.
- Location of care: Patients and their families may access palliative care services in hospital, rehabilitative or skilled nursing facility, and ambulatory setting.
- Hospice: In the United States, hospice is available for patients whose average life expectancy is 6 months or less and whose principal goal is to stay home (including long-term care or assisted living facility), avoid hospitalizations, and disease-directed care with a curative intent. Unlike regular nursing services in the home, hospice does not require a patient to be homebound and offers backup support for patients 24 hours a day and 7 days per week.

COMMONLY ASSOCIATED CONDITIONS

Symptoms/syndromes commonly treated in palliative care:

- Pain
  - Chronic pain
  - Headache
  - Neuropathic pain
  - Pain from bone metastases

  - Pruritus
- GI symptoms (~60% incidence)
  - Ascites
  - Anorexia/cachexia
  - Nausea (and vomiting)
    - Consider underlying etiology and treat accordingly.
      - GI causes: constipation, bowel (full or partial) obstruction, ileus, heart burn, reflux, inflammation
      - Intrathoracic causes: cardiac, effusions (cardiac, pulmonary), mediastinal causes, esophageal
      - Autonomic dysfunction
      - Centrally mediated: intracranial pressure change, inflammation, cerebellar, vestibular, medication or metabolic cause stimulating vomiting center and/or chemoreceptor trigger zone
  - Bowel obstruction
  - Constipation and impaction of stool
  - Diarrhea
  - Dysphagia
  - Mucositis/stomatitis
  - Sialorrhea
- General medical
  - Delirium (40–85%)
- Pulmonary symptoms
  - Cough, chronic
  - Breathlessness or dyspnea (60%): often due to heart failure, COPD, lung cancer, and so forth
- Psychological symptoms
  - Anxiety
  - Depression
  - Insomnia
- Skin
  - Decubitus ulcer
  - Pruritus
  - Complex wounds (fungating tumors, etc.)

DIAGNOSIS

The PEACE tool evaluates the following (1):

- Physical symptoms
- Emotive and cognitive symptoms
- Autonomy and related issues
- Communication: contribution to others and closure of life affairs–related issues
- Economic burden and other practical issues, also transcendent and existential issues

HISTORY

A comprehensive palliative care assessment includes addressing the following:

- Underlying medical conditions and their associated physical symptoms
- Comprehensive pain and symptom assessment and review of systems (consider use of Edmonton Symptom Assessment Tool)
- Psychological symptom assessment
- Cultural, social, and practical concerns
- Spiritual and existential issues
  - FICA assessment (**F**aith, **I**mportance and influence, **C**ommunity, **A**ddress—how does the patient wish to be addressed?)
  - HOPE (sources of **H**ope/strength/comfort, **O**rganized religion's role, **P**ersonal spirituality and practices, **E**ffects on medical care and end-of-life care) (2)
- Patient's identified presence and sources of suffering: personhood concerns
- Goals of care: including posthospital care, practical needs, hopes, and fears
- Prognosis: including functional status and patient's interest in knowing prognosis

PHYSICAL EXAM

Comprehensive physician examination is warranted, especially as directed by underlying diagnosis, symptoms, and functional decline.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

Per diagnosis and symptoms

TREATMENT

GENERAL MEASURES

- Targeted interventions to maximize quality of life and minimize symptom burden while taking into consideration the patient's values, goals, fears, and social setting.
- Treatment should involve an interdisciplinary team—addressing potential and realized suffering, whether physical, emotional, social, or spiritual.

MEDICATION

- Attempt to minimize polypharmacy
- Consider discontinuing medications that offer little improvement in the quality of life.
- Medication should focus on symptom management.
- Continue to use appropriate disease-modifying medications especially if they lessen symptom burden and enhance immediate quality of life.
- Improve compliance by addressing patient/caregiver understanding.
- *Pain* (3)[A]
  - Use immediate-release opioids PO/IV/SC and titrate to control.
  - Once pain is controlled, convert to long-acting **opioids** with short-acting agents made available as tolerance develops and/or patient develops breakthrough pain.
- Bone pain: NSAIDs added to narcotics are more effective than narcotics alone.
- Neuropathic pain: may use adjuvant treatment, such as gabapentin, other anticonvulsants. Glucocorticoids may also help.

ALERT

Avoid morphine in patients with renal failure, can induce delirium, hyperalgesia, agitation, and seizures.

- *Vomiting* associated with a particular opioid may be relieved by substitution with an equianalgesic dose of another opioid or a sustained-release

formulation (4).
  - Dopamine receptor antagonists (metoclopramide, prochlorperazine, promethazine) are commonly used. Haloperidol may help with nausea.
  - Droperidol: insufficient evidence to advise on the use for the management of nausea and vomiting
- *Constipation*: Consider prophylactic stool softeners (docusate) and stimulants (bisacodyl or senna) or osmotic laxatives.

ALERT

Laxatives should be started when opioid treatment has begun to avoid constipation.

- SC methylnaltrexone is effective in inducing bowel movements without inducing withdrawal with opioid-induced constipation.
- Dyspnea: consider oxygen, if congestive heart failure (CHF); diuretics and/or long-acting nitrates, **benzodiazepines**
  - In addition to treating the underlying cause of breathlessness, as the disease advances, low-dose opioids may be beneficial to patients (3,5)[C]. Immediate-release **opioids** PO/IV treat dyspnea effectively and typically at doses lower than necessary for the relief of moderate pain.
- *Delirium*: lowest doses necessary of **benzodiazepines** or **antipsychotics** (haloperidol, etc.)
  - Monitor patient safety and use nonpharmacologic strategies to assist orientation (clocks, calendars, environment, and redirection).
  - Droperidol: When cause of delirium cannot be identified/corrected rapidly, consider neuroleptics (haloperidol or risperidone).
- Pruritus: no optimal therapy
- Anxiety: insufficient data for recommendations of specific medication, but anxiolytics and/or other agents may be tried
- Megestrol acetate improves appetite and slight weight gain in patients with anorexia-cachexia syndrome.

ISSUES FOR REFERRAL

- Referral to palliative care
  - Any patient with a serious, life-limiting illness who could benefit from help with burdensome symptoms or suffering and/or complex goals of care

discussion.
  - Early referral to palliative care may improve quality of life and longevity for patients with advanced cancer.
- Referral to hospice care
  - Any patient with an average life expectancy of 6 months or less. Consider the question, “Would you be surprised if the patient died within the next 6 months?” If the answer is no, they likely meet prognostic criteria for hospice.
    - Consider patients who have multiple hospitalizations and/or emergency department visits in the prior 6 months.
    - Refer to local hospice guidelines for additional disease-specific criteria.

CODES

ICD10

Z51.5 Encounter for palliative care

CLINICAL PEARLS

- Early referral to palliative care may help enhance the quality of life and potential longevity of patients living with serious illness.
- Consider the type of pain: the addition of adjuvant treatments such as NSAIDs or gabapentin to narcotics may be more effective than narcotics alone.
- Laxatives should be started when opioid treatment has begun to avoid constipation.

PANCREATIC CANCER

Marcelle Meseeha, MD • Maximos Attia, MD, FAAFP

BASICS

DESCRIPTION

- Adenocarcinoma of the exocrine pancreas (90% of pancreatic cancers) is the fourth most common cause of cancer death in the United States and the ninth most common cancer in women.
- Rarely curable: overall 5-year relative survival rate of 7.7%
- 60–70% occurs in the head, 20% in the body and tail, 20% diffusely involve the gland.
- As few as 9% are localized at diagnosis. For localized, small cancers (<2 cm) with no lymph node metastases and no extension beyond the capsule, surgical resection has 5-year survival of about 29%.
- Majority of tumors have metastasized at diagnosis and are thus, largely incurable and have a 5-year survival rate of 2–3%.
- In apparently resectable disease, 20–40% have unresectable lesions at surgery.
- Ampullary, duodenal, or distal bile duct tumors may mimic pancreatic carcinoma and are more likely to be resectable and curable.
- For advanced or unresectable cancers, survival is <1% at 5 years; most patients die within 1 year.

EPIDEMIOLOGY

During 2003 to 2007, median age at diagnosis = 70 years; rare <40 years; after 45 years of age, occurrence rises.

Incidence

- According to the American Cancer Society, an estimated 53,000 diagnoses and 42,000 deaths in the United States in 2016
- About 3% of all cancers and about 7% of cancer deaths
- Lifetime risk is about 1 in 65 (1.5%).
- More common in black and white races, 16.7 and 10.3 in 100,000 men and 14.4 and 10.3 in 100,000 women, respectively. Among Hispanic and

Asian/Pacific Islanders, there is an incidence of 10.9 and 8.3 in 100,000 men and 10.1 and 8.3 in 100,000 women, respectively.

Prevalence

In 2008, in the United States, ~34,600 men and women (16,811 men and 17,846 women) were alive who had a history of pancreatic cancer.

RISK FACTORS

- Smoking: relative risk (RR) 2 to 3; correlates with amount smoked
- Diabetes: RR 2.1 (95% CI 1.6–2.8); 1 in 6 become diabetic within 6 months before diagnosis.
- Prior partial gastrectomy or cholecystectomy: 2- to 5-fold increased risk 15 to 20 years after gastrectomy
- Familial aggregation/genetic factors: 5–10% of patients have a first-degree relative with the disease, which confers a 9-fold increase in risk versus the general population; subgroup may carry germline mutations of DNA repair genes (*BRCA2*).
- Hereditary chronic pancreatitis (autosomal dominant, highly penetrant): cumulative risk by ages 50 and 75 years is 10% and 54%, respectively.
- Peutz-Jeghers syndrome: RR 30 to 40
- Familial atypical multiple mole and melanoma syndrome (p16): RR 10 to 20
- Hereditary nonpolyposis colon cancer (Lynch syndrome: RR 4
- Sporadic chronic pancreatitis
- Non-O blood type: RR 1 to 2
- High dietary fat, red meat, obesity, *Helicobacter pylori*
- Alcohol: Recent data indicate a modest increase in risk confined to heavy alcohol consumers.
- Coffee intake and NSAID use *NOT* regarded as risk factors.

GENERAL PREVENTION

No effective screening modality exists to detect early cancer. Even with a strong family history or predisposition syndromes, use and cost-effectiveness of screening are unclear.

COMMONLY ASSOCIATED CONDITIONS

- Chronic pancreatitis, diabetes mellitus, cystic fibrosis

- KRAS mutations are present in >90% of pancreatic ductal adenocarcinomas.
- Mutation inactivation of tumor suppressors (SMAD4, p53, CDKN2A) allows for tumor progression.
- Subsets of familial pancreatic cancer involve germline cationic trypsinogen or *PRSS1* mutations (hereditary pancreatitis), *BRCA2* mutations (usually with hereditary breast–ovarian cancer syndrome), *CDKN2* mutations (familial atypical mole, multiple melanoma), or DNA repair gene mutations (e.g., *ATM* and *PALB2*, apart from *BRCA2*).
- Majority of familial pancreatic cancers have no genetic underpinnings.
- Precursor lesions are potentially curable—pancreatic intraepithelial neoplasia, intraductal papillary mucinous neoplasia, and mucinous cystic neoplasms.

DIAGNOSIS

HISTORY

- Depends on tumor location; majority become symptomatic late in disease. About 60–70% of pancreatic cancers develop in the pancreatic head and block the periampullary bile duct, causing obstructive jaundice.
- Weight loss 90%; pain 75% (progressive midepigastric dull ache that often radiates to the back); malnutrition 75%; jaundice 70%; anorexia 60%; pruritus 40%; diabetes mellitus 50%; weakness, fatigue, malaise 30–40%; alcoholic stools, dark urine, steatorrhea; depression is common.
- Pancreatic cancer is a consideration in acute pancreatitis in the elderly and with new-onset diabetes, but most new-onset diabetes are not associated with cancer; thus, evaluation for cancer is warranted only in selected cases.
- Uncommon: unexplained thrombophlebitis; acute pancreatitis from tumor obstruction of pancreatic duct; duodenal obstruction or GI bleeding

PHYSICAL EXAM

- Muscle wasting and malnutrition are common; skin lesions are indicative of pruritus. Exam can be normal.
- Palpable abdominal mass or ascites in 20%
- Jaundice: 70% if tumor obstructs bile duct; 10% with body or tail carcinoma
- Courvoisier sign (painless jaundice with a palpable gallbladder): uncommon;

usually associated with pancreatic head tumors, periampullary or primary bile duct tumors; hepatomegaly in advanced disease
- Virchow node (left supraclavicular) and Sister Mary Joseph node (umbilical) in metastatic disease; palpable rectal shelf (nonspecific sign of carcinomatosis)
- Migratory thrombophlebitis (Trousseau sign) (uncommon) due to hypercoagulability in mucin-producing pancreatic cancer
- GI bleeding from tumor erosion into adjacent viscera (colon); portal hypertension-related bleeding (uncommon)
- Pancreatic panniculitis: subcutaneous areas of nodular fat necrosis

DIFFERENTIAL DIAGNOSIS

- Chronic pancreatitis, duodenal cancer, cholangiocarcinoma, lymphoma, islet cell tumor, sarcoma, cystic neoplasms, tumor metastatic to pancreas (rare)
- Nonmalignant conditions: choledocholithiasis, acute or chronic pancreatitis, biliary tract stricture, adenoma; chronic mesenteric ischemia
- Tuberculosis or fungal abscess in AIDS
- Patients may present with back pain mimicking musculoskeletal disease.

DIAGNOSTIC TESTS & INTERPRETATION

- Cross-sectional imaging (usually CT scan as first-line choice) to evaluate symptoms or abnormal lab results (1)[B]
- Endoscopic ultrasound (EUS)-guided biopsy: best modality for tissue diagnosis; sensitivity 75–90%; specificity ~100% for diagnosis of a mass (1) [A]
- Routine laboratory tests may reveal elevated serum bilirubin and alkaline phosphatase (cholestasis), anemia, or decreased serum albumin (malnutrition).

Initial Tests (lab, imaging)

- Most patients do not require measurement of serum tumor markers (CA19-9) for diagnosis or management. Some evidence suggests use in predicting outcome and response to adjuvant chemotherapy.
- CEA and CA19-9 are not recommended as screening tests; useful in following patients with known disease (2)[A]
- Elevated CA19-9 antigen: 80% sensitivity; 90% specificity; individuals with

Lewis-negative blood group antigen phenotype (5–10%) are unable to synthesize CA19-9; elevations can occur in benign pancreatic or biliary diseases and in nonpancreatic malignancy.

Follow-Up Tests & Special Considerations

- During therapy, increase in CA19-9 may identify progressive tumor growth. Normal CA19-9 does not exclude recurrence.
- CT scan (pancreatic protocol) using thin section, multiphase multidetector helical CT with a pancreatic protocol is the choice for diagnosis and staging: 85–90% sensitivity; 90–95% specificity; useful for evaluation of distant metastasis and prediction of resectability
- Abdominal ultrasound: common initial test to assess jaundice and duct dilatation; less sensitive than CT for pancreatic masses
- EUS is accurate for tissue biopsy, local tumor and node staging, predicting vascular invasion (90% specificity; 73% sensitivity), and when no mass is identified on CT.
- Endoscopic retrograde cholangiopancreatography (ERCP): 90% sensitivity; 95% specificity for ductal cancer; useful if endoscopic stent is indicated for biliary obstruction; generally confined to high probability for therapeutic intervention on biliary or pancreatic ductal systems
- MRI: no advantage over contrast-enhanced CT
- MR cholangiopancreatography: 90% sensitivity; 95% specificity. Preferred in specific settings: gastric outlet or duodenal stenosis or after surgical rearrangement (Billroth II) or ductal disruption; to detect bile duct obstruction, after attempted ERCP is unsuccessful or provides incomplete information
- Cystic pancreatic lesions may be benign or malignant; must be differentiated from pancreatic pseudocysts. Cystadenocarcinomas have better prognoses than typical pancreatic cancers.

Diagnostic Procedures/Other

- Percutaneous fine-needle biopsy with US or CT guidance: 80–90% sensitivity; 98–100% specificity
- EUS-guided biopsy: 85–90% sensitivity; virtually 100% specificity for pancreatic mass
- Staging laparoscopy and US: 92% sensitivity; 88% specificity; 89% accuracy

- Positive peritoneal cytology has a positive predictive value of 94%, specificity of 98%, and sensitivity of 25% for determining unresectability.
- PET scan: 90% sensitivity but 70% specificity; limited anatomic information
- Tumor staging
  - Stage I: tumors limited to the pancreas
  - Stage II: regionally invasive; may involve lymph nodes but without celiac or mesenteric artery involvement
  - Stage III: direct involvement of celiac or superior mesenteric artery involvement
  - Stage IV: distant metastases

Test Interpretation

- Duct cell carcinoma: 90%
- Other less common tumors: acinar, papillary mucinous, signet ring, adenosquamous, mucinous, giant or small cell, cystadenocarcinoma, undifferentiated, unclassified carcinoma

ALERT

Chronic pancreatitis can present with similar pain, weight loss, jaundice, and an inflammatory mass on imaging.

TREATMENT

- Surgical resection: only chance of cure; no role for pancreatic resection in metastatic disease. As few as 15–20% are candidates for resection.
- Criteria for unresectability: extrapancreatic spread, encasement or occlusion of major vessels, distant metastases
- New combination chemotherapy regimens may offer advantages over gemcitabine. Standard therapies remain unsatisfactory; thus, patients should be considered for clinical trials (2)[B].

MEDICATION

- Analgesics
- Stages I and II
  - Radical pancreatic resection plus chemotherapy

  - ESPAC-3 trial after resection: compared with 5-fluorouracil (5-FU) and folinic acid, gemcitabine did not improve overall survival.
  - Currently, postoperative gemcitabine alone or in combination with 5-FU–based chemoradiation is the current standard of care; preoperative neoadjuvant treatment trials are in progress (1)[A].
- Stage III
  - Standard: 6 months of chemotherapy with gemcitabine-based regimens (1)[A]; added chemoradiation (capecitabine and radiotherapy) is controversial (1)[B].
  - FOLFIRINOX (leucovorin, fluorouracil, irinotecan, and oxaliplatin) or gemcitabine—nab-paclitaxel were recently shown to have a benefit in patients with metastatic disease; may be tried in patients with locally advanced disease. These regimens are used for patients with no or minimal performance restrictions (1,3)[A].
  - Palliation of biliary obstruction by endoscopic, surgical, or radiologic methods
  - Intraoperative radiation therapy and/or implantation of radioactive substances
- Stage IV
  - Chemotherapy: Gemcitabine ± erlotinib, or capecitabine may modestly prolong survival compared with gemcitabine alone. This regimen is used for patients with significant performance restrictions (1,3)[A].
  - Pain-relieving procedures (celiac or intrapleural block); supportive care; palliative decompression
  - Duodenal obstruction: endoscopic expandable metal stent placement rather than surgery (1)[C]
  - Biliary obstruction: Endoscopic biliary stenting is safer than percutaneous insertion and is as successful as surgical hepatojejunostomy (1)[A].

ADDITIONAL THERAPIES

- For resected tumors: postoperative radiation therapy with other chemotherapeutic agents
- Intraoperative radiation therapy and/or implantation of radioactive substances (ongoing trials)

- Biliary decompression with endoprosthesis or transhepatic drainage for bile duct obstruction
- Celiac axis and intrapleural nerve blocks can provide effective pain relief for some patients.
- Opiates may be needed for pain control.

SURGERY/OTHER PROCEDURES

- Standard treatment options
  - Pancreaticoduodenectomy, Whipple procedure, en bloc resection of the head of the pancreas, distal common bile duct, duodenum, jejunum, and gastric antrum
  - Total pancreatectomy
  - Distal pancreatectomy for body and tail tumors
- Nonstandard surgeries
  - Pylorus-preserving pancreaticoduodenectomy, regional pancreatectomy
  - Palliative bypass
    - Biliary decompression; gastrojejunostomy for gastric outlet obstruction; duodenal endoprosthesis for obstruction

 ONGOING CARE

DIET

- Anorexia, asthenia, pain, and depression may contribute to cachexia.
- Fat malabsorption due to exocrine pancreatic insufficiency may contribute to malnutrition; pancreatic enzyme replacement may help to alleviate symptoms.
- Fat-soluble vitamin deficiency may require replacement therapy.

PROGNOSIS

- 90% diagnosed with pancreatic cancer die from the disease, predominantly from metastatic disease (2).
- 5-year survival: ~30% if node-negative; 10% if node-positive. Median survival: 10 to 20 months
- Metastatic cancer: 1–2% 5-year survival
- For localized disease and small cancers (<2 cm) with no lymph node involvement and no extension beyond the capsule, complete surgical resection

can yield a 5-year survival of 18–24%.
- Detection of curable precursor lesions is a focus of current efforts to improve diagnosis and prognosis.

COMPLICATIONS

- Diabetes mellitus, malabsorption, thrombophlebitis
- Duodenal or distal bile duct obstruction
- Surgical complications: intra-abdominal abscess, postgastrectomy syndromes, pancreaticojejunostomy, gastric and biliary anastomotic leaks; operative mortality varies.

CODES

ICD10

- C25.9 Malignant neoplasm of pancreas, unspecified
- C25.0 Malignant neoplasm of head of pancreas

- C25.1 Malignant neoplasm of body of pancreas

CLINICAL PEARLS

- Sudden onset of diabetes mellitus in nonobese adults aged >40 years may warrant consideration of pancreatic cancer in selected cases.
- Cancer of the exocrine pancreas is rarely curable; overall 5-year survival rate of <4%. Fewer than 20% of cases are localized at diagnosis.
- Be wary of chronic pancreatitis, which can present with similar pain pattern, weight loss, jaundice, and an inflammatory mass on imaging.
- Because of the dismal prognosis on standard therapy, all patients with pancreatic cancer should be considered for appropriate clinical trials.

PANCREATITIS, ACUTE

Robert L. Frachtman, MD, FACG • Marni L. Martinez, APRN

BASICS

DESCRIPTION

- Acute inflammatory process of the pancreas with variable involvement of regional tissue or remote organ systems
- Inflammatory episode with symptoms related to intrapancreatic activation of enzymes with pain, nausea and vomiting, and associated intestinal ileus
- Varies widely in severity, complications, and prognosis, accounting for 280,000 hospital admissions per year in the United States
- Complete structural and functional recovery if there is no necrosis or pancreatic ductal disruption

EPIDEMIOLOGY

Incidence

- 1 to 5/10,000
- Predominant age: none
- Predominant sex: male = female

Prevalence

- Acute: 19/10,000
- Acute pancreatitis is the most common gastrointestinal diagnosis for inpatient hospitalization.

ETIOLOGY AND PATHOPHYSIOLOGY

- Alcohol
- Gallstones (including microlithiasis)
- Trauma/surgery
- Acute discontinuation of medications for diabetes or hyperlipidemia
- Following endoscopic retrograde cholangiopancreatography (ERCP)
- Medications (most common, not an exhaustive list)

  - ACE inhibitors; angiotensin receptor blockers (ARBs); thiazide diuretics and furosemide
  - Antimetabolites (mercaptopurine and azathioprine)
  - Corticosteroids; glyburide; exenatide (Byetta)
  - Mesalamine; pentamidine
  - Sulfamethoxazole/trimethoprim
  - Valproic acid
  - HMG-CoA reductase inhibitors, especially simvastatin
  - Review all medications and continue only if the benefit outweighs risk.
- Metabolic causes
  - Hypertriglyceridemia (>1,000 mg/dL); hypercalcemia; acute renal failure
  - Diet with high glycemic load
  - Systemic lupus erythematosus/polyarteritis
  - Autoimmune pancreatitis, with elevated IgG4
  - Infections
    - Mumps, coxsackie, cryptosporidiosis
- Penetrating peptic ulcer (rare)
- Cystic fibrosis and *CFTR* gene mutations
- Tumors (e.g., pancreatic, ampullary)
- Pancreas divisum; sphincter of Oddi dysfunction
- Scorpion venom; vascular disease
- Acute fatty liver of pregnancy
- Idiopathic/autoimmune
- **Pathophysiology**—enzymatic "autodigestion" of the pancreas, interstitial edema with severe interstitial acute fluid accumulation ("3rd spacing"), hemorrhage, necrosis, release of vasoactive peptides (within 6 weeks), pseudocyst or acute necrotic collection (>6 weeks), pancreatic ductal disruption, injury to surrounding vascular structures-splenic vein (thrombosis) and splenic artery (pseudoaneurysm)
- The severity of the first episode of acute pancreatitis, alcohol abuse, and smoking all increase the risk of acute recurrent pancreatitis, which, in turn, increases the risk of progression to chronic pancreatitis.

Genetics

Hereditary pancreatitis is rare; autosomal dominant

GENERAL PREVENTION

- Avoid excess alcohol consumption.
- Tobacco cessation
- Correct underlying metabolic processes (hypertriglyceridemia or hypercalcemia).
- Discontinue offending medications.
- Cholecystectomy (symptomatic cholelithiasis)
- Diet with low glycemic load

COMMONLY ASSOCIATED CONDITIONS

- Alcohol withdrawal, alcoholic hepatitis, diabetic ketoacidosis, and ascending cholangitis
- Morbid obesity, a proinflammatory state, increases severity and adverse outcomes (organ failure, mortality).

DIAGNOSIS

Symptoms do not always correlate with objective findings.

HISTORY

- Acute onset of “boring” epigastric pain, which may radiate posteriorly toward the back
- Nausea/vomiting
- Alcohol use
- Personal or family history of gallstones
- Medication use
- Abdominal trauma
- Recent significant rapid weight loss

PHYSICAL EXAM

- Vital signs—assess hemodynamic stability; fever
- Abdominal findings: epigastric tenderness, loss of bowel sounds, peritoneal signs
- Other findings, jaundice, rales/percussive dullness
- Rare (with hemorrhagic pancreatitis)

- Flank discoloration (Grey-Turner sign) or umbilical discoloration (Cullen sign)

DIAGNOSTIC TESTS & INTERPRETATION

- Interpret laboratory and radiographic findings in the context of the clinical history, as false-positive and false-negative findings are common.
- Bedside Index in Severity in Acute Pancreatitis (BISAP) score
- Patients receive 1 point for each condition in the first 24 hours: BUN > 25 mg/dL, impaired mental status, systemic inflammatory response syndrome (SIRS)—a score of 0 predicts mortality of <1%, and a score of 5 correlates with a mortality rate of 22%.
- Ranson criteria is an older model of predicting severity of pancreatitis. It includes 11 criteria, 5 of which are measured at admission and 6 are measured in the following 48 hours. A score of 3 or less represents mild pancreatitis, and as the score increases, the mortality rises sharply.
- American College of Gastroenterology requires at least two of the three following elements to make a diagnosis of acute pancreatitis: characteristic abdominal pain, specific radiographic findings, and lipase level 3 times the upper limits of normal (ULN).
- Elevated serum amylase >3× ULN (Severity is not related to degree of elevation.)
- Elevated serum lipase >3× ULN (may stay elevated longer than amylase in mild cases)
- Elevated total bilirubin. If >3 mg/dL, consider common bile duct obstruction.
- Transaminases rise quickly with acute bile duct obstruction. They also fall rapidly as alkaline phosphatase rises; a 3-fold elevation in the alanine aminotransferase (ALT) in the setting of acute pancreatitis has a 95% positive predictive value for gallstone pancreatitis. Triglyceride levels >1,000 mg/dL suggest hypertriglyceridemia as the cause.
- Glucose is increased in severe disease.
- Calcium is decreased in severe disease.
- WBC elevation to 10,000 to 25,000/μL possible and not indicative of active infection
- Elevated baseline hematocrit >44 or rising hematocrit are poor prognostic signs (severe 3rd spacing with associated hemoconcentration) (1)[A].

- Rising BUN and creatinine imply volume depletion or acute renal failure (1) [A].

DIFFERENTIAL DIAGNOSIS

- Penetrating peptic ulcer
- Acute cholecystitis or cholangitis
- Macroamylasemia, macrolipasemia
- Mesenteric vascular occlusion and/or infarction
- Perforation of a viscus
- Intestinal obstruction
- Aortic aneurysm (dissecting or rupturing)
- Inferior wall myocardial infarction
- Lymphoma

Initial Tests (lab, imaging)

- Use follow-up labs to assess renal function, hydration, sepsis, biliary obstruction, and tissue oxygenation.
- Plain film of abdomen helps rule out mechanical small bowel obstruction. Ileus is common.
- Chest x-ray (CXR) to evaluate for early acute respiratory distress syndrome (ARDS) and pleural effusion; can also rule out subdiaphragmatic air (perforated viscus)
- Ultrasound to look for gallbladder/biliary stones
- CT scan
  - Confirms the diagnosis, assesses severity, establishes a baseline, and rules out most other pathologies (excluding noncalcified cholelithiasis)
  - IV contrast is not essential for the initial CT scan; avoid contrast in volume-depleted patients.
  - If not contraindicated, a CT scan with IV contrast on day 3 can assess the degree of necrosis if necrotizing pancreatitis is suspected.
- Magnetic resonance cholangiopancreatography (MRCP) helps assess choledocholithiasis, pancreas divisum, dilated pancreatic duct, and ductal changes.
- Esophagogastroduodenoscopy (EGD) may be necessary to rule out a penetrating duodenal ulcer or an obstructing ampullary neoplasm.

- ERCP may be necessary to decompress common bile duct due to an impacted stone.
- Endoscopic ultrasonography (EUS) is useful if patients present with "idiopathic pancreatitis" (2)[B].
- FNA may be added to EUS if autoimmune pancreatitis is suspected (3)[B].

Follow-Up Tests & Special Considerations

If renal function is stable, a contrast-enhanced CT scan at day 3 to assess for necrosis. Later in the course, if there is a spike in the temperature, CT guidance assists aspiration and drainage of abscess.

TREATMENT

MEDICATION

First Line

- Analgesia: no consensus; guidelines vary widely on types and dosing for analgesia.
  - Hydromorphone (Dilaudid) 0.5 to 1 mg IV q1–2h PRN
  - AVOID Demerol due to the potential of accumulation of a toxic metabolite.
- Antibiotics
  - The use of prophylactic antibiotics is no longer recommended, even with necrotizing pancreatitis, in the clear absence of infection.
  - In patients with ascending cholangitis or necrotizing pancreatitis, β-lactam/β-lactamase inhibitor (e.g., piperacillin/tazobactam 4.5 g IV q8h) can be considered for initial treatment, before cultures (especially of aspirated collections) return, if there is a strong suspicion of active infection.
  - Levofloxacin 500 mg QD IV if cholangitis and there is an allergy to penicillin
  - Be vigilant for fungal superinfections when giving prophylactic antibiotics.

GENERAL MEASURES

Most cases of acute pancreatitis require hospitalization; ICU if multiorgan dysfunction or hypotension/respiratory failure; 15–20% of cases of acute pancreatitis progress from mild to severe (including persistent organ failure)

- Fluid resuscitation

  - Significant volume deficit due to 3rd spacing
  - Infuse bolus of 1,000 to 2,000 mL (lactated Ringers may be better than normal saline, unless hypercalcemic), followed by 250 to 300 mL/hr, adjusted on the basis of age, weight, hemodynamic response, and comorbid conditions.
  - Target urine output should be 0.5 to 1 mL/kg/hr. Lower infusion rate when this goal is achieved or once BUN decreases; 4 L should be the maximum fluid on day 1.
- Eliminate unnecessary medications, especially those potentially causing pancreatitis.
- Nasogastric (NG) tube for intractable emesis
- Follow renal function, volume status, calcium, and oxygenation. Organ failure is more important prognostic indicator than pancreatic necrosis.
- Intermittent pneumatic compression device
- Begin oral alimentation after pain, tenderness, and ileus have resolved; small amounts of high-carbohydrate, low-fat, and low-protein foods; advance as tolerated; NPO or NG tube if vomiting persists
- Enteral nutrition at level of ligament of Treitz if oral feeding not possible within 5 to 7 days (preferable to total parenteral nutrition [TPN] due to decreased infection rate and decreased mortality). Discontinue with increases in pain, amylase/lipase levels, or fluid retention.
- TPN (without lipids if triglycerides are elevated) if oral or nasoenteric feedings are not tolerated (4)[A]

ISSUES FOR REFERRAL

Refer to a tertiary center if pancreatitis is severe or actively evolving and when advanced imaging or endoscopic therapy is being considered.

SURGERY/OTHER PROCEDURES

- Consider cholecystectomy before discharge in patients with cholelithiasis and nonnecrotizing pancreatitis to reduce risk of recurrent acute gallstone pancreatitis.
- Necrosectomy should be performed nonsurgically for either infected or noninfected necrosis. Walled-off necrosis should be observed for 4 weeks (treated with antibiotics if infected), followed by percutaneous or dual-

modality drainage if available (5)[B].

- ERCP early if evidence of acute cholangitis or at 72 hours if evidence of ongoing biliary obstruction; ERCP with pancreatic ductal stent placement, if ductal disruption persists longer than 1 to 2 weeks
- Resection or embolization for bleeding pseudoaneurysms
- Plasma exchange with insulin if necrotizing pancreatitis secondary to hypertriglyceridemia

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Discharge Criteria

- Pain controlled
- Tolerating oral diet
- Alcohol rehabilitation and tobacco cessation
- Low-grade fever and mild leukocytosis do not necessarily indicate infection and may take weeks to resolve. Infections may occur even after 10 days (33% of patients with necrotizing pancreatitis) due to secondary infection of necrotic material, requiring surgical débridement.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Follow-up imaging studies in several weeks, if the original CT scan showed a fluid collection or necrosis or if the amylase/lipase continues to be elevated. Follow-up findings may include:
  - Pseudocyst (occurs in 10%) or abscess (sudden onset of fever): Conservative management is an option for asymptomatic pseudocysts up 6 cm in diameter.
  - Splenic vein thrombosis (gastric variceal hemorrhage rarely occurs)
  - Pseudoaneurysm (splenic, gastroduodenal, intrapancreatic) hemorrhage can be life-threatening.
- Mild exocrine and endocrine dysfunction is usually subclinical. Patients with necrotizing pancreatitis, steatorrhea, or ductal obstruction, however, should receive enzyme supplementation.

- After the first episode of acute pancreatitis, the risk of lifetime diabetes doubles.
- After the first episode of acute pancreatitis, the risk of developing acute recurrent pancreatitis is ~17%. The risk for developing chronic pancreatitis is ~8%.

DIET

Continue to advance diet as tolerated; dietary modification to reduce dietary fats, alcohol, and added sugars

PROGNOSIS

85–90% of cases of acute pancreatitis resolve spontaneously; 3–5% mortality (17% in necrotizing pancreatitis)

CODES

ICD10

- K85.9 Acute pancreatitis, unspecified
- K85.8 Other acute pancreatitis
- K85.2 Alcohol induced acute pancreatitis

CLINICAL PEARLS

- Pancreatitis remains a common indication for hospitalization. Alcohol misuse and gallstones are the leading causes for pancreatitis
- The BISAP score is easier to apply than Ranson criteria and is just as accurate for predicting mortality in patients with acute pancreatitis.
- Review all medications and discontinue any that may cause (or contribute to) pancreatitis.
- Patients with mild pancreatitis can progress to severe pancreatitis over the initial 48 hours, often due to inadequate fluid replacement.
- Referral to tertiary center is needed if acute pancreatitis is severe or evolving/worsening.

PANIC DISORDER

Yash Kothari, MD • Hugh Peterson, MD, FACP

BASICS

DESCRIPTION

- A classic panic attack that is characterized by rapid onset of a brief period of sympathetic nervous system hyperarousal accompanied by intense fear.
- In panic disorder, multiple panic attacks occur (including at least one without a recognizable trigger). Worried anticipation of additional attacks, which can be disabling, is present for at least 1 month, and often, maladaptive (e.g., avoidance) behaviors develop.

EPIDEMIOLOGY

Incidence

- Predominant age: All ages; in school-aged children, panic disorder can be confused with conduct disorder and school avoidance.
- Peak age of onset is early to mid-20s.
- Predominant sex: female > male (2:1)

Prevalence

- Lifetime prevalence: 4.7%
- 4–8% of patients in a primary care practice population have panic disorder.
- Of patients presenting with chest pain in the emergency room, 25% have panic disorder.
- Chest pain is more likely due to panic if atypical, younger age, female, and known problems with anxiety.

ETIOLOGY AND PATHOPHYSIOLOGY

Unknown

- Biologic theories focus on limbic system malfunction in dealing with anxiety-evoking stimuli.
- Psychological theories posit deficits in managing strong emotions such as fear and anger.

- Noradrenergic neurotransmission from the locus coeruleus causes increased sympathetic stimulation throughout the body.
- Current neurobiologic research focuses on abnormal responses to anxiety-producing stimuli in the hippocampus, amygdala, and prefrontal cortex; for example, there appears to be limbic kindling in which an original frightening experience dominates future responses even when subsequent exposures are not objectively threatening.
- Brain pH disturbances (e.g., excess lactic acid) from normal mentation in genetically vulnerable patients may activate the amygdala and generate unexpected fear responses.

Genetics

Twin and family studies support a genetic predisposition.

RISK FACTORS

- Life stressors of any kind can precipitate attacks.
- History of sexual abuse and physical abuse, anxious, and overprotective parents
- Substance abuse, bipolar disorder, major depression, obsessive-compulsive disorder (OCD), and simple phobia

COMMONLY ASSOCIATED CONDITIONS

- Of patients with panic disorder, >70% also have ≥1 other psychiatric diagnoses: PTSD (recalled trauma precedes panic attack), social phobia (fear of scrutiny precedes panic attack), simple phobia (fear of something specific precedes panic), major depression, bipolar disorder, substance abuse, OCD, separation anxiety disorder.
- Panic disorder is more common in patients with asthma, migraine headaches, hypertension, mitral valve prolapse, reflux esophagitis, interstitial cystitis, irritable bowel syndrome, fibromyalgia, nicotine dependence, and suicidality.

DIAGNOSIS

- Panic attack: an abrupt surge of intense fear, reaching a peak within minutes in which ≥4 of the following symptoms develop abruptly: (i) palpitations,

pounding heart, or accelerated heart rate; (ii) sweating; (iii) trembling or shaking; (iv) sensations of shortness of breath or feeling smothered; (v) a choking sensation; (vi) chest pain or discomfort; (vii) nausea or abdominal distress; (viii) feeling dizzy, unsteady, lightheaded, or faint; (ix) derealization (feelings of unreality) or depersonalization (feeling detached from oneself); (x) fear of losing control or going crazy; (xi) fear of dying; (xii) paresthesias; (xiii) chills or hot flashes (1)[C]

- Panic disorder: recurrent unexpected panic attacks not better accounted for by another psychiatric condition (e.g., PTSD, OCD, separation anxiety disorder, social anxiety disorder, or specific phobia) *and* not induced by drugs of abuse, medical conditions, or prescribed drugs *and* with >1 month of at least one of the following: (i) worry about additional attacks or worry about the implications of the attack (e.g., losing control, having a heart attack, "going crazy"); (ii) a significant maladaptive change in behavior related to the attacks (1)[C]
- Unlike *DSM-IV*, *DSM-5* defines agoraphobia as separate from panic disorder (1)[C].

HISTORY

- The best way to get a good history is through tactful, nonjudgmental questioning after the worst of the attack is over. Use open-ended questions and be unhurried. Interviewing family members may also be helpful.
- A thorough medication and substance abuse history is important.
- Patients must have a month of fear of out-of-the-blue panic attacks to diagnose panic disorder.

PHYSICAL EXAM

- During an attack, there will be tachycardia, hyperventilation, and sweating.
- Check the thyroid for fullness or nodules.
- Cardiac exam to check for a murmur or arrhythmias
- Lung exam to rule out asthma (limited airflow, wheezing)

DIFFERENTIAL DIAGNOSIS

- Medication use may mimic panic disorder and create anxiety: Antidepressants to treat panic may paradoxically initially cause panic; antidepressants in

bipolar patients can cause anxiety/mania/panic; short-acting benzodiazepines (alprazolam), β-blockers (propranolol), and short-acting opioids can cause interdose rebound anxiety; benzodiazepine treatment causes panic when patients take too much and run out of these medicines early; bupropion, levodopa, amphetamines, steroids, albuterol, sympathomimetics, fluoroquinolones, and interferon can cause panic.

- Substances of abuse: alcohol withdrawal, benzodiazepine withdrawal, opioid withdrawal, caffeine, marijuana (panic with paranoia), amphetamine abuse, MDMA, hallucinogens (PCP, LSD), dextromethorphan abuse, synthetic cathinones (bath salts) abuse.
- Medical conditions: hypo-/hyperthyroidism, asthma/chronic obstructive pulmonary disease (COPD), reflux esophagitis with hyperventilation, tachyarrhythmias, premenstrual dysphoric disorder, menopause, pregnancy, hypoglycemia (in diabetes), hypoxia, inner ear disturbances (labyrinthitis), myocardial infarction (MI), pulmonary embolus (PE), transient ischemic attacks (TIAs), carcinoid syndrome, pre- and postictal states (e.g., in TLE), autoimmune disease, pheochromocytoma, Cushing syndrome, hyperaldosteronism, Wilson disease
- Psychiatric conditions that have overlapping symptomatology include mood, anxiety, and personality disorders such as major depression, bipolar disorder, PTSD, borderline personality disorder, social phobia, OCD, and generalized anxiety disorder. In PTSD, there is always a recollection or visual image that precedes the panic attack. In social phobia, fear of scrutiny precedes the panic attack. In bipolar disorder, major depression, borderline personality disorder, and particularly substance abuse, the patient often complains first of panic symptoms and anxiety and minimizes other potentially relevant symptoms and behaviors.
- Somatic symptom disorder is also an illness of multiple unexplained medical symptoms, but the presenting picture is usually one of chronic symptoms rather than the acute, dramatic onset of a panic attack. Somatic symptom disorder and panic disorder can be (and often are) diagnosed together.

DIAGNOSTIC TESTS & INTERPRETATION

Consider ECG and pulse oximetry to rule out certain serious causes of panic; consider Holter monitoring. No specific lab tests are indicated except to rule out

conditions in the differential diagnosis.

- Finger stick blood sugar in acute setting in a diabetic patient
- Thyroid-stimulating hormone (TSH), electrolytes, CBC
- Consider ordering echocardiogram if you suspect mitral valve prolapse.

Diagnostic Procedures/Other

- If a medical cause of anxiety is strongly suspected, do the workup appropriate for that condition.
- Panic Disorder Severity Scale (PDSS) is a physician- or self-administered instrument for monitoring changes in severity of symptoms and response to treatment (2).
  - https://www.outcometracker.org/library/PDSS.pdf

TREATMENT

Combined antidepressant therapy and psychotherapy is superior to either alone during initial treatment for panic disorder (3)[A]. Cognitive-behavioral therapy (CBT) provides long-lasting treatment, often without subsequent need for medications.

GENERAL MEASURES

CBT, tailored for panic disorder, consists of several steps: education, changing cognitions about the attack and the illness, relaxation and controlled breathing techniques, and, if appropriate, exposure to anxiety-provoking conditions coupled with in vivo relaxation exercises.

MEDICATION

- Medication management is indicated if psychotherapy is not successful (or not available) and may be combined with psychotherapy.
- Patient preference plays a big part in this decision.
- Because patients typically are anxious about their treatment, the therapeutic alliance is critical for the chronic care of this disorder.
- If medications are started, they should be maintained for at least 6 months after symptom control.

First Line

- FDA-approved choices for the treatment of panic disorder include sertraline, paroxetine, fluoxetine, alprazolam, and clonazepam, but avoid giving benzodiazepines to those with a history of substance abuse or who are currently abusing alcohol or benzodiazepines, unless following a detoxification protocol.
- Most antidepressants except bupropion may treat panic disorder, but fluoxetine and selegiline patch can cause more initial nervousness than other antidepressants.
- In nonbipolar patients, start a low-dose SSRI, e.g., 5 mg (escitalopram), 25 mg (sertraline), 10 mg (paroxetine), and consider doubling the dose after 2 to 4 weeks; while waiting for the antidepressant to work, schedule frequent visits, give the patient reassurance, teach a relaxation technique, encourage the patient to do vigorous aerobic exercise as soon as a panic attack begins (if medically appropriate and in an appropriate situation); refer the patient to a competent therapist for CBT (4)[A].
- In bipolar patients, panic symptoms often resolve when treated with a mood stabilizer rather than an antidepressant (which may cause mania).

Second Line

- Among serotonin-norepinephrine reuptake inhibitors, venlafaxine extended release (ER) is effective. Start at 37.5 mg/day and titrate up to 75 mg/day after 7 days (maximum dose of 225 mg/day). Taper slowly over weeks to discontinue. Risk of hypertension at higher doses (5)[A].
- Tricyclic antidepressants, particularly imipramine (start 25 mg/day in the evening and increase up to 25 mg every 3 days to a maximum of 200 mg/day); slower titration and lower doses are often as effective. Imipramine is as efficacious as SSRIs in the treatment of panic disorder. Tricyclic antidepressants are considered second line because of difficulty in dosing, more side effects, and greater risk associated with overdose compared with SSRIs (6)[A].
- Benzodiazepines like alprazolam (start 0.5 mg TID and up to 5 mg/day) and clonazepam (0.25 mg BID to target 1 mg/day) are FDA approved for panic disorder. Clonazepam has a longer half-life, less interdose anxiety, and lower abuse potential than alprazolam.

ISSUES FOR REFERRAL

Consider referral to a psychiatrist for panic disorder that is comorbid with bipolar disorder, borderline personality disorder, schizophrenia, suicidality, alcohol, or substance abuse.

ADDITIONAL THERAPIES

Aerobic exercise can be helpful to reduce symptoms.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- If certain life-threatening mimics of panic disorder have not been ruled out, such as an MI or PE, hospitalize patient to complete the evaluation.
- If a panic disorder patient has concrete suicidal ideation, a psychiatric admission is indicated.

ONGOING CARE

PATIENT EDUCATION

- www.nlm.nih.gov/medlineplus/panicdisorder.html
- Patient information handouts in *American Family Physician*. 2005;71:740 and 2006;74:1393.
- http://www.nimh.nih.gov/health/publications/panic-disorder-when-fear-overwhelms/index.shtml

PROGNOSIS

- Most patients recover with treatment.
- It can recur, but treatment of recurrence is usually successful.

COMPLICATIONS

- Iatrogenic benzodiazepine dependence
- Iatrogenic mania in bipolar patients treated for panic with unopposed antidepressants
- Misdiagnosis of more difficult-to-treat psychiatric conditions as panic and vice versa

Algorithm: Anxiety

CODES

ICD10

- F41.0 Panic disorder without agoraphobia
- F40.01 Agoraphobia with panic disorder

- F43.0 Acute stress reaction

CLINICAL PEARLS

Encouraging patients (who are medically able) to do 10 minutes of vigorous aerobic exercise the moment a panic attack seems to be starting is often a very effective way to help patients feel safe during panic attacks. Always evaluate a patient with panic for suicidality. Patients with panic disorder are at increased risk for suicide, particularly if depressed.

PARKINSON DISEASE

Donald M. Chaffee, III, MD

BASICS

DESCRIPTION

- Parkinson disease (PD) is a progressive neurodegenerative disorder caused by degeneration of dopaminergic neurons in the substantia nigra pars compacta.
- Cardinal symptoms include resting tremor, rigidity, bradykinesia, and postural instability.
- Diagnosis is based primarily on history and examination.

EPIDEMIOLOGY

Incidence

- Average age of onset: ~60 years
- Slightly more common in men than women

Prevalence

- Second most common neurodegenerative disease after Alzheimer disease
- 0.3% of general population and 1–2% of those ≥60 years of age and up to 4% of those ≥80 years of age
- Affects approximately 1 million people in the United States and 5 million worldwide

ETIOLOGY AND PATHOPHYSIOLOGY

Dopamine depletion in the substantia nigra and the nigrostriatal pathways results in the major motor complications of PD.

- Pathologic hallmark: selective loss of dopamine-containing neurons in the pars compacta of the substantia nigra
- Loss of neurons accompanied by presence of Lewy bodies, pale bodies (predecessor of the Lewy body), and Lewy neuritis

Genetics

Mutations in multiple autosomal dominant and autosomal recessive genes have been linked to PD/parkinsonian syndrome particularly when the age at symptom

onset is <50 years. Genes investigated in PD include *SNCA*, Parkin, Pink-1, DJ-1 and *LRRK2*.

RISK FACTORS

- Age and family history of PD or tremor are the greatest risk factors.
- History of smoking as well as coffee and caffeine intake may reduce risk.
- Weak association with exposure to toxins (herbicides and insecticides); however, relationship is not clear.

COMMONLY ASSOCIATED CONDITIONS

Non–motor-associated symptoms include cognitive abnormalities, autonomic dysfunction (e.g., constipation, urinary urgency), sleep disturbances, mental status changes (depression, psychosis, hallucinations, dementia), orthostatic hypotension, and pain.

DIAGNOSIS

- Diagnosis is based on clinical features of bradykinesia, resting tremor, asymmetry of symptoms, and response to dopaminergic therapy.
- Gold standard for diagnosis is neuropathologic exam.
- Generally, bradykinesia plus either tremor or rigidity must be present in order to make the diagnosis of idiopathic PD.

HISTORY

Symptoms often subtle or attributed to aging:

- Decreased emotion displayed in facial features
- General motor slowing and stiffness (one or both arms do not swing with walk)
- Resting tremor (often initially one hand)
- Speech soft/mumbling
- Falls/difficulty with balance (tends to occur with disease progression)

PHYSICAL EXAM

- Tremor
  - Resting tremor (4 to 6 Hz) that is often asymmetric
  - Disappears with voluntary movement

  - Frequently emerges in a hand while walking and may present as pill rolling
  - May also present in jaw, chin, lips, tongue
- Bradykinesia
- Rigidity: cogwheel (catching and releasing) or lead pipe (continuously rigid)
- Postural instability

DIFFERENTIAL DIAGNOSIS

- Essential tremor: Bradykinesia is not present; often symmetric and occurs mostly during action or when holding hands outstretched
- SWEDD: scans without evidence of dopaminergic deficit; isolated upper extremity resting and postural tremor resembling PD but failing to progress to generalized PD; no akinesia
- Dementia with Lewy bodies: characterized clinically by visual hallucinations, fluctuating cognition, and parkinsonism; dementia occurs concomitantly with or before the development of parkinsonism.
- Corticobasal degeneration: asymmetric parkinsonism, absence of tremor, no response to levodopa
- Multiple system atrophy: presets with parkinsonism but with varying degrees of dysautonomia, cerebellar involvement, and pyramidal signs
- Progressive supranuclear palsy: impairment in vertical eye movements (particularly down gaze), hyperextension of neck, and early falling; pseudobulbar palsy
- Idiopathic basal ganglia calcification
- Associated neurodegenerative disorders: late stages of Alzheimer disease, Huntington disease, frontotemporal dementia, spinocerebellar ataxias
- Secondary parkinsonism
  - Drug induced: reversible; may take weeks/months after offending medication is stopped
    - Neuroleptics (most common cause)
    - Antiemetics (e.g., prochlorperazine and promethazine), metoclopramide
    - SSRIs
    - Calcium channel blockers (e.g., flunarizine and cinnarizine) metoclopramide
    - Amiodarone
    - Lithium

- Cholinergics
- Chemotherapeutics
- Amphotericin B
- Estrogens
- Valproic acid

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Diagnosis is mainly clinical, and there are no physiologic or blood tests to confirm the diagnosis.
- Excellent response to an acute dopaminergic challenge test supports the diagnosis.
- MRI of brain is nondiagnostic but can be used to rule out structural abnormalities.
- DaTscan: Striatal dopamine transporter imaging can distinguish PD and other parkinsonian syndromes but cannot differentiate between them.
- PET and single-photon emission CT may be helpful with diagnosis but are not required.

TREATMENT

GENERAL MEASURES

- Multidisciplinary rehabilitation with standard physical and occupational therapy components to improve functional outcomes
- Physiotherapy to help with gait reeducation, enhancement of aerobic capacity, improvement in movement initiation, improvement in functional independence, and help with home safety

MEDICATION

- PD goal: Improve motor and nonmotor deficits.
- Agents are chosen based on patient age and symptoms present.
- No treatment shown to slow progression

First Line

- First-line agents in early PD: levodopa, dopamine agonists, monoamine

oxidase B (MAO-B) inhibitors (1)[A]

- Levodopa combined with carbidopa is still the most effective treatment for symptoms of PD, particularly bradykinesia.
- Levodopa versus dopamine agonist is controversial (2)[B]:
  - Most patients eventually will develop motor fluctuations with levodopa. Younger patients are more likely to develop motor fluctuations. Some recommend delaying initiation of levodopa to decrease drug-induced motor fluctuations early in the disease.
  - Older patients often are less able to tolerate the adverse events of dopamine agonists.
  - All patients eventually will require levodopa.
- MAO-B inhibitors (rasagiline) should be considered as initial monotherapy; investigated for potential neuroprotective effects (2)[B]

- Carbidopa + levodopa (carbidopa inhibits peripheral conversion of levodopa)
  - Immediate release (Sinemet)
    - Tablets (mg): 10/100, 25/100, 25/250
    - Usual initial maintenance dose: 25/100 mg PO TID. Most patients require 25 mg of carbidopa to inhibit peripheral conversion of levodopa.
    - Watch for nausea/vomiting, orthostatic hypotension, sedation, and vivid dreams.
  - Orally disintegrating (Parcopa)
    - Tablets (mg): 10/100, 25/100, 25/25
  - Sustained release (Sinemet CR):
    - Tablets (mg): 25/100, 50/200
    - Dose agents initially BID
- Carbidopa + levodopa + entacapone (Stalevo)
  - Tablets (mg): 12.5/50/200, 18.75/75/200, 25/100/200, 31.25/125/200, 37.5/150/200, 50/200/200
  - Addition of entacapone as a single agent should be initiated prior to use of this combination:
    - Once daily dose of carbidopa/levodopa has been identified; may convert to Stalevo
    - Dose of levodopa may need to be decreased with the addition of entacapone.

  - Side effects are the same, plus diarrhea and brownish orange urine.
- Dopamine agonists (nonergot): side effects: nausea, vomiting, hypotension, sedation, edema, vivid dreaming, compulsive behavior, confusion, light-headedness, and hallucinations:
  - Pramipexole (Mirapex): tablets (mg): 0.125, 0.25, 0.5, 1, 1.5
    - Start with 0.125 mg TID; gradually increase every 5 to 7 days; usual maintenance of 0.5 to 1.5 mg TID
    - CrCl 30 to 59 mL/min 0.125 mg PO BID
    - CrCl 15 to 29 mL/min 0.125 mg PO daily
  - Pramipexole ER (Mirapex ER): tablets (mg): 0.375, 0.75, 1.5, 3, 4.5; start with 0.375 PO daily
  - Ropinirole (Requip): tablets (mg): 0.25, 0.5, 1, 2, 3, 4, 5; start with 0.25 mg TID; increase gradually to 3 to 8 mg TID
  - Requip XL: tablets (mg): 2, 4, 6, 8, 12; start at a 2-mg dose once daily; increase in 1 to 2 weeks
- Selective MAO-B inhibitors: side effects: insomnia, jitteriness, hallucinations; mostly found with selegiline; rasagiline similar adverse events as placebo in clinical trials. Rasagiline is metabolized via *CYP1A2*; caution with other medications using this enzyme system (e.g., ciprofloxacin):
  - Both agents contraindicated with meperidine and numerous other agents metabolized via *CYP1A2*
  - At therapeutic doses, unlikely to induce a “cheese reaction” (tyramine storm)
- Selegiline (Eldepryl)
  - Tablets: 5 mg; initiate 5 mg PO BID.
  - Orally disintegrating tablet (Zelapar): 1.25 mg; 1.25 mg PO daily for 6 weeks; increase as needed to max of 2.5 mg daily.
- Rasagiline (Azilect): tablets: 0.5 mg, 1.0 mg; initiate 0.5 to 1 mg daily.

Second Line

- Second-line agents in early PD: β-adrenergic antagonists (postural tremor), amantadine, anticholinergics (young patients with tremor); there is lack of good evidence for symptom control (1)[A].
- Dopamine agonists (ergot): Increased adverse event profile makes these

agents nonpreferred to nonergot dopamine agonists; bromocriptine (Parlodel)

- Treatment of levodopa-induced motor complications
  - End of dose wearing off
    - Entacapone (with each levodopa dose) or rasagiline preferred (3)[B]
    - May also consider dopamine agonist, apomorphine, selegiline (4)[B]
  - Dyskinesias
    - Typically occur at peak dopamine level
    - Amantadine may be considered; however, its efficacy is questionable (1)[B].
- Anticholinergic agents: usually avoided due to lack of efficacy (only useful for tremor) and increased adverse event profile, including blurred vision, confusion, constipation, dry mouth, memory difficulty, sedation, and urinary retention
  - Trihexyphenidyl
    - Tablets: 2 mg, 5 mg
    - Start with 1 to 2 mg daily; increase by 2 mg every 3 to 5 days until usual dose is 6 to 10 mg in 3 to 4 divided doses.
  - Benztropine (Cogentin)
    - Tablets: 0.5 mg, 1 mg, 2 mg
    - Start with 0.5 to 1 mg in 1 to 2 divided doses; increase by 0.5 mg every 5 to 6 days; usual dose is 1 to 2 mg/day in divided doses.
- *N*-methyl-D-aspartic acid antagonist: Exact mechanism is unknown and efficacy is questionable; however, it may be useful for dyskinesias. Side effects include confusion, dizziness, dry mouth, livedo reticularis, and hallucinations:
  - Amantadine (Symmetrel)
    - Tablets: 100 mg
    - Start with 100 mg BID; may increase to 300 mg daily in divided doses; renally adjusted
- Catechol-O-methyl transferase (COMT) inhibitors: entacapone preferred due to hepatotoxicity associated with tolcapone. Adverse events include nausea and orthostatic hypotension:
  - Entacapone (Comtan)
    - Tablets: 200 mg

    - 200 mg with each dose of carbidopa/levodopa; max dose 1,600 mg/day
  - Tolcapone (Tasmar)
    - Tablets: 100 mg, 200 mg
    - Start 100 mg TID; max dose 600 mg/day; must be taken with carbidopa/levodopa
    - Requires LFT monitoring
- Apomorphine (Apokyn): nonergot-derived dopamine agonist given SC for off episodes in advanced disease; adverse events: nausea, vomiting, dizziness, hallucinations, orthostatic hypotension, somnolence
  - Only for "off" episodes with levodopa therapy
  - Requires initial "test" dose (2 mg); monitor for orthostatic hypotension after initial dose; this is a potent emetic, so initiate an antiemetic (e.g., trimethobenzamide) 3 days prior to start and continue for 2 months. Avoid ondansetron (combination contraindicated due to profound hypotension) and dopamine antagonists, such as prochlorperazine and metoclopramide.
  - Effective dose ranges from 2 to 6 mg per injection.

ISSUES FOR REFERRAL

Early specialty referral for patients with suspected PD for an accurate diagnosis and management

ADDITIONAL THERAPIES

- Emotional and psychological support of patient family
- Physical therapy and manual medicine has been shown to improve balance, muscle strength, and walking speed.
- Speech therapy: may be helpful in improving speech volume and maintaining voice quality
- Treatment of nonmotor symptoms
  - Sildenafil to treat erectile dysfunction (5)[C]
    - Tablets: 25 mg, 50 mg, 100 mg
    - Take once daily 1 hour prior to sexual activity
    - Caution with orthostatic hypotension; avoid with nitrates.
  - Polyethylene glycol to treat constipation (5)[C]
    - Mix 17 grams in 8 oz of water once daily.
    - May titrate to one soft bowel movement per day

– Carbidopa + levodopa to treat periodic limb movements (5)[B]

SURGERY/OTHER PROCEDURES

Deep brain stimulation (bilateral subthalamic nucleus/globus pallidus interna) is an effective therapeutic option for patients with motor complications refractory to best medical treatment who are healthy, have no significant comorbidities, are responsive to levodopa, and do not have depression or dementia.

ONGOING CARE

DIET

- Increase dietary fluids and fiber and increase activity for constipation.
- For dysphagia, consider soft food, swallowing evaluation, and increased time for meals.
- Avoid large, high-fat meals that slow digestion and interfere with medication absorption.

PATIENT EDUCATION

- www.apdaparkinson.org
- www.parkinson.org
- www.michaeljfox.org

PROGNOSIS

- PD is a chronic progressive disease; prognosis varies based on patient-specific symptoms.
- Increased mortality in PD; on average, PD survival reduced by 5% every year of follow-up (4).

COMPLICATIONS

Most commonly, the result of adverse effects of medications used to treat

CODES

ICD10

- G20 Parkinson's disease
- G21.9 Secondary parkinsonism, unspecified
- G31.83 Dementia with Lewy bodies

CLINICAL PEARLS

- Emphasize the importance of exercise and movement to help preserve function.
- Pharmacotherapeutic regimens need to be individualized based on patient-specific symptoms and age.

PARONYCHIA

Nancy V. Nguyen, DO

BASICS

DESCRIPTION

- Superficial inflammation of the lateral and posterior folds of skin surrounding the fingernail or toenail
  - Acute: characterized by pain, erythema, and swelling; usually a bacterial infection, appears after trauma. It can progress to abscess formation.
  - Chronic: characterized by swelling, tenderness, cuticle elevation, and nail dystrophy and separation lasting at least 6 weeks, or recurrent episodes of acute eponychial inflammation and drainage.
  - May be considered work-related among bartenders, waitresses, nurses, and others who often wash their hands
- System(s) affected: skin and nail bed
- Synonym(s): eponychia; perionychia

Pediatric Considerations

Less common in pediatric age groups. Thumb/finger-sucking is a risk factor (anaerobes and *Escherichia coli* may be present).

EPIDEMIOLOGY

Incidence

- Common in the United States
- Predominant age: all ages
- Predominant sex: female > male

ETIOLOGY AND PATHOPHYSIOLOGY

- Acute: *Staphylococcus aureus* (1) most common and *Streptococcus pyogenes* (1)*;* less frequently, *Pseudomonas pyocyanea* and *Proteus vulgaris*. In digits exposed to oral flora especially in pediatric age group, consider *Eikenella corrodens*, *Fusobacterium*, and *Peptostreptococcus*.
- Chronic: eczematous reaction with secondary *Candida albicans* (~95%) (2)

- A paronychial infection commonly starts in the lateral nail fold.
- Recurrent inflammation, persistent edema, and fibrosis of nail folds cause nail folds to round up and retract, exposing nail grooves to irritants, allergens, and pathogens.
- Inflammation compromises ability of proximal nail fold to regenerate cuticle leading to decreased vascular supply. This can cause decrease efficacy of topical medications.
- Early in the course, cellulitis alone may be present. An abscess can form if the infection does not resolve quickly.

RISK FACTORS

- Acute: direct or indirect trauma to cuticle or nail fold, manicure/sculptured nails, nail biting, and thumb sucking and predisposing conditions such as diabetes mellitus (DM)
- Chronic: frequent immersion of hands in water with excoriation of the lateral nail fold (e.g., chefs, bartenders, housekeepers, swimmers, dishwashers, nurses), DM, immunosuppression (reported association with antiretroviral therapy for HIV and with use of epidermal growth factor inhibitors) (3)

GENERAL PREVENTION

- Acute: Avoid trauma such as nail biting; prevent thumb sucking.
- Chronic: Avoid allergens; keep fingers/hands dry; wear rubber gloves with a cotton liner. Prevent excoriation of the skin.
- Keep nails short. Avoid manicures. Apply moisturizer after washing hands.
- Good glycemic control in diabetic patients

COMMONLY ASSOCIATED CONDITIONS

- DM
- Eczema or atopic dermatitis
- Certain medications: antiretroviral therapy (3) (especially protease inhibitors, indinavir, and lamivudine, in which toes more commonly involved) (3)
- Immunosuppression (4)

DIAGNOSIS

HISTORY

- Localized pain or tenderness, swelling, and erythema of posterior or lateral nail folds
  - Acute: fairly rapid onset
  - Chronic: 4 to 6 weeks' duration
- Previous trauma (bitten nails, ingrown nails, manicured nails)
- Contact with herpes infections
- Contact with allergens or irritants (frequent water immersion, latex) (4)

PHYSICAL EXAM

- Acute: red, warm, tender, tense posterior or lateral nail fold ± abscess
- Chronic: swollen, tender, boggy nail fold ± abscess
- Occasional elevation of nail bed
- Separation of nail fold from nail plate
- Red, painful swelling of skin around nail plate
- Fluctuance, purulence at the nail margin, or purulent drainage
- Secondary changes of nail platelike discoloration
- Suspect *Pseudomonas* if with green changes in nail (chloronychia) (5).
- Positive fluctuation when mild pressure over the area causes blanching and demarcation of the abscess
- Chronic: retraction of nail fold and absence of adjacent healthy cuticle, thickening of nail plate with prominent transverse ridges known as Beau lines and discoloration

DIFFERENTIAL DIAGNOSIS

- Felon (abscess of fingertip pulp; urgent diagnosis required)
- Contact dermatitis
- Herpetic whitlow (similar in appearance, very painful, often associated with vesicles)
- Acute osteomyelitis of the distal phalanx
- Psoriasis especially acute flare
- Allergic contact dermatitis (latex, acrylic)
- Reiter disease
- Pustular psoriasis
- Proximal/lateral onychomycosis (nail folds not predominantly involved)

- Malignancy: squamous cell carcinoma of the nail, malignant melanoma, metastatic disease

DIAGNOSTIC TESTS & INTERPRETATION

None required unless condition is severe; resistant to treatment or if recurrence or methicillin-resistant *S. aureus* (MRSA) is suspected, then

- Gram stain
- Culture and sensitivity
- Potassium hydroxide wet mount plus fungal culture especially in chronic
- Drugs that may alter lab results: Use of over-the-counter antimicrobials or antifungals.

Diagnostic Procedures/Other

- Incision and drainage recommended for suppurative cases or cases not responding to conservative management or empiric antibiotics
- Tzanck testing or viral culture in suspected viral cases
- Biopsy in cases not responding to conservative management or when malignancy suspected

TREATMENT

GENERAL MEASURES

- Acute: warm compresses, elevation, splint protection if pain severe
- Chronic: Keep fingers dry; apply moisturizing lotion after hand washing; avoid exposure to irritants; improved diabetic control

MEDICATION

First Line

- Tetanus booster when indicated
- Acute (mild cases, no abscess formation)
  - Topical antibiotic cream alone or in combination with a topical steroid (6) [B]
  - Antibiotic cream applied TID–QID after warm| soak (e.g., mupirocin or gentamicin/neomycin/polymyxin B) for 5 to 10 days
  - If eczematous: low-potent topical steroid applied BID (e.g., betamethasone

0.05% cream) for 7 to 14 days (7)[B]

- Acute (no exposure to oral flora)
  - Dicloxacillin 250 mg TID for 7 days
  - Cephalexin 500 mg TID–QID for 7 days
- Acute (suspected MRSA)
  - Trimethoprim/sulfamethoxazole 160 mg/800 mg BID for 7 days
  - Doxycycline 100 mg BID for 7 days
- Acute (exposure to oral flora)
  - Amoxicillin clavulanate: 875 mg/125 mg BID or 500 mg/125 mg TID for 7 days; pediatric, 45 mg/kg q12h (for <40 kg)
  - Clindamycin 300 to 450 mg TID–QID for 7 days; pediatric, 10 mg/kg q8h; *plus* either doxycycline or trimethoprim/sulfamethoxazole
- Chronic
  - Topical steroids: betamethasone 0.05%; applied BID for 7 to 14 days (8)[B]
  - Topical antifungal: clotrimazole or nystatin; applied topically TID for up to 30 days
  - Other topical: Tacrolimus 0.1% ointment BID for up to 21 days has been shown to be effective but is more expensive.

Second Line

- Systemic antifungals (rarely needed, use if topical fails)
  - Itraconazole 200 mg for 90 days (may have longer action because it is incorporated into nail plate); pulse therapy may be useful (i.e., 200 mg BID for 7 days, repeated monthly for 2 months) (1)[C],(8)
  - Terbinafine 250 mg/day for 6 weeks (fingernails) or 12 weeks (toenails)
  - Fluconazole 100 mg daily for 7 to 14 days
  - Ciclopirox 0.77% topical suspension BID for 2 to 4 weeks along with strict irritant avoidance (7)[B]
- Antipseudomonal drugs (e.g., ceftazidime, aminoglycosides) when pseudomonas is suspected

ISSUES FOR REFERRAL

Chronic; in treatment failure, consider biopsy and/or, in cases of chronic paronychia, referral for possible partial excision of the nail fold or eponychial marsupialization with or without complete nail removal.

SURGERY/OTHER PROCEDURES

- Incision and drainage of abscess, if present
- A subungual abscess or ingrown nail requires partial or complete removal of nail with phenolization of germinal matrix.
- Recalcitrant cases may also need nail removal.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Chronic: Avoid frequent immersion, triggers, allergens, or nail biting and finger sucking.

DIET

If patient is diabetic, consider appropriate dietary and medication changes for better control.

PATIENT EDUCATION

- Avoid trimming cuticles; avoid nail trauma; and stress importance of good diabetic control and diabetic education.
- Avoid contact irritants; use rubber gloves with cotton liners to avoid exposure to excess moisture.
- Use moisturizing lotion after washing hands; do not bite nails/suck on fingers.

PROGNOSIS

- With adequate treatment and prevention, healing can be expected in 1 to 2 weeks.
- Chronic paronychia may respond slowly to treatment, taking weeks to months.
- If no response in chronic lesions, rarely benign or malignant neoplasm may be present and referral should be considered.

COMPLICATIONS

- Acute: subungual abscess
- Chronic: nail thickening, discoloration of nail, and nail loss

Onychomycosis

CODES

ICD10

- L03.019 Cellulitis of unspecified finger
- L03.039 Cellulitis of unspecified toe

CLINICAL PEARLS

- Consider tetanus booster when indicated.
- Consider incision and drainage when appropriate. Send culture.
- For chronic paronychia, topical steroid is first-line treatment. Consider other differentials in nonresponders (e.g., rare causes: Raynaud, metastatic cancer, psoriasis, drug toxicity)
- For chronic nonhealing lesion, consider dermatology referral.
- Consider possibility of cancer if chronic inflammatory process is unresponsive to treatment.
- Consider presence of more than one nail disease at the same time (e.g., paronychia and onychomycosis).

PAROTITIS, ACUTE AND CHRONIC

Morgan Greenfield, MD • Kathleen Ferrer, MD, AAHIVS

BASICS

DESCRIPTION

- Parotitis is inflammation of the parotid gland caused by infection (viral or bacterial), noninfectious systemic illnesses, mechanical obstruction, or medications.
- Parotitis can be unilateral or bilateral, acute or chronic. Unilateral parotitis is usually associated with duct obstruction, whereas bilateral parotitis more commonly indicates a systemic cause.
- The parotid gland is the largest of the salivary glands, located lateral to the masseter muscle anteriorly and extending posteriorly over the sternocleidomastoid muscle behind the angle of the mandible. It produces exclusively serous secretions, which lack the bacteriostatic properties of mucinous secretions, making the parotid gland more susceptible to infection than other salivary glands.
- The parotid duct, also called Stensen duct, pierces the buccinator muscle to enter the buccal mucosa just opposite the second maxillary molar.
- The branches of the 7th cranial nerve or “facial nerve” divide the gland into lobes.
- The parotid gland contains lymph nodes.

EPIDEMIOLOGY

- Viral parotitis is the most common cause of parotitis in children, although the exact incidence is unknown and has decreased since the advent of the mumps vaccine.
- Acute bacterial parotitis occurs more frequently in elderly patients, neonates (especially preterm infants), and postoperative patients.
- Juvenile recurrent parotitis is the second most common inflammatory cause of parotitis in children in the United States; first episode usually occurs between the ages of 3 and 6 years.
- Chronic parotitis mainly affects adults, more often females. The average age

of presentation is between 40 and 60 years.
- Chronic bilateral parotid enlargement is a common manifestation of HIV infection; for perinatally HIV-infected children, the average age of onset for parotid enlargement is 5 years.

RISK FACTORS

- Acute viral parotitis: lack of mumps, measles, rubella (MMR) vaccination
- Acute bacterial parotitis
  - Conditions that predispose to salivary stasis such as dehydration, debilitation, poor oral hygiene, Sjögren syndrome, cystic fibrosis, bulimia/anorexia, sialolithiasis (stones), ductal stenosis, trauma
  - Immunosuppression, HIV, chemotherapy, radiation, malnutrition, alcoholism
- Neonatal parotitis: prematurity, low birth weight, ductal obstruction, oral trauma, structural abnormalities, immunosuppression
- Juvenile recurrent parotitis: dental malocclusion, congenital duct malformation, genetic factors, immunologic anomalies
- Drug-induced parotitis: medications such as anticholinergics, antihistamines, diuretics, tricyclic antidepressants, antipsychotics, antineoplastic agents, and iodine
- Chronic parotitis: ductal stenosis, HIV, tuberculosis, Sjögren syndrome, and sarcoidosis

GENERAL PREVENTION

- MMR vaccination with the first dose between 12 and 15 months and second dose between 4 and 6 years of age; childhood mumps vaccination does not guarantee prevention, possibly due to waning immunity in adolescence.
  - Students in post-high school education without documented mumps immunity should also receive two doses of the MMR vaccine, 28 days apart.
- Maintain adequate hydration and good dental hygiene.
- Suck on hard or sour candy and use hot compresses with parotid massages to stimulate salivary flow and prevent salivary stasis.
- Smoking cessation, abstinence from alcohol, and avoidance of chronic purging

ETIOLOGY AND PATHOPHYSIOLOGY

- Acute viral parotitis begins as a systemic infection that localizes to the parotid gland, resulting in inflammation and swelling of the gland.
  - Mumps, or paramyxovirus, has a predilection for the parotid gland and classically has been linked to parotitis.
- Acute bacterial parotitis results from stasis of salivary flow that allows retrograde introduction of bacterial pathogens into the parotid gland, resulting in localized infection.
- Acute parotitis pathogens
  - Viral
    - Paramyxovirus (mumps), parainfluenza virus types 1 and 3, influenza A, coxsackievirus, Epstein-Barr virus (EBV)
    - Cytomegalovirus (CMV) and adenovirus have been seen in patients with HIV.
  - Bacterial
    - *Staphylococcus aureus* and anaerobes (oral flora) are most commonly seen.
    - *Streptococcus pneumoniae*, viridans streptococci, *Escherichia coli*, and *Haemophilus influenza* (less common)
    - Gram-negative rods such as *E. coli*, *Klebsiella, Enterobacter*, and *Pseudomonas* can be seen in chronically ill or hospitalized patients.
  - Fungal
    - *Candida* has been isolated in chronically ill or hospitalized patients.
    - *Actinomyces* can be found in patients with a history of trauma or dental caries.
- Acute, recurrent parotitis
  - Juvenile recurrent parotitis may be secondary to chronic inflammation; etiology is unknown, but a genetic predisposition may exist.
  - Mechanical: sialolithiasis, ductal stenosis; repeated sialolith formation can lead to ductal wall damage, fibrosis, and stricture formation, which further decreases salivary flow and perpetuates obstruction.
  - Pneumoparotitis may occur when air is trapped in the ducts of the parotid gland; may be seen in wind instrument players, glass blowers, scuba divers, and with dental cleaning

  - Medications: anticholinergics, antihistamines, tricyclic antidepressants, antipsychotics (especially phenylbutazone, thioridazine, clozapine), iodine (especially contrast media), and L-asparaginase
  - Other: diabetes, alcoholism, bulimia, “anesthesia mumps” (Possible mechanisms include transient mechanical compression of Stensen duct by airway devices, loss of muscle tone around the Stensen orifice after neuromuscular relaxants, increased salivary secretion, and increased flexion or rotation of the head during general anesthesia.)
- Chronic parotitis in HIV-infected patients can be due to the presence of benign lymphoepithelial cysts, follicular hyperplasia of parotid lymph nodes, or diffuse infiltrative lymphocytosis syndrome (DILS), causing infiltration of the parotid gland by CD8 cells.
  - Parotitis may also be secondary to immune reconstitution after initiation of combination antiretroviral therapy in HIV-infected patients.

COMMONLY ASSOCIATED CONDITIONS

HIV, Sjögren syndrome, sarcoidosis, sialolithiasis

DIAGNOSIS

HISTORY

- Acute parotitis presents with sudden-onset pain and swelling of the cheek usually extending to and obscuring the angle of the mandible.
  - Viral parotitis is usually bilateral and accompanied by a prodrome of malaise, anorexia, headaches, myalgias, arthralgias, and fever; typically, overlying skin is not warm or erythematous, and no pus is reported at the opening of Stensen duct.
  - Bacterial parotitis is typically unilateral with induration, warmth, and erythema over the affected cheek; fever is often present.
  - Juvenile recurrent parotitis is usually unilateral; pain and swelling usually resolve within 2 weeks, and exacerbations occur until puberty; purulent exudate is not typical, but superinfection may occur.
  - Sialolithiasis is characterized by recurrent acute swelling and pain, exacerbated by eating; sialolithiasis affects the submandibular gland more

frequently.
  - Other frequently reported symptoms include trismus (inability to open mouth), pain exacerbated by chewing or worsened by foods that stimulate production of saliva (i.e., sour candies), dry mouth with abnormal taste, difficulty with drinking/eating, anorexia, or dehydration.
- Chronic parotitis presents with recurrent or chronic nontender swelling of one or both parotid glands; can have periods of remission lasting weeks to years
  - Sjögren syndrome, sarcoidosis, HIV, tuberculosis
  - Chronic parotitis may predispose to superinfection, which would present similarly to an acute parotitis.

PHYSICAL EXAM

- Parotitis is characterized by swelling or enlargement of the parotid gland(s) overlying the masseter muscle; it may obscure the angle of the mandible or cause the ear to protrude upward and outward.
- Palpation of the parotid gland is best done by using one hand to start at the attachment of the earlobe and palpating anteriorly and inferiorly along the mandibular ramus while the other hand simultaneously palpates the Stensen duct orifice.
  - Tender and bilateral suggests viral etiology, whereas tender, erythematous, warm, and unilateral suggests bacterial etiology.
  - Nontender in HIV, tuberculosis, Sjögren syndrome, sarcoidosis
- Trismus may be noted.
- Pus from Stensen duct is suggestive of bacterial parotitis or superinfection; opening of duct may appear edematous and erythematous in both bacterial and viral parotitis.
- In juvenile recurrent parotitis, Stensen duct is often enlarged, dilated, erythematous, and swollen.
- Halitosis and dental decay are often associated with acute exacerbations.
- Facial nerve palsy can be seen in severe cases.

DIFFERENTIAL DIAGNOSIS

- Lymphoma, neoplasm, lymphangitis, cervical adenitis, otitis externa, dental abscess, odontogenic infections, Ludwig angina, and cellulitis should be considered in the differential.

- Parotid swelling or enlargement typically obscures the angle of the mandible (unlike cervical adenitis).
- Involvement of Stensen duct is unique to parotitis.

DIAGNOSTIC TESTS & INTERPRETATION

- History and physical exam are usually sufficient for diagnosis of parotitis.
- Performing aerobic culture and Gram stain of purulent drainage from Stensen duct or aerobic and anaerobic culture from needle aspiration of gland or abscess can be helpful to identify causative organism.
  - Anaerobic culture from Stensen duct will likely contain oropharyngeal contamination; hence, it is recommended to perform anaerobic cultures only from needle aspirate fluid.
- Acute bacterial parotitis often demonstrates an elevated white blood cell count and amylase.
- For suspected mumps, obtain mumps IgM antibody or mumps reverse transcription-polymerase chain reaction (RT-PCR). Viral PCR is best obtained from buccal swab within 1 to 3 days of parotitis onset. In areas of high vaccination rates, IgM may be falsely negative. A 4-fold increase of mumps IgG antibody indicates infection.
- Consider sending EBV titers and respiratory virus PCR panel if viral parotitis suspected; CMV titers should be sent in immunocompromised patients.
- For chronic, recurrent, or nontender parotitis, obtain HIV test, PPD, SS-A SS-B antibodies, rheumatoid factor, and antinuclear antibodies to evaluate for underlying etiology.
- Consider obtaining ultrasound or CT scan of parotid area to assess for abscess, cystic masses, parotid tumors, ductal stenosis, or sialolithiasis if no response to initial treatment.
- Consider sialography with chronic parotitis to assess the anatomy and functional integrity of the gland; can be diagnostic and therapeutic.

Diagnostic Procedures/Other

Consider performing a biopsy or fine-needle aspiration of gland if there is suspicion for tuberculosis, Sjögren syndrome, or sarcoidosis.

Test Interpretation

- Findings characteristic of HIV are described in the “Etiology and Pathophysiology” section.
- Noncaseating granulomas may be seen in sarcoidosis, and caseating granulomas may be found in tuberculosis.

TREATMENT

GENERAL MEASURES

- Usually a self-limiting course that requires primarily supportive treatment with rest, adequate hydration, analgesia, and antipyretics
  - Can stimulate glands to produce saliva by sucking on hard candies or glycerin swabs
  - Local heat and gentle massage of gland can provide symptomatic relief.
  - For chronic presentations, encourage good dental hygiene and treat underlying etiology of parotitis (HIV, Sjögren syndrome, etc.).
- Patients diagnosed with mumps should be isolated with standard and droplet precautions for 5 days after onset of parotid swelling.
- Data are limited regarding use of MMR vaccine for postexposure prophylaxis (PEP) in fully vaccinated individuals during a mumps outbreak; current evidence suggests no statistically significant decrease in mumps attack rate with PEP (1)[C].

MEDICATION

- Viral parotitis: with an uncertain diagnosis or toxic presentation, can empirically initiate antibiotics to cover *Staphylococcus aureus*, anaerobes (oral flora), and *Streptococcus pneumoniae*
- Acute bacterial parotitis
  - Outpatient management: amoxicillin/clavulanate, 1st-generation cephalosporin, clindamycin
  - Chronically ill or hospitalized: ampicillin/sulbactam or clindamycin and nafcillin; if methicillin resistance is probable, consider vancomycin or linezolid.
- Pilocarpine and cevimeline can stimulate saliva production and inhibit ascending infection as well as provide symptomatic relief for patients with

underlying Sjögren syndrome.

SURGERY/OTHER PROCEDURES

- Consider needle aspiration for bacterial parotitis with abscess formation or clinical deterioration with increasing pain, erythema, and swelling not responding to medication.
- May perform serial drainage for symptomatic cysts
- Consider superficial parotidectomy for severe recurrent parotid infections in patients with underlying predisposing etiology (such as Sjögren syndrome).
- For sialolithiasis, ductal stenosis, or for patients with >1 recurrence per year, consult otolaryngologist for possible sialendoscopy, duct ligation, ductoplasty, or parotidectomy.
- Sialendoscopy with cortisone irrigation is effective and safe for the treatment of juvenile recurrent parotitis (JRP); cortisone irrigation alone may be just as effective; performing parotid ultrasound is recommended first to differentiate JRP from ductal stones (2)[A],(3)[C].
- Sclerotherapy with methyl violet or tetracycline has been shown to be effective in the treatment of cysts in HIV parotitis and is also considered definitive treatment for chronic parotitis (4)[C].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Admission is recommended for patients with comorbidities, systemic involvement, and inability to tolerate PO, as well as neonates and patients for whom close outpatient follow-up is not feasible.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Antibiotic therapy initiated at diagnosis combined with adequate hydration should result in improvement within 48 hours. If not, patient should be reevaluated.

DIET

- Ensure adequate fluid intake.

- Hard or sour candies to promote salivary flow

PROGNOSIS

- Viral infection in immunocompetent individuals often resolves with excellent prognosis.
- Parotid cysts found in HIV-infected patients are usually benign lymphoepithelial lesions with infrequent malignant transformation.
- Increased incidence of malignant lymphoma or lymphoepithelial carcinoma may be seen in patients with Sjögren syndrome.

COMPLICATIONS

- For mumps, potential complications include orchitis, oophoritis, mastitis, aseptic meningitis, pancreatitis, myocarditis, sensorineural hearing loss, and nephritis.
- Untreated bacterial parotitis can lead to local extension, abscess formation, and facial paralysis.

CODES

ICD10

- K11.20 Sialoadenitis, unspecified
- K11.21 Acute sialoadenitis
- K11.23 Chronic sialoadenitis

CLINICAL PEARLS

- History and physical exam are usually sufficient for diagnosis (parotid swelling and tenderness with or without purulent drainage from Stensen duct).
- In recurrent or chronic cases, consider other underlying etiologies such as HIV.
- *S. aureus* and anaerobes (oral flora) are the most common organisms isolated in acute bacterial parotitis.
- Encouraging good oral hygiene and adequate hydration in chronically ill, debilitated, and hospitalized patients can reduce parotitis occurrence.

PARVOVIRUS B19 INFECTION

David L. Anderson, MD • Thomas P. Garigan, MD, MA

BASICS

DESCRIPTION

- Human parvovirus B19 is the primary cause of acute erythema infectiosum (EI, or fifth disease).
- Complications in susceptible individuals with increased RBC turnover (e.g., sickle cell anemia [SS]) include transient aplastic crisis (TAC). In immunocompromised individuals, pure red cell aplasia (PRCA) and chronic anemia are significant complications. In normal hosts, arthritis and arthralgias are common.
- System(s) affected: hematologic/lymphatic/immunologic, musculoskeletal, skin/exocrine, possibly central nervous system, cardiac, renal

Pregnancy Considerations

A documented acute infection during pregnancy should prompt referral to a maternal–fetal medicine specialist. Maternal parvovirus B19 infection between 9 and 20 weeks' gestation may carry a significant fetal risk.

EPIDEMIOLOGY

- Infection is common in childhood.
- EI has an extremely low mortality rate.
- Peak age for EI is 4 to 12 years.
- Males and females are equally affected.
- Adult females are more likely to develop postinfectious arthritis.
- No known racial predilection
- In temperate climates, infections often occur from late winter to early summer.
- Local outbreaks may occur every 2 to 4 years.

Prevalence

Extremely common in the United States. Based on IgG serology:

- 1 to 5 years of age: 2–15% seropositive

- 6 to 15 years of age: 20–40% seropositive
- 16 to 40 years of age: 50–60% seropositive
- >40 years of age: 70–85% seropositive

ETIOLOGY AND PATHOPHYSIOLOGY

- Small (20 to 25 mm), nonenveloped, single-stranded DNA virus in *Parvoviridae* family
  - Only known parvovirus to infect humans; does not cross-infect dogs or cats
- Natural host of B19 is human erythroid progenitor.
- Respiratory, hematogenous, and vertical transmission are sources of human spread.
- 4- to 14-day incubation. Rash and joint symptoms occur 2 to 3 weeks after initial infection.
- Most contagious 5 to 10 days after exposure
- EI rash thought to be autoimmune due to IgM complexes concurrent with viral clearance.
- Cytotoxic infection of proerythroblasts reduces RBC production.

Genetics

Erythrocyte P antigen–negative individuals are resistant to infection.

RISK FACTORS

- School-related epidemic and nonimmune household contacts have a secondary attack rate of 20–50%.
- Highest secondary attack rates are for daycare providers and school personnel in contact with affected children.
- Those with increased cell turnover (e.g., hemoglobinopathy, SS, thalassemia) are at risk for TAC.
- Immunodeficiency (e.g., HIV, congenital) increases risk of PRAC and chronic anemia.
- As many as 40% of pregnant women are not immune. 1.5% seroconversion rate per year

GENERAL PREVENTION

- Respiratory spread. Standard measures include hand washing and barrier protection.

- Droplet precautions are recommended around patients with TAC, chronic infection, or anemia.
- Difficult to eliminate exposure because the period of maximal contagion occurs prior to the onset of clinical symptoms (rash).
- Pregnant health care workers should avoid caring for patients with TAC.
- No significant risk of infection based on occupational exposure. Exclusion from the workplace is neither necessary nor recommended.
- No preventive vaccine is available.

COMMONLY ASSOCIATED CONDITIONS

- Nondegenerative arthritis
  - In adults, 80% of patients may manifest polyarthritis and/or arthralgia (female > male).
  - In children, joint symptoms are less common.
  - Knees, hands, wrists, and ankles (frequently symmetric) are most commonly involved.
  - Joint symptoms usually subside within 3 weeks but may persist for months. Routine radiography is not necessary.
- TAC
  - Involves patients with increased RBC turnover (SS, spherocytosis, thalassemia) or decreased RBC production (iron deficiency anemia).
  - Patients present with fatigue, weakness, lethargy, and pallor (anemia).
  - Aplastic event may be life-threatening but is typically self-limited. Reticulocytes typically reappear in 7 to 10 days and full recovery in 2 to 3 weeks.
  - In children with sickle cell hemoglobinopathies and heredity spherocytosis, fever is the most common symptom (73%). Rash is uncommon in these patients.
- Chronic anemia
  - Seen in immunocompromised individuals (HIV, cancer, transplant) with poor IgM response
  - Usually no clinical manifestations (fever, rash, or joint symptoms)
- Fetal/neonatal infection (1)
  - Risk of transplacental spread of virus is ~33% in infected mothers.
  - Test pregnant women with a rash or arthralgias consistent with parvovirus

B19.
  - Clinical manifestations vary. Many patients are seroconvert without symptoms and have a normal pregnancy. Other patients develop variable degrees of fetal hydrops. 2nd- and 3rd-trimester pregnancy loss can occur without hydrops.
  - Suspect B19 infection in cases of nonimmune fetal hydrops.
  - Fetal bone marrow is primarily impacted. RBC survival is shortened, resulting in anemia and (potentially) high-output cardiac failure.
  - >95% of fetal complications (fetal hydrops and death) occur within 12 weeks of acute maternal parvovirus B19 infection.
  - Risk of fetal loss is highest (2–5%) in the 1st trimester.
  - Infants requiring intrauterine transfusions due to parvovirus B19 infection are at risk for long-term neurodevelopmental impairment.
- Papular purpuric gloves and socks syndrome (PPGSS) is an uncommon dermatosis associated with parvovirus B19 infection. It results in a petechial and ecchymotic rash of the hands and feet associated with febrile tonsillopharyngitis and oral ulcerations (2).

DIAGNOSIS

HISTORY

- Rash
- Headache
- Pharyngitis
- Coryza and rhinorrhea
- Arthralgias and arthritis
- Nausea and GI disturbances are more frequent and severe in adults (nonspecific flulike illness).
- Pruritus (especially soles of feet)
- Fever, myalgia, and malaise

PHYSICAL EXAM

- “Slapped cheek” appearance is a well-known facial rash that spares the nasolabial folds.

- A lacy, reticular rash on the trunk, buttocks, and limbs often follows 1 to 4 days later lasting 1 to 6 weeks.
- The rash may be pruritic and recurrent, exacerbated by bathing, exercise, sun exposure, heat, or emotional stress.
- B19 may manifest as painful pruritic papules and purpura on the hands and feet.

DIFFERENTIAL DIAGNOSIS

- Rubella
- Enteroviral disease
- Systemic lupus erythematosus
- Drug reaction
- Lyme disease
- Rheumatoid arthritis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- No need for routine lab studies in typical cases. Diagnosis is clinical; illness is mild and self-limiting.
- IgG and IgM serology in immunocompetent patients
- B19-specific DNA polymerase chain reaction (PCR) testing for fetal infection (via cord blood or amniotic fluid) as well as for patients with chronic infection or those who are immunocompromised
- PCR increases diagnostic sensitivity and specificity to confirm infections in IgM-negative patients.
- For patients with TAC, CBC with reticulocyte count shows anemia and reticulocytopenia. IgM antibodies are present by day 3, and IgG antibodies are detectable at time of clinical recovery. PCR shows high levels of viremia.
- Pregnant women exposed to B19 require serial IgG and IgM serology to assess fetal risk.

Follow-Up Tests & Special Considerations

Fetal/neonatal infection (3)[C]

- To exclude congenital B19 in infants with negative B19 IgM, follow IgG serology over the 1st year of life.
- Maternal serum α-fetoprotein may be increased with hydrops fetalis.

- Documented acute maternal infection in the 1st trimester warrants serial fetal ultrasound to assess for hydrops: ascites, pericardial effusion, oligohydramnios, cardiomegaly, and placental thickening.
- Weekly peak systolic velocity measurements of the middle cerebral artery by Doppler US is recommended to evaluate for heart failure fetal anemia and the potential need for intrauterine transfusion (>1.5 MoM).
- Cerebral MRI to explore CNS damage in infected neonates with prolonged hydrops fetalis or hematocrit <15%.

Diagnostic Procedures/Other

- Skin biopsy is usually normal but may show mild inflammation consisting of perivascular infiltrations of mononuclear cells.
- In stillbirths related to maternal B19 infection, virus can be detected in all tissues.
- In hydrops fetalis, nucleated RBCs may have intranuclear inclusion bodies.

TREATMENT

GENERAL MEASURES

- No therapy is usually needed (4)[C].
- Cessation of immunosuppressive therapy allows some patients to clear chronic infections.
- B19-associated anemia in HIV-positive patients may resolve with highly active antiretroviral therapy.

MEDICATION

First Line

- Anti-inflammatory agents for arthritic symptoms
- Antipyretics for fever. Avoid aspirin in children.

Second Line

- RBC transfusions for aplastic crisis
- Intravenous immunoglobulin (IVIG) for B19-related refractory anemia or PRAC, especially in immunodeficient states (5)[C]
- Intrauterine RBC transfusions reduce mortality in cases of fetal hydrops.

ISSUES FOR REFERRAL

- Acute infection during pregnancy should prompt referral to a maternal–fetal medicine specialist.
- TAC patients require treatment by a hematologist.
- Patients with chronic or abnormal B19 infections may benefit from consultation with immunology or infectious disease specialists.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Outpatient management is typical for EI.
- Inpatient management for aplastic crisis, which may require RBC transfusions

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Periodic blood counts for anemic patients

PATIENT EDUCATION

- Parvovirus B19 (fifth disease): http://www.cdc.gov/parvovirusB19/fifth-disease.html
- Parvovirus B19: What You Should Know: http://www.aafp.org/afp/2007/0201/p377.html
- Parvovirus B19 infection and pregnancy: http://www.cdc.gov/parvovirusB19/pregnancy.html
- March of Dimes Fifth Disease and Pregnancy: http://www.marchofdimes.org/complications/fifth-disease-and-pregnancy.aspx
- Counsel pregnant women regarding prevention of maternal B19 infection.
- Pregnant women should avoid exposure to patients with active/chronic infections. Exclusion of pregnant women from the workplace where EI is occurring is not recommended because they have likely been exposed.
- Children with typical rash are no longer infectious and may attend childcare or school.

PROGNOSIS

- Usually self-limited
- Joint symptoms subside in weeks (often by 2 weeks but may last months).
- ~20% of infections result in delayed virus elimination and viremia persisting for several months to years.
- Full recovery from aplastic crisis in 2 to 3 weeks

COMPLICATIONS

Conditions associated with B19 but where causality is unconfirmed.

- Chronic fatigue syndrome
- Glomerulonephritis, nephrotic syndrome, and other renal diseases
- Hepatitis
- Neurologic manifestations/stroke/meningoencephalitis
- Henoch-Schönlein purpura, idiopathic thrombocytopenic purpura, and vasculitis
- Myocarditis and pericarditis
- Hemophagocytic syndrome

CODES

ICD10

- B34.3 Parvovirus infection, unspecified
- B08.3 Erythema infectiosum [fifth disease]

CLINICAL PEARLS

- Parvovirus B19 infection is usually a benign, self-limited illness with no long-term effects.
- The rash of EI, a “slapped cheek” appearance, signifies that the patient is no longer infectious.
- Patients with increased RBC turnover (SS, thalassemia) are at risk for TAC.

- Immunocompromised patients may be at risk for chronic anemia.
- Documentation of acute infection in pregnant women under 20 weeks' gestation merits maternal–fetal consultation.

PATELLOFEMORAL PAIN SYNDROME

Munawar Hayat, MD • Robert J. Dimeff, MD

BASICS

DESCRIPTION

- Pain in or around the patella that increases after prolonged sitting, squatting, kneeling, and stair climbing (1)
- System(s) affected: musculoskeletal

EPIDEMIOLOGY

Prevalence

- Most frequently diagnosed condition in patients <50 years old with knee complaints (1)
- Women have higher incidence than men (1,2).
- More predominant in female adolescents and physically active young adults (3)
- High incidence in physically active (runners and cyclists) (4)
- Incidence of 16–25% in running injuries (4)
- Accounts for 25% of all knee injuries (5)

ETIOLOGY AND PATHOPHYSIOLOGY

- Exact pathogenesis is not completely understood (4).
- Multifactorial etiology (1)
- Direct relationship with hip weakness and poor functional control of the femur during weight-bearing activities
- Structural anomalies and lower extremity malalignment also contribute (1).
- Improper tracking of the posterior patella over the femoral condyles due to an imbalance in the complex interactions between the quadriceps tendon, IT band, portions of the vastus medialis/lateralis, and patellar tendon insertion (4).

Genetics

Unknown

RISK FACTORS

- Weak quadriceps (1)
- Female gender
- Q angle >20 degrees (1)
- Limited quadriceps and gastrocnemius flexibility
- Excessive knee valgus during landing
- Subtalar hyperpronation
- Tight iliotibial band and/or lateral retinaculum
- Decreased strength (or timing) of (between) the medial quadriceps and the gluteus medius
- Decreased hamstring flexibility
- Decreased explosive strength
- Improper training equipment
- Decreased trochlear groove depth
- Increased medial patellar mobility
- Patella alta
- Increased medial tibial intercondylar distance

GENERAL PREVENTION

- Mitigate modifiable risk factors through strengthening exercises (1), stretching, and activity modification.
- Reduce training volume.

COMMONLY ASSOCIATED CONDITIONS

- Overuse
- Knee ligament injury/surgery
- Patellar tendinopathy
- Prolonged synovitis
- Iliotibial band friction syndrome

DIAGNOSIS

HISTORY

- An accurate history should differentiate retropatellar pain from knee instability (e.g., pain quality, swelling, giving way, mechanical symptoms, and

grinding, inciting events, overuse, and history of trauma).

- Most common symptom is anteromedial knee pain. Pain also described as underneath the patella (1)
- Pain often exacerbated when squatting, running, jumping, or going up stairs (3)[A].
- Pain can also be present during rest and after activity.

PHYSICAL EXAM

- Perform standing, sitting, and supine knee exam: Assess patella height, quadriceps size, check for effusions, test range of motion, and assess gait (4).
- Patellar tilt test: With patient supine, grasp patella between thumb and forefinger and try to lift up the outside edge of the patella using the thumb (3) [A].
- Squatting (3)[A]
- Vastus medialis coordination test: While patient is laying down supine, place fist under patient's knee and ask the patient to extend the knee slowly without pressing down or lifting away from you (3)[A].
- Apprehension sign: Compress the patella against the femur and ask the patient to contract quadriceps muscles; pain upon contraction is consistent with patellofemoral pain syndrome (PFPS), although pain may be present in normal individuals as well (3)[A].
- Compression test: reproduction of pain with compression of patella against the trochlea (3)[A]

DIFFERENTIAL DIAGNOSIS

- Prepatellar bursitis; patellar and quadriceps tendinitis/tendinopathy
- Patellofemoral arthrosis; patellar subluxation and dislocation
- ACL, PCL, and meniscal pathology
- Soft tissue and bony tumors
- Iliotibial band syndrome
- Plica syndrome
- Patellar fat pad inflammation; patellofemoral osteoarthritis
- Chondromalacia patella/osteochondral defect
- Sinding-Larsen-Johansson syndrome
- Osgood-Schlatter disease

- Referred pain from hip or spine
- Traction apophysitis

DIAGNOSTIC TESTS & INTERPRETATION

- The diagnosis is generally clinical (4). *Imaging is not typically necessary*. If imaging is indicated because of severity, atypical symptoms, or persistence of symptoms despite treatment, four views (plain films) of the knee are recommended to view patellar tilt:
  - Lateral
  - Merchant (also called sunrise)
  - Standing anteroposterior
  - Posteroanterior tunnel views:
- Radiographic findings may not correlate with symptoms but can be useful in determining other causes of anterior knee pain.

Follow-Up Tests & Special Considerations

Radiographic images may be normal until late stages, when the posterior patellar surface becomes irregular and cartilage erosion becomes radiographically detectable.

Test Interpretation

Tests not generally necessary

TREATMENT

Conservative therapy is the gold standard.

GENERAL MEASURES

- Initial care during painful stage includes use of ice, compression, elevation, and refraining from physical activity (1).
- Stretching and strengthening exercises, especially hip flexors, quadriceps, IT band, and hamstrings, help decrease pain and increase strength (4)[A].
- Taping and bracing used in conjunction with physiotherapy are helpful for pain and function (4)[A].
- Activity modification (4)[A]
- Cast immobilization (4)[A]

- NSAIDs for pain management (4)[A]
- Neuromuscular retraining interventions (especially with physical therapy) (4)[A]
- Supervised exercise therapy program including quadriceps training (1)[A]
- Foot orthoses (short term)
- Electrotherapy and biofeedback

MEDICATION

- NSAIDs for pain management (4)[A]
- The evidence for beneficial effects of glucosamine and chondroitin supplementation is inconclusive.
- Nandrolone is controversial and not currently recommended.

ISSUES FOR REFERRAL

Surgery is a last resort after conservative measures fail. Surgery is rarely needed.

ADDITIONAL THERAPIES

Ice packs after activity improve clinical symptoms.

SURGERY/OTHER PROCEDURES

- No additional benefits of surgery compared to conservative treatment.
- Attempts to correct maltracking of the patellofemoral joint with a lateral retinacular release or tibial tubercle transposition have shown variable results (4)[A].
- Rarely indicated

ONGOING CARE

PATIENT EDUCATION

Patient education and exercises: http://hprc-online.org/physical-fitness/rehab/faqs/knee-pain

PROGNOSIS

- PFPS often improves spontaneously with relative rest and physical therapy.
- Conversely, established chondromalacia patella, which involves actual injury to the patellofemoral joint cartilage has a poorer prognosis.

SEE ALSO

Algorithm: Knee Pain

CODES

ICD10

- M25.569 Pain in unspecified knee
- M25.561 Pain in right knee
- M25.562 Pain in left knee

CLINICAL PEARLS

- PFPS is the most common cause of anterior knee pain in active adults. Women are more commonly affected.
- PFPS is diagnosed with an accurate history and physical exam. The apprehension sign is the most sensitive finding on physical exam.
- Treatment should focus on quadriceps strengthening, hamstring/IT band flexibility, and hip stabilizer stretching/strengthening.

PEDICULOSIS (LICE)

Kaelen C. Dunican, PharmD • Cynthia Jeremiah, MD

BASICS

DESCRIPTION

- A contagious parasitic infection caused by ectoparasitic blood-feeding insects (lice)
- Two species of lice infest humans:
  - *Pediculus humanus* has two subspecies: the head louse (var. *capitis*) and the body louse (var. *corporis*). Both species are 1-to 3-mm long, flat, and wingless and have three pairs of legs that attach closely behind the head.
  - *Phthirus pubis* (pubic or crab louse): resembles a sea crab and has widespread claws on the second and third legs
- System(s) affected: skin/exocrine
- Synonym(s): lice; crabs

EPIDEMIOLOGY

Incidence

- In the United States: 6 to 12 million new cases per year
- Predominant age
  - Head lice: most common in children 3 to 12 years of age; more common in girls than boys
  - Pubic lice: most common in adults

Prevalence

Head lice: 1–3% in industrialized countries

ETIOLOGY AND PATHOPHYSIOLOGY

- Infestation by lice: *P. humanus* (var. *capitis*), *P. humanus* (var. *corporis*), or *P. pubis*
- Characteristics of lice:
  - Adult louse is dark grayish and moves quickly but does not jump or fly.
  - Eggs (nits) camouflage with the individuals' hair color and are cemented to

the base of the hair shaft (within 4 mm of the scalp).
  - Nits (empty egg casings) appear white (opalescent) and remain cemented to the hair shaft.
  - Lice feed solely on human blood by piercing the skin, injecting saliva (anticoagulant properties to allow for blood meal), and then sucking blood.
  - Itching is a hypersensitivity reaction to the saliva of the feeding louse.
- Transmission: direct human-to-human contact
  - Head lice: direct head-to-head contact or contact with infested fomite (less likely)
  - Body lice: contact with contaminated clothing or bedding
  - Pubic lice: typically transmitted sexually (fomite transmission much less likely)

RISK FACTORS

- General: overcrowding and close personal contact
- Head lice
  - School-aged children, gender (girls; longer hair)
  - Sharing combs, hats (including helmets), clothing, and bed linens
  - African Americans rarely have head lice; theories include twisted hair shaft and increased use of pomades
- Body lice: poor hygiene, homelessness
- Pubic lice: promiscuity (very high transmission rate)

GENERAL PREVENTION

- Environmental measures: Wash, dry-clean, or vacuum all items that may have come in contact with infected individuals.
- Screen and treat affected household contacts.
- Head lice: Follow-up by school nurses may help to prevent recurrence and spread.
- Pubic lice: Limit the number of sexual partners (condoms do not prevent transmission nor does shaving pubic hair).
- Body lice: proper hygiene

COMMONLY ASSOCIATED CONDITIONS

Up to 1/3 of patients with pubic lice have at least one concomitant STI.

DIAGNOSIS

HISTORY

- Pruritus is common, mostly at night.
- Often associated with “outbreak” in school settings
- Investigate contacts of infected individuals.

PHYSICAL EXAM

- Diagnosis is confirmed by visualization of live lice.
- *P. capitis* (head lice)
  - Found most often on the back of the head and neck and behind the ears (warmer areas)
  - Eyelashes may be involved.
  - Eggs, found cemented on the base of a hair shaft, are difficult to remove.
  - Pruritus may be accompanied by local erythema and small papules.
  - May see excoriations around hairline
  - Scratching can cause inflammation and secondary bacterial infection.
  - Pyoderma and lymphadenopathy may occur in severe infestation.
- *P. corporis* (body lice)
  - Poor general hygiene
  - Adult lice and nits in the seams of clothing
  - Intense pruritus involving area covered by clothing (trunk, axillae, and groin)
  - Uninfected bites present as erythematous macules, papules, and wheals.
  - Pyoderma and excoriation may be seen.
- *P. pubis* (pubic lice)
  - Pubic hair is the most common site, but lice may spread to hair around anus, abdomen, axillae, chest, beard, eyebrows, and eyelashes.
  - Eggs are present at the base of hair shafts.
  - Anogenital pruritus
  - Blue macules may be seen in surrounding skin.
  - Delay in treatment may lead to development of groin infection and regional adenopathy.

DIFFERENTIAL DIAGNOSIS

- Scabies and other mite species that can cause cutaneous reactions in humans
- Dandruff and other hair debris sometimes look like head lice eggs and nits but is less adherent.

DIAGNOSTIC TESTS & INTERPRETATION

- Diagnosis is based on visualization of live louse.
- Head lice: Comb hair thoroughly with a fine-toothed louse comb (0.2 to 0.3 mm between teeth) to identify live lice (1)[C]. Wet hair may limits static electricity. Simple visual inspection has same sensitivity as wet combing but is only ~25% as effective as dry combing with a metal comb (2).
- Body lice: Examine the seams of clothing to locate lice and eggs (3).
- Lice and eggs are more easily visualized under a microscope.
- In contrast to dandruff, eggs and nits cannot be removed easily from a hair shaft.

Follow-Up Tests & Special Considerations

- Empty nits remain on hair shafts for months after eradication of the live infestation. On Wood lamp exam, live nits fluoresce white and empty nits fluoresce gray.
- Pubic lice: Evaluate for concurrent STIs.

TREATMENT

MEDICATION

Permethrin (over the counter [OTC]), synergized pyrethrin (OTC), spinosad (Rx), benzyl alcohol (Rx), malathion (Rx), and topical ivermectin (Rx) are all effective for head lice (1)[A],(2)[C]. Permethrin, synergized pyrethrin, and malathion are effective for pubic lice (2)[C]:

- Permethrin generally preferred because it has residual activity for up to 3 weeks. However, newer shampoos and conditioners may reduce the residual effect (1)[C].
- Malathion and spinosad are considered second line for head lice but may not require a second application due to ovicidal activity (1)[B],(2)[C].
- Ivermectin 0.5% lotion is also effective for head lice (2)[C].

First Line

- Head and pubic lice
- Pyrethrum insecticides: permethrin 1% cream rinse (Nix) or pyrethrins 0.33% with piperonyl butoxide 4% (synergized pyrethrin, Rid, Pronto): are first line unless there is proven resistance in the community.
  - Apply for 10 minutes, then wash.
  - Reapply synergized pyrethrin in 7 to 10 days (day 9 is optimal). Also be necessary with permethrin, if live lice are observed.
  - Side effects: application-site erythema, ocular erythema, and application-site irritation
- Body lice: best treated with synergized pyrethrin lotion applied once and left on for several hours
- Eyelash infestation: Apply petroleum jelly BID for 10 days.
- Precautions
  - Pyrethrin: Avoid in patients with ragweed allergy (may cause respiratory symptoms).
  - Pediculicides should never be used to treat eyelash infections.

Second Line

Head lice and pubic lice

- Malathion 0.5% lotion (Ovide)
  - Apply for 8 to 12 hours, then wash off
  - Excipients isopropyl alcohol (78%) and terpineol (12%) may contribute to its efficacy:
    - Flammable and has a bad odor
    - Despite ovicidal activity, a second application may be necessary after 7 to 10 days (day 9 is optimal) if live lice are observed.
  - Lindane 1% shampoo, no longer recommended by the American Academy of Pediatrics
    - Apply for 4 minutes, then wash (should *not* be repeated).
    - Side effects: neurotoxicity (seizures, muscle spasms), aplastic anemia
    - Contraindications: uncontrolled seizure disorder, premature infants
    - Precautions: Do not use on excoriated skin, in immunocompromised patients, conditions that increase seizure risk, or with medications that

decrease seizure threshold.
    - Possible interactions: concomitant use with medications that lower the seizure threshold
- Head lice
  - Spinosad 0.9% lotion (Natroba)
    - Apply to dry hair and scalp for 10 minutes, then rinse with warm water. Repeat in 7 days if live lice are observed.
    - Side effects: application-site erythema, ocular erythema, and application-site irritation
  - Benzyl alcohol 5% lotion (Ulesfia)
    - Apply to dry hair using enough to saturate scalp and hair (amount depends on hair length), rinse after 10 minutes, and repeat in 7 days.
    - Side effects: pruritus, erythema, pyoderma, ocular irritation, application-site irritation
  - Ivermectin 0.5% lotion (Sklice)
    - Apply to dry hair by using enough to saturate the scalp and hair (max. 4 oz) then rinse after 10 minutes.
    - Side effects: burning sensation at application site, dandruff, dry skin, eye irritation
  - Mechanical removal of lice and nits by wetting hair and then systematically combing with a fine-toothed comb every 3 to 4 days for 2 weeks to remove all lice as they hatch

ALERT

Lindane: FDA black box warning of severe neurologic toxicity (use only when first-line agents have failed). The National Pediculosis Association strongly advises against using lindane at all.

GENERAL MEASURES

- Head lice: Clean items that have been in contact with the head of the infected individual within 48 hours.
- Wash all bedding, towels, clothes, headgear, combs, brushes, and hair accessories in hot water (60°C).
- Vacuum furniture and carpets
- Seal any personal articles that cannot be washed in hot water, dry cleaned, or

vacuumed in a plastic bag and store for at least 2 weeks.

- Examine and treat household members and close contacts concurrently.
- Insecticide sprays are not necessary.
- Pubic lice: Avoid sexual activity until both partners are successfully treated.
- Nit and egg removal
  - Remove eggs that are within 1 cm of the scalp to prevent reinfestation.
  - After treatment with shampoo or lotion, eggs and nits remain in the scalp or pubic hair until mechanically removed. Hair conditioner facilitates nit removal.
  - Eggs and nits are best removed with a very fine nit comb.

Pediatric Considerations

- Avoid synergized pyrethrin and permethrin in infants <2 months of age. Avoid benzyl alcohol, topical ivermectin, and spinosad in children <6 months of age; and avoid malathion in children <2 years of age.
- Lindane: not recommended in patients <50 kg

Pregnancy Considerations

Permethrin, synergized pyrethrin, malathion, spinosad, and benzyl alcohol are pregnancy Category B. Lindane and topical ivermectin are Category C.

ADDITIONAL THERAPIES

- For “difficult to treat” cases of head lice, oral ivermectin 400 μg/kg (not approved by the FDA for lice), given twice at a 7-day interval, is superior to topical 0.5% malathion lotion (4,5)[B].
- Ivermectin: 200 μg/kg PO repeated in 10 days or 300 μg/kg PO repeated in 7 days
  - Should not be used in children <15 kg; pregnancy Category C
  - Not approved by the FDA for lice
- Dual therapy with 1% permethrin and oral trimethoprim/sulfamethoxazole (TMP/SMX) only for cases of multiple treatment failures or suspected cases of lice-related resistance to therapy (TMP/SMX is not approved by the FDA for lice).
- Permethrin 5% cream (Rx) is not FDA approved for lice and is unlikely to be effective for lice that are resistant to 1% cream rinse (1)[B].

COMPLEMENTARY & ALTERNATIVE MEDICINE

Head lice

- Dry-on, suffocation-based pediculicide: Cetaphil lotion
  - Apply thoroughly to hair, comb, dry with hair dryer, shampoo after 8 hours.
  - Repeat once a week until cured, up to a maximum of three applications.
  - Not approved by the FDA for lice
- Dimethicone 4% lotion: Apply to hair for 8 hours; repeat in 1 week (not approved by the FDA for lice).
- No home remedies (e.g., vinegar, isopropyl alcohol, olive oil, ylang ylang oil, mayonnaise, melted butter, and petroleum jelly) have been proven effective to treat head lice infestations.
- Herbal shampoos and pomades have not been evaluated in clinical trials and are not approved by the FDA for lice.
- Lavender oil and tea tree oil have been implicated in triggering prepubertal gynecomastia in boys and should not be used to treat lice.
- Electronic louse combs have not proven effective and are not approved by the FDA.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Children may return to school after completing topical treatment, even if nits remain in place. No-nit policies are not necessary.

Patient Monitoring

Drug resistance should be suspected if no dead lice are observed in 8 to 12 hours after treatment.

PATIENT EDUCATION

- National Pediculosis Association: http://www.headlice.org/
- CDC: http://www.cdc.gov/parasites/lice/
- http://www.guideline.gov/content.aspx?id=46429&search=lice

PROGNOSIS

- With appropriate treatment, >90% cure rate

- Recurrence is common, mainly from reinfection or treatment nonadherence. Resistance to synthetic pyrethroids is increasing.

COMPLICATIONS

- Poor sleep due to pruritus
- Persistent itching may be caused by too frequent use of the pediculicide.
- Missed school; social stigma
- Secondary bacterial infections
- Body lice can transmit typhus and trench fever.

CODES

ICD10

- B85.0 Pediculosis due to Pediculus humanus capitis
- B85.1 Pediculosis due to Pediculus humanus corporis
- B85.3 Phthiriasis

CLINICAL PEARLS

- School-based no-nit policies are not necessary because empty nits may remain on hair shafts for months after successful eradication.
- Proper product application is essential; consider improper product application when assessing treatment failure.
- Prevalence of resistant infestations is increasing, so if no dead lice are observed in 8 to 12 hours after treatment, suspect resistance and use an alternative agent.
- Routine retreatment on day 9 is recommended for nonovicidal products (permethrin and synergized pyrethrin).
- With all treatment options, reinspect hair after 7 to 9 days and, if live lice are detected, repeat treatment on day 9.

PELVIC INFLAMMATORY DISEASE

Fozia Akhtar Ali, MD • Paula A. Shelton, MD

BASICS

DESCRIPTION

- Pelvic inflammatory disease (PID) is an infectious and inflammatory disorder of the upper female genital tract, including the uterus, fallopian tubes, ovaries, and adjacent pelvic structures. It is community acquired from sexually transmitted organisms (1).
- Salpingitis is the most important component due to its impact on future fertility.
- Diagnosis may be challenging due to variation in signs and symptoms as many patients with PID have subtle or nonspecific symptoms (2).

EPIDEMIOLOGY

- Predominant age: 15 to 25 years; this number has remained constant since early 1900s.
- Predominant sex: female only (1)

Incidence

Over 770,000 cases of acute PID are diagnosed annually in the United States. Incidence decreased from 1885 to 2001. The CDC has estimated that more than 1 million women experience an episode of PID every year. The disease leads to approximately 2.5 million office visits, 200,000 hospitalizations, and 100,000 surgical procedures yearly. The cost of PID is approximately $2 billion annually; however, costs have decreased over the past decade (3).

ETIOLOGY AND PATHOPHYSIOLOGY

Multiple organisms may be etiologic agents in PID. Most cases are polymicrobial. The proportion of PID cases due to *Chlamydia trachomatis* and *Neisseria gonorrhoeae* appears to be declining. Fewer than 50% of women diagnosed with acute PID have a test positive for either of these organisms.

- *C. trachomatis*, *N. gonorrhoeae*, genital tract mycoplasmas (particularly

Mycoplasma genitalium), aerobic and anaerobic (*Bacteroides fragilis*), and vaginal flora (e.g., *Prevotella*, *Peptostreptococci*, *Gardnerella vaginalis*, *Escherichia coli*, *Haemophilus influenzae*) are recognized as etiologic agents (1,4).

- Many nongonococcal, nonchlamydial microorganisms recovered from upper genital tract in acute PID are associated with bacterial vaginosis (especially *Prevotella bivius*, *Prevotella disiens*, and *Prevotella capillosus*) (3).
- The precise mechanism by which microorganisms ascend from the lower genital tract is unclear. Possible mechanisms include the following: (i) travel from cervix to endometrium to salpinx to peritoneal cavity; (ii) lymphatic spread via infection of the parametrium (from an IUD); and (iii) hematogenous route, although this is rare.
- Of cases, 75% occur within 7 days of menses, when cervical mucus favors ascent of organisms.

RISK FACTORS

- Sexually active and age <25 years (5)
- First sexual activity at young age (<15 years)
- New/multiple sexual partners
- Nonbarrier contraceptive methods (i.e., oral contraceptive pills)
- Previous history of PID; 20–25% will have a recurrence.
- Cervical ectopy
- History of *C. trachomatis*; 10–40% will develop PID.
- History of gonococcal cervicitis; 10–20% will develop PID.
- Gynecologic procedures such as endometrial biopsy, curettage, and hysteroscopy break the cervical barrier, predisposing women to ascending infections.

GENERAL PREVENTION

- Educational programs about safer sex practices such as barrier contraceptives, especially condoms and spermicidal creams or sponges, provide some protection (5).
- The U.S. Preventive Services Task Force recommends screening for chlamydia in all sexually active women <25 years and in those 25 years and older at increased risk (new sex partner/multiple sex partners). Moderate-

quality evidence suggests that chlamydia screening reduces cases of PID (2) [A].

- Routine STI screening in pregnancy
- Early medical care with occurrence of genital lesions or abnormal discharge

COMMONLY ASSOCIATED CONDITIONS

- If PID is suspected in a patient with an IUD and a pelvic abscess is present; an *Actinomyces* infection requiring penicillin treatment may be present.
- Rupture of an adnexal abscess is rare but life-threatening. Early surgical exploration is mandatory (4).
- Chlamydial or gonococcal perihepatitis may occur with PID. This combination is called Fitz-Hugh-Curtis (FHC) syndrome and is characterized by severe pleuritic right upper quadrant pain. FHC syndrome complicates 10% of PID cases.
- Plasma cell endometritis has also been seen in the majority of females with PID; the density of plasma cell infiltration has been related to severity of symptoms (4).

DIAGNOSIS

- The diagnosis of PID is based primarily on clinical evaluation. Clinical diagnosis alone is 87% sensitive and 50% specific.
- The CDC recommends empiric treatment for PID in sexually active female or other female at risk with pelvic or lower abdominal pain with no other cause identified and it one or more of the following is present:
  - Cervical motion tenderness
  - Uterine tenderness
  - Adnexal tenderness
- Additional criteria used to enhance specificity: fever >101°F, new/abnormal cervical mucopurulent discharge or cervical friability, presence of abundant numbers of WBCs on wet prep, elevated CRP, elevated ESR, and laboratory documentation of cervical infection with *N. gonorrhoeae* or *C. trachomatis* (1,6)
- Most specific criteria for diagnosing PID: Endometrial biopsy reveals

endometritis; transvaginal ultrasound showing thickened, fluid-filled salpinges; and laparoscopic abnormalities consistent with PID (1,2).

HISTORY

- Lower abdominal or pelvic pain: typically described as dull, aching or crampy, bilateral, and constant; accentuated by motion, exercise, or coitus
- New/abnormal vaginal discharge (~75% of cases)
- Fever, chills, cramping, dyspareunia
- Low back pain
- Urinary discomfort
- Unanticipated vaginal bleeding, often postcoital, is reported in about 40% of cases.
- Recent hysterosalpingogram (HSG)
- IUD insertion within the past 21 days (1,4)

PHYSICAL EXAM

- Fever
- Lower abdominal pain and particularly cervical motion tenderness
- Findings of cervicitis with/without vaginal discharge (1)

DIFFERENTIAL DIAGNOSIS

- Appendicitis
- Constipation
- Gastroenteritis
- Ectopic pregnancy
- Ovarian tumor/torsion
- Hemorrhagic/ruptured ovarian cyst
- Endometriosis/dysmenorrhea
- Functional pelvic pain
- Inflammatory bowel disease
- Diverticulitis
- UTI/pyelonephritis
- Nephrolithiasis (1)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Pregnancy test must be performed to rule out ectopic pregnancy and complications of an intrauterine pregnancy.
- Specific testing for chlamydia and gonorrhea (usually nucleic acid amplification test [NAAT] and/or ligase chain reaction)
- Urinalysis (4)
- Saline microscopy of vaginal fluid (for WBC)
- Consider CBC: WBC count ≥10,500/mm^3, although ≤50% of PID cases present with leukocytosis.
- CRP (optional)
- Consider transvaginal ultrasound: not necessary for diagnosis; may show thickened, fluid-filled tubes (hydrosalpinges) ± free fluid, or tubo-ovarian abscess (TOA)

Follow-Up Tests & Special Considerations

- ESR >15 mm/hr or elevated C-reactive protein used in some diagnostic criteria
- Consider HIV testing in patients with PID.
- Follow-up ultrasound as outpatient for resolution of adnexal abscess.

Diagnostic Procedures/Other

- Culdocentesis with culture is rarely necessary.
- Laparoscopy is best used for confirming, as opposed to making, the diagnosis of PID and should be reserved for the following situations:
  - Ill patient with competing diagnosis (e.g., appendicitis)
  - Ill patient who has failed outpatient treatment.
  - Any patient not improving after 72 hours of inpatient treatment
- Endometrial biopsy (rarely indicated): reveals endometritis/plasma cells (4)

TREATMENT

- Outpatient treatment, if appropriate
- Criteria for hospitalization and parenteral treatment are described below.

GENERAL MEASURES

Avoid intercourse until treatment is completed. IUD removal is NOT required

for mild PID.

MEDICATION

First Line

- Several antibiotic regimens are highly effective, with no single regimen of choice (4)[A].
- Outpatient treatment regimen
  - Ceftriaxone 250 mg IM single dose *plus*
  - Doxycycline 100 mg PO BID for 14 days ±
  - Metronidazole 500 mg PO BID for 14 days
- On the basis of the recent emergence of fluoroquinolone-resistant gonococci, the CDC no longer recommends the use of fluoroquinolones for the treatment of gonococcal infections and associated conditions such as PID.
- Metronidazole should be considered in cases where risk of infection with anaerobic organisms is considered high.

Second Line

- Because of emerging resistance in gonococci, resistance testing and confirmation of treatment success is advisable (4).
- Outpatient treatment regimen
  - Cefoxitin 2 g IM single dose and probenecid 1 g PO administered concurrently in single dose *plus*
  - Doxycycline 100 mg PO BID for 14 days ±
  - Metronidazole 500 mg PO BID for 14 days
- In persons with documented severe allergic reactions to penicillin or cephalosporins, azithromycin or spectinomycin might be an option for therapy of uncomplicated gonococcal infections.
- Special consideration
  - Refer sex partners for appropriate evaluation and treatment if they had sexual contact with patient during preceding 60 days or most recent sexual contact. Partners should be treated, irrespective of evaluation, with regimens effective against chlamydia and gonorrhea (4).

SURGERY/OTHER PROCEDURES

Reserved for failures of medical treatment and for suspected ruptured adnexal

abscess with resulting acute surgical abdomen

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Criteria for hospitalization if any of following (4)[C]:
  - Surgical emergencies (e.g., appendicitis) cannot be excluded.
  - Patient is pregnant.
  - Patient does not respond clinically to oral antimicrobial therapy.
  - Failure to either tolerate or respond to outpatient therapy; the patient has severe illness, nausea and vomiting, or high fever; or the patient has a tubo-ovarian abscess
- For inpatient treatment of PID, the CDC recommends following treatment regimens (6):
  - Parenteral regimen A
    - Cefotetan 2 g IV every 12 hours or cefoxitin 2 g IV q6h + doxycycline 100 mg orally or IV every 12 hours
    - Parenteral therapy for 24 hours after clinical improvement. Doxycycline should be preferred orally when possible as oral and IV provide similar bioavailability. Continue doxycycline for a total of 14 days (2).
  - Parenteral regimen B
    - Clindamycin 900 mg IV every 8 hours plus gentamicin loading dose IV or IM (2 mg/kg of body weight) followed by a maintenance dose (1.5 mg/kg) q8h or single daily dosing at 3 to 5 mg/kg can be substituted (2).
    - Parenteral therapy may be discontinued 24 hours after clinical improvement; and oral therapy with doxycycline as aforementioned or clindamycin 450 mg PO QID for a total of 14 days should be continued.
  - Parenteral regimen C
    - Ampicillin/sulbactam 3 g IV every 6 hours PLUS doxycycline 100 mg orally or IV every 12 hours
- PID is rare in pregnant patients; however, may appear prior to 12 weeks' gestation before mucous plug appears. Change doxycycline to azithromycin + second-generation cephalosporin (6).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Follow up in 72 hours after initiation of treatment is recommended particularly for patients with moderate or severe clinical presentation (2).
- Observe for clinical signs and symptoms particularly for fever, leukocytosis, abdominal, and cervical motion tenderness.
- Retest for gonorrhea and chlamydia in 3 to 6 months. The likelihood of reinfection is high.
- Follow adnexal abscess size and position with serial ultrasounds.

PATIENT EDUCATION

- Abstinence from any type of sexual contact until treatment of patient/partner (if necessary) is complete
- Consistent and correct condom use should be enforced.
- Hepatitis B and human papilloma virus (HPV) vaccines should be given to patients who meet criteria.
- Advise comprehensive STI screening (6).

PROGNOSIS

- Wide variation with good prognosis if early effective therapy is instituted and further infection is avoided.
- Poor prognosis related to late therapy and continued high-risk sexual behavior
- Nongonococcal, nonchlamydial PID is more often associated with severe PID and with worse prognosis for future fertility (3).

COMPLICATIONS

- TOA will develop in ~7–16% of patients with PID.
- Recurrent infection occurs in 20–25% of patients.
- Risk of ectopic pregnancy is increased 7- to 10-fold among women with a history of PID.
- Tubal infertility occurs in 8%, 19.5%, and 40% of women after 1, 2, and 3 episodes of PID, respectively.
- Chronic pelvic pain occurs in 20% of cases and is related to adhesion

formation, chronic salpingitis, or recurrent infection (1,3).

- Hydrosalpinx: After PID resolves, fallopian tube may fill with sterile fluid and become blocked; it may be associated with pain and infertility related to negative outcomes with IVF.

CODES

ICD10

- N73.9 Female pelvic inflammatory disease, unspecified
- N73.0 Acute parametritis and pelvic cellulitis
- N70.93 Salpingitis and oophoritis, unspecified

CLINICAL PEARLS

- Most often, PID starts with gonorrhea or chlamydia infection, but it can be

polymicrobial.

- Physicians should treat on the basis of clinical judgment without waiting for confirmation from laboratory or imaging tests. PID is a common cause of infertility.
- Complications include hydrosalpinx, adhesions, pelvic pain, and 10-fold increased risk of ectopic pregnancy.
- Three major predictors of preserved post-PID fertility: (i) short duration of symptoms (<72 hours) prior to initiation of treatment, (ii) first episode of PID, and (iii) nongonococcal PID

PEPTIC ULCER DISEASE

Fozia Akhtar Ali, MD • Paula A. Shelton, MD

BASICS

DESCRIPTION

- Duodenal ulcer
  - Most common form of peptic ulcer
  - Usually located in the proximal duodenum
  - Multiple ulcers or ulcers distal to the second portion of duodenum raise possibility of gastrinoma (Zollinger-Ellison syndrome).
- Gastric ulcer
  - Less common than duodenal ulcer in absence of NSAID use
  - Commonly located along lesser curvature of the antrum
- Esophageal ulcers
  - Located in the distal esophagus; usually secondary to gastroesophageal reflux disease (GERD); also seen with gastrinoma
- Ectopic gastric mucosal ulceration
  - May develop with Meckel diverticulum

GENERAL PREVENTION

- NSAID ulcers: Use acetaminophen instead of NSAIDs, when appropriate, and discontinue NSAID use (or add a proton pump inhibitor) in patients with previous NSAID-related ulcer.
  - If NSAIDs are absolutely necessary, use lowest possible dose to decrease risk of ulcerogenesis and use in combination with a proton pump inhibitor (PPI) or misoprostol.
  - To reduce ulcer risk, consider testing for and eradicating *Helicobacter pylori* before starting therapy with NSAIDs.
- Maintenance therapy with PPIs or H_2 blockers is indicated for patients with a history of ulcer complications, recurrences, refractory ulcers, or persistent *H. pylori* infection.
- Consider maintenance PPI treatment in patients with *H. pylori*–negative, non–

NSAID-induced ulcer.
  - *H. pylori* infection: present in 95% of duodenal and 70% of gastric ulcers. Lifetime risk for peptic ulcer disease (PUD) in those with *H. pylori*–infection: 10–20%
  - Annual risk of developing duodenal ulcer in those with *H. pylori*–infection: ≤1%

EPIDEMIOLOGY

Incidence

- Predominant sex: male = female
- Predominant age
  - 70% of ulcers occur between ages 25 to 64 years.
  - Ulcer incidence increases with age.
- Peptic ulcer: 500,000 new cases/year
- Recurrence: 4 million/year
- Global incidence rate: 0.1–0.19%

Prevalence

- Peptic ulcer: 2% in the United States
- Lifetime prevalence is 5–10% for patients not infected with *H. pylori*; 10–20% if infected

Genetics

Increased incidence of PUD in families is likely due to familial clustering of *H. pylori* infection and inherited genetic factors reflecting response to the organism.

RISK FACTORS

- *H. pylori* infection (1)
- Chronic NSAID use (5–20%)
- Tobacco use
- Family history of ulcers
- Stress (after acute illness, ventilator support, extensive burns, head injury)
- Gastrinoma
- Alcohol use
- Medications: corticosteroids (high-dose and/or prolonged therapy), bisphosphonates, potassium chloride, chemotherapeutic agents

COMMONLY ASSOCIATED CONDITIONS

- Gastrinoma (Zollinger-Ellison syndrome)
- Multiple endocrine neoplasia type 1
- Carcinoid syndrome
- Chronic illness: Crohn disease, chronic obstructive pulmonary disease (COPD), chronic renal failure, hepatic cirrhosis, cystic fibrosis
- Hematopoietic disorders (rare): systemic mastocytosis, myeloproliferative disease, hyperparathyroidism, polycythemia rubra vera

DIAGNOSIS

HISTORY

- Signs and symptoms:
  - The main symptom is gnawing or burning nonradiating epigastric pain that occurs when the stomach is empty; that is, 2 hours to 3 hours after meals or at night. Pain often is relieved by food or antacids.
  - Specific symptoms that increase the likelihood of PUD in patients with dyspepsia include pain relieved by food, nighttime awakening accompanied by relief with food, and episodic pain
  - Nonspecific dyspeptic symptoms: indigestion, nausea, vomiting, loss of appetite, and heartburn, epigastric fullness
- Red flag or alarm symptoms
  - Onset of symptoms after age 55 years
  - Progressive dysphagia
  - Recurrent vomiting
  - Heme positive stool, melena, hematemesis, anemia
  - Progressive dysphagia or persistent/recurrent vomiting
  - Severe abdominal pain
  - Weight loss, anorexia, or family history of gastric malignancy
- NSAID-induced ulcers are often silent; perforation or bleeding may be the initial presentation.

PHYSICAL EXAM

Physical exam for uncomplicated peptic ulcer may be nonspecific: Check vital

signs for hemodynamic stability, conjunctival pallor (anemia); epigastric tenderness (absent in at least 30% of older patients); guaiac-positive stool from occult blood loss

DIFFERENTIAL DIAGNOSIS

Functional dyspepsia, gastritis, GERD, biliary colic, pancreatitis, cholecystitis, Crohn disease, intestinal ischemia, cardiac ischemia, GI malignancy

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Lab tests to consider:
  - CBC: Rule out anemia.
  - Fecal occult blood test
  - If multiple/refractory ulcers: Consider fasting serum gastrin to rule out gastrinoma.
- Indications for *H. pylori* testing: new-onset PUD, prior history of PUD, persistent symptoms after empiric antisecretory therapy, gastric mucosa–associated lymphoid tissue (MALT) lymphoma, noninvestigated dyspepsia in patients <50 years of age without alarm symptoms *H. pylori* diagnostic tests: False-negative results may occur if patient was recently treated with antibiotics, bismuth, or PPIs; or in patients with active bleeding. Diagnostic yield improved by checking 2 different tests:
  - Noninvasive tests:
    - Serology: *H. pylori* antibody: commonly used in primary care, slow to normalize after treatment, cannot be used to document successful eradication (sensitivity, 85%; specificity, 79%)
    - Urea breath test: identifies active *H. pylori* infection; also used for posttreatment testing (sensitivity, >95%; specificity, >90%)
    - Stool antigen: can be used for screening and posttreatment testing (sensitivity, 91%; specificity, 94%)
    - If proof of eradication is desired (urea breath test or stool antigen), stop antibiotics and bismuth for at least 4 weeks and proton pump inhibitors for 1 week prior to testing because of high false-negative rates.
  - Invasive tests:
    - Diagnostic upper endoscopy (sensitivity, >95%; specificity, >95%)

        - Endoscopy is the most accurate test for diagnosing PUD and active *H. pylori* infection but is costly and invasive and therefore, is recommended only for patients with "red flag" symptoms (1)[B].
    - Rapid urease test: conducted on gastric biopsies (sensitivity, 93–97%; specificity, 95%)
- Barium or Gastrografin contrast radiography (double-contrast hypotonic duodenography): indicated when endoscopy is unsuitable or not feasible

TREATMENT

MEDICATION

First Line

- Acid suppression: PPIs
  - Omeprazole 20 mg/day PO; lansoprazole 30 mg/day PO; rabeprazole 20 mg/day PO; esomeprazole 40 mg/day PO; pantoprazole 40 mg/day PO; dexlansoprazole 30 mg/day PO
  - Administer PPIs on an empty stomach and before breakfast.
  - Administer PPI for 4 weeks to treat duodenal ulcer and 8 weeks to treat gastric ulcer.
- H_2 blockers: ranitidine or nizatidine 150 mg PO BID or 300 mg PO at bedtime; cimetidine 400 mg PO BID or 800 mg PO at bedtime; famotidine 20 mg PO BID or 40 mg PO at bedtime
- Treat ulcers for 8 to 12 weeks or until healing is confirmed in patients with complicated ulcers.
- PPIs help heal peptic ulcers more rapidly.
- Precautions:
  - Renal insufficiency: Decrease H_2 blocker dosage by 50% if CrCl <50 mL/min cimetidine: Use caution with theophylline, warfarin, phenytoin, and lidocaine.
  - PPIs may decrease bone density. Obtain interval bone densitometry with long-term PPI use (2).
  - PPIs may cause hypomagnesemia. Consider baseline and interval levels in patients, especially for long-term use and in patients taking diuretics.

- PPIs may be associated with increased risk of *Clostridium difficile* infection (2). Short-term use associated with development of community-acquired pneumonia; long-term use does not appear to have an increased risk.
- Despite earlier concerns, PPIs do not appear to decrease the efficacy of clopidogrel (2).

- NSAID-induced ulcers
  - Discontinue NSAID use.
  - Treat acutely with PPIs for 8 to 12 weeks; may use longer as maintenance for patients with recurrent, complicated, or idiopathic ulcers; or in patients who require long-term aspirin or NSAID use.
- *H. pylori*-induced ulcers
  - *H. pylori* eradication regimens: Preferred duration of therapy is 14 days.
  - Triple therapy: standard dose PPI given BID plus clarithromycin 500 mg PO BID plus amoxicillin 1 g PO BID or metronidazole 500 mg PO BID in patients with allergy to amoxicillin; bacterial resistance: clarithromycin 10%; amoxicillin 1.4%; metronidazole 37%: Culture-guided choice of triple therapy is preferred (3).

Second Line

- For *H. pylori* eradication: Use second-line therapy if first-line fails (3):
  - Bismuth quadruple therapy for 14 days
    - Bismuth subsalicylate 525 mg PO QID plus
    - Metronidazole 250 mg PO QID plus
    - Tetracycline 500 mg PO QID plus
    - Standard dose PPI PO twice daily
- Sequential therapy
  - Standard-dose PPI PO twice daily plus amoxicillin 1,000 mg PO QID for 5 days followed by
  - Standard-dose PPI PO twice daily plus clarithromycin 500 mg PO BID plus tinidazole (or metronidazole) 500 mg PO BID for 5 days
    - Levofloxacin 250 mg PO BID may be substituted in those with PCN allergy or in areas of high clarithromycin resistance rates.
  - Another alternative salvage therapy:
    - Rifabutin 300 mg PO daily plus
    - Amoxicillin 1,000 mg PO BID plus

    - PPI orally BID
  - Alternative ulcer-healing drugs:
    - Sucralfate and antacids are additional options; however, antisecretory options are preferred.
- Significant possible interactions:
  - Cimetidine inhibits cytochrome P450 isozymes (avoid with theophylline, warfarin, phenytoin, and lidocaine).
  - Omeprazole may prolong elimination of diazepam, warfarin, and phenytoin.
  - Sucralfate reduces absorption of tetracycline, norfloxacin, ciprofloxacin, and theophylline; it leads to subtherapeutic levels.

Pregnancy Considerations

PPIs are *not* associated with an increased risk for major birth defects, spontaneous abortions, or preterm delivery.

Breastfeeding

Both ranitidine and esomeprazole are secreted in breastmilk; however, at considerably lower doses than those used for treatment in infants with reflux disease. Use in breastfeeding women is generally safe.

SURGERY/OTHER PROCEDURES

- Endoscopy is indicated for patients age >55 years with new onset of dyspeptic symptoms, those who do not respond to treatment, and those of any age with alarm/red flag symptoms (4)[B].
- At endoscopy:
  - Biopsy stomach for *H. pylori* testing (CLO test)
  - Biopsy ulcer margin to exclude malignancy
  - Interventions to stop active bleeding or prevent rebleeding in those with certain stigmata include injection with epinephrine, heater probe treatment, or placement of endoscopic clips (2).
- Indications for surgery: Ulcers that are refractory to treatment and patients at high risk for complications (e.g., transplant recipients, patients dependent on steroids/NSAIDs); surgery also may be needed acutely to treat perforation and bleeding refractory to endoscopic therapy (5).

- Surgical options:
  - Duodenal ulcers: truncal vagotomy and drainage (pyloroplasty/gastrojejunostomy), selective vagotomy (preserving the hepatic and/or celiac branches of the vagus) and drainage, or highly selective vagotomy (1)
  - Gastric ulcers: partial gastrectomy, Billroth I or II
  - Perforated ulcers: laparoscopy/open patching (1)

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Discontinue ulcerogenic agents (e.g., NSAIDs).
- Bleeding peptic ulcers
  - Stable: Give PPI to reduce transfusion requirements, need for surgery, and duration of hospitalization (6).
  - Unstable: Fluid/packed RBC resuscitation followed by emergent esophagogastroduodenoscopy (EGD); use IV PPI.
  - Insufficient evidence for concluding superiority, inferiority, or equivalence of high-dose PPI treatment over lower doses in peptic ulcer bleeding (2)[A]
- Oral PPIs are as effective as IV after endoscopic treatment (6).
- Perforated peptic ulcers: Free peritoneal perforation with bacterial peritonitis is a surgical emergency (1).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- *H. pylori* eradication: expected in >90% (with double antibiotic regimen): Confirm eradication by urea breath test.
- Acute duodenal ulcer: Monitor clinically.
- Acute gastric ulcer: Confirm healing via endoscopy after 12 weeks (if biopsy not done initially) to confirm that the lesion is benign.
- Tobacco cessation

PROGNOSIS

After *H. pylori* eradication (4):

- Low ulcer relapse rate; if relapse, consider surreptitious use of NSAIDs.
- Reinfection rates <1% per year
- Low risk of rebleeding
- Decreased NSAID ulcer recurrence (4)

COMPLICATIONS

- Hemorrhage: up to 25% of patients (initial presentation in 10%)
- Perforation: <5% of patients
- Gastric outlet obstruction: up to 5% of duodenal or pyloric channel ulcers; male predilection found
- Risk of gastric adenocarcinoma is increased in *H. pylori*–infected patients.
- Refractory peptic ulcer disease (5–10% after eradication of *H. pylori*, or completion of 12 weeks of PPI)

CODES

ICD10

- K27.9 Peptic ulc, site unsp, unsp as ac or chr, w/o hemor or perf
- K26.9 Duodenal ulcer, unspecified as acute or chronic, without hemorrhage or perforation
- K25.9 Gastric ulcer, unspecified as acute or chronic, without hemorrhage or perforation

CLINICAL PEARLS

- In patients with PUD, eradicate *H. pylori* to assist healing and reduce the risk of recurrence.
- Upper endoscopy is indicated in patients with suspected peptic ulcers who are >55 years of age, in the presence of red flag symptoms, and for those who do not respond to treatment.

PERICARDITIS

Veronica J. Ruston, DO, Capt, USAF, MC • Angela M. Riegel, DO

BASICS

DESCRIPTION

Inflammation of the pericardium, with or without associated pericardial effusion. Myopericarditis or perimyocarditis refers to cases that have myocardial involvement in addition to the pericardial sac.

EPIDEMIOLOGY

Incidence

Epidemiologic studies are lacking. Exact incidence is unknown but occurs in up to 5% of patients evaluated in the ER for chest pain without myocardial infarction (MI); appears to be a slightly increased prevalence in men.

ETIOLOGY AND PATHOPHYSIOLOGY

- Inflammation of the pericardial sac can be *acute* or *chronic* (recurrent). Chronic/recurrent inflammation may result in constrictive pericarditis.
- Can produce serous/purulent fluid/dense fibrinous material (depending on etiology), which may or may not lead to hemodynamic compromise

Genetics

No known genetic factors:

- Idiopathic: 85–90% of cases; likely related to viral infection, which may trigger immune-related process
- Infectious
  - Viral: coxsackievirus, echovirus, adenovirus, Epstein-Barr virus, cytomegalovirus, hepatitis viruses, influenza virus, HIV, measles, mumps, varicella
  - Bacterial: gram-positive and gram-negative organisms
  - Fungal (more common in immunocompromised populations): *Blastomyces dermatitidis, Candida* sp., *Histoplasma capsulatum*

  - Mycobacterial: *Mycobacterium tuberculosis*
  - Parasites: *Echinococcus*
- Noninfectious causes
  - Acute MI (2 to 4 days after MI), Dressler syndrome (weeks to months after MI)
  - Aortic dissection
  - Renal failure, uremia, dialysis-associated
  - Malignancy (e.g., breast cancer, lung cancer, Hodgkin disease, leukemia, lymphoma)
  - Radiation therapy
  - Trauma
  - Postpericardiotomy
  - After cardiac procedures (e.g., catheterization, pacemaker placement, ablation)
  - Autoimmune disorders: connective tissue disorders, systemic lupus erythematosus (SLE), rheumatoid arthritis, scleroderma, hypothyroidism, inflammatory bowel disease, spondyloarthropathies, Wegener granulomatosis
  - Sarcoidosis
- Medication induced: dantrolene, doxorubicin, hydralazine, isoniazid, mesalamine, methysergide, penicillin, phenytoin, procainamide, rifampin

COMMONLY ASSOCIATED CONDITIONS

Depends on etiology

DIAGNOSIS

HISTORY

- Prodrome of fever, malaise, myalgias
- Acute, sharp, stabbing chest pain
- Duration typically hours to days
- Pleuritic pain
- Pain reduced by leaning forward, worsened by lying supine
- Shortness of breath

PHYSICAL EXAM

- Heart rate is usually rapid and regular.
- Pericardial friction rub: coarse, high-pitched sound best heard during end expiration at left lower sternal border with patient leaning forward. Highly specific for diagnosis (but not sensitive); may be transient and mono-, bi-, or triphasic
- New S_3 may suggest myopericarditis.
- Cardiac tamponade
- Diagnostic clinical criteria
  - Acute pericarditis (at least two of four criteria)
    - Typical (pleuritic) chest pain
    - Pericardial friction rub
    - ECG changes with widespread ST elevation
    - New/increasing pericardial effusion
  - Myopericarditis
    - Definite pericarditis *plus*
    - Symptoms (dyspnea, chest pain, or palpitations) *and* ECG changes not previously documented (ST/T wave abnormalities, supraventricular/ventricular tachycardia) *or* focal/diffuse depressed left ventricular (LV) function documented on imaging study
    - Absence of evidence of other cause
    - One of the following: elevated cardiac enzymes (creatine kinase [CK]-MB, troponin I or T) *or* new focal/diffuse depressed LV function *or* abnormal imaging consistent with myocarditis (MRI with gadolinium, gallium-67 scanning, antimyosin antibody scanning)
  - Case definitions
    - *Suspected myopericarditis*: criteria 1, 2, and 3
    - *Probable myopericarditis*: criteria 1, 2, 3, and 4
    - *Confirmed myopericarditis*: histopathologic evidence of myocarditis by endomyocardial biopsy (EMB) or autopsy (Note: In the clinical setting, for self-limited cases with predominantly pericarditis, EMB is rarely indicated.)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- It is not necessary to order tests for uncomplicated cases or when the diagnosis is clear. Following labs may be helpful (1)[C]:
  - CBC: typically shows leukocytosis
  - Inflammatory markers: elevated erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and lactodehydrogenase (LDH)
  - Cardiac biomarkers: typically elevated creatine kinase, troponins
    - Elevated troponins associated with younger age, male sex, pericardial effusion at presentation, and ST segment elevation on ECG
    - Adverse outcomes are not predicted by elevated troponin.
- ECG: Findings include widespread upward concave ST segment elevation and PR segment depression that may evolve through four stages. ECG may be normal/show nonspecific abnormalities:
  - Stage 1: diffuse ST segment elevation and PR segment depression
  - Stage 2: Normalization of the ST and PR segments and T waves begin to flatten and invert.
  - Stage 3: widespread T wave inversions
  - Stage 4: normalization of T waves; may have persistent inversions if chronic pericarditis
- ECG may demonstrate low voltage and electrical alternans with tamponade.
- Transthoracic echocardiogram is recommended to evaluate for the presence of pericardial effusion, tamponade, or myocardial disease (presence of effusion helps to confirm diagnosis of pericarditis) (1)[C].
- Chest x-ray (CXR) is performed to rule out pulmonary/mediastinal pathology. Enlarged cardiac silhouette suggests large pericardial effusion (at least 200 mL).
- CT and MRI allow visualization of pericardium to assess for complications or if initial workup is inconclusive (1)[C].
- Additional testing (if clinically appropriate based on history or atypical presentation or course) may include tuberculin skin test, sputum cultures, rheumatoid factor, antinuclear antibody, and HIV serology (1)[C].
- Viral cultures and antibody titers rarely clinically useful (1)[C]

Diagnostic Procedures/Other

- Pericardiocentesis indicated for cardiac tamponade; for suspected purulent, tuberculous, or neoplastic pericarditis; and for effusions >20 mm on echocardiography (2)[C]
- Surgical drainage with pericardial biopsy recommended if recurrent tamponade, ineffective pericardiocentesis, or hemodynamic instability (2)[C]

Test Interpretation

- Microscopic examination may reveal hyperemia, leukocyte accumulation, or fibrin deposition.
- Purulent fluid with neutrophilic predominance if bacterial etiology
- Lymphocytic predominance in viral, tuberculous, and neoplastic pericarditis

TREATMENT

- Goal of treatment is to relieve pain and reduce complications (e.g., recurrence, tamponade, chronic restrictive pericarditis).
- Outpatient therapy is reported to be successful in 85% patients with low-risk features.

GENERAL MEASURES

Specific therapy directed toward underlying disorder for patients with identified cause other than viral/idiopathic disease.

MEDICATION

First Line

- NSAIDs are considered the mainstay of therapy for acute pericarditis:
  - Ibuprofen 400 to 800 mg TID for 1 to 2 weeks (2 to 4 weeks for recurrence) then taper (3)[C]
  - Aspirin 650 to 975 mg TID to QID for 1 to 2 weeks (2 to 4 weeks for recurrence) then taper; preferable for patients with recent MI because other NSAIDs impair scar formation in animal studies (4)[C]
  - Indomethacin 50 mg TID for 1 to 2 weeks (2 to 4 weeks for recurrence) then taper; should avoid in elderly due to flow restrictions to coronaries (3)[C]
  - Ketorolac 15 to 30 mg IV/IM q6h while inpatient; maximum duration of 5

days (3)[C]
  - GI protection should be provided (3)[C].
  - Tapering should be done only if the patient is asymptomatic and CRP/ESR are normal and are done every 1 to 2 weeks (3)[C].
  - Treatment duration using NSAIDs for initial attacks is 1 to 2 weeks, but for recurrences, consider 2 to 4 weeks of therapy (3)[C].
  - Monitoring: NSAIDs: CBC and CRP at baseline and weekly until CRP normalizes
  - Contraindications: hypersensitivity to aspirin or NSAIDs, active peptic ulcer/GI bleeding
  - Precautions: Use with caution in patients with asthma, 3rd-trimester pregnancy, coagulopathy, and renal/hepatic dysfunction.
- Colchicine: common practice to use in combination with NSAIDs; 0.6 mg BID for up to 3 months (up to 6 months for recurrence); taper is not required. Efficacious as therapy for initial occurrence and if multiple recurrences. This is the only agent proven to prevent recurrences in RCTs. Adjunctive therapy can reduce rate of recurrence by 50% (2)[A]. Monitoring: Consider CBC, CRP, transaminases, creatine kinase, and creatinine at baseline and at least after 1 month.
- Pregnant: <20 weeks' gestation: Aspirin is first choice, but NSAIDs and prednisone are also allowed; >20 weeks' gestation: Prednisone is allowed with avoidance of NSAIDs, aspirin, and colchicine (1)[C].

Second Line

- Corticosteroid treatment is indicated in connective tissue disease, tuberculous pericarditis, or severe recurrent symptoms unresponsive to NSAIDs or colchicine; should be avoided in uncomplicated acute pericarditis. *Corticosteroid use alone has been found to be an independent risk factor for recurrence* (4)[C].
- If steroids are used, consider low dose (0.25 to 0.5 mg/kg/day for 2 weeks for first attack; 0.25 to 0.5 mg/kg/day for 2 to 4 weeks for recurrence); then slow taper (if >50 mg: 10 mg/day every 1 to 2 weeks; if 25 to 50 mg: 5 to 10 mg/day every 1 to 2 weeks; if 15 to 25 mg: 2.5 mg/day every 2 to 4 weeks; if <15 mg/day: 1 to 2.5 mg/day every 2 to 6 weeks) following remission.

Remember adequate prophylaxis treatment for osteoporosis prevention (4)[C].

- If unable to taper from steroids, resume lowest steroid dose and begin slow taper of 1 to 2 mg every 2 to 4 weeks (3)[C].
- Intrapericardial administration of steroids may be effective and limits systemic side effects.

ISSUES FOR REFERRAL

- Refractory cases include those on unacceptably high long-term steroid doses (>25 mg/day).
- Consider trial of aspirin and/or NSAIDs plus steroid and colchicine.
- Uremic or dialysis-related cases require more frequent or urgent dialysis without significant benefit from pharmacologics (1)[C].

SURGERY/OTHER PROCEDURES

- Pericardiocentesis is indicated in cases of cardiac tamponade, high likelihood of tuberculous/purulent/neoplastic pericarditis, and large symptomatic effusions refractory to medical therapy.
- Pericardial biopsy may be considered for diagnosis in those with persistent worsening pericarditis without a definite diagnosis.
- Pericardioscopy for targeted diagnostic imaging may be performed at experienced tertiary referral centers in refractory and difficult cases.
- Pericardial window may be performed in cases of recurrent cardiac tamponade with large pericardial effusion despite medical therapy and severe symptoms.
- Pericardiectomy can be considered. The 2004 European Society of Cardiology guidelines recommend pericardiectomy (Class IIa) for frequent and highly symptomatic recurrences of pericarditis refractory to medical therapy. However, this is rarely performed in the United States and has high morbidity and mortality (1)[C].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Inpatient therapy recommended for pericarditis associated with clinical predictors of poor prognosis:
  - Major predictors: fever >38°C, subacute onset, large pericardial effusion, cardiac tamponade, lack of response to NSAID/aspirin therapy after at least

1 week (5)[C]
  - Minor predictors: immunosuppressed state, trauma, oral anticoagulation therapy, myopericarditis (5)[C]
- IV fluids considered for hypotension or in the setting of pericardial tamponade
- Discharge criteria
  - Response to therapy with symptom improvement
  - Hemodynamic stability

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- 7 to 10 days to assess response to treatment
- 1 month to check CBC and CRP and thereafter if symptoms continue to be present
- Those with clinical predictors of poor prognosis may require closer follow-up based on lab data and echocardiographic findings.

Patient Monitoring

Myopericarditis

- Use lower doses of anti-inflammatory drugs to control symptoms for 1 to 2 weeks while minimizing deleterious effects on myocarditic process.
- Exercise restrictions for 4 to 6 weeks or until symptoms resolved and biomarkers normalized (2)[C].
- Echocardiographic monitoring at 1, 6, and 12 months (especially in those with left ventricular dysfunction)

DIET

No restrictions

PROGNOSIS

Overall good prognosis; disease usually benign and self-limiting; purulent and tuberculosis pericarditis with high mortality

COMPLICATIONS

- Recurrent pericarditis: occurs in ~30% of patients, with most instances

resulting from idiopathic, viral, or autoimmune pericarditis; inadequate treatment of the initial attack; and, less commonly, neoplastic etiologies. Recurrence usually within 1st weeks following initial episode but may occur months to years later; rarely associated with tamponade/constriction

- Cardiac tamponade: rare complication with increased incidence in neoplastic, purulent, and tuberculous pericarditis
- Effusive-constrictive pericarditis: Reported in 24% of patients undergoing surgery for constrictive pericarditis and in 8% of patients undergoing pericardiocentesis and cardiac catheterization for cardiac tamponade. Failure of right atrial pressure to fall by 50% or to a level below 10 mm Hg after pericardiocentesis is diagnostic.
- Constrictive pericarditis: rare complication in which rigid pericardium produces abnormal diastolic filling with elevated filling pressures. Pericardiectomy remains definitive therapy.

CODES

ICD10

- I31.9 Disease of pericardium, unspecified
- I30.9 Acute pericarditis, unspecified
- I30.1 Infective pericarditis

CLINICAL PEARLS

- Consider *major* and *minor* predictors in deciding which patients should be admitted.
- Therapy aimed at symptomatic relief and NSAIDs are first-line treatment. Colchicine is recommended as an adjunct to NSAIDs.
- Pericardiocentesis is recommended in the setting of cardiac tamponade or possible purulent pericarditis.

PERIODIC LIMB MOVEMENT DISORDER

Donald E. Watenpaugh, PhD • John R. Burk, MD

BASICS

DESCRIPTION

- Sleep-related movement disorder with episodes of periodic limb movements (PLMs) occurring during sleep
  - Movements consist of bilateral ankle dorsiflexion, sometimes with knee and hip flexion.
  - Arm or more generalized movements occur less commonly.
  - Movements may cause brief microarousals from sleep unbeknownst to the patient.
  - Complaints include insomnia, unrestorative sleep, daytime fatigue, and/or somnolence.
  - Bed partner may complain of movements.
  - Another sleep disorder (e.g., obstructive sleep apnea) does not cause the PLMs (1).
- No wakeful perception of the PLMs or associated restlessness.
  - If there is wakeful perception, then diagnosis is not periodic limb movement disorder (PLMD) and instead probably is restless legs syndrome (RLS).
- System(s) affected: musculoskeletal, nervous
- Synonym(s): nocturnal myoclonus; sleep myoclonus; periodic leg movements of sleep

EPIDEMIOLOGY

Incidence

- Increases with age: 1/3 of patients >60 years exhibit PLMs but not necessarily PLMD.
- No predominant sex: male = female
- PLMs in at least 15% of insomnia patients

Prevalence

- PLMs in sleep: common and usually of no clinical consequence
- PLMs constituting PLMD (causing sleep complaints and/or daytime consequences) much less common: <5% of adults (but underdiagnosed)

ETIOLOGY AND PATHOPHYSIOLOGY

- Unstudied
- Primary: probable CNS dopaminergic impairment
- Secondary:
  - Iron deficiency
  - Peripheral neuropathy
  - Arthritis
  - Renal failure
  - Synucleinopathies (multiple-system atrophy)
  - Spinal cord injury
  - Pregnancy
  - Medications:
    - Most antidepressants (not bupropion or desipramine)
    - Some antipsychotic and antidementia medications
    - Antiemetics (metoclopramide)
    - Antihistamines

Genetics

Unstudied, but see the RLS chapter

RISK FACTORS

- Family history of RLS
- Iron deficiency and associated conditions (e.g., pregnancy, gastric surgery, renal disease)
- Attention deficit hyperactivity disorder (ADHD)
- Aging
- Peripheral neuropathy
- Arthritis, orthopedic problems
- Chronic limb pain or discomfort

GENERAL PREVENTION

- Regular physical activity

- Adequate nightly sleep
- Avoid causes of secondary PLMD.
- Avoid causes of RLS.

COMMONLY ASSOCIATED CONDITIONS

- RLS
- Rapid eye movement (REM) sleep behavior disorder
- Narcolepsy
- Iron deficiency
- Renal failure
- Cardiovascular disease; stroke
- Gastric surgery
- Pregnancy
- Arthritis
- Synucleinopathies (multiple-system atrophy)
- Lumbar spine disease; spinal cord injury
- Peripheral neuropathy
- Insomnia, insufficient sleep
- ADHD
- Depression

Pediatric Considerations

- PLMD may precede overt RLS by years.
- Association with RLS is more common than in adults.
- Symptoms may be more consequential than in adults.
- Associated with ADHD

Pregnancy Considerations

- May be secondary to iron or folate deficiency
- Most severe in 3rd trimester
- Usually subsides after delivery

Geriatric Considerations

- May become a significant source of sleep disturbance
- May cause or exacerbate circadian disruption and “sundowning”
- Many medications given to the elderly cause or exacerbate PLMs, which can

lead to PLMD or RLS.

DIAGNOSIS

HISTORY

- Episodes of PLMs during sleep (often reported by bed partner)
- Insomnia: difficulty maintaining sleep
- Unrestorative sleep
- Daytime fatigue, tiredness, and/or somnolence
- Oppositional behaviors
- Memory impairment
- Depression
- ADHD, particularly in children

PHYSICAL EXAM

No specific findings

DIFFERENTIAL DIAGNOSIS

- When PLMs occur along with RLS, REM sleep behavior disorder, or narcolepsy, those disorders are diagnosed as “with PLMs,” and PLMD is not diagnosed separately.
- Obstructive sleep apnea: Limb movements (LMs) occur during microarousals from apneas; treatment of sleep apnea eliminates these LMs.
- Sleep starts: nonperiodic, generalized, occur only at wake–sleep transition, <0.2 seconds duration
- Sleep-related leg cramps: isolated and painful
- Fragmentary myoclonus: 75 to 150 ms of EMG activity, minimal movement, no periodicity
- Nocturnal seizures: epileptiform EEG, motor pattern incongruent with PLMs
- Fasciculations, tremor: no sleep association
- Sleep-related rhythmic movement disorder: voluntary movement during wake–sleep transition; higher frequency than PLMs

DIAGNOSTIC TESTS & INTERPRETATION

- Polysomnography with finding of repetitive, stereotyped LMs:

  - Tibialis anterior electromyographic (EMG) activation lasting 0.5 to 10 seconds
  - EMG amplitude increases >8 μV from baseline.
  - Movements occur in a sequence of ≥4 at intervals of 5 to 90 seconds.
  - Children: ≥5 movements per hour; adults, 15
  - Movement may also involve arms.
  - Associated with heart rate variability from autonomic-level arousals
  - Most PLM episodes occur in the first hours of non-REM sleep.
  - Significant night-to-night PLM variability
- Serum ferritin to assess for iron deficiency

Diagnostic Procedures/Other

- Ankle actigraphy for in-home use
- EMG or nerve conduction studies for peripheral neuropathy/radiculopathy

Test Interpretation

Serum ferritin should be >75 ng/mL.

TREATMENT

Treatment paradigm similar to that for RLS, except that all medications are off-label for PLMD (1,2,3)[B].

GENERAL MEASURES

- Daily exercise, including evening if desired
- Adequate nightly sleep
- Warm the legs (long socks, leg warmers, electric blanket, etc.).
- Hot bath before bedtime
- Assess for and correct iron deficiency
- Avoid nicotine and evening caffeine and alcohol.

MEDICATION

- Use minimum effective dose.
- Goals of medication:
  - Improve subjective sleep quality.
  - Eliminate symptoms and sequelae attributed to PLMs.

- Consider risks, side effects, and interactions individually (e.g., benzodiazepines in elderly).
- Low HS dosing minimizes daytime sleepiness side effect. Treatment should decrease instead of increase daytime somnolence.

First Line

- Dopamine agonists: Take 1 hour before bed; titrate weekly to optimal dose (1,2,3)[C]:
  - Pramipexole (Mirapex): 0.125 to 0.5 mg; titrate by 0.125 mg.
  - Ropinirole (Requip): 0.25 to 4 mg; titrate by 0.25 mg.
  - Transdermal rotigotine (Neupro): 1 to 3 mg/24 hr patch; initiate with 1 mg/24 hr; titrate by 1 mg weekly to effectiveness.
- Avoid dopamine agonists in psychotic patients, especially if taking dopamine antagonists.

Second Line

- Voltage-gated calcium channel α2δ subunit ligands: useful for associated neuropathy (1,2,3)[C]:
  - Gabapentin enacarbil (Horizant): 600 mg/day
  - Pregabalin (Lyrica): 50 to 300 mg/day
- Opioids: low risk for tolerance with bedtime dose
  - Hydrocodone: 5 to 20 mg/day
  - Oxycodone: 2.5 to 20 mg/day
- Benzodiazepines and agonists (1,3)[C]:
  - Clonazepam (Klonopin): 0.5 to 3 mg/day
  - Zaleplon, zolpidem, temazepam, triazolam, alprazolam, diazepam

Pediatric Considerations

- First-line treatment is nonpharmacologic.
- Assess/correct iron deficiency.
- Consider low-dose clonidine.

Pregnancy Considerations

- Initial approach: iron supplementation, nonpharmacologic therapies
- Avoid medications class C or D.
- In 3rd trimester, low-dose opioids may be considered. Monitor for and address

constipation.

Geriatric Considerations

In weak or frail patients, avoid medications that may cause dizziness or unsteadiness.

ADDITIONAL THERAPIES

- If iron deficient, iron supplementation:
  - 325 mg ferrous sulfate with 200 mg vitamin C between meals TID
  - Repletion may require months.
  - Symptoms continue without other treatment.
- Vitamin/mineral supplements, including calcium, magnesium, vitamin B_{12}, folate
- Clonidine: 0.05 to 0.1 mg/day
- Relaxis leg vibration device (see http://myrelaxis.com)

SURGERY/OTHER PROCEDURES

Correction of orthopedic, neuropathic, or peripheral vascular problems

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Control during recovery from orthopedic procedures
- Addition or withdrawal of medications that affect PLMD
- Changes in medical status may require medication changes (e.g., Mirapex contraindicated in renal failure and Requip contraindicated in liver disease).
- Consider iron infusion when oral supplementation is ineffective, not tolerated, or contraindicated.
- When NPO, consider IV opiates.
- Evening walks, hot baths, leg warming
- Sleep interruption risks prolonged wakefulness.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- At monthly intervals until stable
- Annual and PRN follow-up thereafter
- If iron deficient, remeasure ferritin to assess repletion.

DIET

Avoid caffeine and alcohol late in the day.

PATIENT EDUCATION

- National Sleep Foundation: http://sleepfoundation.org/
- American Academy of Sleep Medicine: http://www.sleepeducation.org/

PROGNOSIS

- Primary PLMD: lifelong condition with no current cure
- Secondary PLMD: may subside with resolution of cause(s)
- Current therapies usually control symptoms.
- PLMD often precedes emergence of RLS.

COMPLICATIONS

- Tolerance to medications requiring increased dose or alternatives
- Augmentation (increased PLMs and sleep disturbance, emergence of RLS) from prolonged use of dopamine agonists:
  - Higher doses increase risk.
  - Iron deficiency increases risk.
  - Add alternative medication and then detitrate dopaminergic agent.
- Iatrogenic PLMD (from antidepressants, etc.)

Restless Legs Syndrome

CODES

ICD10

G47.61 Periodic limb movement disorder

CLINICAL PEARLS

- Many patients with PLMs may not require treatment; however, when sleep disturbance from PLMs causes insomnia and/or daytime consequences, PLMD exists and should be treated.
- Many antidepressants and some antihistamines cause or exacerbate PLMs.
- Sleep disturbance, including that from PLMs, may cause or exacerbate ADHD.

PERIPHERAL ARTERIAL DISEASE

Zhen Lu, MD

BASICS

DESCRIPTION

Peripheral arterial disease (PAD) is a manifestation of systemic atherosclerosis in which there is partial or total blockage in the arteries, exclusive of the coronary and cerebral vessels. Objectively, PAD is defined as a resting ankle-brachial index (ABI) of <0.90.

EPIDEMIOLOGY

- Predominant age: >40 years
- Predominant sex: male > female (2:1), based on the Framingham study
- Patients with symptomatic PAD have a 5-year mortality rate of 30%.
- Highly prevalent syndrome that affects 8 to 12 million individuals in the United States

Incidence

Incidence overall: 1 to 3/1,000/year

Prevalence

- U.S. prevalence: 2.7 to 4.1%
- Age-adjusted prevalence of PAD is close to 12%.
- Up to 29% among patients in primary care practices

ETIOLOGY AND PATHOPHYSIOLOGY

- In patients with PAD, arterial stenoses cause inadequate blood flow in distal limbs, which fails to meet the metabolic demand during exertion:
  - The degree of ischemia is proportional to the size and proximity of the occlusion to the end organ.
  - Acidic products of anaerobic metabolism build up within the muscle and result in claudication clinically.
  - Arterial occlusion also causes significantly diminished distal pressure in patients with PAD due to atherosclerotic lesions.

- Most common cause of arterial stenoses is atherosclerosis.

Genetics

Current NIH-funded research focuses on single-nucleotide polymorphisms in candidate genes that are regulated in the vasculature in an attempt to explore genetic factors responsible for PAD.

RISK FACTORS

- Age >40 years
- Cigarette smoking
- Diabetes mellitus
- Obesity
- Hypertension
- Hyperlipidemia
- Hyperhomocysteinemia

GENERAL PREVENTION

Control risk factors.

COMMONLY ASSOCIATED CONDITIONS

- See "Risk Factors."
- Associated with other common complications of atherosclerosis, including myocardial infarction (MI), transient ischemic attack (TIA), stroke, and limb amputation
- Occurs in ~40% of patients with cardiovascular disease

DIAGNOSIS

HISTORY

- Intermittent claudication, with symptoms typically resolving within 2 to 5 minutes of rest (although it is regarded as the classic symptom for PAD, intermittent claudication is present in only 10% of patients with PAD)
- Rest leg pain (especially in a supine position)
- Skin ulceration (in advanced PAD)
- Gangrene (in advanced PAD)
- Impotence

PHYSICAL EXAM

- Skin pallor when leg is elevated above the level of the heart (in mild PAD)
- Dependent rubor
- Dry and scaly skin
- Poor nail growth
- Hair loss
- Reduced/absent extremity pulses (in advanced PAD)

DIFFERENTIAL DIAGNOSIS

- Arterial embolism
- Deep venous thrombosis
- Thromboangiitis obliterans (Buerger disease)
- Osteoarthritis
- Restless legs syndrome
- Peripheral neuropathy
- Spinal stenoses (pseudoclaudication)
- Intervertebral disc prolapse

DIAGNOSTIC TESTS & INTERPRETATION

Serum glucose is recommended screening for diabetes mellitus in suspected or confirmed PAD.

Initial Tests (lab, imaging)

- Fasting lipid profile is indicated for risk assessment of hyperlipidemia.
- Duplex ultrasonography and Doppler color-flow imaging, which are useful in detecting stenosed segments and assessing lesion severity, are initial imaging tests of choice.
- Magnetic resonance angiography, coupled with 3D reconstruction, is highly sensitive and specific for the localization of occluded lesions.
- CT scanning has a limited role in the evaluation of PAD.
- Angiography remains the gold standard in the diagnosis of PAD.

Diagnostic Procedures/Other

- Doppler ABI measures the ratio of the higher systolic BPs between the dorsalis pedis and the posterior tibial artery versus the higher of the systolic BPs in the two brachial arteries: Values for the ABI should be reported as

"incompressible" if >1.40, "normal" if 1.00 to 1.40, "borderline" if 0.91 to 0.99, and "abnormal" if ≤0.90. ABI <0.4: severe ischemia

- Segmental limb pressures: usually obtained if abnormal ABI measurement is identified; a ≤20-mm Hg reduction in pressure is considered significant for PAD.
- Treadmill exercise test assesses the severity of claudication and the response to treatment.
- Segmental volume plethysmography: often used in conjunction with segmental limb pressures to measure the volume changes in an organ or limb; the study is indicated for calcified vessel when the ABI cannot be applied diagnostically.

TREATMENT

GENERAL MEASURES

- Claudication exercise rehabilitation program: patient to walk until symptoms develop, then rest and start again, for a total of 30 minutes initially; walking then is increased by 5 minutes until 50 minutes of intermittent walking is achieved.
- Modification of risk factors, including smoking cessation, diabetes mellitus, hypertension, and hyperlipidemia:
  - Weight loss is associated with a decrease in the risk of cardiovascular disease but has not been shown to improve PAD.
  - Antiplatelet therapy (aspirin) is recommended for patients with PAD when there is no other contraindication; however, neither the addition of an anticoagulant nor anticoagulant therapy alone has demonstrated superior outcome in PAD patients.
  - Lipid-lowering therapy with moderate-intensity statin; simvastatin (20 to 40 mg/day) has been shown to reduce the incidence of new intermittent claudication from 3.6% to 2.3% in patients with coronary artery disease (CAD).
  - No statistical significance for overall improvement of exercise performance or reduction in claudication symptoms for patients on niacin extended-release/lovastatin-combined therapy.

- β-Adrenergic antagonists should be used with caution in individuals with severe PAD.
- Smoking cessation is likely to reduce the severity of claudication.

MEDICATION

First Line

Antiplatelet therapy has been the mainstay treatment to prevent ischemic events in patients with PAD. However:

- The effect of aspirin on the risk reduction of overall ischemic events is inconclusive. Some suggest that aspirin delays disease progression and reduces the need for surgical intervention. AHA/ACCF guidelines (1)[A] note that the use of antiplatelet therapy to reduce cardiovascular risks in asymptomatic patients with borderline ABIs is characterized as "not well-established." Aspirin is recommended to reduce the risk of MI, stroke, and vascular death in symptomatic patients with PAD.
- Low-dose aspirin (75 to 150 mg/day) is as effective as higher doses of aspirin.

Second Line

- Clopidogrel (75 mg/day) is approved by the FDA for the secondary prevention of thrombotic events in patients with symptomatic lower extremity PAD and is recommended as an alternative to aspirin.
- Vorapaxar (Zontivity) 2.08 mg PO daily is a platelet aggregation inhibitor different in mechanism from existing antiplatelet drugs (TRAP inhibitor). It is contraindicated if history of CVA, TIA, or intracranial hemorrhage; concern for bleeding risk; and is expensive
- Other medications that may improve symptoms of claudication include pentoxifylline (1.2 g/day), cilostazol (100 mg BID), and naftidrofuryl (600 mg/day).
- Neither vasodilators nor anticoagulant therapy (e.g., heparin, low-molecular-weight heparin, or oral anticoagulant) has shown any clinically proven efficacy for the treatment of claudication and may be harmful.
- Cilostazol (100 mg BID) improves walking distance in people with intermittent claudication secondary to PAD. There is currently insufficient data on whether taking cilostazol results in a reduction of all-cause mortality and cardiovascular events or an improvement in quality of life (2)[A].

- Other medications that may reduce claudication include pentoxifylline (1.2 g/day), naftidrofuryl (600 mg/day), and prostaglandins (120 μg/day). Ticlopidine (250 mg BID) reduces the risk of MI, stroke, and death in patients with PAD, but it has a complication of thrombocytopenia in 2–3% of patients.

ADDITIONAL THERAPIES

- Weight reduction, smoking cessation, and BP control are essential in treating claudication.
- Exercise programs are of significant benefit compared with placebo or usual care in improving walking time and distance in people with leg pain from intermittent claudication who were considered to be fit for exercise intervention (3)[A]. A walking program should include walking at least 3 times per week for 30 to 60 minutes each time and has been shown to improve quality of life as much as or more so than medication.
- A healthy diet high in complex carbohydrates (e.g., whole grains and pastas), fruits and vegetables, and low in salt and animal fats

SURGERY/OTHER PROCEDURES

Surgical interventions, such as revascularization, are warranted for individuals who have debilitating intermittent claudication, ischemic rest pain, or tissue loss:

- Transluminal balloon angioplasty is a percutaneous method of dilating arterial stenoses or recanalizing occluded vessels with or without stents (reserved for short, isolated, and hemodynamically significant lesions of the iliac or proximal superficial femoral artery).
- Bypass surgery is the standard operative treatment for lower extremity peripheral occlusive disease.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Acupuncture, biofeedback, chelation therapy, and supplements such as *Ginkgo biloba*, omega-3 fatty acids, and vitamin E have been studied.
- Ginkgo biloba modestly reduces the symptoms of intermittent claudication (120 mg/day for up to 6 months) and can be considered as an adjunct to exercise therapy. Inconclusive evidence exists for the use of vitamin E.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- An exercise training program composed of walking/bicycle riding improves maximal treadmill walking distance and, therefore, enhances functional capacity.
- However, little added benefit exists from Ginkgo biloba treatment when added to supervised exercise training in patients with PAD as compared with patients in exercise training program alone.

DIET

A low-fat cardiac diet is recommended.

PROGNOSIS

- Among patients with intermittent claudication, 15–20% will experience worsening claudication; 5–10% will undergo lower extremity bypass surgery; and 2–5% will need primary amputation (rates for smokers and diabetics are much higher).
- 30,000 to 50,000 people in the United States undergo amputations annually because of PAD.

CODES

ICD10

- I73.9 Peripheral vascular disease, unspecified
- I70.209 Unsp athscl native arteries of extremities, unsp extremity
- I70.219 Athscl native arteries of extrm w intrmt claud, unsp extrm

CLINICAL PEARLS

- Screening of a general medical population for PAD is not recommended. Studies have indicated that screening for PAD among asymptomatic adults in the general population could lead to false-positive results and unnecessary workups. The prevalence among the general public who are asymptomatic is low.
- A patient already receiving medical treatment should be referred for further surgical evaluation for any of the following scenarios:
  - Unsatisfactory results despite medical therapy
  - No definitive diagnosis can be made
  - Critical limb ischemia is present, such as rest pain, gangrene, or ulceration.
- The clopidogrel (75 mg/day) versus aspirin (325 mg/day) study in the patients at risk of ischemic events (CAPRIE) trial found a 23.8% relative risk ratio for MI, stroke, or cardiovascular death in PAD patients treated with clopidogrel

compared with aspirin but no statistically significant difference in overall mortality reduction. Clopidogrel is much more expensive than aspirin.

PERITONITIS, ACUTE

Gregory M. Piech, MD, MPH • Marie L. Borum, MD, EdD, MPH

BASICS

DESCRIPTION

- Definition: inflammation of the peritoneum
- Classification:
  - Aseptic: chemical irritation or systemic inflammation of peritoneum
  - Bacterial: infection of peritoneal fluid
- Bacterial peritonitis types:
  - Primary/spontaneous bacterial peritonitis (SBP): infection of ascitic fluid in the absence of an intra-abdominal source; typically monomicrobial
  - Secondary bacterial peritonitis: infection of ascitic fluid from a detectable intra-abdominal source (i.e., perforation, abscess); typically polymicrobial
  - Tertiary bacterial peritonitis: persistent infection despite adequate therapy

EPIDEMIOLOGY

Incidence

- In patients with ascites, the incidence of SBP in a 1-year period is 10–25% (1).
- Secondary bacterial peritonitis correlates with incidence of the underlying pathology (e.g., colitis, appendicitis, diverticulitis, PUD).
- 57% of patients with secondary bacterial peritonitis progressed to tertiary peritonitis (2).

Prevalence

- SBP: In asymptomatic patients with cirrhosis and ascites, the prevalence is <3.5% in outpatients and 8–36% in the nosocomial setting (3).
- In patients with cirrhosis and ascites, 5% of peritonitis is secondary rather than SBP (4).

ETIOLOGY AND PATHOPHYSIOLOGY

- Mechanism

- SBP:
  - Primary mechanism is bacterial translocation via lymphatic spread through mesenteric lymph nodes.
  - Cirrhotic patients have multiple secondary mechanisms:
    - Alterations to gut microbiota with higher prevalence of potentially pathogenic organisms
    - Small intestinal bacterial overgrowth (SIBO) and increased intestinal mucosal permeability to bacteria
    - Decreased cellular and humoral immunity limits peritoneal bacterial clearance.
- Secondary bacterial peritonitis
  - Spillage/translocation of bacteria from inflamed or perforated intraperitoneal organs or introduction of bacterial through instrumentation —that is, peritoneal dialysis, intraperitoneal chemotherapy
- Tertiary bacterial peritonitis
  - Occurs in secondary peritonitis with inadequate source control or altered host immunity

- Microbiology
  - SBP
    - Meta-analysis for microorganisms isolated in SBP from 1998 to 2012: *Escherichia coli* (33%), *Streptococcus* spp. (15%), *Staphylococcus* (13%), *Klebsiella* (8%); reflects increasing rate of gram-positive and resistant organisms (e.g., extended-spectrum β-lactamase-producing [ESBL] *E. coli*, MRSA, *Enterococcus*) in the nosocomial setting compared to earlier studies (5)
  - Secondary bacterial peritonitis:
    - *E. coli*, *Klebsiella*, *Proteus*, *Streptococcus*, *Enterococcus*, *Bacteroides*, *Clostridium*

RISK FACTORS

- SBP: advanced cirrhosis with ascites, bacterascites, malnutrition, upper GI bleed, PPI usage, prior SBP
  - Acid suppression with PPIs promotes SIBO increasing SBP. Hospitalized cirrhotics receiving PPIs have increased risk of developing SBP (3,5).
  - 70% of cases of SBP are seen in patients with Child-Pugh class C cirrhosis

(1).
  - Low ascitic protein level (<1.0 g/dL)
- Secondary bacterial peritonitis: factors associated with perforation or fluid translocation; for example, peritoneal dialysis, *Helicobacter pylori* and NSAIDs causing ulcers, vascular disease causing bowel ischemia, ETOH abuse causing pancreatitis

GENERAL PREVENTION

- SBP prophylaxis is beneficial when risk factors are present, including ascitic fluid protein concentration <1.0 g/dL, esophageal varices, or history of previous SBP.
  - Prior SBP: prophylactic norfloxacin or TMP/SMX PO daily (6)[A]
  - Cirrhosis and GI bleed: 7-day course of ceftriaxone 2 g IV daily or norfloxacin BID; IV while bleeding, PO as tolerated (6)[A]
  - Cirrhotic ascites: low ascitic fluid protein (<1.5 g/dL) with renal impairment (creatinine ≥1.2, BUN ≥25, or serum Na ≤130) or liver failure (Child score ≥9, bilirubin ≥3): prophylactic norfloxacin PO daily (3,6)[A]
- Limit use of PPIs to only proven indications (6)[B].

DIAGNOSIS

HISTORY

- SBP: history of cirrhosis or ascites, fever, mental status changes, abdominal pain, chills, nausea/vomiting, GI bleed
- Secondary bacterial peritonitis: may be clinically indistinguishable from SBP unless history of perforation, abscess, or peritoneal dialysis is present
- Tertiary: persistent signs and symptoms despite initial treatment, or history of recurrent peritonitis

ALERT

30% of patients are asymptomatic (1).

PHYSICAL EXAM

- Tachycardia, fever, tachypnea, altered mental status
- Abdominal distention, ascites, abdominal wall guarding and rigidity, rebound

tenderness, hypoactive/absent bowel sounds

DIFFERENTIAL DIAGNOSIS

- Liver disease: acute hepatitis, decompensated cirrhosis
- Luminal disease: abscess formation, ileus, volvulus, intussusception, mesenteric adenitis, pancreatitis, cholecystitis, malignancy, peritoneal carcinomatosis
- Extraluminal disease: ruptured ectopic pregnancy, tubo-ovarian abscess, PID, severe UTI, and/or pyelonephritis
- Systemic disease: tuberculosis, pneumonia, MI, porphyria, SLE

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

ALERT

Early diagnosis is essential to reduce mortality. Paracentesis should be performed in any patient with ascites who is admitted to the hospital (6)[B].

- Immediate evaluation
  - Perform paracentesis, blood, and urine cultures before administration of antibiotics (1,6)[B]. Even a single dose of effective broad-spectrum antibiotics can decrease ascitic culture yield.
  - Ascitic fluid studies should minimally include culture, Gram stain, cell count with differential, and albumin (1)[B]; if assessing for secondary peritonitis, also include LDH, total protein, glucose, alkaline phosphatase (ALP) and CEA.
  - Bedside inoculation of ascitic fluid into blood culture bottles (aerobic, anaerobic) shown to increase culture yield 80–90% (3,5)[B]

ALERT

Ascitic fluid culture is negative in up to 50% of patients with SBP (1)[A].

- SBP: bacterascites and ascitic fluid PMN >250 cells/mm^3
- Culture-negative neutrocytic ascites: negative ascites culture, ascitic fluid PMN >250 cells/mm^3
- Nonneutrocytic bacterascites: positive ascites culture, ascitic fluid PMN <250 cells/mm^3

- Secondary peritonitis: PMN >250 cells/mm^3 on ascitic fluid analysis (usually thousands), with the following:
  - Polymicrobial culture or two of the following: ascitic fluid total protein >1 g/dL, glucose <50 mg/dL, or LDH >225 mU/mL. More sensitive for perforation (96%) than for nonperforation secondary peritonitis (50%) (6)[B].
  - Secondary peritonitis with perforation is likely with ALP >240 U/l or CEA >5 ng/mL, sensitivity 92% (6)[B]; not useful for detection of nonperforation secondary peritonitis
- Criteria or clinical suspicion for secondary peritonitis necessitates emergent CT scan; not CT diagnostic for secondary peritonitis in 85% of cases (6)[B]
  - Abdominal or chest x-ray may show free air in peritoneal cavity, large/small bowel dilatation, intestinal wall edema in secondary peritonitis.

Follow-Up Tests & Special Considerations

- If asymptomatic bacterascites, recent antibiotic exposure, nosocomial atypical organism, or no clinical improvement, repeat paracentesis in 48 hours to determine resolution, defined as decrease in PMNs of 25% or negative cultures (1)[C].
- In hemorrhagic ascites, PMN count corrected by subtracting 1 PMN per 250 RBCs (3)[A].

TREATMENT

GENERAL MEASURES

- For SBP, control the effects of cirrhosis/ascites with salt restriction, spironolactone +/− furosemide, albumin infusion after large volume paracentesis, and/or lactulose for encephalopathy (6)[A].
- Avoid nephrotoxic medications (e.g., NSAIDs) or other renal insults (5)[C].

MEDICATION

- SBP
  - Community-acquired SBP without recent β-lactam antibiotic use: 3rd-generation cephalosporins, preferably cefotaxime, 2 g IV q8h for 5 days (6)

[A]
  - SBP in absence of previous quinolone use/prophylaxis, vomiting, shock, hepatic encephalopathy, or serum creatinine >3 mg/dL: ofloxacin 400 mg PO can be substituted for cefotaxime (6)[B].
  - Nosocomial SBP or recent β-lactam antibiotic: empiric therapy based on local susceptibility of patients with cirrhosis for resistant bacteria (6)[B]
  - Symptomatic bacterascites with PMN count <250 cells/mm^3: cefotaxime 2 g IV q8h while awaiting sensitivities (6)[B]
  - Second-line antibiotic regimens include fluoroquinolones (levofloxacin), piperacillin/tazobactam, or vancomycin (5)[B],(6)[C].
  - SBP with renal or hepatic impairment (serum creatinine >1 mg/dL, BUN >30 mg/dL, or total bilirubin >4 mg/dL): Add albumin 1.5 g/kg within 6 hours and 1 g/kg on day 3 (1)[A],(6)[B].
- Secondary bacterial peritonitis
  - Empiric broad spectrum antibiotic coverage for polymicrobial infection; IV cefotaxime or other 3rd- to 4th-generation cephalosporin plus metronidazole is one option for an initial regimen.
  - In peritoneal dialysis–associated infection, intraperitoneal route superior to IV.
- Tertiary bacterial peritonitis
  - If no unrepaired perforations or leaks, then continue with medical management. This includes antibiotics (guided by prior susceptibilities) and early enteral nutrition to prevent atrophy and maintain immunocompetence (2)[B].
  - In recurrent or persistent peritoneal dialysis–associated infection, removal of the PD catheter is warranted.

SURGERY/OTHER PROCEDURES

- SBP
  - Medical management
- Secondary bacterial peritonitis
  - Emergent surgical management, including source control with open laparotomy to repair any perforated viscus and eradicate infected material, is first-line treatment (2)[A],(6)[B].

- Tertiary bacterial peritonitis
  - If no unrepaired perforations or leaks, additional surgery for severe abdominal infection is correlated with deterioration and significant mortality (2).

ALERT

Mortality of secondary bacterial peritonitis approaches 100% if not treated surgically, whereas the mortality of SBP approaches 80% if the patient receives unnecessary exploratory laparotomy (1,3).

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Acute peritonitis typically warrants inpatient admission.
- In patients with cardiogenic or septic shock, use invasive monitoring with early goal-directed fluid therapy.
- Patients who present with peritonitis can be severely hypovolemic. In these cases, volume resuscitation is critical. In patients with significant renal or hepatic dysfunction, albumin decreases mortality (1)[A],(6)[B].
- Cirrhotic patients often take β-blockers as part of their outpatient regimen, but during an episode of SBP, β-blockers increase mortality, hepatorenal syndrome, and hospital stay in SBP patients (6)[B].
- Nasogastric tube placement can prevent aspiration in patients with vomiting or GI bleeding.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Normalization of vital signs with resolution of leukocytosis indicates improvement.

- SBP: If follow-up paracentesis is performed after 48 hours to evaluate resolution, PMN decrease >25% is expected.
- Development of leukopenia indicates immune exhaustion and poor prognosis.

DIET

- NPO, total parental nutrition as necessary
- Resume enteral feeding after return of bowel function.
- Sodium restriction can reduce future ascites (3)[A].

PROGNOSIS

- SBP
  - For inpatients with first episode of SBP, mortality ranges from 10% to 50% (3).
  - Prognosis is improved if antibiotics are started early, prior to onset of shock or renal failure.
  - Strongest negative prognostic indicator is renal insufficiency.
  - Other poor prognostic factors include nosocomial acquisition, old age, high Child-Pugh-Turcotte or MELD score, malnutrition, malignancy, peripheral leukopenia, and antibiotic resistance (3).
  - Patients with prior SBP have 1-year recurrence rate of 40–70% and 1-year mortality of 31–93% (1,3).
- Secondary bacterial peritonitis:
  - In-hospital mortality of treated patients is 67% (4).
  - Mortality approaches 100% if not treated surgically, especially if secondary to perforation (2,4).
  - Prognosis is worse in perforated etiologies.

COMPLICATIONS

- Renal failure, liver failure, encephalopathy, coagulopathy
- Secondary infection, iatrogenic infection, abscess, fistula formation, abdominal compartment syndrome
- Sepsis/septic shock, cardiovascular collapse, adrenal insufficiency, respiratory failure, ARDS

SEE ALSO

Appendicitis, Acute; Cirrhosis of the Liver; Diverticular Disease; Peptic Ulcer Disease

CODES

ICD10

- K65.0 Generalized (acute) peritonitis
- K65.2 Spontaneous bacterial peritonitis
- K65.8 Other peritonitis

CLINICAL PEARLS

- Maintain a high index of suspicion for SBP in cirrhotic patients with ascites as up to 30% of cases may be asymptomatic.
- Paracentesis is necessary to diagnose SBP. Ascitic fluid cultures collected via bedside inoculation with blood culture bottles prior to antibiotic administration increases culture yield significantly.
- *E. coli* continues to be the most common bacterial isolate from cases of SBP, and 3rd-generation cephalosporins remain first-line treatment, but the incidence of gram-positive and resistant organisms is increasing.
- Ascitic fluid analysis is essential to stratify patients that may be at risk for secondary peritonitis and in need of additional imaging. Emergent CT scan should be performed if there is suspicion based on history and/or ascitic fluid analysis.
- Renal function is an important prognostic indicator for SBP. Albumin administration decreases the incidence of renal failure and mortality in patients with renal or hepatic impairment or large-volume paracentesis.

PERSONALITY DISORDERS

Moshe S. Torem, MD, DLFAPA

BASICS

DESCRIPTION

- Personality disorders (PDs) are a group of conditions, with onset at or before adolescence, characterized by enduring patterns of maladaptive and dysfunctional behavior that deviates markedly from one's culture and social environment, leading to functional impairment and distress to the individual, coworkers, and family.
  - These behaviors are perceived by patients to be "normal" and "right," and they have little insight as to their ownership, responsibility, and abnormal nature of these behaviors.
  - These conditions are classified based on the predominant symptoms and their severity.
- System(s) affected: nervous/psychiatric
- Synonym(s): character disorder; character pathology

Geriatric Considerations

Coping with the stresses of aging is challenging.

Pediatric Considerations

A history of childhood neglect, abuse, and trauma is not uncommon.

Pregnancy Considerations

Pregnancy adds pressures in coping with the activities of daily living (ADLs).

EPIDEMIOLOGY

Prevalence

- General population: 15% (1)
- Cluster A: 5.7%
- Cluster B: 6.0%
- Cluster C: 9.1%
- Outpatient psychiatric clinic: 3–30% (2)

- In male prisoners, the prevalence of antisocial personality disorder is ~60%.
- Predominant age: starts in adolescence and early 20s and persists throughout patient's life
- Predominant sex: male = female; some PDs are more common in females, and others are more common in males.

ETIOLOGY AND PATHOPHYSIOLOGY

- Environmental and genetic factors (3)
- Criteria for a PD includes an enduring pattern of the following:
  - Inner experience and behavior that deviates markedly from the expectations of one's culture in ≥2 of the following areas: cognition, affectivity, interpersonal functioning, or impulse control
  - Inflexibility and pervasiveness across a broad range of personal and social situations
  - Significant distress or impairment in social or occupational functioning
  - The pattern is stable and of long duration.
  - The enduring pattern is not better explained as a manifestation of another psychiatric disorder.
  - The enduring pattern is not attributable to the effects of a drug or a medical condition.
- PDs are classified into three major clusters:
  - Cluster A: eccentricity and oddness
    - *Paranoid PD*: unwarranted suspiciousness and distrust of others
    - *Schizoid PD*: emotional, cold, or detached; socially isolated
    - *Schizotypal PD*: eccentric behavior, odd belief system/perceptions, social isolation, and general suspiciousness
  - Cluster B: dramatic, emotional, or erratic behavioral patterns
    - *Antisocial PD*: aggressive, impulsive, irritable, irresponsible, dishonest, deceitful
    - *Borderline PD:* unstable interpersonal relationships, high impulsivity from early adulthood, intense fear of abandonment, mood swings, poor self-esteem, chronic boredom, and feelings of inner emptiness
    - *Histrionic PD:* needs to be the center of attention, with self-dramatizing behaviors and attention seeking in a variety of contexts
    - *Narcissistic PD*: grandiose sense of self-importance and preoccupation

with fantasies of success, power, brilliance, beauty, or ideal love; lack of empathy for other people's pain or discomfort, demanding to get their way

- Cluster C: anxiety, excessive worry, fear, and unhealthy patterns of coping with emotions
  - *Avoidant PD*: social inhibition, feelings of inadequacy, hypersensitivity to negative evaluation, avoidance of occupational and interpersonal activities that involve the risk of criticism by others, views self as socially inept and personally unappealing or inferior to others
  - *Dependent PD*: excessive need to be taken care of, leading to submissive and clinging behavior with fears of separation, avoids expressing disagreements with others due to fear of losing support and approval, usually seeks out strong and confident people as friends or spouses and feels more secure in such relationships
  - *Obsessive-compulsive PD*: preoccupation with cleanliness, orderliness, perfectionism; preoccupation with excessive details, rules, lists, order, organization, and schedules to the extent that the major point of the activity is lost
- Personality change due to another medical condition. It is a persistent personality disturbance that is caused by the physiologic effects of a medical condition such as frontal lobe lesion, epilepsy, MS, Parkinson disease, lupus, head trauma, postencephalitis or meningitis, and so forth.
- Other specified *PD and unspecified PD*: A category provided for two situations: (i) the individual's personality pattern meets the general criteria for PD and traits of several PDs are present, but the criteria for any specific PD are not met; (ii) the individual's personality pattern meets the general criteria for PD, but the individual is considered to have a PD that is not included in *DSM-5* classification such as passive-aggressive PD, depressive PD, masochistic PD, and dangerous and severe PD.

Genetics

Major character traits are inherited; others result from a combination of genetics and environment.

RISK FACTORS

- Positive family history
- Pregnancy risk factors
  - Nutritional deprivation
  - Use of alcohol or drugs
  - Viral and bacterial infections
- Dysfunctional family with child abuse/neglect

COMMONLY ASSOCIATED CONDITIONS

Depression; other psychiatric disorders in patient and family members

DIAGNOSIS

HISTORY

- Comprehensive interview and mental status examination
- Screen to rule out alcohol and drug abuse.
- Interview of relatives and friends is helpful in establishing an enduring pattern of behavior.

DIAGNOSTIC TESTS & INTERPRETATION

Psychological testing (e.g., MMPI-II)

Initial Tests (lab, imaging)

- CBC
- Comprehensive metabolic panel
- Thyroid-stimulating hormone
- HIV
- Toxicology screen for substance abuse

Follow-Up Tests & Special Considerations

- EEG to rule out a chronic seizure disorder
- CT and MRI of the brain may be necessary in newly developed symptoms to rule out organic brain disease (e.g., frontal lobe tumor).

DIAGNOSTIC TESTS & INTERPRETATION

- Medical disorders with behavioral changes
- Other psychiatric disorders with similar symptoms

- In obsessive-compulsive disorder (OCD), symptoms are ego-dystonic (i.e., perceived as foreign and unwanted). In addition, OCD has a pattern of relapse and partial remission.
- In obsessive-compulsive personality disorder (OCPD), symptoms are perceived as desirable behaviors (ego-syntonic) that the patient feels proud of and wants others to emulate. In addition, OCPD has a lifelong pattern (i.e., without significant relapse or remission).

TREATMENT

Psychotherapy with family involvement is the foundation of treatment. No specific drugs are indicated to treat PDs; some medications can reduce the intensity, frequency, and dysfunctional nature of certain behaviors (4)[B].

GENERAL MEASURES

- Long-term psychotherapy and cognitive-behavioral therapy (5)[B]
- Group therapy is helpful in the use of therapeutic confrontation and increasing one's awareness of and insight regarding the damaging effects of dysfunctional behavior patterns (6)[B].

MEDICATION

Medications are effective in the treatment of comorbid conditions such as anxiety and depression.

First Line

- Symptom management (7)[B]
  - Minipsychosis (associated with paranoid, schizoid, borderline, and schizotypal PDs): atypical antipsychotics: risperidone (Risperdal), quetiapine (Seroquel), olanzapine (Zyprexa), ziprasidone (Geodon), aripiprazole (Abilify), asenapine (Saphris), lurasidone (Latuda); start with a low dose, gradually adjusting to the patient's needs.
  - Anxiety: anxiolytics (benzodiazepines, buspirone [Buspar], and serotonin reuptake inhibitors)
  - Depressed mood: antidepressants
  - Many patients with borderline PD respond well to small doses of atypical

neuroleptics and mood stabilizers (8)[B].

- Precautions: Some atypical neuroleptic drugs may be associated with hyperglycemia and insulin-resistant metabolic syndrome.

Second Line

Mood stabilizers: lithium carbonate, lamotrigine (Lamictal), carbamazepine (Tegretol, Equetro), and valproate (Depacon, Depakene, Depakote) (9)[B]

ISSUES FOR REFERRAL

- When psychiatric comorbidity of other psychiatric disorders is present (e.g., mood disorders, anxiety disorders, substance abuse)
- Suicidal ideation or attempts
- Presence of psychotic symptoms
- Thoughts and impulses for violent behavior
- Management of complex pharmacotherapy
- Presence of intense countertransference feelings
- When the patient or family requests it

ADDITIONAL THERAPIES

- Cognitive-behavioral therapy
- Dialectical behavior therapy
- Psychoanalytic therapy
- Interactive psychotherapy
- Ego-State therapy
- Mindfulness-based psychotherapy
- Group therapy

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Disorders with complications of suicide attempts and other behaviors involving a risk to self or others

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Continue outpatient treatment, potentially long term.

Patient Monitoring

- Regular physical exercise (e.g., 30 to 60 min/day, helps with stress and improving the ADLs)
- If substance abuse is suspected, check drug screens.
- Infrequent sessions with relatives or friends are helpful in monitoring behavioral progress.

DIET

Emphasize variety of healthy foods; avoid obesity.

PATIENT EDUCATION

- Bibliotherapy and writing therapy, specific assignments, and watching certain movies to better understand the nature and origin of one's specific condition are helpful.
  - Kreger R. *The Essential Family Guide to Borderline Personality Disorder*. Center City, MN: Hazelden; 2008.
  - Mason PT, Kreger R. *Stop Walking on Eggshells*. Oakland, CA: New Harbinger Publishers; 2010.
- The movie *As Good as It Gets* illustrates someone with obsessive-compulsive behaviors and their impact on ADLs and relationships with family and friends.
- The movie series *The Godfather* includes several characters with antisocial PD and shows how this affects their interpersonal relationships and their own physical and mental health.
- The movie *What About Bob?* illustrates the challenges involved in treating certain patients with a borderline PD, especially in the management of boundaries in the doctor–patient relationship.
- The movie *A Streetcar Named Desire* illustrates an example of a woman with a histrionic PD.
- The movie *Wall Street* illustrates an example of a person with a narcissistic PD.
- The movie *The Caine Mutiny* illustrates an example of a person with a paranoid PD.
- The movie *Four Weddings and a Funeral* illustrates an example of a person

with an avoidant PD.

PROGNOSIS

PDs are enduring patterns of behavior throughout one's lifetime and are not readily responsive to brief therapies.

COMPLICATIONS

- Disruptive family life with frequent divorces and separations, alcoholism, substance abuse, and drug addiction
- Disruptive behaviors in the workplace may cause absenteeism and loss of productivity.
- Violation of the law and disregard for the concerns and rights of others

SEE ALSO

Obsessive-Compulsive Disorder (OCD)

CODES

ICD10

- F60.9 Personality disorder, unspecified
- F60.0 Paranoid personality disorder
- F60.1 Schizoid personality disorder

CLINICAL PEARLS

- PDs are enduring patterns of behavior throughout one’s lifetime and are not readily responsive to brief treatments.
- In spite of the initial lack of self-awareness and accepting responsibility for one’s dysfunctional behaviors, many patients can benefit from long-term treatment.
- No specific drugs are effective to treat PDs; however, specific medications can reduce the intensity, frequency, and dysfunctional nature of certain behaviors,

thoughts, and feelings.

- Patients with a personality disorder frequently elicit intense feelings in others, such as anger, hostility, likability, or sexual attraction.
- Health care professionals must be alert to potential blurring of interpersonal boundaries in the clinical care of these patients.
- Most patients with a PD require a well-trained and experienced mental health professional.
- A stable, trustful alliance with the patient is the foundation for any therapeutic progress.
- Many PD patients begin treatment in a crisis involving symptoms of anxiety, fear of abandonment, depressed mood, and intense interpersonal conflict at home or work. The focus at this initial phase of treatment should be symptom control and behavioral stabilization with restoration of hope.
- Lifelong pattens of dysfunctional behaviors should not be confronted at the initial phase of treatment.
- Therapeutic confrontation of dysfunctional behavioral patterns is effective only after a working and therapeutic alliance has been established.
- Showing genuine interest in the patient as a whole person including the patient’s life history and current life circumstances may be helpful in establishing a therapeutic and working alliance that is necessary for continuing treatment of PD patients.
- Regular meetings with a spouse, another family member, or significant other are essential for receiving feedback on therapeutic progress.

PERTUSSIS

Mary Cataletto, MD, FAAP, FCCP • Margaret J. McCormick, MS, RN, CNE

BASICS

Highly contagious disease; aka whooping cough

DESCRIPTION

- Human host: adults most common reservoir
- Can affect all ages
- Worldwide distribution
- May be endemic or epidemic with outbreaks every 3 to 5 years
- Seasonality: can occur year-round; peaks late summer–autumn
- Transmission: person to person via aerosolized respiratory droplets
- Effective vaccine available but neither vaccine nor infection confer lifelong or 100% immunity.
- System(s) affected: respiratory
- Synonym(s): whooping cough

EPIDEMIOLOGY

Incidence

2012 was the most recent peak year with 48,277 reported cases in the United States (1)

ETIOLOGY AND PATHOPHYSIOLOGY

- Toxin mediated
- Infectious process with predilection for ciliated respiratory epithelium
- *Bordetella pertussis* (responsible for ~95% of cases)
- *Bordetella parapertussis*

RISK FACTORS

- Exposure to a confirmed case
- Non- or underimmunized infants and children
- Pregnancy

- Premature birth
- Chronic lung disease
- Immunodeficiency (e.g., AIDS)
- Infants <6 months of age account for ~90% pediatric pertussis hospitalizations (2).

GENERAL PREVENTION

- Public health measures
  - Surveillance activities
  - Prevention programs
  - Outbreak management
- Care of exposed persons
  - Household and close contacts
  - Child care workers
  - Health care workers
- Immunization
  - Vaccine products
  - Boosters
  - CDC and the Advisory Committee on Immunization Practices recommends one Tdap (tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis) vaccination to all adolescents 11 to 12 years of age and one dose of Tdap for all adults age 18 years and older to provide increased herd immunity.

Pediatric Considerations

- Primary immunization series against pertussis followed by boosters
- Maternal immunization and cocooning are important strategies to help reduce neonatal pertussis (3).

ALERT

Tdap vaccine recommended with each pregnancy, preferably after 20 weeks' gestation regardless of Tdap/Td history (4)

Geriatric Considerations

The incidence of pertussis in individuals age 50 years and older has increased between 2006 and 2010 (5).

COMMONLY ASSOCIATED CONDITIONS

- Apnea
- Secondary bacterial pneumonia
- Sinusitis
- Seizures
- Encephalopathy
- Urinary incontinence

DIAGNOSIS

HISTORY

- Exposure to pertussis
- Incubation period 7 to 10 days (range 5 to 21 days)
- Classic symptoms are more common in adults and adolescents and include paroxysmal cough, posttussive whoop, and/or vomiting.
- Infants with pertussis may present with apnea or sudden death.

PHYSICAL EXAM

- Classic pertussis has three phases, which occur over 6 to 10 weeks:
  - Catarrhal phase: rhinorrhea, mild cough, low-grade fever
  - Paroxysmal phase: Cough occurs in bursts, with increased intensity and frequency, often followed by an inspiratory whoop and/or posttussive vomiting.
  - Convalescent phase: Coughing paroxysms decrease in frequency and intensity.
- In the absence of paroxysms or complications, the physical exam may be normal.

ALERT

Infants <6 months of age may have atypical presentations.

DIFFERENTIAL DIAGNOSIS

- *B. parapertussis*
- *Mycoplasma pneumoniae*
- *Chlamydia trachomatis*

- *Chlamydophila pneumoniae*
- *Bordetella bronchiseptica*
- Respiratory syncytial virus
- Adenovirus

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Nasopharyngeal culture (gold standard): 100% specific and permits strain identification and antimicrobial resistance testing. Collect secretions from the back of the throat through the nose, using a Dacron or calcium alginate swab or syringe filled with saline. For best results, collect specimen during the first 2 weeks of cough—sensitivity decreases after 2 weeks (6)[C].
- Polymerase chain reaction (PCR) assays: Most commonly used because of improved sensitivity and turnaround time (6)[C].
- Specificity may vary between assays and must be interpreted within clinical context and local pertussis epidemiology. CDC “Best Practice” guidelines exist for PCR assays, although they have not yet received FDA approval. Six accurate results can be obtained during the first 3 weeks from onset of cough. Dacron swabs should be used as calcium alginate swabs are inhibitory to PCR (2,3).
- Serology: available commercially; however, there is no FDA-approved test or standardization
  - The CDC uses single point serology obtained between 2 and 8 weeks following cough onset when titers are expected to be at their peak (3).

Follow-Up Tests & Special Considerations

- Evaluation and follow-up for associated conditions and complications
- Chest radiograph (2 views) to evaluate for the presence of pneumonia
- EEG/neuroimaging may be considered in infant with seizures or acute life-threatening events (ALTEs).
- Infants <1 month of age who are treated with macrolides should be monitored for the possible development of hypertrophic pyloric stenosis.

TREATMENT

GENERAL MEASURES

Waiting rooms, during transport and procedures: Patients with suspected pertussis should wear masks.

MEDICATION

Pertussis illness may be less severe only if antibiotics are started early, that is, before the onset of paroxysms or during the catarrhal phase (2). Antibiotics can also help to prevent the spread of pertussis to close contacts and is necessary for stopping the spread of pertussis.

First Line

- Empiric antibiotic therapy should be initiated at the time diagnostic testing is performed if sufficient clinical suspicion for pertussis is present.
- Azithromycin is the first line of treatment for treatment and for postexposure prophylaxis (5-day course) (6)[C].
- If administered during catarrhal stage, these antibiotics may ameliorate disease.
- If administered after cough is established, antibiotics will have no individual benefit but may help to limit spread (6)[C].

ALERT

Risk of infantile hypertrophic pyloric stenosis has been associated with the use of macrolides in infants <1 month of age, but are still the drugs of choice. Consultation and monitoring are recommended.

ALERT

Due to reports of *fatal cardiac dysrhythmias* with azithromycin, consider alternate drugs in the elderly and in those with cardiovascular disease (7)[C].

Second Line

Trimethoprim-Sulfamethoxazole (TMP-SMX) (for persons >2 months of age) if:

- They cannot tolerate macrolides.
- They are infected with a macrolide-resistant strain.

ALERT

- TMP-SMX is *contraindicated* in infants <2 months of age (6)[C].
- Clarithromycin is not recommended in infants <1 month of age (6)[C].

ISSUES FOR REFERRAL

Evaluation and treatment of infants <6 months of age, especially those born prematurely, who are unimmunized and those who require hospitalization.

ADDITIONAL THERAPIES

Symptomatic treatment of the cough in pertussis (e.g., corticosteroids, β_2-adrenergic agonists, pertussis-specific immunoglobulin, antihistamine, and leukotriene receptor antagonist) have not shown consistent benefit (4)[B].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Small, frequent meals may be necessary to ensure adequate nutrition.
- Correct fluid and electrolyte abnormalities.
- Infants may require IV fluids.
- IV Fluids Indicated for dehydration and when oral fluids are either contraindicated or poorly tolerated.
- In addition to standard precautions, hospitalized patients should be isolated with respiratory precautions for 5 days after the initiation of effective antibiotic treatment and for 3 weeks after onset of paroxysms in older patients if antibiotics are not used.
- Gentle suctioning of nasal secretions
- Avoid stimuli that trigger paroxysms.
- Respiratory monitoring including pulse oximetry
- Educate each family about the importance of immunizations.
- Discuss chemoprophylaxis with each family.
- Discharge criteria
  - Clinically stable
  - Able to tolerate oral feedings

ONGOING CARE

Supportive

FOLLOW-UP RECOMMENDATIONS

- Monitor infants who received EES or azithromycin for pyloric stenosis.

- Neurologic and/or pulmonary follow-up as necessary

Patient Monitoring

ICU care may be necessary for severely ill or compromised patients.

DIET

IV fluids/nutrition may be required to treat dehydration or supplement poor oral intake.

PATIENT EDUCATION

- American Academy of Pediatrics: http://www.aap.org
- Centers for Disease Control and Prevention: http://www.cdc.gov

PROGNOSIS

- Complete recovery in most cases
- Most severe morbidity and highest mortality in infants <6 months of age

COMPLICATIONS

- Highest and most severe in infants; may include apnea, cyanosis, and sudden death
- In children: may include conjunctival hemorrhage, inguinal hernia, pneumonia, and seizures
- More frequent in adults than adolescents: may include sinusitis, otitis media, pneumonia, weight loss, fainting, rib fracture, urinary incontinence, seizures, encephalopathy, and death

- Wang K, Bettiol S, Thompson MJ, et al. Symptomatic treatment of the cough in whooping cough. *Cochrane Database Syst Rev*. 2014;(9):CD003257.

CODES

ICD10

- A37.90 Whooping cough, unspecified species without pneumonia
- A37.80 Whooping cough due to other Bordetella species w/o pneumonia
- A37.10 Whooping cough due to Bordetella parapertussis w/o pneumonia

CLINICAL PEARLS

- Pertussis is a highly contagious infection.
- A high index of suspicion is needed. During the primary or catarrhal phase, the presentation may be nonspecific.
- Immunization (primary series and boosters), isolation, and early treatment of

affected cases as well as chemoprophylaxis are key components to controlling the spread of pertussis.

PHARYNGITIS

Bryce L. Coombs, DO • David A. Moss, MD

BASICS

DESCRIPTION

- Acute or chronic inflammation of the pharynx
- Most commonly caused by acute viral infection
- Group A *Streptococcus* (GAS) pharyngitis is a common clinical focus due to its potential for preventable suppurative (e.g., retropharyngeal or peritonsillar abscess) and nonsuppurative (e.g., rheumatic sequelae) complications.
- Synonym(s): sore throat; tonsillitis; “strep throat”
- Generally infection mediated but can be due to caustic injury, allergies, gastroesophageal reflux disease (GERD), smoking, endotracheal intubation, or trauma-related

EPIDEMIOLOGY

- Estimated 15 million cases diagnosed yearly
- Accounts for 1–2% of all outpatient visits and 6% of all pediatric visits to primary care physicians.
- Most commonly viral (40–60%)
- GAS is the most common bacterial cause of acute pharyngitis, accounting for 15–30% of pediatric and 5–15% of adult cases.
- Rheumatic fever is rare in the United States (incidence <1 per 100,000). Early antibiotic intervention has significantly diminished disease rates.
- All age groups, but some etiologies may predilect specific age groups
- No gender predilection

Pediatric Considerations

Rheumatic fever has its greatest incidence in children aged 5 to 18 years, but is currently a rare sequela of streptococcal pharyngitis in modern medicine.

ETIOLOGY AND PATHOPHYSIOLOGY

- Acute, viral (lower grade fever)

  - Rhinovirus
  - Adenovirus (associated with conjunctivitis)
  - Parainfluenza virus
  - Coxsackievirus (hand-foot-mouth disease)
  - Coronavirus
  - Echovirus
  - Herpes simplex virus (vesicular lesions)
  - Epstein-Barr virus (EBV/mononucleosis)
  - Cytomegalovirus
  - HIV
- Acute, bacterial (higher fevers)
  - Group A β-hemolytic streptococci
  - *Neisseria gonorrhoeae*
  - *Corynebacterium diphtheriae* (diphtheria)
  - *Haemophilus influenzae*
  - *Moraxella catarrhalis*
  - *Chlamydia pneumonia*
  - *Fusobacterium necrophorum* (20% young adult cases)
  - Group C or G *streptococcus*
  - *Arcanobacterium haemolyticum*
  - *Francisella tularensis* (tularemia)
- Acute, noninfectious
  - Various caustic, mechanical, or trauma-related (incl. endotracheal intubation)
- Chronic
  - More likely noninfectious
  - Chemical irritation (GERD)
  - Smoking
  - Neoplasms
  - Vasculitis
  - Radiation changes

Genetics

Patients with a positive family history of rheumatic fever have a higher risk of rheumatic sequelae following an untreated group A β-hemolytic streptococcal

infection.

RISK FACTORS

- Epidemics of group A β-hemolytic streptococcal disease occurrence
- Cold and flu seasons
- Age (especially children/adolescents)
- Family history of rheumatic fever
- Close contact with infectious individuals (home, daycare, military barracks)
- Immunosuppression
- Fatigue
- Smoking/second-hand smoke exposure
- Acid reflux
- Oral sex
- Diabetes mellitus
- Recent illness (secondary postviral bacterial infection)
- Chronic colonization of bacteria in tonsils/adenoids

GENERAL PREVENTION

- Avoid close contact with infectious patients.
- Wash hands frequently.
- Avoid first- or second-hand smoke.
- Home humidifier at home
- Manage preventable causes (e.g., GERD).

DIAGNOSIS

HISTORY

- Sore throat
- Difficulty swallowing (odynophagia)
- Cough (though rarely associated with GAS pharyngitis)
- Hoarseness
- Fever
- Anorexia
- Chills
- Malaise

- Contacts with similar symptoms or diagnosed infection

PHYSICAL EXAM

- Enlarged tonsils (tonsillar exudate or possible peritonsillar abscess/deep neck space infection)
- Pharyngeal erythema
- Cervical adenopathy
- Fever (higher in bacterial infections)
- Pharyngeal ulcers (CMV, HIV, Crohn, other autoimmune vasculitides)
- Scarlet fever rash: punctate erythematous macules with reddened flexor creases and circumoral pallor suggests streptococcal pharyngitis
- Tonsillar/soft palate petechiae suggests infectious mononucleosis (EBV/CMV).
- Gray oral pseudomembrane suggests diphtheria and occasionally infectious mononucleosis (EBV/CMV).
- Characteristic erythematous-based clear vesicles suggests HSV.
- Conjunctivitis suggests adenovirus.

DIFFERENTIAL DIAGNOSIS

- Viral syndrome
- Streptococcal infection
- Allergic rhinitis/postnasal drip
- GERD
- Malignancy (lymphoma or squamous cell carcinoma)
- Irritants/chemicals (detergent/caustic ingestion)
- Atypical bacterial (e.g., gonococcal, chlamydial, syphilis, pertussis, diphtheria)
- Oral candidiasis (patients typically complain mostly of dysphagia)

DIAGNOSTIC TESTS & INTERPRETATION

- Acute pharyngitis evaluation includes Prediction Rule Use to determine further testing (see below)
- Additional testing generally not needed if viral-like clinical features (e.g., cough, rhinorrhea, hoarseness, oral ulcers, diarrhea, conjunctivitis, rash) (1) [A].

- Avoid testing for GAS pharyngitis in children <3 years old as acute rheumatic flare is rare, unless there is a close sick contact who is GAS-positive (1)[B].
- Modified Centor clinical prediction rule for group A streptococcal infection (2)[A]:
  - +1 point: tonsillar exudates
  - +1 point: tender anterior chain cervical adenopathy
  - +1 point: absence of cough
  - +1 point: fever by history
  - +1 point: age <15 years
  - 0 point: age 15 to 45 years
  - −1 point: age >45 years
- Scoring:
  - If 4 points, positive predictive value of ~80%; treat empirically.
  - If 2 to 3 points, positive predictive value of ~50%, rapid strep antigen; treat if GAS-positive.
  - If 0 or 1 point, positive predictive value <20%; do not test; treat empirically with follow-up as needed.

Initial Tests (lab, imaging)

- Testing, if performed, is usually for the presence of group A β-hemolytic streptococci. Options include the following:
  - Rapid strep antigen test from throat swab with agglutination or molecular kits; provides quicker, more practical alternative to throat culture with 96% specificity and 86% sensitivity (though sensitivity varies by modality kit) (3)[A].
  - Blood agar throat culture from swab. Gold standard of diagnosis (3)[A]
  - Antistreptolysin-O (carrier state suspected if positive culture, and unchanged ASO titers)
- Special tests usually done only if history is suggestive of a different diagnosis.
  - Warm Thayer-Martin plate or antigen testing for *Neisseria gonorrhoeae*
  - Viral cultures for HSV and so forth, though expensive and often not indicated.
  - Monospot for EBV

Test Interpretation

Bacitracin disk sensitivity of hemolytic colonies suggests group A β-hemolytic streptococcus.

TREATMENT

GENERAL MEASURES

Conservative therapy recommended for most cases, (unless bacterial etiology suspected):

- Salt water gargles
- Viscous lidocaine (2%) 5 to 10 mL PO q4h swish/spit
- Acetaminophen 10 to 15 mg/kg/dose q4h PRN pain or fever (pediatric). In adults, do not exceed >3 g per day.
- NSAIDs for pain or fever
- Anesthetic lozenges
- Cool-mist humidifier
- Hydration (PO or IV)

Pediatric Considerations

Opioids not recommended due to black box warnings.

MEDICATION

- Antibiotics (particularly penicillin) are chosen primarily to prevent rheumatic fever and peritonsillar abscess (quinsy) in streptococcal infections, though supportive data lacking.
  - 60–70% primary care visits by children with pharyngitis result in antibiotic prescriptions (4). Empiric therapy results in overuse of antibiotic.
  - Treatment duration generally 10 days (1)[A]
  - Antibiotics do not reduce risk of poststreptococcal glomerulonephritis.
  - Antibiotics shorten duration of symptoms by approximately. 16 hours (5)
  - Antibiotics may prevent pharyngitis/fever by day 3 (NNT 4 if GAS-positive, 6.5 if GAS-negative, 14.4 if untested) (5)[A].
- Ulcers related to autoimmune diseases usually require systemic or intralesional injectable steroids.
- HIV-related ulcers are due to decreasing counts of CD4 and respond when

patients' CD4 titers increase.

First Line

The following first-line therapies are recommended by 2012 IDSA guidelines (1) [A]:

- Penicillin V: children (<27 kg): 250 mg PO TID (BID dosing sufficient if good compliance); adolescents and adults (>27 kg): 250 mg PO QID or 500 mg PO BID
- Amoxicillin:50 mg/kg PO once daily (max 1,000 mg/dose or 25 mg/kg PO BID (max = 500 mg/dose).

ALERT

Use with caution if diagnosis is unclear because using amoxicillin with EBV infection may induce rash.

- Penicillin G: children (<27 kg): 600,000 Units IM injection times one dose; adolescents/adults (≥27 kg): 1.2 million units IM injection times one dose.

Second Line

- If no history of anaphylactic penicillin allergy:
  - Cephalexin 20 mg/kg PO BID or (children) 25 to 50 mg/kg/day divided BID or (adults) 1000 mg PO QID (max = 4 g/day)
  - Cefadroxil 30 mg/kg PO once daily (max = 1 g/day)
- If history of anaphylactic penicillin allergy:
  - Azithromycin 12 mg/kg PO once daily for 5 days (max = 500 mg/dose)
  - Clarithromycin 7.5 mg/kg PO BID (max = 250 mg/dose) or (adults) 250 to 500 mg PO BID
  - Clindamycin 7 mg/kg PO TID (max = 300 mg/dose) or (children) 10 to 30 mg/kg/day PO divided TID–QID or (adults) 150 to 450 mg PO TID–QID
- Penicillin is the most documented treatment to prevent rheumatic sequelae, but cephalosporins have a lower rate of antimicrobial failure against streptococcal pharyngitis.
- Newer macrolides, though effective against streptococcal pharyngitis, are more expensive and unproven at preventing rheumatic complications.
- Macrolide-resistant strains of GAS are currently <10% in the United States but more prevalent worldwide.

- IDSA recommends against adjunctive corticosteroid therapy (1)[B].

ISSUES FOR REFERRAL

Each GAS-confirmed episode should be documented to support the need for future tonsillectomy and adenoidectomy.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Patient should complete a full course of antibiotic therapy, regardless of symptom response.
- Patients are generally noninfectious after 24 hours of antibiotics.
- Follow-up culture for group A strep is not recommended (1)[A].

DIET

As tolerated. Encourage the consumption of fluids.

PROGNOSIS

- Streptococcal pharyngitis runs a 5- to 7-day course with peak fever at 2 to 3 days.
- Symptoms will resolve spontaneously without treatment, but rheumatic complications are still possible.

COMPLICATIONS

- Rheumatic fever (e.g., carditis, valve disease, arthritis)
- Poststreptococcal glomerulonephritis
- Peritonsillar abscess (a.k.a. quinsy tonsillitis): considered a clinical diagnosis and does not warrant ultrasound/computed tomography. Will generally require percutaneous/transoral drainage. Surgery may also involve a quinsy tonsillectomy, which is merely a tonsillectomy in the setting of acute infection. This is generally not advocated unless for special circumstances, as most otolaryngologists recommend infectious resolution before surgery.
- Acute airway compromise (rare) can typically be bypassed with nasal trumpets. Consult anesthesiologist/otolaryngologist.
- Repeated episodes of GAS pharyngitis may represent recurrent viral

infections in a chronic pharyngeal GAS carrier (1)[B]. IDSA recommends against repeated diagnostic efforts/antibiotic therapy in a known chronic pharyngeal GAS carrier, as they are seldom contagious or at risk for serious complications.

- Evidence remains controversial for tonsillectomy as a treatment for chronic/recurrent throat infections. IDSA recommends against it (1)[A] while the American Academy of Otolaryngology proposes tonsillectomy only if there is also one of the following: fever, cervical adenopathy, tonsillar exudate, or confirmed GAS (6)[C]

- Algorithm: Pharyngitis

CODES

ICD10

- J02.9 Acute pharyngitis, unspecified
- J02.0 Streptococcal pharyngitis
- J31.2 Chronic pharyngitis

CLINICAL PEARLS

- Most cases of pharyngitis are viral and do not require antibiotics.
- Risk of undiagnosed group A streptococcal infection is rheumatic sequelae—a rare complication.
- Use Modified Centor Score to guide testing and treatment.
- Penicillin is still first-line therapy for group A streptococcal infection.

PILONIDAL DISEASE

Tam T. Nguyen, MD

BASICS

DESCRIPTION

- Pilonidal disease results from an abscess, or sinus tract, in the upper part of the natal (gluteal) cleft.
- Synonym(s): jeep disease

EPIDEMIOLOGY

Incidence

- 16 to 26/100,000 per year
- Predominant sex: male > female (3 to 4:1)
- Predominant age: 2nd to 3rd decades, rare >45 years
- Ethnic consideration: whites > blacks > Asians

Prevalence

Surgical procedures show male:female ratio of 4:1, yet incidence data are 10:1.

ETIOLOGY AND PATHOPHYSIOLOGY

Pilonidal means “nest of hair”; hair in the natal cleft allows hair to be drawn into the deeper tissues via negative pressure caused by movement of the buttocks (50%); follicular occlusion from stretching, and blocking of pores with debris (50%).

- Inflammation of SC gluteal tissues with secondary infection and sinus tract formation
- Polymicrobial, likely from enteric pathogens given proximity to anorectal contamination

Genetics

- Congenital dimple in the natal cleft/spina bifida occulta
- Follicular-occluding tetrad: acne conglobata, dissecting cellulitis, hidradenitis suppurativa, pilonidal

RISK FACTORS

- Sedentary/prolonged sitting
- Excessive body hair
- Obesity/increased sacrococcygeal fold thickness
- Congenital natal dimple
- Trauma to coccyx

GENERAL PREVENTION

- Weight loss
- Trim hair in/around gluteal cleft weekly
- Hygiene
- Ingrown hair prevention/follicle unblocking

DIAGNOSIS

HISTORY

Three distinct clinical presentations

- Asymptomatic: painless cyst or sinus at the top of the gluteal cleft
- Acute abscess: severe pain, swelling, discharge from the top of the gluteal cleft that may or may not have drained spontaneously
- Chronic abscess: persistent drainage from a sinus tract at the top of the gluteal cleft

PHYSICAL EXAM

- Common: inflamed cystic mass at the top of the gluteal cleft with limited surrounding erythema ± drainage or a sinus tract
- Less common: significant cellulitis of the surrounding tissues near the gluteal cleft

DIFFERENTIAL DIAGNOSIS

- Furunculosis
- Hidradenitis suppurativa
- Anal fistula
- Perirectal abscess
- Crohn disease

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Consider CBC and wound culture but generally not necessary for less-severe infections.
- MRI might be considered to differentiate between perirectal abscess and pilonidal disease.

TREATMENT

GENERAL MEASURES

Shave area; remove hair from crypts weekly.

MEDICATION

- Antibiotics not indicated unless there is significant cellulitis (1).
- If antibiotics are needed, a culture to direct therapy might be useful.
- Cefazolin plus metronidazole or amoxicillin-clavulanate are often used empirically if cellulitis is suspected.

ISSUES FOR REFERRAL

- Patients who cannot comply with frequent dressing changes required after incision and drainage (I&D)
- Patients who have recurrence after I&D
- Patients who have complex disease with multiple sinus tracts

ADDITIONAL THERAPIES

- I&D with only enough packing to allow the cyst to drain; overpacking not indicated
- Antibiotics only if significant cellulitis; temporizing, not curative
- Negative pressure wound therapy (2)[A]
- Laser epilation of hair in the gluteal fold (3,4)[B]

SURGERY/OTHER PROCEDURES

Six levels of care based on severity or recurrence of disease; recent innovations in technique are aimed at expediting healing and minimizing recurrence

- I&D, remove hair, curette granulation tissue (5,6)[A].

- Excision of midline “pits” allows drainage of lateral sinus tracts (pit picking) (7,8)[A].
- Pilonidal cystotomy: Insert probe into sinus tract, excise overlying skin, and close wound (7,9)[B].
- Marsupialization: Excise overlying skin and roof of cyst, and suture skin edges to cyst floor (5,10)[B].
- Excision: use of flap closure. No clear benefit for open healing over surgical closure (11)[B]
- Off-midline surgical excision (cleft lift or modified Karydakis procedure): A systematic review showed a clear benefit in favor of off-midline rather than midline wound closure. When closure of pilonidal sinuses is the desired surgical option, off-midline closure should be the standard management (5,7,12)[A].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Severe cellulitis
- Large area excision

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Frequent dressing changes required after I&D
- Follow-up wound checks to assess for recurrence.

Patient Monitoring

Monitor for fever, more extensive cellulitis.

PATIENT EDUCATION

- Wash area briskly with washcloth daily.
- Shave the area weekly.
- Remove any embedded hair from the crypt.
- Avoid prolonged sitting.

PROGNOSIS

- Simple I&D has a 55% failure rate; median time to healing is 5 weeks.
- More extensive surgical excisions involve hospital stays and longer time to heal.

COMPLICATIONS

Malignant degeneration is a rare complication of untreated chronic pilonidal disease.

CODES

ICD10

- L05.91 Pilonidal cyst without abscess
- L05.92 Pilonidal sinus without abscess
- L05.01 Pilonidal cyst with abscess

CLINICAL PEARLS

- Avoid prolonged sitting.

- Lose weight.
- Trim hair in gluteal cleft weekly.
- Refer recurring infections for more definitive surgical management.

PINWORMS

Jonathan MacClements, MD, FAAFP

BASICS

DESCRIPTION

- Intestinal infection with *Enterobius vermicularis*
  - Characterized by perineal and perianal itching
  - Usually worse at night
- System(s) affected: gastrointestinal; skin/exocrine
- Synonym(s): enterobiasis

EPIDEMIOLOGY

Predominant age: 5 to 14 years

Prevalence

- Most common helminthic infection in the United States
  - 20 to 42 million people harbor the parasite
- ~30% of children are infected worldwide.

Pediatric Considerations

More common in children, who are more likely to become reinfected.

ETIOLOGY AND PATHOPHYSIOLOGY

- Small white worms (2 to 13 mm) inhabit the cecum, appendix, and adjacent portions of the ascending colon following ingestion.
- Female worms migrate to the perineal areas at night to deposit eggs; this causes local irritation and itching.
- Scratching leads to autoingestion of the eggs and continuation of pinworm's life cycle within the host. Eggs incubate 1 to 2 months in the host small intestine. When mature, female pinworms migrate to the colon where they lay eggs around the anus at night and the lifecycle continues.
- Infestation by the intestinal nematode *E. vermicularis*

RISK FACTORS

- Institutionalization
- Crowded living conditions
- Poor hygiene
- Warm climate
- Handling of infected children’s clothing or bedding

GENERAL PREVENTION

- Hand hygiene, especially after bowel movements
- Clip and maintain short fingernails.
- Wash anus and genitals at least once a day, preferably during shower.
- Avoid scratching anus and putting fingers near nose (pinworm eggs can also be inhaled) or mouth.

COMMONLY ASSOCIATED CONDITIONS

Pruritus ani

DIAGNOSIS

HISTORY

Many patients are asymptomatic. Common symptoms include the following:

- Perianal or perineal itching
- Vulvovaginitis
- Dysuria
- Abdominal pain (rare)
- Insomnia (typically due to pruritus)

PHYSICAL EXAM

Perineal and perianal exam. Particularly in early morning to look for evidence of migrating worms.

DIFFERENTIAL DIAGNOSIS

- Idiopathic pruritus ani (1)[A]
- Atopic dermatitis, contact dermatitis
- Psoriasis; lichen planus
- Human papillomavirus (HPV)
- Herpes simplex virus (HSV)

- Fungal infections; erythrasma
- Scabies
- Vaginitis; hemorrhoids

DIAGNOSTIC TESTS & INTERPRETATION

- Adhesive tape test (2)[A]
  - Place cellophane tape on the perianal skin in the early morning before bathing and affixed to a microscope slide to look for pinworm eggs.
  - If performed on three consecutive mornings, this test has 90% sensitivity
  - Alternatively, anal swabs or a pinworm paddle coated with adhesive material can be useful.
  - Scrapings from under fingernails of affected individuals can reveal pinworm eggs.
- Digital rectal exam with saline slide preparation of stool on gloved finger
- Stool samples are not helpful.
- *Routine stool examination for ova and parasites is positive in only 10–15% of infected patients.*

Test Interpretation

Identification of ova on low-power microscopy or direct visualization of the female worm (10-mm long); ova are asymmetric, flat on one side, and measure 56 × 27 μm.

TREATMENT

MEDICATION

First Line

- Treatment options include:
  - Mebendazole (Vermox): chewable 100-mg tablet as a single dose in adults and children >2 years of age; may repeat in 2 to 3 weeks; use with caution in children <2 years of age (3,4)[A].
  - Albendazole (Albenza): 400 mg PO as a single dose in adults and children >2 years of age; may repeat in 2 to 3 weeks; 200 mg PO as a single dose repeated in 7 days in children ≤2 years of age (3,4)[A].

  - Pyrantel pamoate (Pin-X, Reese's Pinworm Medicine): oral liquid or tablet 11 mg/kg as a single dose in adults and children >2 years of age; maximum dose 1 g. Use with caution in children <2 years of age (3,4)[A].
- Repeat treatment after 2 weeks is often recommended due to the high frequency of reinfection. Refractory cases may (rarely) require retreatment every 2 weeks for 4 to 6 cycles.
- All symptomatic family members should be treated.

Pregnancy Considerations

Avoid drug therapy in pregnancy. Treat after delivery. Breastfeeding is OK during mebendazole therapy. (3,4)[A].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Unnecessary unless symptoms recur after initial therapy

PATIENT EDUCATION

- Take medicine with food.
- Practice good hygiene: hand washing and perianal hygiene; particularly after bowel movements
- Encourage frequent and careful hand washing.
- Clip fingernails.
- Wash clothing and bedding after diagnosis to prevent reinfection. Do not shake linen and clothing before laundering because this may spread the eggs.
- Do not share washcloths.
- Do not allow children to cobathe during treatment and for 2 weeks after; showering is preferred.

PROGNOSIS

- Asymptomatic carriers are common.
- Drug therapy is 90% curative.
- Reinfection is common, especially among children.

COMPLICATIONS

- Perianal scratching may lead to bacterial superinfection.
- Females: vulvovaginitis, urethritis, endometritis, and salpingitis (4,5)[A]
- UTIs
- Rarely, ectopic disease with granulomas of the pelvis, genitourinary tract, and appendix

SEE ALSO

Pruritus Ani

CODES

ICD10

B80 Enterobiasis

CLINICAL PEARLS

- Nocturnal or early morning perianal itch with restless sleep or insomnia (particularly in children), is hallmark of symptomatic pinworm infection.
- Treatment includes of mebendazole, albendazole, or pyrantel pamoate.
- Treat close contacts.
- Retreatment after 2 weeks is typically recommended.

PITUITARY ADENOMA

Anup K. Sabharwal, MD, MBA, FACE, CCD • Lewis S. Blevins, Jr., MD

BASICS

DESCRIPTION

Typically benign, slow-growing tumors that arise from cells in the pituitary gland

- Pituitary adenomas have been identified as the third most frequent intracranial tumor; accounts for 10–25%.
- Subtypes (hormonal): prolactinoma (PRL) 50%, nonfunctioning pituitary adenomas 30%, somatotroph adenoma (growth hormone [GH]) 15–20%, corticotroph adenoma (adrenocorticotrophic hormone [ACTH]) 5–10%, thyrotroph adenoma (thyroid-stimulating hormone [TSH]) <1%, gonadotropinoma (luteinizing hormone/follicle-stimulating hormone [LH/FSH]), mixed
- Defined as microadenoma <10 mm and macroadenoma ≥10 mm
- May secrete hormones and/or cause mass effects

EPIDEMIOLOGY

- Predominant age: Age increases incidence.
- Predominant sex: female > male (3:2) for microadenomas (often delayed diagnosis in men)

Incidence

- Autopsy studies have found microadenomas in 3–27% and macroadenomas in <0.5% of people without any pituitary disorders.
- MRI scans illustrate abnormalities consistent with pituitary adenoma in 1/10 persons.
- Clinically apparent pituitary tumors are seen in 18/100,000 persons.

ETIOLOGY AND PATHOPHYSIOLOGY

- Monoclonal adenohypophysial cell growth

- Hormonal effects of functional microadenomas often prompt diagnosis before mass effect.
- Prolactin increased by functional prolactinomas or inhibited dopaminergic suppression by stalk effect

Genetics

- Carney complex
- Familial isolated pituitary adenomas: ~15% have mutations in the aryl hydrocarbon receptor–interacting protein gene (*AIP*); present at a younger age and are larger in size (1)
- McCune-Albright syndrome
- Multiple endocrine neoplasia type 1 (MEN1)–like phenotype (MEN4): germline mutation in the cyclin-dependent kinase inhibitor 1B (CDKN1B) (1)

RISK FACTORS

Multiple endocrine neoplasias

DIAGNOSIS

HISTORY

- Common
  - Hyperprolactinemia: infertility, amenorrhea, galactorrhea, gynecomastia, impotence
  - Headache (sellar expansion)
  - Visual disturbances: bitemporal hemianopsia
- Less common
  - Hypersomatotropinemia: acromegaly (coarse facial features, hand/foot swelling, carpal tunnel syndrome, hyperhidrosis, left ventricular hypertrophy)
  - Hyposomatotropinemia: failure to thrive (FTT) (children), asymptomatic (adults)
  - Intracranial pressure (ICP) elevation: headache, nausea, seizures
  - Hypercorticotropinemia: Cushing disease (supraclavicular/dorsocervical fat pad thickening, moon face, hirsutism, acne, plethora, abdominal striae, centripetal obesity with thin limbs, easy bruising and bleeding,

hyperglycemia)
- Rare
  - Apoplexy: headache, sudden collapse
  - Secondary hyperthyroidism: palpitations, diaphoresis, heat intolerance, diarrhea
  - Secondary adrenal insufficiency: weakness, irritability, anorexia, nausea/vomiting
- Hypothalamic compression: temperature, thirst/appetite disorders

PHYSICAL EXAM

- Common
  - Visual disturbances: bitemporal hemianopsia
  - Hyperprolactinemia: hypogonadism, galactorrhea, gynecomastia
  - Hypersomatotropinemia: acromegaly (coarse features, hand/foot swelling, diaphoresis)
  - Hyposomatotropinemia: FTT (children)
- Less common
  - ICP elevation: papilledema, dementia
  - Cushing disease: centripetal obesity, supraclavicular fat pad thickening, moon face, hirsutism, acne
- Rare
  - Apoplexy: hypotension, hypoglycemia, tachycardia, oliguria
  - Secondary hyperthyroidism: tachycardia, tachypnea, diaphoresis, warm/moist skin, tremor
  - Adrenal crisis: orthostatic hypotension
- Hypothalamic compression: temperature dysregulation, obesity, increased urination

DIFFERENTIAL DIAGNOSIS

Pituitary hyperplasia (e.g., pregnancy, primary hypothyroidism, menopause), Rathke cleft cyst, granulomatous disease (e.g., tuberculosis), lymphocytic hypophysitis, metastatic tumor, germinoma, craniopharyngioma

DIAGNOSTIC TESTS & INTERPRETATION

Select based on dysfunction(s) suspected

- Somatotrophic (GH secreting: 40 to 130/million)
  - Acromegaly/hypersomatotropinemia: serum IGF-1 elevated; oral glucose tolerance test with GH given at 0, 30, and 60 minutes (normally suppresses GH to <1 g/L)
  - Hyposomatotropinemia: low growth hormone–releasing hormone response
- Corticotropic
  - Cushing disease/hypercorticotropinemia
  - 24-hour urinary-free cortisol >50 μg
  - Overnight low-dose dexamethasone suppression test (DMST): normal free plasma cortisol (FPC) >1.8 μg/dL at 8 AM (after 1 mg given at 11 PM on night prior)
  - ACTH level assay (if DMST results abnormal): <20 pg/mL = adrenal tumor; ≥20 pg/mL = ectopic/pituitary source
  - Hypocorticotropinemia/secondary glucocorticoid deficiency: high-dose corticotropin stimulation test: FPC <10 g/dL at baseline, with an increase of <25% 1 hour after 250 μg; metyrapone test: 11-deoxycortisol <150 ng/L after 2 g given (prepare to give steroids because test may worsen insufficiency)
- Gonadotrophic/hypogonadotropinism: gonadotropin-releasing hormone stimulation of LH/FSH blunted in pituitary hypergonadism but increased in primary hypogonadism
- Lactotrophic (prolactin secreting): hyperprolactinemia: serum PRL >20 ng/mL
- Thyrotrophic (TSH secreting): hyper-/hypothyroidism: TSH and free T_4 both increased for pituitary hyperthyroidism and both decreased for pituitary hypothyroidism

Initial Tests (lab, imaging)

- A typical panel for asymptomatic tumors: prolactin, GH, IGF-1, ACTH, 24-hour urinary-free cortisol or overnight DMST, β-HCG, FSH, LH, TSH, free T_4
- Maintain the same GH and IGF-1 through patient management (2)[C].
- Screening for *AIP* mutations may be offered to families of patients with pituitary adenoma, where available.
- MRI preferred (>90% sensitivity and specificity) after biochemically

confirmed

- Octreotide scintigraphy is useful in identifying tumors with somatostatin receptors (2)[B].

Diagnostic Procedures/Other

Inferior petrosal sinus sampling: ACTH sampled from inferior petrosal sinuses to distinguish Cushing disease (pituitary source) from ectopic ACTH

Test Interpretation

- Cell types identified by immunohistochemistry
- Light microscope: eosinophilic (GH, PRL), basophilic (FSH/LH, TSH, ACTH), chromophobic

TREATMENT

Medical therapy is primary therapy for prolactinomas and adjunct for other tumors.

MEDICATION

First Line

- Hyperprolactinemia: Dopamine agonists increase dopaminergic suppression of PRL.
  - Cabergoline (Dostinex): D_2 receptor–specific
    - Initial dose: 0.25 mg PO once or twice weekly
    - Maintenance dose: Increase q4wk by 0.25 mg 2 times/week per PRL (max 2 mg/week).
    - Contraindications: hypersensitivity (ergots), uncontrolled hypertension (HTN), pregnancy
    - Precautions: caution with liver impairment
    - Interactions: may be inhibited by tricyclic antidepressants, phenothiazines, opiates
    - Adverse reactions: orthostatic hypotension, vertigo, dyspepsia, hot flashes
  - Bromocriptine (Parlodel): D_2 receptor–specific
    - Initial dose: 1.25 to 2.5 mg PO daily (give with food)
    - Maintenance dose: increase by 2.5 mg/day q2–7d (max 15 mg/day)

- Contraindications: hypersensitivity (ergots), uncontrolled HTN, pregnancy; preferred over cabergoline if required
- Precautions: caution with liver impairment.
- Interactions: may be inhibited by tricyclic antidepressants, phenothiazines, opiates
- Adverse reactions: orthostatic hypotension, seizures, hallucinations, stroke, myocardial infarction

- Somatotropinoma
  - Long-acting analogues of somatostatin (Sandostatin LAR and lanreotide Autogel)
    - Sandostatin LAR: 20 mg q28d (2)[A]; lanreotide Autogel 90 mg q28d; titrate per package insert.
    - Contraindication: hypersensitivity
    - Precautions: caution with biliary, thyroid, cardiac, liver, or kidney disease
    - Interactions: pimozide increases risk of QT prolongation; variable effects with β-blockers, diuretics, oral glycemic agents
    - Adverse reactions: ascending cholangitis, arrhythmias, congestive heart failure, glycemic instability
    - More effective as adjuvant than as primary treatment for somatotropinomas
    - Consider use of somatostatin analogue or pegvisomant in patients with severe residual disease (2)[A].
    - Consider use of cabergoline in patients with mild residual disease (3)[B].
  - Pegvisomant (Somavert): GH receptor antagonist
    - Initial dose: 40 mg SC × 1, then 10 mg daily and titrate by 5 mg every 4 to 6 weeks based on IGF-1 levels (max 30 mg/day maintenance dose)
    - Contraindication: hypersensitivity
    - Precautions: caution if GH-secreting tumors, diabetes mellitus, impaired liver function
    - Interactions: NSAIDs, opiates, insulins, oral glycemic agents
    - Adverse reactions: hepatitis, tumor growth, GH secretion
- Corticotropinemia: peripheral inhibitors
  - Mitotane (Lysodren)
    - Initial dose: 2 to 6 g/day divided PO TID (max 19 g/day)

    - Maintenance dose: 2 to 16 g TID
    - Contraindication: hypersensitivity
    - Precautions: caution with liver dysfunction and brain damage
    - Interactions: contraindicated with rotavirus vaccine; caution with other vaccines
    - Adverse reactions: HTN, orthostatic hypotension, hemorrhagic cystitis, rash
- Ketoconazole
    - Dosing: 200 mg PO TID (max 1,200 mg/day)
    - Contraindications: hypersensitivity, achlorhydria, fungal meningitis, impaired liver function
    - Precautions: caution with liver dysfunction
    - Interactions: contraindicated with dronedarone, methadone, statins, pimozide, sirolimus; caution with other antifungals
    - Adverse reactions: adrenal insufficiency, thrombocytopenia, hepatic failure, hepatotoxicity, anaphylaxis, leukopenia, hemolytic anemia
- Signifor (pasireotide)
    - Dosing: initially, 0.6 to 0.9 mg twice daily, then 0.3 to 0.9 mg twice daily
    - Contraindication: none
    - Precautions: hypocortisolism, hyperglycemia, bradycardia or QT prolongation, liver test elevations, cholelithiasis, and other pituitary hormone deficiencies
- Korlym (mifepristone):
    - Dosing: Administer PO once daily with a meal. The recommended starting dose is 300 mg once daily. Not to exceed 600 mg daily in renal impairment
- Contraindication: pregnancy, use of simvastatin or lovastatin and CYP3A substrates with narrow therapeutic range, concurrent long-term corticosteroid use, women with history of unexplained vaginal bleeding, women with endometrial hyperplasia with atypia or endometrial carcinoma
- Precautions: adrenal insufficiency, hypokalemia, vaginal bleeding and endometrial changes, QT interval prolongation, use of strong CYP3A inhibitors
- Interactions: potential interactions with drugs metabolized by CYP3A,

CYP2C8/9, CYP2B6, and hormonal contraceptives. Nursing mothers should discontinue drug or discontinue nursing.
  - Adverse reactions: most common adverse reactions in Cushing syndrome (≥20%): nausea, fatigue, headache, decreased blood potassium, arthralgia, vomiting, peripheral edema, HTN, dizziness, decreased appetite, endometrial hypertrophy
- Gonadotropinemia
  - Bromocriptine: See earlier discussion.
- Thyrotropinemia
  - Somatostatin analogues: See earlier discussion.

Second Line

- Corticotropinemia: peripheral inhibitors
  - Metyrapone
    - Dose: 250 mg PO QID
    - Contraindication: porphyria
    - Precautions: caution in liver/thyroid disease
    - Interactions: Dilantin increases metabolism.
    - Adverse reactions: nausea, hypotension
- Gonadotropinemia
  - Octreotide: See earlier discussion.

ISSUES FOR REFERRAL

- Neurosurgery consultation for symptomatic tumors (except for prolactinoma)
- Ophthalmologist evaluation prior to surgery

ADDITIONAL THERAPIES

- Fractionated radiotherapy: often effective as adjunctive when surgery is inadequate (3)[B]
- Stereotactic radiosurgery: alternative to surgery in high-risk patients or as adjunct (3)[B]

SURGERY/OTHER PROCEDURES

- Most are now done endoscopically via translabial/transsphenoidal approach (4)[A].
- Indications: symptoms or treatment-resistant

- Follow-up: serial neurologic/hormonal evaluations to evaluate complications (e.g., diabetes insipidus, CNS damage) and need for more treatment
- Remission rates: 72–87% for microadenoma but only 50–56% for macroadenomas

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Outpatient management unless apoplexy or adrenal crisis
- Treat pituitary apoplexy immediately to prevent death (see "Complications") (4)[A].
- Consider stress-dose steroids in frail or hemodynamically unstable patients.
- Maintain BP with fluids and/or pressor agents.
- Check serum sodium, serum osmolality, and urine specific gravity if polyuric or electrolytes are imbalanced.
- Contact neurosurgery.
- Diabetes insipidus: hyposmolar IV fluids
- Adrenal crisis: normal saline
- Pituitary apoplexy: Monitor inputs/outputs (I/Os), central venous pressure and ICP, and do frequent neurologic checks.
- Adrenal crisis: Monitor BP and I/Os.
- Keep as inpatient postoperatively until diabetes insipidus and/or adrenal insufficiency is managed.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Follow-up MRIs at 6 and 12 months after discharge
- Involved hormone(s) are followed postoperatively, especially after radiation because hypopituitarism may develop 10 to 15 years after treatment.

PROGNOSIS

Depends on type, size, symptoms, therapy

COMPLICATIONS

- Postoperative diabetes insipidus and/or hypogonadism (usually transient/common)
- Pituitary apoplexy (acute/uncommon): acute hemorrhagic pituitary infarction; adrenal crisis with severe headache; surgical decompression required to prevent shock, coma, and death
- Nelson syndrome (subacute/uncommon): rapid adenoma growth postadrenalectomy
- Pituitary hormone insufficiency (chronic/uncommon): often years after treatment
- Optic nerve neuropathy and brain necrosis after >60 Gy radiotherapy (chronic/rare)

CODES

ICD10

D35.2 Benign neoplasm of pituitary gland

CLINICAL PEARLS

- An incidentaloma is an asymptomatic microadenoma found on imaging. General labs include PRL, GH, IGF-1, ACTH, 24-hour urinary-free cortisol/overnight DMST, β-subunit FSH, LH, TSH, and free T_4. Obtain follow-up MRIs at 6 and 12 months if normal, but consult endocrinology if not.
- Initial treatment selected for symptomatic pituitary adenoma includes a dopamine agonist for prolactinomas and surgical resection for all others.
- Pituitary apoplexy is a rapid hemorrhagic pituitary infarction due to compression of the blood supply. It is fatal within hours unless surgically decompressed.

PLANTAR FASCIITIS

Noor Alzarka, MD, MPH • Randolph Taylor, II, MD

BASICS

DESCRIPTION

- Degenerative change of plantar fascia at origin on medial tuberosity of calcaneus
- Pain on plantar surface, usually at calcaneal insertion of plantar fascia upon weight bearing, especially in morning or on initiation of walking after prolonged rest

EPIDEMIOLOGY

Prevalence

- Most common cause of plantar heel pain
- Lifetime: 10–15% of population
- Peak incidence between ages 40 and 60 years
- Data suggest persistence with BMI >30.
- Condition is typically self-limiting, resolving within 12 months.

ETIOLOGY AND PATHOPHYSIOLOGY

- Repetitive microtrauma and collagen degeneration of plantar fascia
- Chronic degenerative change (-osis/-opathy rather than -itis) of plantar fascia generally at insertion on medial tuberosity of calcaneus

RISK FACTORS

- Obesity (BMI >30)
- Dancers, runners, court sport athletes
- Pes planus (flat feet), pes cavus (high arch), overpronation, leg length discrepancy
- Occupations with prolonged standing, especially on hard surfaces (nurses, letter carriers, warehouse/factory workers)
- Female, pregnancy
- Age (>40 to 60 years)

- Hamstring, calf tightness
- Decreased ankle range of motion with dorsiflexion (equinus or tight heel cord; <15 degrees of dorsiflexion)
- Systemic connective tissue disorders

GENERAL PREVENTION

- Maintain normal body weight.
- Avoid prolonged standing on bare feet, sandals, or slippers.
- Avoid training errors (increasing intensity, distance, duration, and frequency of high-impact activities too rapidly); avoid overtraining.
- Proper footwear (appropriate cushion/arch support)
- Runners should replace footwear every 250 to 500 miles.

COMMONLY ASSOCIATED CONDITIONS

- Usually isolated
- Heel spurs common but not a marker of severity
- Posterior tibial neuropathy

DIAGNOSIS

HISTORY

- Pain on plantar surface of foot, usually at fascial insertion at calcaneus (medial calcaneal tubercle), but can have pain anywhere along length of plantar fascia
- Pain is typically worse with first few steps in the morning or after prolonged rest (poststatic dyskinesia).
- Pain typically improves after first few steps only to recur toward the end of the day.
- Pain commonly unilateral but can be bilateral
- Pain can be dull and constant in chronic cases.
- Pain with prolonged ambulation or standing
- Limp with excessive toe walking
- Numbness and burning of medial hindfoot when associated with posterior tibial nerve compression

PHYSICAL EXAM

- Point tenderness on medial tuberosity of calcaneus at insertion of plantar fascia
- Pain along plantar fascia with dorsiflexion of foot
- Windlass test: Extend MTP while allowing passive flexion of IP joint of hallux—pain indicates a positive test; high specificity, low sensitivity; sensitivity improves (13.5→31.8%) if performed while standing.
- Dorsiflexion-eversion test: pain with dorsiflexion plus eversion of the subtalar joint
- Decreased passive range of motion with dorsiflexion
- Evaluate for pes planus, pes cavus, and overpronation.
- Loss of heel fat pad suggests heel fat pad syndrome.
- Point tenderness on posterosuperior aspect of heel suggests Achilles tendinopathy.

DIFFERENTIAL DIAGNOSIS

- Calcaneal stress fracture
- Heel fat pad syndrome (painful or atrophic heel pad)
- Longitudinal arch strain
- Nerve entrapment (posterior tibial nerve—tarsal tunnel syndrome, medial calcaneal branch of posterior tibial nerve, abductor digiti quinti)
- Achilles tendinopathy
- Calcaneal contusion
- Plantar calcaneal bursitis
- Tendonitis of posterior tibialis
- Plantar fascia tear
- Adolescents: calcaneal apophysitis (Sever disease)

DIAGNOSTIC TESTS & INTERPRETATION

- None necessary; typically a clinical diagnosis
- Consider further imaging only to rule out other causes or if diagnosis is in question.
- Two radiographic views of foot can rule out fracture, tumor, cyst, periostitis, bony erosions; weight-bearing films preferred
- Ultrasound: hypoechoic at insertion, thickened plantar fascia (≥4 mm);

diagnostic and even therapeutic when used as an adjunct to treatment; can improve delivery accuracy of injections and ESWT; can objectively evaluate change in plantar fascia thickness to monitor effects of an intervention
- MRI can evaluate for other soft tissue etiologies.
- CT or technetium-99 bone scan can rule out calcaneal stress fracture and evaluate for infection.
- Nerve conduction studies can rule out nerve entrapment.

TREATMENT

Nonoperative management is mainstay of treatment.

GENERAL MEASURES

- Supportive footwear with stable midfoot; avoid sandals or walking barefoot.
- Relative rest/activity modification
- Stretching: plantar fascia stretches more effective than Achilles tendon/gastrocnemius-soleus stretches, and non–weight-bearing stretches may be preferable.
- Weight reduction if BMI >25
- Orthotics
  - Custom orthotics show no benefit over prefabricated orthotics and are more costly.
  - Improved effectiveness of night splints when used in association with orthotics
- Night splints: can be uncomfortable for the first few nights but generally become less bothersome with time; especially effective with calf and Achilles tightness; should be considered an adjunct therapy
- Strengthen calf and interosseous muscles, using the towel drag/pick-up exercise
- Ice (frozen water bottle roll)
- Massage (golf or tennis ball roll)

MEDICATION

First Line

Adjunct to control pain

- NSAIDs: naproxen 500 mg PO BID *or* ibuprofen 600 to 800 mg PO TID PRN for pain
- Acetaminophen 1,000 mg PO TID PRN for pain

Second Line

None

ISSUES FOR REFERRAL

- Podiatry, surgery: Consider referral if conservative measures fail after 3 to 6 months.
- Consider physical therapy for patient instruction on proper stretching and strengthening techniques.

ADDITIONAL THERAPIES

- Corticosteroid injections (1)[A]
  - Short-term pain relief for up to 1 month; benefit fades with time.
  - Recommend ultrasound guidance when possible.
  - Risk for plantar fascia rupture and calcaneal fat pad atrophy with resultant permanent heel pain
  - Can cause injection and postinjection pain for up to 5 to 7 days
- Extracorporeal shock wave therapy (ESWT) (2,3)[B]
  - Growing body of evidence showing benefit
  - Uncomfortable to patients but less risk than injection or surgery
  - Consider prior to surgery and (possibly) prior to steroid injection.
  - Delivery not yet standardized
- Low-dye and calcaneal taping
  - Limited, short-term evidence
  - Less effective in severe cases
- Promising therapies with inconsistent evidence
  - Platelet-rich plasma injections (4)[B]: A systematic review demonstrated PRP improved baseline symptoms and was comparable to prolotherapy and better than corticosteroid injections in the short and long term (up to 12 months).
  - Prolotherapy (4)[B]: comparable in efficacy to PRP for treatment of baseline symptoms, better than corticosteroid injections

- Low-level laser therapy
- Botulinum toxin (BT) A injection (5)[B]
  - Randomized, double-blind, placebo-controlled trials showed improvement in pain with BT injection compared to placebo.
  - RCT comparing steroid injection to BT injection showed similar results in pain reduction and other measures of foot function at 1 month; improvements persisted at 6 months—more so with BT than with steroid injection
- Radiofrequency nerve ablation (6)[B]: prospective, RCT with sham demonstrated efficacy; retrospective case series demonstrated benefit 1 to 2 years after treatment.
- Myofascial trigger point therapy can provide short-term relief, as an adjunct to stretching.
- Intralesional autologous blood injection
- Plantar iontophoresis appears more effective with 5% acetic acid solution than with a corticosteroid.
- Daytime immobilization with a short leg boot for severe refractory cases is controversial.

SURGERY/OTHER PROCEDURES

- Necessary in <10% of patients
- Recommended if conservative treatment fails after 6 to 12 months and pain is unrelenting
- Open/endoscopic plantar fasciotomy (less risk and complications with endoscopic technique but requires specialized equipment and skills; is not widely used)
- Cryosurgery
- Calcaneal spur resection
- More likely beneficial in severely obese
- No RCTs support surgery as a primary treatment.

COMPLEMENTARY & ALTERNATIVE THERAPIES

- Heel cup with magnet has proven ineffective.
- Acupuncture shows limited benefit in a few studies.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Ensure patient adherence to proper stretching technique.
- Following 3 to 6 months of unsuccessful conservative treatment, consider additional therapies or referrals.

PATIENT EDUCATION

- Weight reduction if BMI >25
- Proper footwear (adequate cushion and arch support)
- Stretch plantar fascia: Pull toes into dorsiflexion prior to walking after prolonged sitting or sleep.
- Ice the foot using a frozen water bottle: Roll foot over bottle for 10 minutes in the morning and after work.
- Massage plantar fascia: Roll foot over a golf ball.
- Strengthen foot muscles: Grab cloth or carpet by plantar flexing the toes.
- Decrease repetitive stress.

PROGNOSIS

- Generally good
- Self-limited (resolves within 2 years) in up to 85–90% of patients

COMPLICATIONS

- Rupture of plantar fascia (more common with repeated corticosteroid injections)
- Chronic pain
- Gait abnormality

SEE ALSO

Algorithm: Heel Pain

CODES

ICD10

M72.2 Plantar fascial fibromatosis

CLINICAL PEARLS

- Plantar fasciitis occurs due to degeneration of plantar fascia at origin (medial calcaneal tuberosity) with characteristic pattern of pain.
- Pain with weight bearing (especially first few steps in the morning or after prolonged rest) is hallmark presentation.
- Conservative treatment is preferred. Supportive footwear helps avoid excess pronation and provides adequate cushion. Modify activity, stretch plantar fascia, ice (water bottle roll), massage (golf ball roll), and provide arch support.
- Weight loss helps control symptoms, particularly for BMI ≥25.

PLEURAL EFFUSION

Felix B. Chang, MD, DABMA, FAAMA

BASICS

Abnormal accumulation of fluid in the pleural space

DESCRIPTION

Types: transudate, exudate

- Congestive heart failure: 40%: transudate
- Pneumonia 25%, malignancy 15%, and pulmonary embolism (PE) 10% account for exudative effusions
- Malignant: lung cancer and metastases of breast, ovary, and lymphoma

EPIDEMIOLOGY

Incidence

Estimated 1.5 million cases/year in the United States; CHF: 500,000; pneumonia: 300,000; malignancy: 150,000; PE: 150,000; cirrhosis: 150,000; TB: 2,500; pancreatitis: 20,000; collagen vascular disease: 6,000

Prevalence

- Estimated 320 cases/100,000 people in industrialized countries; in hospitalized patients with AIDS, prevalence is 7–27%.
- No gender predilection: ~2/3 of malignant pleural effusions occur in women.

ETIOLOGY AND PATHOPHYSIOLOGY

- Pleural fluid formation exceeds pleural fluid absorption.
- Transudates result from imbalances in hydrostatic and oncotic forces.
  - Increase in hydrostatic and/or low oncotic pressures; increase in pleural capillary permeability; lymphatic obstruction or impaired drainage; movement of fluid from the peritoneal or retroperitoneal space
- Transudates
  - CHF: 40% of transudative effusions; 80% bilateral. Constrictive pericarditis, atelectasis; superior vena cava syndrome
  - Cirrhosis (hepatic hydrothorax); nephrotic syndrome, hypoalbuminemia;

myxedema
  - Urinothorax, central line misplacement; peritoneal dialysis
  - Dressler syndrome (postmyocardial infarction syndrome
  - Yellow nail syndrome: yellow nails, lymphedema and pleural effusion
- Exudates
  - Lung parenchyma infection, bacterial (parapneumonic, tuberculous pleurisy), fungal, viral, parasitic (amebiasis, *Echinococcus*)
  - Cancer: lung cancer, metastases (breast, lymphoma, ovaries), mesothelioma
  - PE: 25% of PEs are transudate.
  - Collagen vascular disease: rheumatoid arthritis, systemic lupus erythematosus (LE), Wegener granulomatosis, sarcoidosis, Churg-Strauss
  - GI: pancreatitis, esophageal rupture, abdominal abscess, after liver transplant. Chylothorax: thoracic duct tear, malignancy
  - Hemothorax: trauma, PE, malignancy, coagulopathy, aortic aneurysm
  - Others: after coronary artery bypass graft; uremia, asbestos exposure, radiation; drug-induced: nitrofurantoin, bromocriptine, amiodarone, procarbazine, hydralazine, procainamide, quinidine, methotrexate, methysergide, interleukin 2, mitomycin, practolol, minoxidil, bleomycin, cyclophosphamide, dantrolene, valproic acid
  - Meigs syndrome; yellow nail syndrome; ovarian stimulation syndrome; lymphangiomatosis; acute respiratory distress syndrome (ARDS)
  - Chylothorax: thoracic duct tear, malignancy, associated with lymphoma

RISK FACTORS

- Occupational exposures/drugs
- PE, TB, bacterial pneumonias
- Opportunistic infections (in HIV patients when CD4 count is <150 cells/μL)

COMMONLY ASSOCIATED CONDITIONS

Hypoproteinemia, heart failure, cirrhosis

DIAGNOSIS

Presumptive diagnosis in 50% of cases. Small pleural effusions, radiographic area <2 intercostal spaces (<300 mL) are asymptomatic.

HISTORY

Dyspnea, fever, malaise, and weight loss; chest pain, cough, hemoptysis, and dull pain

PHYSICAL EXAM

- Pleural effusion >300 mL: tachypnea, asymmetric expansion of the thoracic cage; decrease/absent tactile fremitus; dullness to percussion; decreased/inaudible breath sounds, egophony, pleural friction rub
- Ascites suggest the following: hepatic hydrothorax, ovarian cancer, and Meigs syndrome.
- If associated with unilateral swelling in lower extremity, consider DVT with PE.

DIFFERENTIAL DIAGNOSIS

Empyema, malignancy, inflammatory, fungal, tuberculosis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Pleural fluid: appearance, pH, WBC differential, total protein, lactate dehydrogenase (LDH), glucose, Gram stain and culture, and acid-fast bacilli staining. Consider polymerase chain reaction (PCR) for *Mycobacterium tuberculosis* and *Streptococcus pneumoniae* (1,2)[A].
- If comorbidities implying risk, consider amylase, triglycerides, cholesterol, LE cells, cytology, antinuclear antibodies (ANAs), adenosine deaminase, tumor markers, rheumatoid factor, cytology, creatinine (2)[A]
- Light criteria, transudate versus exudate (98% sensitivity; 80% specificity); fluid is considered an exudate if any of the following (2)[A]:
  - Ratio of pleural fluid-to-serum protein levels >0.5; ratio of pleural fluid-to-serum LDH levels >0.6; pleural fluid LDH level >2/3 the upper limit for serum LDH level (1,3)[A]
- Other exudate criteria (4)[A]:
  - Serum-effusion albumin gradient ≤1.2 (sensitivity 87%; specificity 92%); cholesterol effusion >45 mg/dL and LDH effusion >200 mg/dL (sensitivity 90%; specificity 98%)
- Empyema: pus, putrid odor; culture. A putrid odor suggests an anaerobic

empyema: LDH levels >1,000 IU/L (normal serum = 200 IU/L); glucose, <60 mg/dL; low pH

- Malignancy: cytology, red, bloody; glucose, normal to low, depending on the tumor burden; RBCs, >100,000/mm^3
- Lupus pleuritis: LE cells present; pleural fluid-to-serum ANAs ratio >1; glucose <60 mg/dL; pleural fluid-to-serum glucose ratio <0.5
- Fungal: positive KOH, culture; peritoneal dialysis: protein, <1 g/dL; glucose, 300 to 400 mg/dL
- Urinothorax: creatinine: pleural/blood >0.5; high LDH pleural fluid, with low protein levels
- Hemothorax: hematocrit: pleural/blood >0.5; benign asbestos effusion: unilateral, exudative; have elevated eosinophil count
- TB pleuritis: lymphocytes >80% predominance effusion; elevated levels of adenosine deaminase >50 U/L and interferon-γ >140 pg/mL; positive acid-fast bacillus (AFB) stain, culture; total protein >4 g/dL, nuclear acid amplification (NAA), LDH levels elevated in about 75% of patients (often >500 units/L)
- Chylothorax: milky; triglycerides >110 mg/dL; lipoprotein electrophoresis (chylomicrons)
- Amebic liver abscess: anchovy paste effusion; Waldenström macroglobulinemia and multiple myeloma: protein >7 g/dL
- Esophageal rupture: high salivary amylase; pleural fluid acidosis, pH <6; amylase-rich: acute pancreatitis, chronic pancreatic pleural effusion, malignancy, esophageal rupture; rheumatoid pleurisy: glucose <60 mg/dL; pleural fluid/serum glucose <0.5
- Lymphocytosis: tuberculous pleurisy, lymphoma, sarcoidosis, chronic rheumatoid pleurisy, yellow nail syndrome, or chylothorax (80–95% of the nucleated cells); carcinomatosis in half of cases (50–70% are lymphocytes)
- Pleural fluid eosinophilia (>10% of total nucleated cells): pneumothorax, hemothorax, malignancy, drugs, pulmonary infarction, fungal (coccidiomycosis, cryptococcosis, histoplasmosis), benign asbestos pleural effusion
- Low glucose (<60 mg/dL): TB, malignancy, rheumatoid pleurisy, parapneumonic, empyema, hemothorax, paragonimiasis, Churg-Strauss syndrome

- RBC count >100,000/mm^3: trauma, malignancy, PE, injury after cardiac surgery, asbestos pleurisy, pancreatitis, TB
- Pleural fluid LDH >1,000 IU/L: suggests empyema, malignant effusion, rheumatoid effusion, or pleural paragonimiasis
- pH >7.3: rheumatoid pleurisy, empyema, malignant effusion, TB, esophageal rupture, or lupus nephritis
- Mesothelial cells in exudates: TB is unlikely if there are >5% of mesothelial cells.
- *S. pneumoniae* accounts for 50% of cases of parapneumonic effusions in AIDS patients, followed by *Staphylococcus aureus*, *Haemophilus influenzae*, *Mycoplasma pneumoniae*, *Legionella*, *Nocardia*, and *Bordetella bronchiseptica*. Exudate with low count of nucleated cells.
- *Pneumocystis jirovecii* is an uncommon cause in HIV. Usually it is a small effusion, unilateral or bilateral, and serous to bloody in appearance. Demonstration of the trophozoite or cyst is mandatory.
- Cancer-related HIV pleural effusion: Kaposi sarcoma, Castleman disease, and primary effusion lymphoma. Kaposi sarcoma: mononuclear predominance, exudate, pH >7.4; LDH, 111 to 330 IU/L; glucose >60 mg/dL.
- Chest x-ray (CXR): posteroanterior–anteroposterior views
  - Upright x-rays show a concave meniscus in the costophrenic angle that suggests >250 mL of pleural fluid; homogeneous opacity, with visibility of pulmonary vessels through diffuse haziness and absence of air bronchogram; 75 mL of fluid will obliterate the posterior costophrenic sulcus.
  - Lateral x-rays show blunting of the posterior costophrenic angle and the posterior gutter; decubitus x-rays to exclude a loculated effusion and underlying pulmonary lesion or pulmonary thickening
  - Supine x-rays show costophrenic blunting, haziness, obliteration of the diaphragmatic silhouette, decreased visibility of the lower lobe vasculature, and widened minor fissure.
- Ultrasonography (US): detects as 5 to 50 mL of pleural fluid; identifies loculated effusions; site for thoracocentesis, pleural biopsy, or pleural drainage
- Chest CT scan with contrast for patients with undiagnosed pleural effusion. CT pulmonary angiography if PE is suspected.

Follow-Up Tests & Special Considerations

75% of patients with exudative effusions have a non-CHF cause.

- NT-ProBNP: biomarker of CHF-associated effusion; >1,500 pg/mL; sensitivity and specificity 94% (2)[A]
- Observation in uncomplicated asymptomatic patients (i.e., CHF, cirrhosis), viral pleurisy, thoracic or abdominal surgery

Diagnostic Procedures/Other

Diagnostic thoracentesis indicated for the following:

- Clinically significant pleural effusion (>10 mm thick on US or lateral decubitus x-ray with no known cause)
- CHF: asymmetric effusion, fever, chest pain, or failure to resolve after diuretics
- Parapneumonic effusions

TREATMENT

Oxygen support

GENERAL MEASURES

- Therapeutic thoracentesis, if symptomatic
- Chest tube thoracostomy drainage: >1/2 hemithorax; complicated parapneumonic effusion (positive Gram stain or culture, pH <7.2, or glucose <60 mg/dL); empyema; hemothorax. Recommended limit is 1,000 to 1,500 mL in a single thoracentesis procedure (5)[B].

MEDICATION

First Line

CHF: diuretics (75% clearing in 48 hours); parapneumonic effusion: antibiotics; rheumatologic conditions/inflammation: steroids and NSAIDs

Second Line

Symptomatic nonmalignant effusions that are refractory to treatment may be managed with repeated therapeutic thoracentesis or pleurodesis.

ISSUES FOR REFERRAL

- Uncertain etiology; malignant effusion; high-risk diagnostic thoracentesis; decortication
- Video-assisted thoracoscopy for sclerosis; peritoneal shunts for symptomatic recurrence

ADDITIONAL THERAPIES

- Pleurodesis for symptomatic patients whose pleural effusion reaccumulates too quickly for repeat therapeutic thoracentesis
- Talc poudrage to be a highly effective method 95% credible interval (Cr-1) 1 to 5 (5)[A]
- Tunneled pleural catheter is the preferred treatment for patients with malignant pleural effusion and limited survival.
- Sclerosing agents for malignant effusions: doxycycline, bleomycin, talc, and minocycline; talc is more efficacious. The relative risk of nonrecurrent effusion was 1.34 (95% CI 1.16–1.55) in favor of talc compared with bleomycin, tetracycline, or mustine.

SURGERY/OTHER PROCEDURES

- Percutaneous pleural biopsy if a cause is not clear after thoracentesis
  - Close pleural biopsy: Pleura is diffusely involved (TB pleuritis, noncaseating granuloma in rheumatoid pleuritis).
  - CT-guided needle biopsy: pleural mass; video-assisted thoracoscopic pleural biopsy: negative percutaneous biopsy, patchy disease, or CT scan does not show obvious mass.
- Parapneumonic effusion should be sampled if free-flowing, but layer is >10 mm on a lateral decubitus film; loculated, thickened pleura on a contrast-enhanced CT scan, clearly delineated by US open pleural biopsy by thoracotomy
- Contraindications for thoracocentesis: anticoagulation, bleeding diathesis, thrombocytopenia <20,000/mm^3, mechanical ventilation
- Bronchoscopy: when malignancy is suspected (pulmonary infiltrate or mass on CXR or CT scan, hemoptysis, massive pleural effusion, or shift of the mediastinum toward the side of effusion)
- Thoracoscopy

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Treat any underlying medical disorder.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Check for the amount and quality of fluid drained, air leak (bubbling), and oscillation.
- Repeat a CXR when drainage decreases to <100 mL/day to evaluate complete clearing.
- For a large effusion, reevaluate catheter position; if positioned appropriately, consider fibrinolytics.

DIET

Cardiac diet in patients with heart failure; correct hypoproteinemia.

PROGNOSIS

- Malignant effusion: poor
- Low-pH malignant effusions have shorter survival and poorer response to chemical pleurodesis than those with pH >7.3.
- Low pleural fluid pH (≤7.15): high likelihood of pleural space drainage
- 68% 30-day and 84% 1-year mortality among patients with bilateral malignant pleural effusion
- Pleural fluid pH ≤7.28 associated with reduced survival (odds ratio 4.42, 95% CI 2.39–8.46 for <1-month survival)

COMPLICATIONS

- Pleural effusion: constrictive fibrosis, pleurocutaneous fistula
- Thoracentesis: pneumothorax (5–10%); hemothorax (~1%); empyema; spleen/liver laceration; reexpansion pulmonary edema (if >1.5 L is removed)

- J94.0 Chylous effusion

CLINICAL PEARLS

- Clinical presentation and pleural fluid analysis allow to diagnose the cause of effusion in 75% of patients at first evaluation.
- Bilateral pleural effusion suggests heart failure, malignancy in absence of

cardiomegaly, and tuberculosis or parasitic infection in children.

- Loculation suggest pleural inflammation and may occur with the following: empyema, hemothorax, and TB.
- Parapneumonic effusion should be tapped ASAP.
- Ascites and pleural effusion suggest hepatic hydrothorax, ovarian cancer, or Meigs syndrome
- Consider diagnostic thoracocentesis in patient with heart failure: fever, pleuritic chest pain, unilateral effusion or effusion of markedly disparate size, effusion not associated with cardiomegaly, effusion fails to respond to management of heart failure
- Most common cause of exudative effusion are pneumonia, neoplasms, and thromboembolism.
- Ultrasound during thoracentesis associated with reduced risk of pneumothorax
- 8–12% of patients with nonspecific pleuritis may develop malignancy.
- Management of nonmalignant pleural effusion primarily involves treatment of underlying etiology

PNEUMONIA, BACTERIAL

Naureen Rafiq, MD • Samrawit A. Tekle, MD

BASICS

Bacterial pneumonia is an infection of the pulmonary parenchyma by a bacterial organism.

DESCRIPTION

Bacterial pneumonia can be classified as the following:

- Community-acquired pneumonia (CAP): lower respiratory tract infection not acquired in a hospital, long-term care facility, or during other recent contact with the health care system
- Medical care–associated pneumonia
  - Hospital-acquired pneumonia (HAP): pneumonia within ≥48 hours after admission and did not appear to be incubating at time of admission
  - Ventilator-associated pneumonia (VAP): Pneumonia that develops >48 hours after endotracheal intubation.
  - Health care–associated pneumonia (HCAP): Pneumonia that occurs in a nonhospitalized patient with extensive health care contact, such as the following:
    - IV therapy/wound care within past 30 days
    - Residing in a nursing home/long-term care
    - Hospitalization in an acute care hospital for ≥2 days within the past 90 days. Hemodialysis clinic within the past 30 days

EPIDEMIOLOGY

- Influenza and pneumonia are the 8th leading cause of death in the United States with about 53,282 deaths in 2013.
- HAP is the leading cause of death among nosocomial infections and is one of the leading causes of death in the ICU.
- Rates of infection are 3 times higher in African Americans than in whites and are 5 to 10 times higher in Native American adults and 10 times higher in Native American children.

- Mortality rate in children is approximately 1.6 million a year. Hospitalization rate for children with CAP is still highest among the very young ages (<18 months). Respiratory viruses are the most commonly detected causes of pneumonia (1).

Incidence

- CAP: 5 to 11 cases/1,000 persons with increased incidence occurring in the winter months.
- HAP: 5 to 10 cases/1,000 admissions; incidence increase 6- to 20-fold in ventilated patients (2)[A].

ETIOLOGY AND PATHOPHYSIOLOGY

- Adults, CAP
  - Typical (85%): *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Staphylococcus aureus*, group A *Streptococcus*, *Moraxella catarrhalis*
  - Atypical (15%): *Legionella* sp., *Mycoplasma pneumoniae*, *Chlamydophila pneumoniae*
- Adults, HCAP/HAP/VAP
  - Aerobic gram-negative bacilli: *Pseudomonas aeruginosa*, *Escherichia coli*, *Klebsiella pneumoniae*, and *Acinetobacter* sp.
  - Gram-positive cocci: *Streptococcus* sp. and *S. aureus* (including MRSA)
- Children
  - Birth to 20 days: *E. coli*, group B *Streptococci*, *Listeria monocytogenes*
  - 3 weeks to 3 months: *Chlamydia trachomatis*, *S. pneumoniae*
  - 4 months to 18 years
    - Typical: *S. pneumoniae*
    - Atypical: *C. pneumoniae*, *M. pneumoniae*

RISK FACTORS

CAP

- Age >65 years
- HIV/immunocompromised
- Recent antibiotic therapy/resistance to antibiotics
- Asthma, CAD, COPD, chronic renal failure, CHF, diabetes, liver disease, VAP, HAP, HCAP

- Hospitalization for ≥2 days during past 90 days
- Severe illness
- Antibiotic therapy in the past 6 months
- Poor functional status as defined by activities of daily living score
- Immunosuppression (including steroid users) (3)

GENERAL PREVENTION

- All children 2 to 59 months of age should be routinely vaccinated with pneumococcal conjugate (PCV13); given at 2, 4, and 6 months of age; a 4th dose at 12 to 15 months of age
- Adults ≥65 years who have not received vaccine naïve, ACIP currently recommends PCV13 followed by pneumococcal polysaccharide (PPSV23) ≥1 year interval. If they received PPSV23 vaccine before age 65 years, they should receive a dose of PCV13 followed by a subsequent PPSV23 ≥1 year after PCV13 and at least 5 years have passed since their previous PPSV23 dose.
- For adults ≥65 years old who have already received PPSV23, a dose of PCV13 is indicated after ≥1 year.
- Adults 19 to 64 years who have chronic diseases, including alcoholism and tobacco use, should receive PPSV23.
- Adults ≥19 years old with immunocompromising conditions, asplenia, CSF leaks, cochlear implants who have not received PPSV23 or PCV13 should receive one dose of PCV13 followed by PPSV23 after ≥8 weeks. If a second dose of PPSV23 is recommended, it should be given 5 years after 1st dose. Adults >19 years, previously given PPSV23 should receive a PPCV13 dose ≥1 year after last PPSV23. If additional PPSV23 is required, it should be given ≥8 weeks after PCV13 and 5 years after most recent dose of PPSV23.
- Annual influenza vaccine

DIAGNOSIS

History

- Fever, chills, rigors, malaise, fatigue
- Dyspnea

- Cough, with/without sputum
- Pleuritic chest pain
- Myalgias
- GI symptoms

ALERT
High fever (>104°F [40°C]), male sex, multilobar involvement, and GI and neurologic abnormalities have been associated with CAP caused by *Legionella*.

Geriatric Considerations
Older adults with pneumonia often present with weakness, mental status change, or history of falls.

PHYSICAL EXAM
- Fever >100.4°F (38°C), tachypnea, tachycardia
- Rales, rhonchi, egophony, increased fremitus, bronchial breath sounds, dullness to percussion, asymmetric breath sounds, abdominal tenderness

DIFFERENTIAL DIAGNOSIS
Bronchitis, asthma exacerbation, pulmonary edema, lung cancer, pulmonary tuberculosis, pneumonitis

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- Routine laboratory testing to establish an etiology in outpatients with CAP is usually unnecessary.
- For hospitalized patients with CAP, a CBC, sputum Gram stain, procalcitonin, and two sets of blood cultures
- More extensive diagnostic testing in patients with CAP is recommended if:
  - Blood cultures: ICU admission, cavitary infiltrates, leukopenia, alcohol abuse, severe liver disease, asplenia, positive pneumococcal urine antigen test (UAT), pleural effusion
  - Sputum Gram stain and cultures: ICU admission, failure of outpatient treatment, cavitary infiltrates, alcohol abuse, severe COPD/structural lung disease, positive *Legionella* UAT, positive pneumococcal UAT, pleural effusion

  - *Legionella* UAT: ICU admission, failure of outpatient treatment, alcohol abuse, travel in past 2 weeks, pleural effusion
  - Pneumococcal UAT: ICU admission, failure of outpatient treatment, leukopenia, alcohol abuse, severe liver disease, asplenia, pleural effusion
- A chest x-ray (CXR) is indicated when pneumonia is suspected or with an acute respiratory infection and
  - Vital signs: temperature >100°F (37.8°C); heart rate (HR) >100 beats/min; respiratory rate (RR) >20 breaths/min
  - At least two of the following clinical findings: decreased breath sounds, rales, no asthma
- Early in disease course, CXR may be negative.
- Evidence of necrotizing/cavitary pneumonia should raise suspicion for MRSA pneumonia, especially with history of prior MRSA skin lesions.

Diagnostic Procedures/Other

- For VAP/HAP: By bronchoscopic or nonbronchoscopic means, obtain a lower respiratory tract sample for culture prior to initiation/change of therapy. Serial evaluations may be needed (2)[A].
- Safe cessation of antibiotics can be done from a good quality negative sputum culture.

TREATMENT

MEDICATION

First Line

- Adults
  - CAP, outpatient
    - No significant differences in efficacy between antibiotic option in adults
    - Previously healthy, no antibiotics in past 3 months
      - Azithromycin 500 mg PO 1 time, then 250 mg PO daily for 4 days; clarithromycin 500 mg PO BID for 10 days; erythromycin 500 mg PO BID for 10 days, or
      - Doxycycline 100 mg PO BID for 10 days
    - Comorbid conditions, immunosuppressed, antibiotic use in past 3 months

        - Levofloxacin 750 mg PO daily for 5 days; moxifloxacin 400 mg PO daily for 5 days; or
        - Amoxicillin 1 g PO TID; amoxicillin-clavulanate 2 g PO BID + macrolide/doxycycline for 5 days
        - Treatment may be stopped if
            - Afebrile for >48 hours
            - Supplemental oxygen no longer needed
            - No more than one of the following:
                - HR >100 beats/min
                - RR >24 breaths/min
                - Systolic blood pressure (BP) ≤90 mm Hg
- CAP, inpatient (non-ICU)
    - IV antibiotics initially, then switch to oral after clinical improvement
    - Treatment duration depends on clinical improvement.
    - Cefotaxime; ceftriaxone; ampicillin-sulbactam + macrolide (clarithromycin; erythromycin) for 5 to 14 days or
    - Moxifloxacin; levofloxacin for 5 to 14 days
    - If *Pseudomonas* is a consideration
        - Piperacillin-tazobactam; cefepime; imipenem; meropenem + levofloxacin or
        - Piperacillin-tazobactam; cefepime; imipenem; meropenem + aminoglycoside and azithromycin or
        - Piperacillin-tazobactam; cefepime; imipenem; meropenem + aminoglycoside + levofloxacin
    - If MRSA is a consideration
- Add vancomycin or linezolid HCAP/HAP/VAP.
    - Use IV antibiotics.
    - Early onset (<5 days) and no risk factors for multidrug-resistant pathogens
        - Ceftriaxone; ampicillin-sulbactam; ertapenem or
        - Levofloxacin; moxifloxacin
    - Late onset (≥5 days) or risk factors for multidrug-resistant pathogens (antibiotic therapy in preceding 90 days; high frequency of antibiotic resistance in community/hospital; immunosuppressive disease/therapy;

risk factors for HCAP)
    - MRSA coverage: linezolid or vancomycin + β-lactam cefepime; ceftazidime; imipenem; meropenem; piperacillin-tazobactam + either fluoroquinolone (levofloxacin) or aminoglycoside (amikacin; gentamicin; tobramycin) (level II)
    - Short-course versus prolonged-course antibiotic therapy for HAP in critically ill adults is only as effective and reduced recurrence of VAP-associated multidrug resistance (4).
    - Drug-resistant *S. pneumoniae* should be treated with high-dose amoxicillin, amoxicillin/clavulanate, cefpodoxime with a macrolide, or a respiratory fluoroquinolone.
  - Adult IV antibiotic doses
    - β-Lactams (ampicillin-sulbactam 3 g q6h; aztreonam 2 g q6h; cefepime 1 to 2 g q8–12h; cefotaxime 1 g q6–8h; ceftazidime 2 g q8h; ceftriaxone 2 g daily; imipenem 500 mg q6h; meropenem 1 g IV q8h)
    - Aminoglycosides (amikacin 20 mg/kg daily; gentamicin 7 mg/kg daily; tobramycin 7 mg/kg daily)
    - Fluoroquinolones (levofloxacin 750 mg daily; moxifloxacin 400 mg daily)
    - Macrolides (azithromycin 500 mg daily; clarithromycin 500 mg daily; erythromycin 500 to 1,000 mg q6h)
    - Vancomycin 15 mg/kg q12h
    - Linezolid 600 mg q12h
    - Telavancin is an antibiotic which covers MRSA infection. Telavancin is approved for the treatment of HAP and VAP caused by *S. aureus*. This medication is indicated only when alternative agents cannot be used.
- Pediatric, outpatient (≥3 months)
  - Antibiotic treatment in preschool-aged children is not routinely required because viral pathogens are more common (5)[A].
  - Oral antibiotics are as efficacious as IV in CAP (length of stay and oxygen requirement were reduced in those given oral antibiotics).
  - Typical bacterial pneumonia
    - Amoxicillin 90 mg/kg/day PO BID (max 4 g/day) (5)[A]
    - Amoxicillin-clavulanate 90 mg/kg/day PO BID (max 4 g/day) (5)[A]

- Alternative: levofloxacin 16 to 20 mg/kg/day PO BID for children 6 months to 5 years, 10 mg/kg/day daily for children ≥5 years (max 750 mg/day) (5)[C]

– Atypical bacterial pneumonia
  - Azithromycin 10 mg/kg PO on day 1 (max 500 mg), then 5 mg/kg/day (max 250 mg) on days 2 to 5 (4)[C]
  - Clarithromycin 15 mg/kg/day PO BID (max 1 g/day) (4)[C]
  - Erythromycin 40 mg/kg/day PO daily (4)[C]

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Clinical judgment and use of a validated severity of illness score are recommended to determine if inpatient management is indicated.
- The Pneumonia Severity Index (PSI) is a clinical prediction rule used to calculate the probability of morbidity and mortality among patients with CAP. PSI is risk stratified from I to V. PSI risk class from I to III can be treated as outpatients and IV to V should be hospitalized. PSI can be calculated at http://pda.ahrq.gov/clinic/psi/psicalc.asp.
- The CURB-65 or CRB 65 (confusion, urea nitrogen RR, BP, age >65 years) (http://www.mdcalc.com/curb-65-severity-score-community-acquired-pneumonia/) is a severity of illness score for stratifying adults with CAP into different management groups.
- The SMART-COP (systolic BP, multilobar chest radiography, albumin, RR, tachycardia, confusion, oxygen level, and arterial pH) is a new method to predict which patients will require intensive respiratory/vasopressor support. A score of ≥3 has sensitivity of 92% to identify those patients who will receive intensive treatment.
- Patients with COPD or CHF are more likely to require ICU admission when suffering from CAP.
- Clinical prediction tools do not replace a physician's clinical judgment.

Pediatric Considerations

Inpatient treatment of children is recommended in the following settings: infants ≤3 to 6 months; presence of respiratory distress (tachypnea, dyspnea, retractions, grunting, nasal flaring, apnea, altered mental status, O_2 sat <90%); or if known

to have CAP as result of a virulent pathogen such as community-associated MRSA should be hospitalized (6).

- Discharge criteria: clinical stability: temperature ≤100°F (37.8°C); HR ≤100 beats/min; RR ≤24 beats/min; systolic BP ≤90 mm Hg; O_2 sat ≥90% or PaO_2 ≥60 mm Hg on room air; ability to maintain oral intake; normal mental status

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Consider chest CT if patient is failing to improve on current management.

PATIENT EDUCATION

Smoking cessation, vaccinations

COMPLICATIONS

Necrotizing pneumonia, respiratory failure, empyema, abscesses, cavitation, bronchopleural fistula, sepsis

CODES

ICD10

- J15.9 Unspecified bacterial pneumonia
- J15.4 Pneumonia due to other streptococci
- J14 Pneumonia due to Hemophilus influenzae

CLINICAL PEARLS

- Bacterial pneumonia can usually be treated empirically based on its classification as CAP or HCAP/HAP/VAP.
- A severity of illness score is helpful in determining the need for hospitalization of adult patients but does not replace a physician’s clinical judgment.

PNEUMONIA, MYCOPLASMA

Kenneth A. Ballou, MD • Andrew G. Alexander, MD • Maegen Dupper, MD

BASICS

DESCRIPTION

- Bronchopulmonary infection caused by the *Mycoplasma* species, *Mycoplasma pneumonia* (MP)
- Smallest free-living organism; fastidious and slow-growing; first isolated in cattle in 1898
- Most frequently affects children/young adults but can also occur in the elderly; often causes epidemics in close communities
- Infection may be asymptomatic, most often confined to the upper respiratory tract; however, may progress to pneumonia (5–10%).
- Course is usually acute with an incubation period of 1 to 4 weeks.
- Synonym(s): primary atypical pneumonia (PAP); Eaton agent pneumonia; cold agglutinin–positive pneumonia; walking pneumonia

Geriatric Considerations

The highest rate of ICU admissions for CAP due to MP occurs in seniors

Pediatric Considerations

- Plays a significant role in pneumonias in children of all ages (pneumonia <5 years is more commonly viral)
- Increased incidence of asthma exacerbation in older children
- All infants 3 to 6 months with suspected bacterial pneumonia should be hospitalized.

EPIDEMIOLOGY

Incidence

- Estimated 1 million cases per year in the United States
- Responsible for 20% of community-acquired pneumonia (CAP) requiring hospitalizations annually

- Infection occurs most frequently in fall/winter seasons but may develop year round.

Prevalence

- Predominant sex: male = female
- Predominant age group affected: 5 to 20 years
  - May occur at any age
  - Rare in children <5 years of age
- Responsible for 15–20% of all cases of CAP yearly
  - Most common cause of pneumonia in school children and young adults who do not have a chronic underlying condition

ETIOLOGY AND PATHOPHYSIOLOGY

- *M. pneumoniae* is a short-rod mucosal pathogen, which lacks a cell wall and thus not visible on Gram stain.
- Can grow under both aerobic and anaerobic conditions
- Highly contagious, *M. pneumoniae* is transmitted primarily by aerosol droplets.
- Pathogenicity linked to its filamentous tips, which adhere selectively to respiratory epithelial cell membrane proteins with production of H_2O_2 and superoxide radicals, damaging cilia
- Many pathogenic features of infection are believed to be immune-mediated, not directly induced.
- Decreased ciliary movement produces prolonged paroxysmal, hacking cough.

ALERT

- Infection by *M. pneumoniae* has come to be recognized as a worldwide cause of CAP.
- *M. pneumonia* infection may worsen asthma symptoms as well as cause wheezing in children without asthma.

RISK FACTORS

- Immunocompromised state (e.g., HIV, transplant recipients, chemotherapy)
- Smoking
- Close community living (e.g., military barracks, prisons, hospitals, dormitories, schools, household contacts)

GENERAL PREVENTION

Consider droplet isolation of active cases.

COMMONLY ASSOCIATED CONDITIONS

- Asthma exacerbations as a result of proinflammatory cytokine release
- Chronic obstructive pulmonary disease

DIAGNOSIS

HISTORY

- Infection may be asymptomatic.
- Gradual onset of headache, malaise, low-grade fevers, chills
- Symptoms of upper respiratory infection then occur, including incessant, nonproductive, worsening cough (which may become mildly productive late in the disease); rhinorrhea, pharyngitis, and sinusitis (1)[A]
- Pneumonia may occur with associated pleural effusion.
- The presence of pleuritic chest pain warrants a higher suspicion of M. pneumoniae (1)[A].
- Extrapulmonary findings may develop in 5–10% of patients, including arthralgias, skin rashes, cervical adenopathy, hemolysis, congestive heart failure (CHF), and cardiac conduction abnormalities.
- Neurologic symptoms develop more commonly in children and may include encephalitis, aseptic meningitis, cranial nerve palsies, cerebellar ataxia, ascending paralysis, and coma (2)[C].
- Persistent cough is common during convalescence; other sequelae are rare.

PHYSICAL EXAM

- Toxicity increases with advancing age or co-morbidity.
- Hacking/pertussis-like cough may be present along with fever and lassitude.
- Normal lung findings with early infection, but rhonchi, rales, and/or wheezes may develop several days later (1)[A].
- Mild pharyngeal injection without exudates
- Minimal/no cervical adenopathy
- Erythematous tympanic membranes or bullous myringitis in patients >2 years

of age is an uncommon but unique sign.
- Some patients may develop a pleural friction rub.
- Various exanthems, including erythema multiforme and Stevens-Johnson syndrome

DIFFERENTIAL DIAGNOSIS

- Viral/bacterial/fungal pneumonia
- Tuberculosis
- Other atypical pneumonias, including *Chlamydia pneumoniae, Chlamydophila psittaci, Coxiella burnetii* (Q fever), *Francisella tularensis* (tularemia), *Pneumocystis jiroveci, Legionella pneumophila*

DIAGNOSTIC TESTS & INTERPRETATION

- *M. pneumoniae* is typically a clinical diagnosis and treated empirically; however, when specific pathogen testing is indicated, polymerase chain reaction (PCR) is the test of choice (3)[C].
- No clinical or radiographic findings can differentiate between *M. pneumoniae* and other atypical pneumonia pathogens (Chlamydia/Legionella).

Initial Tests (lab, imaging)

- WBC count may be normal or elevated.
- Hemolytic anemia has been described but is rare.
- Elevated erythrocyte sedimentation rate (ESR) may be present but is nonspecific.
- When available, PCR for *M. pneumoniae* DNA in respiratory secretions, CSF, and tissue samples may be the most sensitive and specific
- CXR shows reticulonodular pattern with patchy areas of lower lobe consolidation, although this is not specific. Small pleural effusion may be present in 10–15% cases.

Follow-Up Tests & Special Considerations

- Sputum Gram stains are not helpful because *M. pneumoniae* lacks a cell wall and cannot be stained.
- *M. pneumoniae* is difficult to culture and requires 7 to 21 days to grow; culturing is successful in 40–90% of cases but does not provide information to guide treatment, thus infrequently performed.

- Complement fixation serologic assay shows 4-fold rise in IgM antibody titer at 2 to 4 weeks after symptom onset; this is an older technique.
- Positive cold agglutinins (titer of ≥1:128 or rising 4-fold) in 50% of infections but can take 1 to 2 weeks to develop; not sensitive/specific; not routinely recommended
- CT of chest may show a combination of patchy tree-in-bud opacities with segmental ground glass opacities.

TREATMENT

GENERAL MEASURES

- Avoid sick contacts.
- Treatment is usually empiric and must be comprehensive to cover all likely pathogens in the context of the clinical setting.
- Calculation of pneumonia severity score (CAP score: http://www.mdcalc.com/psi-port-score-pneumonia-severity-index-adult-cap) may be helpful in determining inpatient versus outpatient treatment.

ALERT

There is insufficient evidence regarding the efficacy of antibiotics in pediatric patients <24 months of age infected with *M. pneumoniae*. However, some studies show benefit to treating with a macrolide and amoxicillin to cover *M. pneumoniae* in addition to other likely agents causing CAP (4)[A].

Pregnancy Considerations

- Azithromycin: pregnancy Category B (preferred treatment)
- Clarithromycin, levofloxacin, and moxifloxacin: pregnancy Category C
- Doxycycline: pregnancy Category D

MEDICATION

First Line

- Azithromycin
  - <3 months of age: not established
  - >3 months of age: day 1, 10 mg/kg PO × 1 (not to exceed 500 mg); days 2 to 5: 5 mg/kg PO daily (not to exceed 250 mg/day)

  - Adults: 500 mg PO × 1 followed by 250 mg PO daily × 4 day
- Minocycline
  - 200 mg PO/IV × 1 dose and then 100 mg BID for 7 to 10 days
- Clarithromycin
  - Children <6 months of age: not established
  - Patients >6 months of age: 15 mg/kg/day PO divided q12h for 10 to 14 days
  - Adults: 250 to 500 mg PO BID for 10 to 14 days
- Erythromycin
  - Children: 20 to 50 mg/kg/day (base) PO divided q6–8h for 10 to 14 days
  - Adults: 500 mg (base) PO q6h × 10 to 14 days
- Doxycycline
  - Children <8 years of age: not recommended
  - Children >8 years of age (≤45 kg): 2 to 4 mg/kg/day up to 200 mg/day PO divided BID for 10 to 14 days
  - Children >8 years of age (≥45 kg): Refer to adult dosing.
  - Adults: 100 mg PO BID × 7 to 14 days
  - Useful in macrolide-resistant strains of *M. pneumoniae*.

Second Line

- Levofloxacin
- Children <18 years of age: not recommended
- Adults: 750 mg PO daily × 5 days
- Moxifloxacin
  - Children <18 years of age: not recommended
  - Adults: 400 mg/day PO for 7 to 10 days
- Levofloxacin and moxifloxacin show good activity against *M. pneumoniae*. Consider use with comorbid conditions and other pneumonia pathogens; also useful if macrolide resistance is suspected.

ADDITIONAL THERAPIES

- Albuterol inhaler: 2 puffs q4–6h as needed for wheezing
- Dexamethasone may downregulate cytokine release (5)[B].
- Acetaminophen/ibuprofen as needed for fever
- Up to 10.9% of hospitalized patients may require mechanical ventilation.
- Plasmapheresis in cases of severe hemolytic anemia.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- CAP score risk class IV/V
- Advanced age with comorbidities
- Complicating neoplastic disease
- Significant cerebrovascular, cardiac, renal, liver, or GI symptoms
- Altered mental status
- Inability to maintain oxygen saturation
- Tachycardia/tachypnea
- Hypotension
- Neurologic symptoms
- Signs of Stevens-Johnson syndrome
- Significant hemolysis (autoimmune hemolytic anemia, cold agglutinin disease)
- Change from IV to PO antibiotic may be made when:
  - Respiratory distress and hypoxia have resolved.
  - Patients are tolerating oral hydration.
  - No significant complications are present.
- Generally, no need for 24-hour observation on PO antibiotics prior to discharge.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Clearing of condition on CXR should be documented in patients >50 years of age.
- In smokers, document a clear CXR in 6 to 8 weeks.
- Worsening symptoms/development of rash or meningeal/neurologic signs should prompt immediate presentation to medical attention.
- Antibiotic prophylaxis for exposed contacts is not routinely recommended.
- For household contacts who may be predisposed to severe mycoplasmal infection, macrolide or doxycycline prophylaxis should be used.

DIET

- No special diet considerations
- Ensure adequate hydration.

PATIENT EDUCATION

- Smoking cessation
- Contact and droplet precautions
- Adequate handwashing techniques

PROGNOSIS

- Symptoms usually resolve in 2 weeks.
- Some constitutional symptoms may persist for several weeks.
- With correct therapy, even most severe cases can expect complete recovery.

COMPLICATIONS

- All complications are rare, except reactive airway disease, hemolytic anemia, and erythema multiforme.
- Reactive airway disease may persist indefinitely and can cause acute chest syndrome in patients with sickle cell anemia.
- Meningoencephalitis
- Aseptic meningitis
- Peripheral neuropathy
- Transverse myelitis/acute transverse myelitis
- Cerebellar ataxia
- Acute disseminated encephalomyelitis
- Guillain-Barré syndrome
- Encephalitis (especially in children)
- Polyneuritis/polyarthritis
- Stevens-Johnson syndrome
- Pericarditis/myocarditis
- Respiratory distress syndrome
- Cerebral ataxia
- Thromboembolic phenomena
- Pleural effusion
- Nephritis
- Occasional deaths occur primarily among the elderly and persons with sickle

cell disease.

CODES

ICD10

J15.7 Pneumonia due to Mycoplasma pneumoniae

CLINICAL PEARLS

- Most common atypical respiratory pathogens include *M. pneumoniae*, *C. pneumoniae*, and *L. pneumophila*.
- Atypical pneumonia is usually a clinical diagnosis.
- Watch closely for complicating symptoms that could indicate worsening disease.
- Atypical pneumonia with *M. pneumoniae* usually responds to empiric treatment.
- Outbreaks of *M. pneumoniae* can be seen in close communities (i.e., dormitories).
- Presentation of infection is typically a gradual onset of symptoms.

PNEUMONIA, PNEUMOCYSTIS JIROVECI

Thomas J. Hansen, MD

BASICS

DESCRIPTION

- *Pneumocystis jiroveci* causes pneumonia primarily in immunocompromised patients.
- The fungus that causes this pneumonia in humans was previously called *Pneumocystis carinii*.
- The name was formally changed to *Pneumocystis jiroveci* in 2001, following the discovery that the fungus that infects humans is unique and distinctive from the fungus that infects animals (1).
- *P. jiroveci* is extremely resistant to traditional antifungal agents, including both amphotericin and azole agents (2).
- To prevent confusion, the term PCP, which used to represent *P. carinii* pneumonia, now represents *Pneumocystis* pneumonia (3).

ALERT

No combination of symptoms, signs, blood chemistries, or radiographic findings is diagnostic of *P. jiroveci* pneumonia (4).

EPIDEMIOLOGY

- *P. jiroveci* has a worldwide distribution, and most children have been exposed to the fungus by 2 to 4 years (5).
- The reservoir and mode of transmission for *P. jiroveci* is still unclear.
  - Human studies favor an airborne transmission model, with person-to-person spread being the most likely mode of infection acquisition (4).

Incidence

- Infants with HIV infection have a peak incidence of PCP between 2 and 6 months (5).
- HIV-infected infants have a high mortality rate, with a median survival of only 1 month.

Prevalence

- The prevalence of *P. jiroveci* colonization among healthy adults is 0–20% (2).
- Recent studies have demonstrated the transient nature of *P. jiroveci* colonization in asymptomatic, immunocompetent patients (4).
- 50% of patients with PCP are coinfected with ≥2 strains of *P. jiroveci* (5).
- There is evidence that distinct strains are responsible for each episode in patients who develop multiple episodes of PCP (5).

ETIOLOGY AND PATHOPHYSIOLOGY

Mode of transmission is unknown; likely respiratory from infected host

RISK FACTORS

Individuals at risk (4)

- Patients with HIV/AIDS infection, especially if not receiving prophylactic treatment for PCP
- Patients who are receiving high doses of glucocorticoids
- Patients who have an altered immune system not due to HIV
- Patients who are receiving chronic immunosuppressive medications
- Patients who have hematologic or solid malignancies resulting in malignancy-related immune depression

GENERAL PREVENTION

- Indications for prophylaxis
  - HIV-infected adults (5)
    - Should start when CD4 count is <200 cells/μL or if the patient develops oropharyngeal candidiasis
  - HIV-infected children (5)
    - Prophylaxis should be provided for children ≥6 years based on adult guidelines.
    - For children aged 1 to 5 years, start when CD4 count is <500 cells/μL.
    - For infants <12 months, start when the CD4 percentage is <15%.
  - Non–HIV-infected adults receiving immunosuppressive medications or with underlying immune system deficits should receive PCP prophylaxis, but currently, there are no specific guidelines on when to start this.
- Medication

  - Trimethoprim-sulfamethoxazole (TMP-SMX)
    - Adults: 1 double-strength tablet daily or 1 double-strength tablet 3 times per week
    - Children >2 months: 150 mg TMP/m^2/day in divided doses q12h for 3 days per week
  - Atovaquone suspension
    - Adults: 1,500 mg PO once daily with food
    - Children: not to exceed 1,500 mg/day
      - 1 to 3 months: 30 mg/kg/day PO once daily
      - 4 to 24 months: 45 mg/kg/day PO once daily
      - >24 months: 30 mg/kg/day PO once daily
      - Adolescents ≥13 years: Refer to adult dosing.
  - Dapsone
    - Adults only: 50 mg BID or 100 mg once daily
  - Pentamidine
    - Adults only: 300 mg aerosolized every 4 weeks
- Discontinuation of prophylaxis
  - When CD4+ cell counts are >200 cells/μL for a period of 3 months in the adult population (2)[C]
  - There are no clear guidelines for discontinuation of prophylaxis in children.

COMMONLY ASSOCIATED CONDITIONS

- HIV/AIDS
- Chronic obstructive pulmonary disease (COPD)
- Interstitial lung disease
- Connective tissue diseases treated with corticosteroids
- Cancer and organ transplant patients on immunosuppressive medication

DIAGNOSIS

HISTORY

- HIV-infected patients
  - Subacute onset over several weeks
    - Progressively worsening dyspnea

    - Tachypnea
    - Cough: nonproductive or productive of clear sputum
    - Low-grade fever, chills
    - Weakness, fatigue, malaise
- Non–HIV-infected immunocompromised patients
  - More acute onset with fulminant respiratory failure
    - Abrupt tachypnea, dyspnea
    - Fever
    - Dry cough

PHYSICAL EXAM

- Fever
- Tachypnea
- Tachycardia
- Lung exam is normal or near normal.

DIFFERENTIAL DIAGNOSIS

- Tuberculosis
- Bacterial pneumonia
- Fungal pneumonia
- Viral pneumonia

DIAGNOSTIC TESTS & INTERPRETATION

P. jiroveci cannot be cultured. Therefore, a diagnosis relies on detection of the organism by colorimetric or immunofluorescent stains or by polymerase chain reaction (PCR) (5)[C].

- ABG: reveals hypoxemia and increased alveolar–arterial gradient that varies with severity of disease
- LDH: Serum lactate dehydrogenase is frequently increased (nonspecific; likely due to underlying lung inflammation and injury).
- CD4 cell count is generally <200 cells/μL in HIV-infected patients with PCP.
- S-adenosylmethionine levels are significantly lower in a patient with PCP. The levels increase with successful treatment (6)[B].
- Comprehensive metabolic profile
- Chest x-ray (CXR) (4)[C]

- Bilateral, symmetric, fine, reticular interstitial infiltrates involving perihilar areas; becomes more homogeneous and diffuse as severity of infection progresses
- Less common patterns include upper lobe involvement in patients receiving aerosolized pentamidine, solitary or multiple nodular opacities, lobar infiltrates, pneumatoceles, and pneumothoraces.
- May be normal in up to 30% of patients with PCP (3)[C]

- High-resolution CT is more sensitive than CXR.

Diagnostic Procedures/Other

- Fiberoptic bronchoscopy with bronchoalveolar lavage (BAL) is the preferred diagnostic procedure to obtain samples for direct fluorescent antibody staining.
  - Sensitivities range from 89% to >98%.
- *Pneumocystis* trophic forms or cysts obtained from induced sputum, BAL fluid, or lung tissue, which can be visualized using conventional stains.
- PCR can detect *Pneumocystis* from respiratory sources, but the potential remains for false positives (4)[C].

TREATMENT

The recommended duration of therapy differs in patients who are with/without AIDS:

- In patients with PCP who do not have AIDS, the typical duration of therapy is 14 days.
- Treatment of PCP in patients who have AIDS was increased to 21 days due to the risk for relapse after only 14 days of treatment (4)[C].

MEDICATION

- Trimethoprim-sulfamethoxazole (TMP-SMX) (2,4)[C]
- Adult dosing
  - TMP: 15 to 20 mg/kg/day, PO or IV, divided into 4 doses
- Pediatric dosing (>2 months) (4)[C]
  - TMP: 15 to 20 mg/kg/day in divided doses q6–8h
- Reduce doses of TMP-SMX in patients with renal failure.

- Patients should receive 21 days of therapy.
- Treatment response to *Pneumocystis* therapy often requires at least 7 to 10 days before clinical improvement is documented (2)[C].
- Pregnancy risk factor: Category C (4)[C]
- Precautions
  - History of sulfa allergy
  - There is an emergence of drug-resistant PCP, especially against TMP-SMX.

Second Line

- Pentamidine (for moderate to severe cases)
  - Adults and children: 4 mg/kg IV or IM once daily
- Dapsone + trimethoprim (adults only)
  - Dapsone 100 mg PO once daily, *plus*
  - Trimethoprim 5 mg/kg PO TID
    - Check the glucose-6-phosphate dehydrogenase level before beginning dapsone, as hemolysis may result.
- Clindamycin + primaquine (adults only)
  - Clindamycin 600 to 900 mg IV q8h or 300 to 450 mg PO QID, *plus*
  - Primaquine 30 mg PO once daily
- Atovaquone
  - Adults: 750 mg PO BID (>13 years of age)
  - Children: 40 mg/kg/day PO divided BID (max 1,500 mg)
- Note: Pentamidine has greater toxicity than TMP-SMX: hypotension, hypoglycemia, pancreatitis (4)[C].

ADDITIONAL THERAPIES

Adjunctive corticosteroid (prednisone or methylprednisolone) (4)[C],(7)[A]

- Adjunctive corticosteroids are shown to provide benefits in patients who have HIV and symptoms of moderate to severe PCP.
- Corticosteroids provide the greatest benefit to HIV patients who have hypoxemia manifested as a partial pressure of arterial oxygen <70 mm Hg or an alveolar–arterial gradient >35 mm Hg on room air.
- Adults and children >13 years of age: prednisone, 40 mg PO BID on days 1 to 5; 40 mg daily on days 6 to 11; 20 mg daily on days 12 to 21

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- No set criteria for hospital admission
- Five predictors of mortality in HIV-associated *Pneumocystis* pneumonia (8)
  - Increased age of the patient
  - Recent IV drug use
  - Total bilirubin >0.6 mg/dL
  - Serum albumin <3 g/dL
  - Alveolar–arterial oxygen gradient ≥50 mm Hg (8)[C]

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

In patients with HIV/AIDS: Patients with previous episodes of PCP should receive lifelong secondary prophylaxis unless they respond well to highly active antiretroviral therapy (HAART) and have a CD4 count >200 cells/μL for at least 3 months.

Patient Monitoring

Serum lactate dehydrogenase levels, pulmonary function test results, and ABG measurements generally normalize with treatment.

DIET

No special diet needed

SEE ALSO

HIV/AIDS

CODES

ICD10

B59 Pneumocystosis

CLINICAL PEARLS

- Colonization with *P. jiroveci* is common in the pediatric population.
- PCP only occurs in immunocompromised patients.
- Patients with HIV are at risk once their CD4 count is <200 cells/μL. At that time, TMP-SMX should be initiated as prophylaxis. Prophylaxis may end after HAART has been initiated and the CD4 count is >200 cells/μL for 3 months.
- Patients who are immunocompromised are also at risk. Currently, no clear clinical guidelines are available as to when to initiate or end prophylaxis.
- The first-line treatment is TMP-SMX. The typical duration of therapy is 14 days in non–AIDS-infected patients and 21 days in AIDS-infected patients.

POLYARTERITIS NODOSA

Katherine S. Upchurch, MD • Rajandeep S. Paik, MD

BASICS

DESCRIPTION

- Polyarteritis nodosa (PAN) is an antineutrophil cytoplasmic antibody (ANCA)-negative necrotizing arteritis of medium or small arteries without glomerulonephritis or vasculitis of arterioles, capillaries, or venules (1).
- Involved systems include GI tract, peripheral nervous system (sensory and motor), central nervous system (CNS), renal (without glomerulonephritis), skin, testes/epididymis, heart (1–3)
- Features depend on location of vasculitis: mesenteric ischemia–related symptoms, new onset or worsening hypertension, mononeuritis multiplex, purpuric or nodular skin lesions, or livedo reticularis (3).
- Renal disease in PAN usually manifests as hypertension (HTN) and mild proteinuria with/without azotemia. Renal infarction may occur (3).
- PAN formerly encompassed several distinct entities (classic PAN, microscopic PAN, cutaneous PAN). With the advent of ANCA testing, microscopic PAN appears unrelated to the other two, pathophysiologically.
  - Patients with classic PAN are *typically ANCA-negative* (1,4).
  - Patients with microscopic PAN have ANCAs directed against myeloperoxidase (MPO) and (generally) involvement of small arterioles (microscopic polyangiitis [MPA]). This is now classified as ANCA-associated vasculitis (1).
  - Cutaneous (or limited) PAN is a chronic disease with cutaneous lesions with characteristic histopathologic features of PAN. There are few systemic manifestations, although myalgias and peripheral motor neuropathy (mononeuritis multiplex) or sensory neuropathy may be present. ANCA positivity is variable (5).
- Synonym(s): periarteritis; panarteritis; necrotizing arteritis

EPIDEMIOLOGY

Incidence

- Predominant age: Peak onset is in the 5th to 6th decade; incidence rises with age.
- 1.5:1 male predominance (6)

Prevalence

Rare: 2 to 33 cases/1 million adults (6)

ETIOLOGY AND PATHOPHYSIOLOGY

- Segmental, transmural, necrotizing inflammation of medium and small muscular arteries, with intimal proliferation, thrombosis, and ischemia of the organ/tissue supplied by the affected arteries. Aneurysm formation at vessel bifurcations (3)
- Hepatitis B–related PAN results in direct injury to the vessel due to viral replication or deposition of immune complexes, with complement activation and subsequent inflammatory response (3).
- Most cases are idiopathic; 20% are related to hepatitis B or C infection (7).
- In patients with PAN and hepatitis B, HBsAg has been recovered from involved vessel walls (7).

Genetics

Mutations of adenosine deaminase 2 (ADA 2) have been identified in families with PAN (8).

RISK FACTORS

Hepatitis B infection >> hepatitis C infection (cutaneous PAN) (7)

COMMONLY ASSOCIATED CONDITIONS

- Hepatitis B (strong association with classic PAN) (7)
- Hepatitis C (less strongly linked to cutaneous PAN)
- Hairy cell leukemia
- 27 existing case reports of systemic PAN following hepatitis B vaccination (9)
- Minocycline (symptoms resolve on stopping drug, reoccur if rechallenged) (10)
- Case reports also associating PAN with CMV infection, amphetamines, and interferon (11)

DIAGNOSIS

There are no formal diagnostic criteria for PAN (1,3).

Suspect PAN in patients with the following:

- Acute, sometimes fulminant multisystem disease with a relatively short prodrome (i.e., weeks to months)
- Vasculitic skin rash with sensorimotor symptoms/findings
- Recent-onset HTN with systemic symptoms
- Unexplained sensory and/or motor neuropathy with systemic symptoms
- Hepatitis B infection with multisystem disease

HISTORY

General: systemic symptoms with multiorgan involvement (3)

- Constitutional symptoms (fever, weight loss, malaise)
- Organ-specific symptoms
  - Focal muscular weakness/extremity numbness
  - Myalgia and arthralgia
  - Rash
  - Recurrent postprandial pain, intestinal angina, nausea, vomiting, and bleeding
  - Altered mental status, headaches, mononeuritis multiplex
  - Testicular/epididymal pain, neurogenic bladder (rare)

PHYSICAL EXAM

Related to involved organ system (may dominate clinical picture and course) (2,3)

- Peripheral nervous system: peripheral neuropathy
- Renal: HTN
- Skin: purpura, urticaria, polymorphic rashes, subcutaneous nodules (uncommon, but characteristic), livedo reticularis; deep skin ulcers, especially in lower extremities; Raynaud phenomenon (rare); single digit gangrene (rare)
- GI: acute abdomen; rebound, guarding, tenderness
- CNS: seizures, altered mental status, papillitis
- Lung: signs of pleural effusion—dullness to percussion; decreased breath sounds

- Cardiac: signs of congestive heart failure and/or myocardial infarction—S3 gallop; pericarditis (friction rub is rare)
- Genitourinary: testicular/epididymal tenderness (can mimic testicular torsion)
- Musculoskeletal: arthritis (usually large joint in lower extremities)

DIFFERENTIAL DIAGNOSIS

- Other forms of vasculitis (ANCA-associated, such as GPA, Churg-Strauss syndrome, and MPA; Henoch-Schönlein purpura, drug-induced vasculitis, cryoglobulinemia, Goodpasture syndrome)
- Buerger disease
- Systemic lupus erythematosus (SLE)
- Embolic disease (atrial myxoma, cholesterol emboli)
- Thrombotic disease (antiphospholipid antibody syndrome)
- Dissecting aneurysm
- Ehlers-Danlos syndrome
- Multiple sclerosis, systemic amyloidosis
- Infection (subacute endocarditis, HIV infection, trichinosis, rickettsial diseases)

DIAGNOSTIC TESTS & INTERPRETATION

- No specific laboratory abnormalities. Confirm diagnosis with biopsy if possible (4)[C].
- Angiography (conventional, CT angiography, or MR angiography) may reveal microaneurysms and/or beading of bifurcating blood vessels.
- Avoid contrast in renal disease.
- Nonspecific laboratory abnormalities:
  - Elevated ESR and CRP
  - Mild proteinuria, elevated creatinine
  - Hepatitis B surface antigen positive in 10–50%
  - Hepatitis C antibody/hepatitis C virus RNA
  - ANCA, antiproteinase 3 (PR3), and anti-MPO are negative. Positive ANCA argues against PAN.
  - Rheumatoid factor may be positive.
  - Anemia of chronic disease (3,4):

Initial Tests (lab, imaging)

Lab tests performed to look for evidence of systemic disease and rule out other causes (3,4) are as follows:

- CBC, ESR, CRP (elevated) (4)[C]
- Chemistries: elevated creatinine/BUN (4)[C]
- Hepatitis B serology: often positive; hepatitis C less commonly positive
- LFTs: abnormal if involving the liver/biliary tract
- Urinalysis: proteinuria/hematuria, generally no cellular casts or active urinary sediment (4)[C]
- ANA, cryoglobulins (4)[C]
- ANCA, anti-MPO, and anti-PR3 (4)[A]
- Complement levels (C3, C4)
- Angiographic demonstration of aneurysmal changes/beading of small and medium-sized arteries

Diagnostic Procedures/Other

- Electromyography and nerve conduction studies in patients with suspected mononeuritis multiplex. If abnormal, consider sural nerve biopsy.
- Arterial/tissue biopsy
- Skin biopsy from edges of ulcers; include deep dermis and subcutaneous (SC) fat to assess small muscular artery involvement (excisional *not* punch biopsy) (3,4)

Test Interpretation

- Necrotizing inflammation with fibrinoid necrosis of small and medium-sized muscular arteries; segmental, often at bifurcations and branchings. Venules not involved in classic PAN.
- Capillaritis/other lung parenchymal involvement by vasculitis *strongly suggests* another process (microscopic PAN, granulomatosis with polyangiitis [GPA; formerly known as Wegener granulomatosis], Churg-Strauss syndrome, or antiglomerular basement membrane disease).
- Acute lesions with infiltration of polymorphonuclear cells through vessel walls into perivascular area; necrosis, thrombosis, infarction of involved tissue
- Aneurysmal dilatations, including aortic dissection
- Peripheral nerves: 50–70% (vasa nervorum with necrotizing vasculitis)

- GI vessels: 50% (at autopsy) with bowel necrosis; gallbladder and appendix vasculature: 10%
- Muscle vessels: 50%
- Testicular vessels involved in symptomatic males
- *The key differences from other necrotizing vasculitides are lack of granuloma formation and sparing of veins and pulmonary arteries* (2,3).

TREATMENT

GENERAL MEASURES

Aggressively treat HTN to prevent associated complications (stroke, myocardial infarction, heart failure)

MEDICATION

First Line

- Severe (life-threatening) disease: corticosteroids (CS) (high-dose prednisone, methylprednisolone or parenteral Solu-Medrol) (4,10)[A]
  - Only 50% of patients achieve and maintain remission with CS. Other patients require additional immunosuppressive therapy.
  - Cyclophosphamide (CTX) in combination with CS: Improves survival and spares use of chronic steroids in moderate/severe PAN (4,10)[A]
    - CTX has risk of infertility and malignancy.
  - Plasma exchange for refractory and renal disease (4,7)[A]
  - Rituximab use for refractory disease suggested by its efficacy in ANCA+ vasculitis (4,12,13)[C].
- Less severe disease: CS alone ± other immunosuppressive agents (azathioprine, (4)[A] methotrexate, mycophenolate mofetil (4,10,14)[B])
- HBV-associated PAN: antiviral agents, short-term CS, plasma exchange (7,10) [C]

Second Line

- Tumor necrosis factor inhibitors anecdotally reported to be of use in PAN (15)
- PAN disease activity correlates with serum IL-6 levels; tocilizumab, an inhibitor of IL-6 approved for use in rheumatoid arthritis; no evidence-based

data for PAN (16).

ADDITIONAL THERAPIES

- For patients receiving IV CTX, concurrent administration of mercaptoethane sulfonate reduces bladder exposure to carcinogenic metabolites (4)[C].
- Prophylactically treat patients on CTX for *Pneumocystis jiroveci (carinii)* pneumonia with trimethoprim sulfamethoxazole (use dapsone or atovaquone in intolerant/allergic patients) (4).

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Depends on extent and involvement of specific organs

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- CBC, urinalysis, renal and hepatic function tests
- Acute-phase reactants (e.g., ESR, CRP) may help monitor disease activity.
- Be alert for the following:
  - Treatment specific side effects of CS and immunosuppressant medications
  - Delayed appearance of neoplasms after treatment, especially bladder malignancy in patients treated with CTX. (Check annual U/A, urinary cytology with urologic evaluation if microscopic hematuria.) (4)[C]
  - Steroid-induced osteoporosis

DIET

Low salt (HTN)

PATIENT EDUCATION

- Patient education materials are available from the Arthritis Foundation, 1314 Spring St, NW, Atlanta, GA 30309; 800-283-7800
- ACR website: www.rheumatology.org

PROGNOSIS

- Expected course of untreated PAN is poor, with an estimated 5-year survival

of 13% (17).

- Steroid and cytotoxic treatment increase 5-year survival rate to 75–80% (3,17).
- Survival is greater for hepatitis B–related PAN as a result of the introduction of antiviral treatments (7).
- Patients presenting with proteinuria, renal insufficiency, GI tract involvement, cardiomyopathy, or CNS involvement have a worse prognosis.

COMPLICATIONS

- End-organ damage from ischemia
- Complications from immunosuppressive agents

SEE ALSO

Hepatitis B; Hepatitis C

CODES

ICD10

- M30.0 Polyarteritis nodosa
- M30.1 Polyarteritis with lung involvement [Churg-Strauss]
- M30.8 Other conditions related to polyarteritis nodosa

CLINICAL PEARLS

- PAN is a necrotizing vasculitis of small- to medium-sized muscular arteries with lack of granuloma formation that spares veins and pulmonary arteries.
- Clinical features of PAN depend on target organ involvement.
- Skin biopsies at ulcer edges (include deep dermis and SC fat) improve diagnostic yield.
- Check hepatitis B and C serologies.
- ANCA is negative in classic PAN.
- Treatment involves immunosuppression; choice of agent depends on extent and severity of disease.

POLYCYSTIC KIDNEY DISEASE

Maricarmen Malagon-Rogers, MD

BASICS

DESCRIPTION

- A group of monogenic disorders that results in renal cyst development
- The most frequent are two genetically distinct conditions: autosomal dominant polycystic kidney disease (ADPKD) and autosomal recessive polycystic kidney disease (ARPKD).
- ADPKD is one of the most common human genetic disorders.

EPIDEMIOLOGY

- ADPKD is generally late onset.
  - Mean age of end-stage kidney disease (ESKD) 57 to 69 years
  - More progressive disease in men than in women
  - Up to 90% of adults have cysts in the liver.
- ARPKD usually present in infants.
  - A minority in older children and young adults may manifest as liver disease.
  - Nonobstructive intrahepatic bile dilatation is sometimes seen.
  - Found on all continents and in all races

Incidence

- Mean age of ESKD: *PKD1 mutation*, 54.3 years versus *PKD2 mutation*, 74 years
- ARPKD affects 1/20,000 live births; carrier level is 1/70.
- ADPKD affects 1/400 to 1,000 live births.

Prevalence

As ESKD, ADPKD: 8.7/1 million in the United States; 7/1 million in Europe

ETIOLOGY AND PATHOPHYSIOLOGY

- ADPKD
  - *PKD1* and *PKD2* mutations disrupt the function of polycystins on the

primary cilium, forming fluid-filled cysts that progressively increase in size, leading to gross enlargement of the kidney, and distortion of the renal architecture.
  - Glomerular hyperfiltration compensates for the progressive loss of healthy glomeruli, and therefore, by the time GFR decline becomes detectable, as much as ½ of the original functional glomeruli are irreversibly lost.
  - The majority of patients with ADPKD ultimately progress to ESKD (1).
- ARPKD
  - *PKHD1* product fibrocystin is also located in cilia.
- ADPKD: Cysts arise from only 5% of nephrons:
  - Autosomal dominant pattern of inheritance but a molecularly recessive disease with the 2-hit hypothesis
  - Requires genetic and environmental factors
- ARPKD: Mutations are scattered throughout the gene with genotype–phenotype correlation.

Genetics

- ADPKD
  - Autosomal dominant inheritance
  - 50% of children of an affected adult are affected.
  - 100% penetrance; genetic imprinting and genetic anticipation are seen as well.
  - Two genes isolated
    - *PKD1* on chromosome 16p13.3 (85% of patients) encodes polycystin 1
    - *PKD2* on chromosome 4q21 (15% of patients) encodes polycystin 2
- ARPKD
  - Autosomal recessive inheritance
  - Siblings have a 1:4 chance of being affected; gene *PKHD1* on chromosome 6p21.1–p12 encodes fibrocystin.

RISK FACTORS

- Large inter- and intrafamilial variability
- A more rapidly progressive clinical course is predicted by onset of ESKD at <55 years, development of stage 3 CKD at <40 years old, onset of HTN at <18 years, total kidney volume greater than the expected for a given age, or

presence of multiple complications (gross hematuria, microalbuminuria) (1).

GENERAL PREVENTION

Genetic counseling

COMMONLY ASSOCIATED CONDITIONS

- ADPKD
  - Cysts in other organs
    - Polycystic liver disease in 58% of young age group to 94% of 45-year-olds
    - Pancreatic cysts: 5%
    - Seminal cysts: 40%
    - Arachnoid cysts: 8%
  - Vascular manifestations
    - Intracerebral aneurysms in 6% of patients without family history and in 16% with family history
    - Aortic dissections
  - Cardiac manifestations: mitral valve prolapse: 25%
  - Diverticular disease
- ARPKD: liver involvement: affected in inverse proportion to renal disease; congenital hepatic fibrosis with portal HTN

DIAGNOSIS

HISTORY

- ADPKD
  - Positive family history (15% are de novo mutations)
  - Flank pain: 60%
  - Hematuria
  - UTI
  - HTN: 50% aged 20 to 34 years; 100% with ESKD
  - Renal failure
  - Presymptomatic screening of ADPKD is not currently recommended for at-risk children (2).
    - Blood pressure should be routinely measured in these patients.

- ARPKD
  - 30% of affected neonates die:
    - Enlarged echogenic kidneys and oligohydramnios are diagnosed in utero.
    - Later in childhood: HTN
  - Adolescents and adults present with complications of portal HTN: esophageal varices
  - Hypersplenism

PHYSICAL EXAM

- HTN
- Flank masses

DIFFERENTIAL DIAGNOSIS

- ADPKD and ARPKD
- Tuberous sclerosis: prevalence 1/6,000
- Von Hippel-Lindau syndrome: prevalence 1/36,000
- Nephronophthisis: accounts for 10–20% of cases of renal failure in children; medullary cystic kidney disease
- Renal cystic dysplasias: multicystic dysplastic kidneys: grossly deformed kidneys; most common type of bilateral cystic diseases in newborns (prevalence: 1/4,000)
- Simple cysts: most common cystic abnormality
  - Localized or unilateral renal cystic disease
  - Medullary sponge kidney
  - Acquired renal cystic disease
- Renal cystic neoplasms: benign multilocular cyst (cystic nephroma)

DIAGNOSTIC TESTS & INTERPRETATION

Electrolytes, BUN/creatinine, urine analysis plus urinary citrate

Initial Tests (lab, imaging)

- ADPKD
  - Renal dysfunction
    - Impaired renal concentration (3), hypocitraturia aciduria
    - Hyperfiltration
    - Elevated creatinine

  - Urinalysis: hematuria and mild proteinuria
- ARPKD
  - Electrolyte abnormalities and renal insufficiency
  - Anemia, thrombocytopenia, leukopenia
- ADPKD
  - US: It is the easiest diagnostic method. However, it is suboptimal for disease exclusion at age <40 years (2)
    - Renal enlargement is universal.
    - In at-risk patients: By age 30 years, two renal cysts (bilateral or unilateral) are 100% diagnostic. In children, it sometimes appears similar to ARPKD; may be diagnosed in utero.
    - Presence of hepatic cysts in young adults is pathognomonic for ADPKD.
    - In the absence of family history, bilateral renal enlargement and cysts make the diagnosis.
  - CT scan/MRI ideally should be part of the initial evaluation (2).
    - Kidney volume assessed by CT or MRI is a main predictor of progression.
    - Helpful in identifying cysts in other organs
    - In subjects <40, fewer than five cysts by MRI excludes the diagnosis (2).
- ARPKD
  - US: Kidneys are enlarged, homogeneously hyperechogenic (cortex and medulla).
  - CT scan is more sensitive if diagnosis is in doubt.
  - Presence of hepatic fibrosis helps the diagnosis.

Follow-Up Tests & Special Considerations

- Diagnosis and prevention of secondary problems because of renal and liver abnormalities
- Follow-up of combined renal volume to assess disease severity
- Beyond age 2 years, renal size decreases in ARPKD but continues to grow in ADPKD at an average rate of 5.27% per year. Total kidney volume identifies patients with progressive disease (2).

Diagnostic Procedures/Other

- Genetic testing is available for *PKD1* and *PKD2* in ADPKD when imaging

results are equivocal and for potential living related donors (4).

- For *PKHD1* in ARPKD, a prenatal diagnosis is feasible in about 72% of patients.

Test Interpretation

- ADPKD
  - Kidneys are diffusely cystic and, although enlarged, retain their general shape.
  - Cysts range from a few millimeters to several centimeters and are distributed evenly throughout the cortex and medulla.
  - They arise in all segments of the nephron, although they arise initially from the collecting ducts.
  - One kidney may be larger than the other.
- ARPKD
  - Disease is a spectrum, ranging from severe renal disease with mild liver damage to mild renal disease with severe liver damage.
  - Renal enlargement is due to fusiform dilatation of the collecting ducts in the cortex and medulla in the newborn period.
  - Liver lesion is diffuse but limited to fibrotic portal areas.

TREATMENT

GENERAL MEASURES

- HTN: moderate sodium restriction, weight control, and regular exercise
- Medications: ACE inhibitors; angiotensin receptor blockers (ARBs)
- Pain: narcotics and other analgesics; bed rest; limit NSAIDs (they worsen renal function)
- Urolithiasis: treated with alkalinization of urine and hydration therapy; surgery as needed
- UTIs/Infections of cysts: lipid-soluble antibiotics more effective (e.g., trimethoprim-sulfamethoxazole and chloramphenicol); fluoroquinolones also useful
- Dialysis for ESKD patients
- Hematuria: Reduce physical activity.

MEDICATION

- No specific drug therapy is yet available for PKD, although several studies are being conducted for specific treatments (2,5).
- HTN: should be very well controlled to prevent complications. ACE inhibitors are preferred if no contraindications are present.
- The use of antihypertensive medications has been found to decrease mortality (6).
- Hyperlipidemia: statins preferred

ISSUES FOR REFERRAL

- Nephrologist primary management
- Urologic consultation for management of symptomatic/infected cysts
- Genetic counseling is critical.

SURGERY/OTHER PROCEDURES

- Indications for surgical intervention
  - Uncontrollable HTN
  - Severe back and loin pain, abdominal fullness
  - Renal deterioration due to enlarging cysts
  - Hematuria/hemorrhage or recurrent UTI
- Open and laparoscopic cyst unroofing: may decrease pain and narcotics requirements; has not been proven to prevent renal failure or to prolong current renal function
- Percutaneous cyst aspiration ± injection of sclerosing agent; not usually performed secondary to recurrent fluid accumulation
- Renal transplant for ESKD

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Severe pain, gross hematuria with clots

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

None in early stages of the disease; avoid vigorous activity if disease advances.

Recurrent gross hematuria is secondary to trauma, associated with faster decline of renal function.

Patient Monitoring

- Monitor BP and renal function. Encourage hydration. Treat UTI and stone disease aggressively.
- Avoid nephrotoxic drugs.
- Creatinine and BP monitoring at least twice a year; more often as needed
- Screening for intracranial aneurysms (7)

DIET

- Low-protein diet may retard renal insufficiency.
- Limit caffeine because this might increase cyst growth.
- High water intake to decrease ADH >3 liters a day (5)

PROGNOSIS

- Renal failure in 2% by age 40 years; 23% by age 50 years; 48% by age 73 years
- ADPKD accounts for 10–15% of dialysis patients.
- No increased incidence of renal cell cancer

COMPLICATIONS

- Cyst rupture, infection, or hemorrhage
- Progression to renal failure
- Renal calculi

SEE ALSO

Chronic Kidney Disease

CODES

ICD10

- Q61.3 Polycystic kidney, unspecified
- Q61.19 Other polycystic kidney, infantile type
- Q61.2 Polycystic kidney, adult type

CLINICAL PEARLS

- Most PKD patients eventually develop ESKD. No specific treatment has been proven to prevent EKRD, but hydration and control of BP are reasonable goals and should be started soon.
- Patients may benefit from a nephrology consultation after the initial diagnosis to counsel regarding disease progression prevention. Then, they can be followed by primary care if the disease was an incidental finding or no significant kidney dysfunction is present.

POLYCYSTIC OVARIAN SYNDROME (PCOS)

Melissa Dennis, MD • Rachel Soffer Parritz, MD

BASICS

DESCRIPTION

- Polycystic ovarian syndrome (PCOS) is a common endocrine disorder with heterogeneous manifestations that affects 6–10% of the U.S. population.
- Hyperandrogenism leading to anovulation, typically presenting as amenorrhea or oligomenorrhea
- Diagnosis is based on clinical assessment, biochemical signs, and ultrasound findings.
- Diagnostic clinical characteristics include menstrual dysfunction, infertility, hirsutism, acne, obesity, and metabolic syndrome. The ovaries are often polycystic on imaging.
- The etiology of PCOS is unknown but can be modified by lifestyle factors.
- System(s) affected: reproductive, endocrine/metabolic, skin/exocrine
- Synonym(s): Stein-Leventhal syndrome; polycystic ovary disease

ALERT

- Condition may begin at puberty.
- Pregnancy does not resolve the syndrome.
- Predisposes to and is associated with obesity, hypertension, diabetes, metabolic syndrome, hyperlipidemia, infertility, insulin-resistance syndrome, endometrial hyperplasia, and uterine cancer

EPIDEMIOLOGY

Prevalence

- Incidence and prevalence are still highly debated due to a wide spectrum of diagnostic features: The National Institutes of Health (NIH) criteria require chronic anovulation in addition to clinical or biochemical signs of hyperandrogenism. The prevalence based on NIH criteria is 6.5–8%.
- Predominant age: reproductive age
- Predominant sex: females only

ETIOLOGY AND PATHOPHYSIOLOGY

- PCOS is a multifactorial functional disorder of unclear etiology.
- Recent evidence points to a primary role for insulin resistance with hyperinsulinemia.
- Increased GnRH pulsations in the hypothalamus lead to increased production of LH with limited production of FSH.
- Hyperandrogenism: Ovaries are the main source of excess androgens. Polycystic ovaries have thickened thecal layers, which secrete excess androgens in response to luteinizing hormone (LH). LH receptors are overexpressed in thecal and granulosa cells of polycystic ovaries.
- Ovarian follicles: Abnormal androgen signaling may account for abnormal folliculogenesis causing polycystic ovaries.
- Insulin resistance: Women with PCOS have insulin resistance similar to that in type 2 diabetes. Elevated levels of insulin decrease sex hormone–binding protein (SHBG), increasing bioavailability of testosterone. Insulin may also act directly on adrenal, ovary, and hypothalamus to enhance androgen production. Insulin resistance also causes elevated insulin levels.
- Insulin resistance may cause the frequently associated metabolic syndrome and frank diabetes mellitus.

Genetics

- Ultimate expression is likely a combination of polygenic and environmental factors.
- Recently implicated genes include DENND1A and THADA.

RISK FACTORS

See "Commonly Associated Conditions"; cause and effect are difficult to extricate in this disorder.

GENERAL PREVENTION

None known; focus on early diagnosis and treatment to prevent long-term complications.

COMMONLY ASSOCIATED CONDITIONS

- Infertility
- Obesity

- Obstructive sleep apnea
- Hypertension
- Diabetes mellitus
- Endometrial hyperplasia/carcinoma
- Fatty liver disease
- Mood disturbances and depression
- Hirsutism

DIAGNOSIS

HISTORY

- A comprehensive history, including a family history of diabetes and premature onset of cardiovascular disease, is important in the differential diagnosis.
- Focus on the onset and duration of the various signs of androgen excess, menstrual history, and concomitant medications, including the use of exogenous androgens (1).

PHYSICAL EXAM

- Vital signs: body mass index (BMI), high BP
- General appearance: central obesity, hirsutism, acne
- Skin: hair pattern and growth, acne, seborrhea, acanthosis nigricans
- Genitalia: ovarian enlargement

ALERT

Look specifically for signs of virilization, such as hair pattern, deepened voice, and clitoromegaly as they indicate significant testosterone levels beyond that of PCOS.

DIFFERENTIAL DIAGNOSIS

- Cushing syndrome
- HAIR-AN syndrome
- Testosterone-producing ovarian or adrenal tumor
- Prolactin-producing pituitary adenoma
- Hyperthecosis
- Adult-onset adrenal hyperplasia

- Partial congenital adrenal hyperplasia (21-hydroxylase deficiency)
- 11β-hydroxylase deficiency
- 17β-hydroxysteroid dehydrogenase deficiency
- Acromegaly
- Drug-induced hirsutism, oligo-ovulation (e.g., danazol, steroids, valproic acid)
- Thyroid disease

DIAGNOSTIC TESTS & INTERPRETATION

- The value of measurement of circulating androgens to document PCOS is uncertain but should include calculating free testosterone concentration using mass spectrometry of total testosterone and measurement of SHBG (2)[C].
- Most common diagnostic criteria used is Rotterdam criteria (need 2 of 3):
  - Oligo- or anovulation
  - Clinical and/or biochemical signs of hyper-androgenism
  - Transvaginal ultrasonographic polycystic ovaries and exclusion of other etiologies; therefore, consider exclusion of Cushing disease, congenital adrenal hyperplasia, and androgen-secreting tumors.
- More recent criteria also focus on similar criteria while acknowledging that there may be forms of PCOS without overt evidence of hyperandrogenism (3) [C].

Initial Tests (lab, imaging)

- Screening workup should include human chorionic gonadotropin (hCG), TSH, prolactin, FSH (exclude premature ovarian failure), DHEA-S, 17-OH progesterone, and testosterone level.
- Hirsute women should have a testosterone or free testosterone determination and a DHEA-S determination.
- Anovulation can be determined by a midluteal phase progesterone level.
- Consider 17-OH progesterone if congenital adrenal hyperplasia is a possibility.
- LH/FSH level ≥2.5 to 3/L in ~50% of women with PCOS, but LH testing is not generally necessary.
- Testosterone increased but <200 ng/dL (6.94 nmol/L).
- Typical findings in PCOS include mild elevation in DHEA-S but <800 μg/dL (20.8 μmol/L), mild increase in 17-OH progesterone level, increased estrogen

level, and decreased SHBG.
- Drugs that may alter lab results:
  – Oral contraceptives (OCs)
  – Steroids
  – Antidepressants
- Transvaginal ultrasound findings: one or both ovaries with ≥12 follicles measuring 2 to 9 mm or increased ovarian volume to 10 cm^3

Follow-Up Tests & Special Considerations
- Consider fasting serum glucose, insulin level, and plasminogen activator inhibitor-1 determinations to establish presence of insulin resistance and glucose intolerance, especially if diagnosis is in doubt.
- Overnight dexamethasone suppression test (Decadron 1 mg PO at 11:00 PM and fasting serum cortisol at 8:00 AM the next morning) to rule out Cushing syndrome in the appropriate setting
- Endometrial biopsy to rule out hyperplasia and/or carcinoma, if indicated
- If the syndrome is diagnosed, determination of fasting glucose and fasting lipid levels should be performed and formal glucose tolerance test is considered.

Test Interpretation
- Ovary usually enlarged with a smooth white glistening capsule
- Ovarian cortex lined with follicles in all stages of development, but most atretic
- Thecal cell proliferation with an increase in the stromal compartment

TREATMENT

GENERAL MEASURES
- No ideal treatment exists.
- Therapy must be individualized according to the needs and desires of each patient and should include lifestyle changes.

MEDICATION
Drug costs related to this condition are high.

First Line

- The goal of treatment in PCOS depends on symptoms and patient's goals for fertility.
- Treatment can be divided into four main categories: (i) Restore menses; (ii) decrease insulin resistance; (iii) ameliorate androgen excess; (iv) assist in fertility.
- Lifestyle changes including appropriate nutrition and exercise to decrease body weight by as little as 5% can restore ovulation and increase insulin sensitivity (4)[A],(5)[C].
- Menstrual irregularity when pregnancy not desired:
  - Low-dose OCs (30 to 35 μg); newer formulations containing progestins with lower androgenicity (e.g., norethindrone, desogestrel, norgestimate, drospirenone) may be particularly beneficial, but all OCs increase SHBG and decrease excess androgen.
  - If unable to tolerate OCs, then intermittent medroxyprogesterone (Provera) 10 mg PO or micronized progesterone (Crinone and Prometrium): 200mg PO for 10 to 14 days can be given every 1 to 3 months (2)[C]. Unlike OCPs, these will not help with signs of hyperandrogenism nor protect against pregnancy. Levonorgestrel IUD offers endometrial protection and pregnancy prevention but will not counteract hyperandrogenism (2)[C].
  - Metformin may help to correct metabolic abnormalities in women who are shown to be insulin resistant. Initial dose is 500 mg daily for 1 week, increasing by 500 mg/week to a total of 1,500 to 2,000 mg/day divided BID; take with food.
    - Overall, data support the usefulness of metformin on both cardiometabolic risk and reproduction assistance in PCOS women.
    - Thiazolidinediones may increase likelihood of ovulation and treat insulin resistance.
- If pregnancy desired:
  - Ovulation induction with clomiphene (Clomid, Serophene) and/or exogenous gonadotropins. Live birth rate with Clomid is 22.5%. Dosing starts on Day 5 with 50mg daily for 5 days.
  - Letrozole: an aromatase inhibitor for management of infertility. Live birth rate with letrozole is 27.5% which is significantly higher than with Clomid.

However, this effect may only be present in obese women.

- Metformin: 500 to 2,000 mg PO divided BID has been shown to improve hyperandrogenism and restore ovulation. Some providers will choose to continue metformin throughout the 1st trimester or the entire pregnancy if there is a history of spontaneous abortion or glucose intolerance. It does improve ovulation rates and insulin resistance but does not improve live birth rates alone or in combination with clomiphene when used for ovulation induction (6)[B].
- Has been demonstrated that metformin reduces the incidence of gestational diabetes

Second Line

- Spironolactone for androgen excess hirsutism not addressed by OC therapy. This medication is unsafe in pregnancy, and potassium levels must be followed closely when used. Cosmetic issues due to hyperandrogenism: Acne may respond best with OCs with low doses of cyproterone or drospirenone.
- Eflornithine hydrochloride 13.9% cream to inhibit hair growth

ADDITIONAL THERAPIES

Weight loss in overweight women results in biochemical and symptomatic improvement in most.

ISSUES FOR REFERRAL

- To reproductive endocrinologist for all women who cannot achieve pregnancy with Clomid
- High-risk pregnancies
- To endocrinologist if Cushing syndrome, congenital adrenal hyperplasia, or adrenal or ovarian tumors are found during the workup

SURGERY/OTHER PROCEDURES

- Ovarian wedge resection and laparoscopic laser drilling are controversial and rarely used today.
- Mechanical means of hair removal, including laser, electrolysis, waxing, and depilatory, may improve cosmesis.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Acupuncture assists with cycle normalization and weight loss.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Follow up at 6-month intervals to evaluate response to therapy and to monitor weight as well as medication side effects.

Patient Monitoring

- Counsel patient about the risk of endometrial and breast carcinoma, insulin resistance, and diabetes as well as obesity and its role in infertility.
- See patient frequently throughout the menstrual cycle, depending on which drug combination is used to induce ovulation.
- All patients with PCOS who have not had bleeding for 1 year should undergo endometrial biopsy.

DIET

In overweight patients, weight loss is the most successful therapy because it improves cardiovascular risk, insulin sensitivity, and menstrual patterns: Counsel on lifestyle dietary changes; consider referral to nutritionist and weight center. No specific diet plan is proven to be better than another.

PATIENT EDUCATION

- Provide patient with information about PCOS, such as from http://www.acog.org/.
- Discuss the chronic nature of this condition and the risks and benefits and side effects of potential treatments.
- Review the importance of weight loss, if applicable. Modest weight loss of 5–10% of initial body weight has been demonstrated to improve many of the features of PCOS.

PROGNOSIS

- Fertility prognosis is good but may need assisted reproductive technologies.
- Proper follow-up and screening can prevent endometrial carcinoma.
- Early detection of diabetes may decrease morbidity and mortality associated

with cardiovascular risk factor.

COMPLICATIONS

- Reproductive: infertility
- Metabolic: insulin resistance, diabetes mellitus, cardiovascular disease
- Psychosocial: increased anxiety, mood disorder, eating disorder, depression
- Predisposes to endometrial hyperplasia and as high as 9% lifetime risk of endometrial cancer

SEE ALSO

Algorithm: Amenorrhea, Secondary

CODES

ICD10

- E28.2 Polycystic ovarian syndrome
- L68.0 Hirsutism

CLINICAL PEARLS

- In the United States, 40% of women with PCOS are not obese.
- Chronic anovulation should be treated because chronic estrogen stimulation in absence of progesterone may lead to endometrial hyperplasia.
- Specific therapies must be individualized according to the needs and desires of each patient.

POLYCYTHEMIA VERA

Imola K. Osapay, MD

BASICS

DESCRIPTION

- Polycythemia vera (PV) is a chronic myeloproliferative clonal stem cell disorder marked by increased production of red blood cells (erythrocytosis) with excessive erythroid, myeloid, and megakaryocytic elements in the bone marrow.
- Morbidity and mortality are primarily related to complications from blood hyperviscosity leading to thrombosis development as well as malignant transformation.
- Myelofibrosis can develop in the bone marrow, leading to progressive hepatosplenomegaly.
- Synonyms: primary polycythemia; Vaquez disease; Waldenstrom disease; primary PV; PV rubra; polycythemia, splenomegalic; Vaquez-Osler disease

EPIDEMIOLOGY

Incidence

- Predominant age: 50 to 75 years; however, can occur in early adulthood and childhood
- Predominant sex: male > female (slightly)
- Incidence in the United States in 2012: 2.8/100,000 population of men and 1.3/100,000 population of women

Prevalence

In the United States in 2010, estimates ranged from 45 to 57 cases per 100,000 patients.

ETIOLOGY AND PATHOPHYSIOLOGY

JAK2 V617F mutation associated with clonal proliferative disorder

Genetics

JAK2 V617F (tyrosine kinase) mutation: >97% of patients with PV have an

activating mutation; this is helpful in differentiating from secondary erythrocytosis. Homozygote carriers will have higher incidence of symptoms such as pruritus but will not have higher incidence of disease than heterozygotes.

RISK FACTORS

- PV may be slightly more prevalent among Jews of Eastern European descent than other Europeans or Asians.
- Familial history is rare.

COMMONLY ASSOCIATED CONDITIONS

- Budd-Chiari syndrome
- Ischemic digits
- Mesenteric artery thrombosis
- Myocardial infarction
- Cerebrovascular accident or transient ischemic attack
- Venous thromboembolism and pulmonary embolism

DIAGNOSIS

HISTORY

- Patients may be asymptomatic or present with nonspecific complaints, including fatigue, malaise, weight loss, sweating, and subjective weakness.
- Erythromelalgia (burning pain of feet/hands, occasionally with erythema, pallor, cyanosis, or paresthesias)
- Pruritus, especially after bathing
- Arterial and venous occlusive events
- Headaches
- Blurred vision or blind spots
- Tinnitus, vertigo, dizziness
- Spontaneous bruising/bleeding
- Peptic ulcer disease (due to alterations in gastric mucosal blood flow)
- Early satiety due to enlarged spleen
- Bone pain (ribs and sternum)
- Gout

PHYSICAL EXAM

- Hypertension
- Splenomegaly (75%)
- Hepatomegaly (30%)
- Facial plethora
- Bone tenderness (especially ribs and sternum)
- Skin excoriations from significant pruritus
- Gouty tophi or arthritis

DIFFERENTIAL DIAGNOSIS

- Secondary erythrocytosis:
  - Sleep apnea
  - Emphysema
  - Cigarette smoking
  - Renal artery stenosis
  - Carbon monoxide poisoning
  - Drugs: diuretics, testosterone, erythropoietin
- Hemoglobinopathy
- Ectopic erythropoietin production
- Spurious polycythemia

DIAGNOSTIC TESTS & INTERPRETATION

CBC; if suspicion is high, then obtain erythropoietin level and gene testing for *JAK2 V617F*.

Initial Tests (lab, imaging)

- 2008 World Health Organization diagnostic criteria requires two major criteria and one minor or the first major criterion with two minor criteria (1).
  - Major criteria:
    - Hemoglobin (Hgb) >18.5 g/dL (men); Hgb >16.5 g/dL (women); or Hgb >17 g/dL (men) or Hgb >15 g/dL (women) if associated with a sustained increase of ≥2 g/dL from baseline that cannot be attributed to correction of iron deficiency.
    - Presence of *JAK2 V617F* or similar mutation such as *JAK2* exon 12 mutation

  - Minor criteria:
    - Bone marrow trilineage myeloproliferation
    - Serum erythropoietin level below normal
    - Endogenous erythroid colony (EEC) growth
- Diagnosis can be made reliably based on clinical symptoms, presence of *JAK2 V617* mutation, and low EPO (2).
- Other lab findings that are common but not specific
  - Hyperuricemia
  - Hypercholesterolemia
  - Elevated serum vitamin B_{12} levels
  - Prolonged PT, aPTT due to low plasma volume
- CT or US to assess for splenomegaly, although not necessary for diagnosis
- Arterial oxygen saturation (SaO2) and carboxyhemoglobin (COHb)
- Bone marrow biopsy is not necessary.

Diagnostic Procedures/Other

- Bone marrow aspiration if performed shows hypercellularity of erythroid, granulocytic and megakaryocytic lines, or myelofibrosis
- Cytogenetic testing (*JAK2 V617F*)

Test Interpretation

- If *JAK2 V617F* mutation testing is negative and the erythropoietin level is normal or high, then PV is excluded; investigate causes of secondary erythrocytosis.
- Other causes of erythrocytosis such as ectopic erythropoietin production from a renal tumor, hypoxia from chronic lung, or cyanotic heart disease can be excluded with low or undetectable serum erythropoietin level and normal oxygen saturation.

TREATMENT

GENERAL MEASURES

- Risk factors: Patients older than 60 years with history of thrombosis are high risk. Those who are less than 60 years with no history of thrombosis but with

elevated platelets (>150,000) are intermediate risk. Younger than 60 years, with normal platelets and no history of thrombosis are low risk.

- Phlebotomy and low-dose aspirin is first-line therapy for all patients.
- If secondary PV, address etiology: aggressive treatment of obstructive sleep apnea, COPD (esp. smoking cessation, renal disease, consider lowering dose in testosterone replacement.
- Phlebotomy reduces the blood hyperviscosity, improves platelet function, restores systemic pressures, and decreases risk of thrombosis.
- Phlebotomy:
  - Reduce hematocrit to <45%; will significantly lower rate of cardiovascular death and major thrombosis (3)[A]
  - Performed initially as often as every 2 to 3 days until normal hematocrit reached; phlebotomies of 250 to 500 mL. Reduce to 250 to 350 mL in elderly patients or patients with cerebrovascular disease.
  - Frail patients should have volume replaced with saline solution to avoid postural hypotension.
  - High risk for thrombosis or presence of elevated platelet count is indication for cytoreductive therapy.
  - Complications of phlebotomy: chronic iron deficiency (symptomatology: pica, angular stomatitis, and glossitis), possible muscle weakness, and dysphagia
- Other therapies:
  - Maintain hydration.
  - Pruritus therapy: H_1 and H_2 blockers, SSRIs, oatmeal baths, interferon 2b
  - Uric acid reduction therapy

MEDICATION

First Line

- Primary therapies:
  - Low-dose aspirin 81 mg PO has been associated with a statistically nonsignificant reduction in the risk of fatal thrombotic events without increasing bleeding complications when used in conjunction with phlebotomy (4)[A].
  - Hydroxyurea is recommended for patients at high risk for thrombosis (age

>60 years or history of thrombotic event) and with splenomegaly and hepatomegaly. Common starting dose 500 to 1,500 mg PO daily, titrating to control hematocrit and platelet count. Be aware that hydroxyurea can lead to higher risk of leukemic transformation (5)[A].

- Radioactive phosphorous (^{32}P) may control Hgb level and platelet count by destroying overactive marrow cells. May take up to 3 months before affecting cells. Consider for patients intolerant or nonadherent to hydroxyurea or short expected survival due to mutagenic potential.
- Tyrosine kinase inhibitor imatinib 400 to 800 mg daily was shown to have moderate cytoreductive effects in PV (6)[B].
- Pegylated interferon-α-2a is effective in controlling erythrocytosis, although dosing is generally limited secondary to intolerable side effects.
- Refer to hematologist/oncologist for further dosing and instructions.

- Symptomatic/adjunctive:
  - Allopurinol 300 mg/day PO for uric acid reduction
  - Cyproheptadine 4 to 16 mg PO daily as needed for pruritus
  - H_2-receptor blockers or antacids for GI hyperacidity; cimetidine is also used for pruritus.
  - SSRIs (paroxetine or fluoxetine) have shown some efficacy in controlling pruritus.
  - Ultraviolet light may help with pruritus.

Second Line

Myelosuppression: chlorambucil or busulfan; busulfan at 2 to 4 mg daily may be effective option for elderly patients with advanced PV refractory or intolerant to hydroxyurea, but significant rate of transformation was observed.

ISSUES FOR REFERRAL

Referral to a hematologist to assist in diagnosis and management

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Monitor hematocrit often and phlebotomize as needed to maintain target goal.

DIET

- Avoid high-sodium diet; can cause fluid retention
- Avoid iron supplement, a permissive chronic state of iron deficiency can help decrease blood production.

PATIENT EDUCATION

- Perform leg and ankle exercises to prevent clots.
- Continuous education regarding possible complications and seeking treatment early for any change or increase in symptoms

PROGNOSIS

- PV cannot be cured but can be controlled with treatment.
- Survival is >15 years with treatment.
- Patients are at risk for developing postpolycythemic myelofibrosis (PPMF) and an increased risk of malignant transformation.

COMPLICATIONS

- Splenomegaly or hepatomegaly
- Budd-Chiari syndrome
- Vascular thrombosis (major cause of death) (20%)
- Transformation to acute leukemia (5%)
- Transformation to myelofibrosis (10%)
- Hemorrhage
- Peptic ulcer
- Uric acid stones
- Secondary gout
- Increased risk for complications and mortality from surgical procedures. Assess risk/benefits and ensure optimal control of disorder before any elective surgery.

SEE ALSO

Myeloproliferative Neoplasms

CODES

ICD10

- D45 Polycythemia vera
- D75.1 Secondary polycythemia

CLINICAL PEARLS

- Erythrocytosis: Hb >18.5g/dL in men, >16.5g/dL in women
- *JAK2* mutations are an important component of myeloproliferative disorders.
- Common complications include thrombosis, malignant transformation, and myelofibrosis.
- All patients should take low-dose aspirin unless there is major bleeding or GI intolerance.
- Phlebotomy is first-line treatment, and consultation with an experienced hematologist is recommended.

POLYMYALGIA RHEUMATICA

Ronald G. Chambers, Jr., MD, FAAFP • Megan Babb, DO

BASICS

DESCRIPTION

- A clinical syndrome characterized by pain and stiffness of the shoulder, hip girdles, and neck. Some patients use the term stiffness and pain interchangeably (1).
- Primarily impacts the elderly, associated with morning stiffness and elevated markers of inflammation
- System(s) affected: musculoskeletal; hematologic/lymphatic/immunologic
- Synonym(s): senile rheumatic disease, polymyalgia rheumatica (PMR) syndrome, pseudo-polyarthrite rhizomélique

Geriatric Considerations

- Incidence increases with age
- Average age of onset ~70 years

Pediatric Considerations

Rare in patients <50 years of age. The peak incidence of PMR occurs between ages 70 and 80 years (2).

EPIDEMIOLOGY

Incidence

- Incidence increases after age 50 years. Incidence of PMR and giant cell arteritis (GCA) in the United States population is 50 and 18 per 100,000 people.
- Predominant sex: female > male (2 to 3:1)
- Most common in Caucasians, especially those of northern European ancestry

Prevalence

Prevalence in those over 50 years old: 700/100,000

ETIOLOGY AND PATHOPHYSIOLOGY

- Unknown. Symptoms appear to be related to enhanced immune system and periarticular inflammatory activity.
- Pathogenesis
  - Polygenic where multiple environmental and genetic factors play a role
  - Significant association found between histologic evidence of GCA and parvovirus B19 DNA in temporal artery specimen

Genetics

Associated with human leukocyte antigen determinants (HLA-DRB1*04 and DRB1*01 alleles) (3)

RISK FACTORS

- Age >50 years
- Presence of GCA

COMMONLY ASSOCIATED CONDITIONS

Concurrent GCA (temporal arteritis) in ~15–30% of patients; more commonly in females than males

DIAGNOSIS

HISTORY

- Suspect PMR in elderly patients with new onset of proximal limb pain and stiffness (neck, shoulder, hip).
- Difficulty rising from chair or combing hair are signs of proximal muscle involvement.
- Nighttime pain
- Difficulty arising from a chair or raising the arms
- Systemic symptoms in ~25% (fatigue, weight loss, low-grade fever)

PHYSICAL EXAM

- Decreased range of motion (ROM) of shoulders, neck, and hips
- Muscle strength is usually normal, although it may be limited by pain and/or stiffness.
- Muscle tenderness

- Disuse atrophy
- Synovitis of the small joints and tenosynovitis
- Coexisting carpal tunnel syndrome

DIFFERENTIAL DIAGNOSIS

- Rheumatoid arthritis (RA)
- Palindromic rheumatism
- Late-onset seronegative spondyloarthropathies (e.g., psoriatic arthritis, ankylosing spondylitis)
- Systemic lupus erythematosus; Sjögren syndrome; fibromyalgia
- Polymyositis-dermatomyositis (check creatine phosphokinase, aldolase)
- Thyroid disease
- Hyperparathyroidism, hypoparathyroidism
- Hypovitaminosis D
- Osteoarthritis
- Rotator cuff syndrome; adhesive capsulitis
- RS3PE syndrome (remitting seronegative symmetrical synovitis with pitting edema)
- Occult infection or malignancy (e.g., lymphoma, leukemia, myeloma, solid tumor)
- Myopathy (e.g., steroid, alcohol, electrolyte depletion)
- Depression

DIAGNOSTIC TESTS & INTERPRETATION

- Consider PMR in patients older than 50 years of age with proximal pain and stiffness. Obtain laboratory work and consider a diagnostic/therapeutic trial of low-dose steroids.
- Temporal artery biopsy if symptoms of GCA present
- ESR (Westergren) elevation >40 mm/hr
  - ESR generally elevated, sometimes >100 mm/hr
  - ESR normal (<40 mm/hr) in 7–22% of patients
- Elevated C-reactive protein
- Normochromic/normocytic anemia
- Anticyclic citrullinated peptide (anti-CCP) antibodies usually negative (in contrast to elderly-onset RA)

- Rheumatoid factor (RF): negative (5–10% of patients over 60 years have positive RF without RA)
- Mild elevations in liver function tests, especially alkaline phosphatase
- Antibodies to ferritin peptide may be a useful marker.
- Prednisone may alter lab results.
- Other disorders may cause elevation of ESR (e.g., infection, neoplasm, renal failure).
- Normal EMG
- Normal muscle histology

Initial Tests (lab, imaging)

- ESR (usually >40 mm/hr)
- C-reactive protein
- CBC
- MRI is not necessary for diagnosis but may show periarticular inflammation, tenosynovitis, and bursitis.
- US may show bursitis, tendinitis, and synovitis.
- MRI, PET, and temporal artery US may help in diagnosis of PMR.
- Recent ACR/EULAR Classification Criteria may help confirm the clinical diagnosis (4).
- A scoring algorithm was devised consisting of the following: morning stiffness >45 minutes (2 points), hip pain/limited ROM (1 point), absence of RF and anti-citrullinated protein antibody (ACPA) (2 points), and absence of peripheral joint pain (1 point). A score of >4 has been associated with 68% sensitivity and 78% specificity. Sensitivity and specificity increase with a positive temporal artery US.

Diagnostic Procedures/Other

Biopsy the temporal artery in patients with symptoms suggestive of GCA. Treat empirically pending biopsy results.

TREATMENT

GENERAL MEASURES

- Document diagnosis accurately as glucocorticoids can mask symptoms of

other diseases.

- Address risk of steroid-induced osteoporosis.
  - Obtain dual energy x-ray absorptiometry and check 25-OH vitamin D levels if necessary.
  - Consider antiresorptive therapies (bisphosphonates) based on recommendations for treatment of corticosteroid-induced osteoporosis.
- Encourage adequate calcium (1,500 mg/day) and vitamin D (800 to 1,000 U/day) supplementation.
- Physical therapy for ROM exercises, if needed

MEDICATION

First Line

- Prednisone: 10 to 20 mg/day PO initially; typically, expect a dramatic (diagnostic) response within days. 15 mg/day is effective in almost all patients.
  - May increase to 20 mg/day if no immediate response
  - If no response to 10 to 20 mg/day within a week, reconsider diagnosis.
- Divided-dose steroids (BID or TID) may be useful initially (especially if symptoms recur in the afternoon).
- Consider using delayed-release prednisone taken at bedtime, which may be more efficient in treating morning stiffness compared to conventional immediate-release prednisone.
- Begin slow taper by 2.5 mg decrements every 2 to 4 weeks to a dose of 7.5 to 10 mg/day. Below this dose, taper by 1 mg/month to prevent relapse.
- Increase prednisone for recurrence of symptoms (relapse common).
- Corticosteroid treatment often lasts at least 1 to 2 years.
- May be stopped at 6 to 12 months if patient is symptom free and there is a normal ESR on maintenance dose
- Contraindications
  - Use steroids with caution in patients with chronic heart failure, diabetes mellitus (or other immunocompromised state), and systemic fungal or bacterial infection.
  - Must treat infections concurrently if steroids are absolutely necessary
- Precautions

- Long-term steroid use (>2 years) is associated with adverse effects, including sodium and water retention, exacerbation of chronic heart failure, hypokalemia, increased susceptibility to infection, osteoporosis, fractures, hypertension, cataracts, glaucoma, avascular necrosis, depression, and weight gain.
- Patients may develop temporal arteritis while on low-dose corticosteroid treatment for polymyalgia. This requires an increase in dose to 40 to 60 mg.
- Alternate-day steroids are not effective.

Second Line

- NSAIDs usually are not adequate for pain relief.
- Methotrexate has a modest effect in reducing relapse rate and lowering the cumulative dose of steroid therapy.
- There is conflicting evidence for antitumor necrosis factor agents (anti-TNF) (infliximab, etanercept) regarding steroid-sparing effects.
- Possibly use of anti-interleukin (anti-IL) 6 therapy in the future (5,6)
- Corticosteroid injection in the shoulder may help reduce pain and duration of morning stiffness and allow for increased levels of activity.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Evaluate patients monthly initially and during medication taper; every 3 months otherwise
- Follow ESR as steroids are tapered; both ESR and CRP should decline as symptoms improve.
- Follow-up with patient for symptoms of GCA. Educate patient to report such symptoms immediately (e.g., headache, visual loss, and diplopia).
- Monitor side effects of corticosteroid therapy such as osteoporosis, hypertension, and hyperglycemia.
- If patient is asymptomatic, do not treat elevated ESR (i.e., do not increase the steroid dose in an attempt to normalize the ESR).

DIET

- Regular diet
- Aim for adequate calcium and vitamin D.

PATIENT EDUCATION

- Review adverse effects of corticosteroids.
- Discuss the symptoms of GCA and instruct the patient to present immediately if any occur.
- Follow up if symptoms recur during the steroid taper.
- Never abruptly stop steroids.
- Ensure calcium and vitamin D requirements are met.
- Patient resources:
  - Arthritis Foundation: www.arthritis.org/
  - American College of Rheumatology: http://www.rheumatology.org/Practice/Clinical/Patients/Diseases_And_Con

PROGNOSIS

- Most patients require at least 2 years of corticosteroid treatment.
- Exacerbation common if steroids tapered too quickly.
- Prognosis is very good with proper treatment.
- Relapse is common (in 25–50% of patients).
- Higher age at diagnosis, female sex, high baseline ESR, increased plasma viscosity, increased levels of soluble IL-6 receptor, or high initial steroid dose have been associated with a prolonged disease course and greater number of disease flares.

COMPLICATIONS

- Complications related to chronic steroid use
- Exacerbation of disease with taper of steroids; development of GCA (may occur when PMR is being treated adequately)

Arteritis, Temporal; Osteoarthritis; Arthritis, Rheumatoid (RA); Depression; Fibromyalgia; Polymyositis/Dermatomyositis

CODES

ICD10

- M35.3 Polymyalgia rheumatica
- M31.5 Giant cell arteritis with polymyalgia rheumatica

CLINICAL PEARLS

- Consider PMR in patients over 50 years who present with hip, neck and/or shoulder pain and stiffness.
- Normal ESR does not exclude the diagnosis of PMR.
- If there is not a dramatic and rapid response to steroids, reconsider the diagnosis.
- Adjust steroids according to symptoms, not ESR.

POLYMYOSITIS/DERMATOMYOSITIS

Christopher M. Wise, MD

BASICS

DESCRIPTION

- Systemic connective tissue disease characterized by inflammatory and degenerative changes in proximal muscles, sometimes accompanied by characteristic skin rash
  - If skin manifestations (Gottron sign [symmetric, scaly, violaceous, erythematous eruption over the extensor surfaces of the metacarpophalangeal and interphalangeal joints of the fingers]; heliotrope [reddish violaceous eruption on the upper eyelids]) are present, it is designated as dermatomyositis.
  - Different types of myositis include the following (1):
    - Idiopathic polymyositis
    - Idiopathic dermatomyositis
    - Polymyositis/dermatomyositis as an overlap (usually with lupus or systemic sclerosis or as part of mixed connective-tissue disease)
    - Myositis associated with malignancy
    - Necrotizing autoimmune myositis (often statin-associated) (2)
    - HIV-associated myopathy
- Inclusion-body myositis (IBM), a variant with atypical patterns of weakness and biopsy findings
- System(s) affected: cardiovascular, musculoskeletal, pulmonary, skin/exocrine
- Synonym(s): myositis; inflammatory myopathy; antisynthetase syndrome (subset with certain antibodies)

EPIDEMIOLOGY

Incidence

- Estimated at 1.2 to 19/million population/year (3)
- Predominant age: 5 to 15 years, 40 to 60 years, peak incidence in mid-40s
- Predominant sex: female > male (2:1)

Prevalence

2.4 to 33.8 patients/100,000 population (3)

Geriatric Considerations

Elderly patients with myositis or dermatomyositis are at increased risk of neoplasm.

Pediatric Considerations

Childhood dermatomyositis is likely a separate entity associated with cutaneous vasculitis and muscle calcifications.

ETIOLOGY AND PATHOPHYSIOLOGY

- Inflammatory process, mediated by T cells and cytokine release, leading to damage to muscle cells (predominantly skeletal muscles)
- In patients with IBM, degenerative mechanisms may be important.
- Unknown; potential viral, genetic factors

Genetics

Mild association with human leukocyte antigen (HLA)–DR3, HLA-DRw52

RISK FACTORS

Family history of autoimmune disease (e.g., systemic lupus, myositis) or vasculitis

COMMONLY ASSOCIATED CONDITIONS

- Malignancy (in 15–25%)
- Progressive systemic sclerosis
- Vasculitis
- Systemic lupus erythematosus (SLE)
- Mixed connective tissue disease

DIAGNOSIS

HISTORY

- Symmetric proximal muscle weakness (1) causing difficulty when
  - Arising from sitting or lying positions

  - Climbing stairs
  - Raising arms
- Joint pain/swelling
- Dysphagia
- Dyspnea
- Rash on face, eyelids, hands, arms

PHYSICAL EXAM

Proximal muscle weakness

- Shoulder muscles
- Hip girdle muscles (trouble standing from seated or squatting position, weak hip flexors in supine position)
- Muscle swelling, stiffness, induration
- Distal muscle weakness is seen only in patients with IBM.
- Rash over face (eyelids, nasolabial folds), upper chest, dorsal hands (especially knuckle pads), fingers (“mechanic’s hands”)
- Periorbital edema
- Calcinosis cutis (childhood cases)
- Mesenteric arterial insufficiency/infarction (childhood cases)
- Cardiac impairment; arrhythmia, failure

DIFFERENTIAL DIAGNOSIS

- Vasculitis
- Progressive systemic sclerosis
- SLE
- Rheumatoid arthritis
- Muscular dystrophy
- Eaton-Lambert syndrome
- Sarcoidosis
- Amyotrophic lateral sclerosis
- Endocrine disorders
  - Thyroid disease
  - Cushing syndrome
- Infectious myositis (viral, bacterial, parasitic)
- Drug-induced myopathies:

  - Cholesterol-lowering agents (statins)
  - Colchicine
  - Corticosteroids
  - Ethanol
  - Chloroquine
  - Zidovudine
- Electrolyte disorders (magnesium, calcium, potassium)
- Heritable metabolic myopathies
- Sleep-apnea syndrome

DIAGNOSTIC TESTS & INTERPRETATION

- Diagnosis of muscle component (myositis) usually relies on four findings:
  - Weakness
  - Creatine kinase (CK) and/or aldolase elevation
  - Abnormal electromyogram (EMG)
  - Findings on muscle biopsy
- Presence of compatible skin rash of dermatomyositis

Initial Tests (lab, imaging)

- Increased CK, aldolase
- Increased serum AST (aspartate aminotransferase)
- Increased LDH (lactate dehydrogenase)
- Myoglobinuria
- Increased ESR
- Positive rheumatoid factor (<50% of patients)
- Positive antinuclear antibody (ANA) (>50% of patients)
- Leukocytosis (<50% of patients)
- Anemia (<50% of patients)
- Hyperglobulinemia (<50% of patients)
- Anti-HMGCR (3-hydroxy-3-methylglutaryl-coenzyme A reductase) seen in patient with statin-associated necrotizing autoimmune myositis
- Myositis-specific antibodies (antisynthetase antibodies) described in a minority of patients:
  - Anti-Jo-1 is the most common but has been found in <20% of patients.
  - Associated with an increased incidence of interstitial lung disease

- Chest radiograph as part of initial evaluation to assess for associated pulmonary involvement or malignancy

Follow-Up Tests & Special Considerations

- Changes in muscle enzymes (CK or aldolase) correlate with improvement and worsening.
- MRI to assess muscle edema and inflammation may be used in some patients to determine best biopsy site or response to therapy.

Diagnostic Procedures/Other

- EMG: muscle irritability, low-amplitude potentials, polyphasic action potentials, fibrillations
- Muscle biopsy (deltoid or quadriceps femoris)

Test Interpretation

- Microscopic findings:
  - Muscle fiber degeneration
  - Phagocytosis of muscle debris
  - Perifascicular muscle fiber atrophy
  - Inflammatory cell infiltrates in adult form
  - Via electron microscopy: inclusion bodies (IBM only)
  - Sarcoplasmic basophilia
- Muscle fiber increased in size
- Vasculopathy (childhood polymyositis/dermatomyositis)

TREATMENT

GENERAL MEASURES

General evaluation for malignancy in all adults, particularly with dermatomyositis, at initial evaluation and during follow up

MEDICATION

First Line

- Prednisone
  - 40 to 80 mg/day PO in divided doses (4)[B]

  - Consolidate doses and reduce prednisone slowly when enzyme levels are normal.
  - Probably need to continue 5 to 10 mg/day for maintenance in most patients.
- For steroid-refractory or steroid-dependent patients: azathioprine 1 mg/kg PO (arthritis dose) once daily or BID
  - Methotrexate 10 to 25 mg PO weekly, useful in most steroid-resistant patients
- Rash of dermatomyositis may require topical steroids or oral. hydroxychloroquine.
- Patients with IBM have very poor response to steroids and other first- and second-line drugs in general.

Second Line

- Other immunosuppressant drugs (e.g., cyclophosphamide, chlorambucil, cyclosporine, mycophenolate, tacrolimus) can be added to steroids.
- Combination methotrexate and azathioprine also may be useful in refractory cases.
- IVIG (5)[B] and rituximab (6)[B] have been reported to be helpful in a small series of patients with refractory disease.
- Contraindications: Methotrexate is contraindicated with previous liver disease, alcohol use, pregnancy, and underlying renal disease (use with extreme caution in patients with serum creatinine >1.5 mg/dL in general).
- Precautions
  - Prednisone: Adverse effects associated with long-term steroid use include adrenal suppression, sodium and water retention, hypokalemia, osteoporosis, cataracts, and increased susceptibility to infection.
  - Azathioprine: Adverse effects include bone marrow suppression, increased liver function tests, and increased risk of infection.
  - Methotrexate: Adverse effects include stomatitis, bone marrow suppression, pneumonitis, and risk of liver fibrosis and cirrhosis with prolonged use.

ISSUES FOR REFERRAL

- Diagnostic uncertainty, usually related to elevated muscle enzymes without typical symptoms of findings of muscle weakness
- Poor response to initial steroid therapy

- Excessive steroid requirement (unable to taper prednisone to <20 mg/day after 4 to 6 months)

SURGERY/OTHER PROCEDURES

None indicated, other than initial biopsy

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Inability to stand, ambulate
- Respiratory difficulty
- Fever or other signs of infection
- Inpatient evaluation seldom needed

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Follow muscle enzymes along with muscle strength and functional capacity.
- Monitor for steroid-induced complications (e.g., hypokalemia, hypertension, and hyperglycemia).
- Bone densitometry and consideration of calcium, vitamin D, and bisphosphonate therapy
- If azathioprine, methotrexate, or other immunosuppressant is used, appropriate laboratory monitoring should be done periodically (e.g., hematology, liver enzymes, and creatinine).
- Attempt to decrease and/or discontinue steroid dose as patient responds to therapy.
- Maintain immunosuppression until patient’s muscle strength stabilizes for prolonged period depending on individual patient parameters, risks of medication, risk of relapse; time period undefined (months, years).

DIET

Moderation of caloric and sodium intake to avoid weight gain from corticosteroid therapy.

PATIENT EDUCATION

- Curtail excess physical activity in early phases when muscles enzymes are markedly elevated.
- Emphasize range-of-motion exercises.
- Gradually introduce muscle strengthening when muscle enzymes are normal or improved and stable (7)[B].

PROGNOSIS

- Residual weakness: 30%
- Persistent active disease: 20%
- 5-year survival 65–75%, but mortality is 3-fold higher than general population (8,9).
- Survival is worse for women and African Americans and those with dermatomyositis, IBM, or cancer.
- Most patients improve with therapy.
- Patients with IBM respond poorly to most therapies (10).
- 20–50% have full recovery.

COMPLICATIONS

- Pneumonia
- Infection
- Myocardial infarction
- Carcinoma (especially breast, lung)
- Severe dysphagia
- Respiratory impairment due to muscle weakness, interstitial lung disease
- Aspiration pneumonitis
- Steroid myopathy
- Steroid-induced diabetes, hypertension, hypokalemia, osteoporosis

CODES

ICD10

- M33.20 Polymyositis, organ involvement unspecified
- M33.90 Dermatopolymyositis, unspecified, organ involvement unspecified
- M33.92 Dermatopolymyositis, unspecified with myopathy

CLINICAL PEARLS

- Corticosteroids alone may be sufficient in patients who have rapid improvement in weakness and muscle enzymes. However, most patients require azathioprine, methotrexate, or other immunosuppressive medications.
- The risk of associated malignancy is higher in patients >50 years and in those with cutaneous manifestations.
- Elevated muscle enzymes (e.g., CK and aldolase) are seen frequently as transient phenomena in patients with febrile illness and injuries; may return to normal on repeat.
- In patients with persistently elevated muscle enzymes and symptoms and findings of muscle weakness, EMG followed by muscle biopsy should be the initial studies considered.
- Suspect IBM in older patients with very slow onset and progression of symptoms, poor response to steroids and immunosuppressive therapy, and atypical patterns (asymmetric, sometimes distal) of muscle weakness.
- Suspect autoimmune necrotizing myositis in patients who develop myopathy while taking lipid-lowering drugs (statins) but fail to improve or worsen after withdrawal of statin therapy.

POPLITEAL (BAKER) CYST

Shane L. Larson, MD

BASICS

DESCRIPTION

- A fluid-filled synovial sac arising in the popliteal fossa as a distention of (typically) the gastrocnemial-semimembranous bursa. Not a true cyst
- Can be unilateral or bilateral
- Most frequent cystic mass around the knee (1)
- Primary cysts are a distention of the bursa (arise independently without an intra-articular disorder).
- Secondary cysts occur if there is a communication between the bursa and knee joint, allowing articular fluid to fill the cyst.
- Associated with synovial inflammation

EPIDEMIOLOGY

Incidence

- Bimodal distribution
  - Children ages 4 to 7 years
  - Adults increasing with age
- Primary cysts usually seen in children <15 years
- Secondary cysts seen in adults

Prevalence

- Variable adult prevalence of 19–47% in symptomatic knees and 2–5% in asymptomatic knees.
- In children: 6.3% in symptomatic knees; 2.4% in asymptomatic knees

ETIOLOGY AND PATHOPHYSIOLOGY

Associated intra-articular pathology includes

- Meniscal tears, mostly of the posterior horn
- Anterior cruciate ligament (ACL) insufficiency
- Degenerative articular cartilage lesions

- Rheumatoid arthritis (20%)
- Osteoarthritis (50%)
- Osteochondritis
- Gout (14%)
- Other potential factors
  - Infectious arthritis
  - Polyarthritis
  - Villonodular synovitis
  - Lymphoma
  - Sarcoidosis
  - Connective tissue diseases (2)
- Extension or herniation of synovial membrane of the knee joint capsule or connection of normal bursa with the joint capsule
- May result from increased intra-articular pressure
- Commonly seen with knee effusions
- Direct trauma to the bursa is likely the primary cause in children because of no communication between the bursa and the joint.
- A valve-like mechanism allowing one-way passage of fluid from the joint to the bursal connection has been described.

RISK FACTORS

- Osteoarthritis of knee (most common) (3)[B]
- Rheumatoid arthritis
- Meniscal degeneration or tear
- Advancing age
- Ligamentous insufficiency

COMMONLY ASSOCIATED CONDITIONS

Any condition causing knee joint effusion

DIAGNOSIS

HISTORY

- Painless mass arising in the popliteal fossa
- Most cysts are asymptomatic.

- Dull ache if cyst is large enough to impede joint motion—typically a restriction of flexion
- Painful if cyst ruptures
- Large cysts may cause entrapment neuropathy of the tibial nerve.
- Vascular compression, most commonly of the popliteal vein, may produce claudication or thrombophlebitis.
- Activity alters the cyst size.

PHYSICAL EXAM

- Examine in full extension and 90 degrees of flexion.
- Foucher sign: Mass increases with extension and disappears with flexion.
- Most commonly found in medial aspect of popliteal fossa lateral to the head of the gastrocnemius and medial to the neurovascular bundle
- Cyst is easiest to palpate when knee is slightly flexed and may occasionally be fluctuant or tender.
- Transillumination helps distinguish cyst from solid mass.
- Ruptured cysts are typically painful with associated swelling and bruising over the ipsilateral calf and ankle at the medial malleolus (Crescent sign).
- Ruptured cysts also are associated with pseudothrombophlebitis, and rarely, compartment syndrome (5).

DIFFERENTIAL DIAGNOSIS

- Infection/abscess
- Lipoma, liposarcoma
- Fibroma, fibrosarcoma
- Hematoma
- Deep venous thrombosis
- Vascular tumor
- Popliteal vein varices
- Xanthoma
- Aneurysm (rare)
- Ganglion cyst
- Thrombophlebitis
- Muscular herniation (rare, related to trauma)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- CBC, ESR (if septic arthritis suspected)
- Ensure not a popliteal aneurysm prior to aspiration. Send aspirate for cell count and culture to determine if fluid is infectious, inflammatory, or mechanical.
- Ultrasound confirms presence and size; Doppler, can differentiate Baker cysts from popliteal vessel aneurysms, DVT, or soft tissue tumors (4).
- MRI helps assess derangements of internal joint structures and to identify cyst leakage.

Follow-Up Tests & Special Considerations

- Consider observation over invasive testing in children.
- Radiographs may show soft tissue density posteriorly.
- Arthrography may demonstrate communication with joint capsule or rupture.
- CT arthrography is superior for visualizing cystic details and can help distinguish lipomas, aneurysms, and malignancies from cysts.

TREATMENT

GENERAL MEASURES

- No treatment if asymptomatic
- Treat any associated underlying conditions.
- Compressive wrap or sleeve for comfort.

MEDICATION

If etiology is identified from cellular fluid examination, treat the underlying condition.

First Line

Analgesics and NSAIDs for symptomatic relief

ADDITIONAL THERAPIES

- Physical therapy improves knee ROM and strength, particularly with coexisting pathology.

- Temporary relief with needle aspiration; recurrence common
- Improvement in joint ROM, knee pain, swelling, accompanied reduction in bursa size after aspiration, and intra-articular/intracystic corticosteroid injection (6)[B]
- A combination of physical therapy and corticosteroid injection leads to best improvements in pain, function, and reduction in cyst size (7)[A].
- Sclerotherapy injections of ethanol or dextrose/sodium morrhuate shown to have good results in small studies (8)[B].

SURGERY/OTHER PROCEDURES

- Consider excision when symptoms persist despite treatment or no etiology is found.
- Surgery usually not required in children
- Recurrence after standard surgery is common and is highest if chondral lesions are present.
- Arthroscopic surgery is highly successful if a valvular mechanism is identified and intra-articular pathology is treated (9,10)[B].
- A modified surgical technique in children has proved effective without recurrence (11)[B].
- Excision via arthroscopy or open procedure often requires concomitant treatment of underlying pathology (12)[B].

ONGOING CARE

PROGNOSIS

- Variable; many cysts remain asymptomatic.
- Some cysts resolve with treatment of underlying etiology (e.g., gout, rheumatoid arthritis).
- In children, most cysts resolve without treatment.

COMPLICATIONS

- Compartment syndrome in ruptured cyst
- Thrombophlebitis from compression of the popliteal vein
- Infection of popliteal cyst

- Hemorrhage into cyst if on anticoagulants

SEE ALSO

Algorithm: Knee Pain

CODES

ICD10

- M71.20 Synovial cyst of popliteal space [Baker], unspecified knee
- M71.21 Synovial cyst of popliteal space [Baker], right knee
- M71.22 Synovial cyst of popliteal space [Baker], left knee

CLINICAL PEARLS

- Conservative treatment of Baker cysts is preferred in children, as most will spontaneously resolve.
- In adults, treatment of underlying cause may resolve Baker cysts.
- Pain, bruising, and swelling over the medial malleolus (crescent sign) suggests cyst rupture.

PORTAL HYPERTENSION

Walter M. Kim, MD, PhD • Jyoti Ramakrishna, MD

BASICS

DESCRIPTION

- Increased portal venous pressure >5 mm Hg that occurs in association with splanchnic vasodilatation, portosystemic collateral formation, and hyperdynamic circulation
- Most commonly secondary to elevated hepatic venous pressure gradient (HVPG; the gradient between portal and central venous pressures)
- Course is generally progressive, with risk of complications including acute variceal bleeding, ascites, encephalopathy, and hepatorenal syndrome.

EPIDEMIOLOGY

Incidence

- Prevalence: <200,000 persons in the United States
- Predominant age: adult
- Predominant sex: male > female

ETIOLOGY AND PATHOPHYSIOLOGY

- Causes generally classified as follows:
  - Prehepatic (portal vein thrombosis or obstruction)
  - Intrahepatic (most commonly cirrhosis)
  - Posthepatic (hepatic vein thrombosis, Budd-Chiari syndrome, right-sided heart failure)
- Cirrhosis accounts for 90% of intrahepatic cases; may be due to the following:
  - Virus (hepatitis B, hepatitis C, hepatitis D)
  - Alcoholism
  - Schistosomiasis
  - Wilson disease
  - Hemochromatosis
  - Primary biliary cirrhosis (PBC)
  - Sarcoidosis

- Increased HVPG results in venous collateral formation in the distal esophagus, proximal stomach, rectum, and umbilicus.
- Gastroesophageal variceal formation is found in 40% of patients with portal hypertension.
- Progression of portal hypertension results in splanchnic vasodilation and angiogenesis.

Genetics

No known genetic patterns except those associated with specific hepatic diseases that cause portal hypertension

RISK FACTORS

See “Etiology.”

Pediatric Considerations

In children, portal vein thrombosis is the most common extrahepatic cause; intrahepatic causes are more likely to be biliary atresia, viral hepatitis, and metabolic liver disease.

DIAGNOSIS

HISTORY

- Weakness/fatigue
- Jaundice
- Symptoms of heart failure including chest pain, shortness of breath, and/or edema
- Hematemesis
- Melena
- Oliguria
- History of chronic liver disease
- Alcoholic hepatitis
- Alcohol abuse

PHYSICAL EXAM

- Exam findings may be general or related to specific complications.
- General

  - Pallor
  - Icterus
  - Digital clubbing
  - Palmar erythema
  - Splenomegaly
  - Caput medusa
  - Spider angiomata
  - Umbilical bruit
  - Hemorrhoids
  - Gynecomastia
  - Testicular atrophy
- Gastroesophageal varices
  - Hypotension
  - Tachycardia
- Ascites
  - Distended abdomen
  - Fluid wave
  - Shifting dullness with percussion
- Hepatic encephalopathy
  - Confusion/coma
  - Asterixis
  - Hyperreflexia

DIFFERENTIAL DIAGNOSIS

Usually related to specific presentations

- Gastroesophageal varices with hemorrhage
  - Portal hypertensive gastropathy
  - Hemorrhagic gastritis
  - Peptic ulcer disease
  - Mallory-Weiss tear
- Ascites
  - Spontaneous bacterial peritonitis (SBP)
  - Pancreatic ascites
  - Peritoneal carcinomatosis
  - Tuberculous peritonitis

  - Nephrotic syndrome
  - Fluid overload from heart failure
  - Hepatic malignancy
- Hepatic encephalopathy
  - Delirium tremens
  - Intracranial hemorrhage
  - Sedative abuse
  - Uremia
- Hepatorenal syndrome
  - Drug nephrotoxicity
  - Renal tubular necrosis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

Direct calculation of HVPG (approximation of the gradient in pressure between portal vein and IVC):

- HVPG = wedged hepatic venous pressure (WHVP) – free hepatic venous pressure (FHVP)
- HVPG >10, esophageal varices generally develop.
- WHVP is estimated by occlusion of the hepatic vein by a balloon catheter and measurement of the proximal static column of blood.
- FHVP is estimated by direct measurement of the patent hepatic vein, intra-abdominal inferior vena cava, or right atrium.
- Nonspecific changes associated with underlying disease:
  - Hypersplenism: anemia (also may be due to malnutrition or bleeding), leukopenia, thrombocytopenia
  - Hepatic dysfunction
    - Hypoalbuminemia
    - Hyperbilirubinemia
    - Elevated alkaline phosphatase
    - Elevated liver enzymes (AST, ALT)
    - Abnormal clotting (prothrombin time, international normalized ratio, partial thromboplastin time)
  - GI bleeding

    - Iron deficiency anemia
    - Elevated serum ammonia
    - Fecal occult blood
    - Thrombocytopenia
- Hepatorenal syndrome
    - Elevated serum creatinine (Cr), blood urea nitrogen (BUN)
    - Urine Na <5 mEq/L (<20 mmol/L)
- US and CT scan/MRI may detect cirrhosis, splenomegaly, ascites, and varices.
- US/duplex Doppler
    - Can determine presence and direction of flow in portal and hepatic veins
    - Useful in diagnosing portal vein thrombosis, shunt thrombosis, or the presence of ascites
- CT scan/MRI: angiographic measurement of hepatic venous wedge pressure via jugular or femoral vein
    - Correlates with portal pressure
    - Risk of variceal bleeding is increased if hepatic venous pressure gradient >12 mm Hg.
- Upper GI series may outline varices in esophagus and stomach.
- Transient elastography is an emerging method to determine hepatic fibrosis and to predict portal hypertension (1).

Diagnostic Procedures/Other

Endoscopy can diagnose esophageal and gastric varices and portal hypertensive gastropathy.

Test Interpretation

Specific for underlying disease

TREATMENT

GENERAL MEASURES

- Avoid sedatives that may precipitate encephalopathy.
- Limit sodium intake because cirrhotic patients avidly retain sodium.

MEDICATION

Therapy for encephalopathy: See "Hepatic Encephalopathy."

First Line

- Prophylaxis against variceal bleeding (2,3)[A]:
  - Nonselective β-blockade
    - Propranolol: start with 10 to 20 mg/day PO BID to TID
    - Nadolol: 40 to 80 mg/day PO once-daily dosing
  - Doses may be titrated up as tolerated to maximum recommended doses; goal resting HR of 55 to 60 bpm
- Therapy for acute variceal hemorrhage:
  - Vasopressin: start with 0.2 to 0.4 U/min IV; increase to maximum dose 1 U/min as needed; pediatric dose: 0.002 to 0.005 U/kg/min; do not exceed 0.01 U/kg/min. After bleeding stops, continue at same dose for 12 hours and then taper off over 24 to 48 hours.
  - Octreotide: 50μg IV bolus, followed by 25 to 50 μg/hr continuous infusion; pediatric dose: 1 μg/kg bolus followed by 1 μg/kg/hr is used traditionally; treat for up to 5 days.
- For prevention of recurrence and for overall reduction in mortality:
  - Propranolol: 10 to 60 mg/day PO BID to QID; pediatric dose: 0.5 to 1 mg/kg/day PO divided q6–8h
  - Nadolol: 40 to 80 mg/day PO reduces portal venous blood inflow by blocking the adrenergic dilatation of the mesenteric arterioles.
  - Tetrandrine, a calcium channel blocker, also has been found to reduce the rate of rebleeding with fewer side effects.
- Initial treatment for ascites (along with salt and fluid restriction):
  - Furosemide: 20 to 40 mg/day PO; pediatric dose: 1 to 2 mg/kg/dose PO ± IV albumin infusion
  - Spironolactone: 50 to 100 mg/day PO; pediatric dose: 1 to 3 mg/kg/day PO

Second Line

- Terlipressin (2 mg IV q4h; titrate down to 1 mg IV q4h once hemorrhage is controlled; may be used for up to 48 hours) is a more selective splanchnic vasoconstrictor and may be associated with fewer complications. It is currently used when standard therapy with somatostatin or octreotide fails.

- Addition of nitrates, such as nitroglycerin or isosorbide mononitrate, reduces portal pressures and bleeding rates and has been shown to reduce mortality. Because the risk–benefit ratio is not clear, nitrates are not considered first-line treatment.
- Studies are ongoing for possible benefits of other agents including simvastatin, clonidine, verapamil, and losartan.

ISSUES FOR REFERRAL

Patients with portal hypertension should be managed longitudinally by both a primary care physician and a gastroenterologist.

SURGERY/OTHER PROCEDURES

- Treatments available for specific complications of portal hypertension (in addition to or if refractory to medications):
  - Gastroesophageal varices with hemorrhage
    - Endoscopic variceal banding or sclerosis (the first-line treatment in many cases for acute hemorrhage) within 12 hours of presentation (4)[A]
    - Balloon tamponade (not used commonly when endoscopic treatment is available)
    - Transjugular intrahepatic portosystemic shunt (TIPS)
    - Portocaval shunting
  - Ascites refractory to medical management
    - Large-volume paracentesis
    - Peritoneovenous shunt
    - TIPS
- Liver transplantation should be considered for patients with advanced disease.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Acute GI bleeding should be managed in the inpatient setting, either on the regular medical floor if the patient is hemodynamically stable or occasionally in the ICU if the patient is unstable.
- Patients with mental status changes from encephalopathy need to be evaluated in the inpatient setting.
- Admission criteria/initial stabilization

- Acute bleeding from the intestinal tract, either vomiting or per rectum
- Acute confusional state/mental status changes
- If acute variceal bleeding:
  - Type and cross patient's blood.
  - Initial resuscitation with isotonic fluid until packed RBCs are available
  - Correct coagulopathy with vitamin K and fresh frozen plasma (FFP).
  - Endoscopy as soon as the patient is stabilized (for diagnosis and treatment)
- Avoid sedatives that may precipitate encephalopathy.
- Limit sodium administration because cirrhotic patients avidly retain sodium.
- Restrict protein only if encephalopathic.

ALERT

If the patient is an active alcohol drinker, watch for signs and symptoms of withdrawal. Follow inpatient protocols for alcohol withdrawal management.

- Use isotonic fluid for hydration.
- Discharge criteria
  - For GI bleeding:
    - No active bleeding in 24 hours
    - Stable hemoglobin and hematocrit
    - Hemodynamically stable (especially heart rate)
  - For encephalopathy: improvement in or resolution of mental status changes to baseline

ONGOING CARE

DIET

In patients with cirrhosis, sodium restriction is important because cirrhotic patients avidly retain sodium.

PATIENT EDUCATION

Refrain from drinking alcohol. Resources for patients who have difficulty with not drinking alcohol can be obtained from Alcoholics Anonymous at

http://www.aa.org/.

PROGNOSIS

- Hepatic reserve defined by Child-Pugh classification: rating based on encephalopathy, ascites, bilirubin, albumin, prothrombin
- Variceal bleeding
  - 1/3 of patients with known varices will bleed eventually.
  - 50% rebleed, usually within 2 years, unless portal pressure is reduced by surgical or TIPS procedure.
  - 15–20% mortality rate
- Ascites and encephalopathy often recur.
- Prognosis of patients with ascites is poor: 50% 1-year survival without liver transplant (compared with 90% for patients with cirrhosis and no ascites)

CODES

ICD10

K76.6 Portal hypertension

CLINICAL PEARLS

- Portal hypertension can be diagnosed based on physical examination in the setting of known risk factors, specifically cirrhosis.
- Endoscopic treatment is successful for acute variceal hemorrhage 85% of the time.
- Prognosis of patients with ascites is poor: 50% 1-year survival without liver transplant (compared with 90% for patients with cirrhosis and no ascites).
- Advantages and disadvantages of balloon tamponade for acute variceal bleed:
  - Advantages include rapid and often effective control of bleeding (30–90%) and common availability of device.
  - Disadvantages include recurrence of bleeding when balloon is deflated, patient discomfort, and risk of esophageal perforation.

POSTCONCUSSION SYNDROME (MILD TRAUMATIC BRAIN INJURY)

Vicki R. Nelson, MD, PhD

BASICS

DESCRIPTION

- Postconcussion syndrome (PCS) is a constellation of symptoms involving physical, cognitive, and/or behavioral symptoms that persist after a concussion (mild traumatic brain injury [MTBI]) and may continue for weeks to years (1).
- It is unclear at what point concussive symptoms become postconcussive syndrome. Symptoms persistent beyond 4 weeks following MTBI is frequently used as a time point, but a consensus has not been established.
- Symptoms of PCS can include any symptom of concussion (1,2).
  - Cognitive
    - Poor focus
    - Poor organization
    - Diminished academic/intellectual performance
    - Slowed response time
  - Physical
    - Headache
    - Nausea
    - Visual changes
    - Light and noise sensitivity
    - Tinnitus
    - Dizziness and balance problems
    - Fatigue and sleep disturbance
  - Behavioral
    - Depression
    - Irritability/emotional lability
    - Apathy
    - Increased sensitivity to alcohol

- Diagnosis is based on history and clinical symptoms.

EPIDEMIOLOGY

Incidence

The reported range of MTBI patients who develop PCS varies widely between 5% and 80%.

- The variation is due to difficulty in differentiating postconcussion *symptoms* from postconcussion *syndrome*.
- Consensus is that 80–90% of concussion victims recover from postconcussion *symptoms* within 7 to 10 days, slightly longer in children/adolescents (3). A diagnosis of PCS is generally made in those patients whose concussive symptoms persist beyond the usual course.

Prevalence

Predominant sex: Female > male, although female gender is not universally considered a risk factor.

ETIOLOGY AND PATHOPHYSIOLOGY

- Controversial; exact mechanism(s) unknown
- It is postulated that microscopic axonal injury from shearing forces leads to inflammation that causes secondary brain injury.
- There is conflicting data on structural brain damage and the correlation of imaging findings with physical symptoms (1,2,4,5).
- Because the pathophysiology of PCS is not well understood and because of symptom overlap with other psychiatric conditions, PCS remains a difficult condition to diagnose and to manage.
  - Only some people with MTBI develop PCS; it is unclear what causes PCS symptoms to occur and to persist (5).
  - Psychiatric factors are commonly associated with, and may play a role in, the development of PCS. It can be a challenge to differentiate pure psychiatric dysfunction from PCS (1,5,6).
  - Neuropsychiatry evaluation may be helpful to differentiate PCS from psychiatric disorders.
  - Patient reported high symptom burden following MTBI is associated with increased risk of PCS (7)[B].

RISK FACTORS

- Retrograde amnesia, migraine, self-reported cognitive decline, insomnia, noise and light sensitivity developing or worsening in the first day to weeks after MTBI (1,4)
- Preexisting psychiatric disease including depression, anxiety, personality disorder, and posttraumatic stress disorder (PTSD)
- Preexisting expectation of poor outcomes in patients following MTBI (1,4)
- Nonsport concussion/MTBI
- Unclear if previous history of concussion(s) is a risk factor for PCS (2)
- Low socioeconomic status
- Loss of consciousness does not appear to be predictive of PCS.

GENERAL PREVENTION

- Education of players, coaches, parents, and athletic trainers about concussion, PCS, and following game safety rules designed to protect players
- Head injury precautions with activities are advised, but no good evidence that these decrease incidence of MTBI or PCS.
- Early screening and intervention(s) for anxiety and depression

COMMONLY ASSOCIATED CONDITIONS

- PTSD
- Anxiety
- Depression
- Fibromyalgia
- Personality disorders (namely, compulsive, histrionic, and narcissistic)
- ADHD

DIAGNOSIS

HISTORY

- Detailed history of recent impact and closed head injury, including the following:
  - Mechanism
  - Timing of injury related to symptoms
  - Previous head injuries, including concussion, and timing of those injuries

  - Previous medical, psychiatric, or social history
  - Thorough characterization of associated symptoms, intensity, and duration
- Report of neurologic, cognitive, or behavioral symptoms by patient/family

PHYSICAL EXAM

Complete neurologic exam, including the following:

- Glasgow Coma Scale (GCS)
- Anxiety/depression screening
  - Patient Health Questionnaire-9 (PHQ-9)
  - GAD-7
- Sport Concussion Assessment Tool, NFL Sideline Concussion Assessment Tool, or computerized neuropsychological (CNP) testing both pre- and post-MTBI is common practice, although data are limited on validity (3)[C]. More info regarding CNP below

DIFFERENTIAL DIAGNOSIS

- Postconcussive symptoms
- PTSD
- Anxiety/depression
- Personality disorders
- Migraine headaches
- Chronic fatigue syndrome, fibromyalgia
- Evolving intracranial hemorrhage
- Exposure to toxins, including prescription and recreational drugs
- Endocrine/metabolic abnormality

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- If clinically warranted, consider evaluation for infection, intoxication, and endocrine/metabolic abnormality.
- Brain imaging both on initial evaluation of MTBI and PCS is generally neither fruitful nor indicated.
- Imaging to evaluate for bleeding may be helpful in patients with comorbid conditions or who are taking anticoagulation therapy.
- Recommend cervical imaging when concomitant cervical spine injury is

suspected.

Follow-Up Tests & Special Considerations

- Several CNP testing programs can be used to guide decisions regarding return to play. If baseline testing is available, scores can be used as controls against scores achieved after MTBI.
- Formal neuropsychiatric evaluations are likely superior to CNP testing when available. None of these tests should be used alone in decision making, especially if a patient is still having symptoms despite improving or "baseline" scores (1,3)[C].
- Common neuropsychological testing programs for PCS
  - Immediate Post-Concussion Assessment and Cognitive Testing (ImPACT)
  - Post Concussion Symptom Scale (PCSS)
  - Balance Error Scoring System (BESS)
  - Axon Sports Computerized Cognitive Assessment Tool (CCAT)
  - Automated Neuropsychological Assessment Metrics (ANAM)

TREATMENT

GENERAL MEASURES

- Subthreshold exercise has been shown to help resolution of symptoms and can be started 21 days after MTBI (6)[B].
- Consider physical therapy for coexistent cervical or vestibular injury.
- Return to play
  - Persons with concussion or PCS should be restricted from sport activity until they are off all medications that may mask PCS symptoms and clinical symptoms have resolved (1,3)[C].
  - Return to full activity should progress according to stepwise concussion recommendations (1,3)[C].

MEDICATION

First Line

Headache/neck pain

- Nonopioid pain control (e.g., NSAIDs)
  - Sedation may obscure cognitive evaluation with use of opioid medications.

- Possible association between the use of opiates and increased risk of anxiety/depression in PCS patients (5)[B]
- Consider occipital nerve block.

ALERT

Avoid opiates and benzodiazepines (5)[B].

- Depression/sleep disorders
  - Anxiety/depression screening starting in the 1st week post-MTBI
    - Melatonin for sleep
    - Tricyclic antidepressants, or trazodone if there is concomitant sleep disturbance, may be beneficial.
    - SSRIs
  - Consider referral to mental health specialist(s).
- Cognitive disorders
  - Evaluation by neuropsychologist
  - (Methylphenidate may be considered.
  - SSRIs may be considered, especially if concomitant anxiety/depression.

ISSUES FOR REFERRAL

- Neuropsychiatric therapy including comprehensive cognitive evaluation for potential TBI rehabilitation
- Cognitive-behavioral therapy for anxiety and depression symptoms
- Occupational therapy for vocational rehabilitation, if needed
- Physical therapy for vestibular rehabilitation
- Neurology referral if primary care interventions for seizures, headache, vertigo, or cognition are unsuccessful
- Substance abuse counseling, if needed

COMPLEMENTARY & ALTERNATIVE MEDICINE

Massage therapy/osteopathic manipulative treatment for headache and neck pain

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Schedule regular follow-up to evaluate for persistent symptoms, efficacy of/need

for neuropsychiatric evaluation, and the efficacy of/need for pharmacologic therapy.

Patient Monitoring

- Consider serial neuropsychological testing.
- Follow return to play guidelines (3)[C].

PATIENT EDUCATION

- Centers for Disease Control and Prevention: http://www.cdc.gov/headsup/
- Mayo Clinic Health Information: http://www.mayoclinic.com/health/post-concussion-syndrome/DS01020/
- Brain Injury Association of America: http://www.biausa.org/; (800) 444-6443

PROGNOSIS

- Prognosis generally is good.
- Adolescents may recover more slowly than adults.

COMPLICATIONS

- Repeat head injury or return to play before resolution of PCS can worsen/prolong symptoms.
- Case studies of second-impact syndrome, a rare but potentially fatal condition owing to a second head injury soon after the first, have been reported.

SEE ALSO

Concussion (Mild Traumatic Brain Injury)

CODES

ICD10

- F07.81 Postconcussional syndrome
- S06.9X0A Unsp intracranial injury w/o loss of consciousness, init

- S06.9X9A Unsp intracranial injury w LOC of unsp duration, init

CLINICAL PEARLS

- Imaging rarely useful for PCS; head CT scan is the test of choice for acute injury to exclude intracranial bleeding.
- Coordinate multidisciplinary treatment plans for patients with persistent symptoms.
- Return to play/activity should not occur until symptoms return to baseline and any pre-PCS medications are optimized by the prescribing clinician.

POSTTRAUMATIC STRESS DISORDER (PTSD)

Crystal H. Chavez, MD • Fozia Akhtar Ali, MD

BASICS

DESCRIPTION

- Posttraumatic stress disorder (PTSD) is an anxiety disorder defined as a reaction that can occur after exposure to an extreme traumatic event involving death, threat of death, serious physical injury, or a threat to physical integrity.
- This reaction has three cardinal characteristics:
  - Reexperiencing the trauma
  - Avoidance of anything related to the traumatic event and/or numbing of general responsiveness
  - Increased arousal
- Traumatic events that may trigger PTSD include natural/human disasters, serious accidents, war, sexual abuse, rape, torture, terrorism, hostage-taking, or being diagnosed with life-threatening disease.
- PTSD can be:
  - Acute: symptoms lasting <3 months
  - Chronic: symptoms lasting ≥3 months
  - Delayed: onset 6 months after trauma exposure, <5% of cases
  - Subclinical: waxing and waning course

EPIDEMIOLOGY

- ~30% of men and women who have spent time in a war zone experience PTSD.
- Current estimates of PTSD in military personnel who served in Iraq range from 12% to 20%.
- 16% children and adolescents exposed to trauma develop PTSD (1).

Incidence

~7.7 million American adults aged ≥18 years (3.5% of this age group) are diagnosed with PTSD each year.

Prevalence

Lifetime prevalence for PTSD is 8–9%.

ETIOLOGY AND PATHOPHYSIOLOGY

- Biologic dimensions: Hyperactivity/hypersensitivity of catecholamine pathways and overactivity/oversensitivity of the central opioid pathways is seen; the amygdala and hippocampus dysfunction, with possible atrophy from overexposure to catecholamines, serotonergic dysregulation, glutaminergic dysregulation, and increased thyroid activity.
- Learning theory: Life-threatening fear is classically conditioned by event exposure; any internal or external cue reminiscent of the event produces an intense "fight or flight" fear response. The person avoids cues that trigger fear. This avoidance maintains fear.
- Cognitive theories: These models suggest that severe trauma becomes represented in complex memory structures. The activation of these memories triggers intense thoughts and emotions that are pathologic (causing personal discomfort and dysfunction).
- Psychodynamic theory: Traumatic memories overwhelm defense mechanisms. Repeated recall of the traumatic event with associated fear is an effort to understand the event in a less threatening way.

Genetics

- Monozygotic twins exposed to combat in Vietnam were at increased risk of the co-twin having PTSD compared with twins who were dizygotic.
- Data suggest an association between dopamine system variants and PTSD.

RISK FACTORS

- Pretrauma environment:
  - Female sex
  - Younger age
  - Psychiatric history
  - Sexual abuse
- Peritrauma environment:
  - Severity of the trauma
  - Peritrauma emotionality

  - Perception of threat to life
  - Perpetration of the trauma
- Posttrauma environment:
  - Perceived injury severity
  - Medical complications
  - Perceived social support
  - Persistent dissociation from traumatic event
- Subsequent exposure to trauma-related stimuli

GENERAL PREVENTION

- There is moderate evidence for hydrocortisone (2) and some evidence for propranolol (3) reducing development of full posttraumatic syndrome.
- Trauma-focused cognitive-behavioral therapy (CBT) and modified prolonged exposure delivered within weeks of a potentially traumatic event for people showing signs of distress have the most evidence in the treatment of acute stress and early PTSD symptoms, and the prevention of PTSD (4).

COMMONLY ASSOCIATED CONDITIONS

- Major depressive disorder
- Alcohol/substance abuse
- Panic disorder
- Obsessive-compulsive disorder
- Agoraphobia and/or social phobia
- Traumatic brain injury
- Smoking (especially with assaultive trauma)
- Major neurocognitive disorders, dementia, or amnesia

Pediatric Considerations

Oppositional defiant disorder and separation anxiety are common comorbid conditions.

DIAGNOSIS

HISTORY

Diagnosis is based on *DSM-5* criteria:

- Criterion A: exposure to trauma (≥1 of the following):
  - Direct experience of a traumatic event
  - In-person witnessing of a traumatic event
  - Learning of a traumatic event involving a close friend or family member
  - Repeated exposure to details of a traumatic event
- Criterion B: intrusive symptoms associated with the traumatic event (≥1 of the following):
  - Recurrent, involuntary, and intrusive distressing memories of the event
  - Recurrent distressing dreams related to the event
  - Dissociative reactions that simulate a recurrence of the event
  - Intense or prolonged distress to stimuli that resemble an aspect of the event
- Criterion C: avoidance of stimuli associated with the trauma (≥1 of the following):
  - Avoidance of memories, thoughts, or feelings about the event
  - Avoidance of external reminders that trigger memories, thoughts, or feelings about the event
- Criterion D: negative cognitive and mood changes associated with the trauma (≥2 of the following):
  - Inability to remember aspects of event
  - Persistent and exaggerated negative opinion of self, others, or the world
  - Distorted beliefs about the cause or consequences of the event
  - Negative emotional state
  - Diminished interest in significant activities
  - Feeling detached from others
  - Inability to experience positive emotions
- Criterion E: hyperarousal (≥2 of the following):
  - Difficulty sleeping/falling asleep
  - Decreased concentration
  - Hypervigilance
  - Outbursts of anger/irritable mood
  - Exaggerated startle response
  - Self-destructive behavior
- Criterion F: duration of the relevant criteria symptoms should be >1 month
- Criterion G: clinically significant distress/impairment in functioning

- Criterion H: relevant criteria not attributed to substance effects or other medical conditions

Pediatric Considerations

- Memories of the traumatic event may not appear distressing and may be seen as play reenactment.
- Reactions can include a fear of being separated from a parent, crying, whimpering, screaming, immobility and/or aimless motion, trembling, frightened facial expressions, excessive clinging, or regressive behavior.
- Older children may show extreme withdrawal, disruptive behavior, and/or an inability to pay attention. Regressive behaviors, nightmares, sleep problems, irrational fears, irritability, refusal to attend school, outbursts of anger, fighting, somatic complaints with no medical basis, and decline in schoolwork performance. Furthermore, depression, anxiety, feelings of guilt, and emotional numbing are often present.
- Parental posttraumatic stress has been shown to be a robust predictor of pediatric PTSD (5)[A].

PHYSICAL EXAM

- Patients may present with physical injuries from the traumatic event.
- Mental status examination:
  - Thoughts and perceptions (e.g., hallucinations, delusions, suicidal ideation, phobias)
  - General appearance: disheveled, poor hygiene
  - Behavior: agitation; startle reaction extreme
  - Psychological numbness
  - Orientation may be affected.
  - Memory: forgetfulness, especially concerning the details of the traumatic event
  - Poor concentration
  - Poor impulse control
  - Altered speech rate and flow
  - Mood and affect may be changed: depression, anxiety, guilt, and/or fear.

Pediatric Considerations

Elevated heart rate immediately following trauma is associated with development of PTSD (5)[A].

DIFFERENTIAL DIAGNOSIS

- Acute stress disorder (symptoms <4 weeks)
- Generalized anxiety disorder
- Adjustment disorder
- Obsessive-compulsive disorder
- Schizophrenia
- Major depressive disorder
- Mood disorder with psychotic features
- Substance abuse
- Personality disorders
- Dissociative disorders
- Conversion disorder

TREATMENT

Combination psychotherapy and pharmacotherapy, initiated soon after the trauma, result in better prognosis.

MEDICATION

First Line

- SSRIs: can improve depression, panic attacks, startle response, sleep disruption (6)[A]. All commonly used SSRIs have been shown to be effective.
  - Sertraline: 50 to 200 mg every day (FDA approved)
  - Paroxetine: starting dose: 10 mg every day; may be increased in 10 mg increments at intervals ≥1 week (FDA approved)
  - Fluoxetine: 20 mg every day/BID not to exceed 80 mg/day (demonstrates some efficacy for all three symptom clusters)
- Sleep disruption: Sleep disruption due to hyperarousal is ubiquitous in PTSD; standard sedatives, such as trazodone 50 to 300 mg at bedtime, mirtazapine 7.5 to 30 mg qhs, or amitriptyline 25 to 100 mg qhs
- Nightmares/nighttime hyperarousal: prazosin 2 to 15 mg qhs (7)[A], clonidine

0.1 to 0.2 mg qhs, amitriptyline 25 to 100 mg qhs

Second Line

Refractory/residual symptoms: Consider augmentation with:

- Depression: mirtazapine 15 to 45 mg/day; consider switch to a serotonin-norepinephrine reuptake inhibitor (SNRI), such as venlafaxine XR 37.5 to 300 mg/day, duloxetine 60 to 120 mg/day or desvenlafaxine 50 to 100 mg/day. Nefazodone 300 to 600 mg/day in divided doses can be very effective but requires quarterly LFTs.
- Reexperiencing/intrusive thoughts: 1st-/2nd-generation antipsychotic medications: aripiprazole 5 to 15 mg/day, risperidone 0.5 to 2 mg/day, olanzapine 2.5 to 10 mg/day, quetiapine 50 to 400 mg/day (8)[A]. 2nd-generation Rx less prone to extrapyramidal symptoms (EPS): cognitive dulling.
- Hyperarousal: clonidine, start 0.05 mg BID/TID; slowly titrate to as much as 0.45 mg/day divided doses; guanfacine 1 to 3 mg/day in divided doses (long-acting forms of both clonidine and guanfacine now available). Also consider 2nd-generation antipsychotics quetiapine, risperidone, and olanzapine as above. Divided doses often more helpful.
- Impulsivity/explosiveness: anticonvulsants: valproic acid 500 to 2,000 mg/day, carbamazepine 200 to 600 mg/day, topiramate 50 to 200 mg/day
- Anxiety: Benzodiazepines (especially short-acting) should be avoided given the risk of substance abuse and questionable benefit in PTSD (9)[A]. Consider hydroxyzine 25 to 50 mg TID/QID PRN or risperidone 0.25 to 0.5 mg TID PRN.

ADDITIONAL THERAPIES

- Psychotherapeutic interventions:
  - Exposure therapies have shown the highest effectiveness for treatment of PTSD (10)[A]:
    - Behavioral and CBT: Early CBT, including virtual exposure, has been shown to speed recovery. CBT is considered the standard of care for PTSD by the U.S. Department of Defense.
    - 1-week intensive CBT was as effective as 3 months weekly CBT in one study (11)[A].

    - Prolonged exposure therapy: Reexperience distressing trauma-related memories and reminders to facilitate habituation and successful emotional processing of memory.
    - EMDR (eye movement desensitization and reprocessing) has been shown to benefit patients with PTSD (12)[A].
  - Stress-reduction techniques:
    - Immediate symptom reduction (e.g., rebreathing in a bag for hyperventilation)
    - Early recognition and removal from a stress
    - Relaxation, meditation, and exercise techniques are also helpful in reducing the reaction to stressful events.
  - Telemedicine-based collaborative care (nurse, case manager, pharmacy, psychology, psychiatry) is more effective than usual care
- Interpersonal psychotherapy:
  - Supportive psychotherapy with an emphasis on the here and now
- Social:
  - Establish the social framework of the problem. This allows the patient to begin viewing it within the proper context (e.g., change of job/relocation of adult-dependent offspring)

Pediatric Considerations

There is very little evidence to support use of pharmacologic interventions for pediatric PTSD (13).

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Inpatient care is necessary only if the patient becomes suicidal/homicidal or for treatment of comorbid conditions (e.g., uncontrolled depression, substance abuse).

ONGOING CARE

PATIENT EDUCATION

National Center for PTSD: www.ptsd.va.gov

PROGNOSIS

- Varies significantly from patient to patient
- In 50% of cases, the symptoms spontaneously remit after 3 months; however, in other cases, symptoms may persist, often for many years, and cause long-term impairment in life functioning.
- Factors associated with a good prognosis include:
  - Rapid engagement of treatment
  - Early and ongoing social support
  - Avoidance of retraumatization
  - Absence of other psychiatric disorders/substance abuse

COMPLICATIONS

Increased risk for panic disorder, agoraphobia, obsessive-compulsive disorder, social phobia, specific phobia, major depressive disorder, somatization disorder; impulsive behavior, suicide, and homicide. Victims of sexual assault are at especially high risk for developing mental health problems and committing suicide.

CODES

ICD10

- F43.10 Post-traumatic stress disorder, unspecified

- F43.11 Post-traumatic stress disorder, acute
- F43.12 Post-traumatic stress disorder, chronic

CLINICAL PEARLS

- Treatment is often best accomplished with a combination of psychotherapy and pharmacotherapy.
- Symptoms usually wax and wane over the years.

PREECLAMPSIA AND ECLAMPSIA (TOXEMIA OF PREGNANCY)

Jessica Marabella, MD • Amy M. Zack, MD, FAAFP

BASICS

DESCRIPTION

- Preeclampsia:
  - A disorder of pregnancy occurring after 20 weeks gestation characterized by new-onset hypertension (HTN), new-onset proteinuria, ± impaired organ function:
    - May progress from mild to life-threatening in hours to days
    - Reversible by delivery
- Eclampsia:
  - New-onset grand mal seizure activity with no history of underlying neurologic disease
- Most postpartum cases of preeclampsia and eclampsia occur within 48 hours of delivery but can occur up to 4 weeks postpartum.
- System(s) affected: cardiovascular, renal, reproductive, fetoplacental, CNS, hepatic, pulmonary
- Synonym(s): toxemia of pregnancy

EPIDEMIOLOGY

Incidence & Prevalence

- Predominant age
  - Most in younger women, primiparous women
  - Older (>40 years) patients with preeclampsia have 4 times the incidence of seizures compared with patients in their 20s.
- Preeclampsia occurs in 5–8% of all pregnancies.
- Eclampsia occurs:
  - 1.6 to 10 out of 10,000 deliveries in developed countries
  - 6 to 157 out of 10,000 deliveries in developing countries
- 40% of eclamptic seizures occur before delivery; 16% occur >48 hours after

delivery.

- Preeclampsia is a main cause of perinatal mortality and morbidity (2–8% of all pregnancies).

ETIOLOGY AND PATHOPHYSIOLOGY

- Cause of preeclampsia is becoming clearer.
  - Abnormal placental implantation
  - Angiogenic factors
  - Genetic predisposition
  - Immunologic phenomena
  - Vascular endothelial damage and oxidative stress
- Systemic derangements in eclampsia include the following:
  - Cardiovascular: generalized vasospasm
  - Hematologic: decreased plasma volume, increased blood viscosity, hemoconcentration, coagulopathy
  - Renal: decreased glomerular filtration rate
  - Hepatic: periportal necrosis, hepatocellular damage, subcapsular hematoma
  - CNS: cerebral vasospasm and ischemia, cerebral edema, cerebral hemorrhage

Genetics

2 to 4 times increased risk in pregnant women with family history of preeclampsia

RISK FACTORS

- Nulliparity
- Age >40 years
- Family history of preeclampsia
- High body mass index
- Diabetes
- Chronic HTN
- Chronic renal disease, or both
- Multifetal pregnancy
- Previous pregnancy preeclampsia
- Systemic lupus erythematosus

- In vitro fertilization

GENERAL PREVENTION

- Adequate prenatal care
- Inadequate prenatal care results in 7 times increase in mortality.
- Good control of preexisting HTN
- Low-dose acetylsalicylic acid (ASA) (60 to 80 mg):
  - ASA started early (12 to 20 weeks gestational age [GA]) may lower the risk of developing preeclampsia and the rate of preterm delivery and neonatal death in moderate- to high-risk patients (see "Risk Factors" as mentioned earlier) (1)[A].
- Low-dose calcium supplementation has been shown to reduce the risk and severity of preeclampsia in calcium-deficient populations (1)[A].
- Some evidence suggests vitamin C (1,000 mg/day) and vitamin E (400 U/day) may reduce the risk for preeclampsia, recent guidelines recommend against their use.

COMMONLY ASSOCIATED CONDITIONS

Abruptio placentae, placental insufficiency, fetal growth restriction, preterm delivery, fetal demise maternal seizures (eclampsia), maternal pulmonary edema, maternal liver/kidney failure, or maternal death

DIAGNOSIS

- Preeclampsia diagnosis:
  - New-onset elevated BP: SBP ≥140 mm Hg or DBP ≥90 mm Hg (on two occasions at least 4 hours apart) or ≥160/110 mm Hg after 20 weeks of gestation, AND EITHER
    - Proteinuria (>300 mg/24 hr or spot protein: creatinine ≥0.3) OR
    - New-onset thrombocytopenia, renal insufficiency, impaired liver function, pulmonary edema, or cerebral/visual symptoms (1)[C].
  - Define preeclampsia as either without or with severe features (see below) (1)[C].
- Eclampsia diagnosis:
  - New-onset grand mal seizure

- No history of neurologic disease

HISTORY

May be asymptomatic. In some cases, rapid excessive weight gain (>5 lb/week; >2.3 kg/week); more severe cases are associated with epigastric/right upper quadrant (RUQ) pain, headache, altered mental status, and visual disturbance.

PHYSICAL EXAM

- BP criteria:
  - Preeclampsia without severe features: Elevated BP ≥140/90 mm Hg on two occasions at least 4 hours apart or more rapid diagnosis may be made with BP ≥160/110 mm Hg.
  - Preeclampsia with severe features: Elevated BP ≥160 systolic mm Hg or 110 mm Hg diastolic on two BP readings 4 hours apart while the patient is on bedrest, AND new onset of one or more of below:
    - Platelets <100,000/μL
    - >2 times normal liver transaminase levels, severe persistent RUQ/epigastric pain, or both
    - Creatinine >1.1 mg/dL or doubling of serum creatinine levels
    - Pulmonary edema
    - Cerebral or visual symptoms
- Eclampsia: tonic-clonic seizure activity (focal/generalized)
  - Note: Headache, visual disturbance, and epigastric or RUQ pain often precede seizure.
  - Seizures may occur once/repeatedly.
  - Normal BP, even in response to treatment; does not rule out potential for seizures

DIFFERENTIAL DIAGNOSIS

- Chronic HTN: HTN before pregnancy; high BP before the 20th week
- Chronic HTN with superimposed preeclampsia
- Gestational HTN: Increased BP first discovered after 20 weeks, often close to term, with no proteinuria and without evidence of organ dysfunction. BP becomes normal by 12 weeks postpartum, or it is reclassified as chronic HTN.
- Seizures in pregnancy: epilepsy, cerebral tumors, meningitis/encephalitis, and

ruptured cerebral aneurysm. Until other causes are proven, however, all pregnant women with convulsions should be considered to have eclampsia.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Routine spot urine testing or urinalysis for protein should be done at each prenatal visit in all hypertensive patients.
- Complete blood count (CBC), including platelets, creatinine, serum transaminase levels, and uric acid as baseline in hypertensive patients and if preeclampsia suspected or possible
- Coagulation profiles: abnormalities suggest severe disease.
- 24-hour urine or protein/creatinine ratio if urine protein dips 1+ on more than one occasion, or if preeclampsia is being considered
- Daily fetal movement monitoring by mother (“kick counts”)
- US imaging is used to monitor growth and cord blood flow; perform, as indicated, based on clinical stability and laboratory findings.
- Nonstress test (NST) at diagnosis and then twice-weekly until delivery
- Biophysical profile (BPP) if NST is nonreactive (1)[C].
- US imaging for growth progress every 3 weeks, and amniotic fluid volume at least once weekly (1)[C]
- With seizures, CT scan and MRI should be considered if focal findings persist or uncharacteristic signs/symptoms are present.

Follow-Up Tests & Special Considerations

Disseminated intravascular coagulation, thrombocytopenia, liver dysfunction, and renal failure can complicate preeclampsia associated with HELLP syndrome.

Test Interpretation

CNS: cerebral edema, hyperemia, focal anemia, thrombosis, and hemorrhage. Cerebral lesions account for 40% of eclamptic deaths.

TREATMENT

GENERAL MEASURES

- Preeclampsia without severe features:

- Outpatient care
- Maternal: daily home BP monitoring; daily weights; weekly labs (CBC, creatinine, liver function test [LFT])
- Fetal:
  - Patient-measured: daily “kick counts”
  - NST/BPP/US (see imaging section above)
  - Delivery at 37 weeks (induction of labor) (1,2)[C]
  - Steroids for gestation <37 weeks

- Preeclampsia with severe features:
  - Inpatient care
  - Maternal:
    - Daily labs
    - IV magnesium sulfate ($MgSO_4$) as seizure prophylaxis
    - Antihypertensive therapy titrated to keep systolic BP <160 mm Hg and diastolic BP <110 mm Hg (some recommend <150/100 mm Hg postpartum)
  - Fetal:
    - Continuous heart monitoring
    - Daily US with BPP
    - Check amniotic fluid levels and fetal growth.
  - Definitive management (delivery) depends on GA (1,2)[C].
  - <23 weeks:
    - Offer to terminate pregnancy.
  - At 23 to 34 weeks:
    - Antihypertensives
    - Evaluate maternal–fetal condition.
    - Steroids to enhance fetal lung maturity
    - Plan delivery at 34 weeks with magnesium sulfate prophylaxis.
    - If HELLP syndrome (full or partial), severe oligohydramnios, significant renal dysfunction, persistent symptoms, fetal growth restriction, onset of labor, OR PROM, proceed to delivery.
  - At ≥34 weeks: magnesium sulfate, steroids, and proceed to delivery (1)[C]. Steroids indicated up to 37 weeks

ALERT

- Regardless of GA, emergent delivery is recommended if there are signs of maternal hypertensive crisis, abruptio placentae, uterine rupture, or fetal distress.
- Seizures: control of convulsions, correction of hypoxia and acidosis, lowering of BP, steps to effect delivery as soon as convulsions are controlled
- Administer betamethasone 12 mg IM daily × 2 doses or dexamethasone 6 mg every 12 hours × 4 doses if delivery <37 weeks possible.

MEDICATION

First Line

- Seizure prophylaxis for women with severe preeclampsia:
  - Magnesium sulfate: loading dose 4 g IV in 200 mL normal saline over 20 to 30 minutes; maintenance dose 1 to 2 g/hr IV continuous infusion (Although recent guidelines suggest it not be universally administered for seizure prophylaxis to prevent eclampsia, the quality of the evidence is low, and the strength of the recommendation is qualified.) (1)[C]
- Blood pressure control:
  - Antihypertensives are inadvisable for mildly elevated BP (without severe features).
  - Labetalol (IV): 20 mg over 2 minutes followed at 20 to 30 minutes intervals with doses of 20 to 80 mg titrated to keep BP <160/110 mm Hg; max of 300 mg/24 hr. (Contraindicated in asthma, heart disease, congestive heart failure.)
  - Hydralazine (IV): 5 to 10 mg over 2 minutes, followed at 20 minutes intervals with 5 to 10 mg IV boluses; titrated to keep BP<160/110 mm Hg; max of 25 mg/24 hr.
  - Nifedipine sustained-release (PO) (used in the postpartum): 30 to 120 mg/day (caution with combination of nifedipine and magnesium sulfate resulting in hypotension and neuromuscular blockade) (3)[A]
- Eclampsia/seizures:
  - Magnesium sulfate for seizures
    - 4 to 6 g IV over 15 to 20 minutes followed by 1 to 2 g/hr infusion
    - Further boluses of magnesium may be given for recurrent convulsions

with the amount given based on the neurologic examination and patellar reflexes.
    - Contraindications: myasthenia gravis, renal failure, pulmonary edema
  - Levels of 6 to 8 mEq/mL are considered therapeutic, but monitor clinical status of:
    - Patellar reflexes are present.
    - Respirations are not depressed.
    - Urine output is ≥25 mL/hr.
  - May be given safely, even in the presence of renal insufficiency
- Fluid therapy
  - Ringer lactated solution with 5% dextrose at 60 to 120 mL/hr, with careful attention to fluid–volume status
- Calcium carbonate (1 g, administered slowly IV) may reverse magnesium-induced respiratory depression (1,2)[C].

Second Line

- In randomized trials, magnesium sulfate was found to be superior to phenytoin in treatment and prevention of eclampsia and probably more effective and safer than diazepam
- Diazepam 2 mg/min until resolution or 20 mg given or
- Lorazepam 1 to 2 mg/min up to total of 10 mg or
- Phenytoin 15 to 20 mg/kg at a maximum rate of 50 mg/min or
- Levetiracetam 500 mg IV or oral may be repeated in 12 hours (dose needs to be adjusted in renal impairment) or
- Phenobarbital 20 mg/kg infused at 50 mg/min; may repeat with additional 5 to 10 mg/kg after 15 minutes

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Without severe features: restricted activity and close monitoring; with severe features: restricted activity, in hospital
- Women with a history of preeclampsia should report this to physicians caring for them in later life. It is a potent cardiovascular disease risk factor.

DIET

- Salt restriction is inadvisable because the patient often is experiencing intravascular hypovolemia.
- Calcium supplementation may be recommended for women who have low calcium intake (<600 mg/day)

PATIENT EDUCATION

American Congress of Obstetricians and Gynecologists, 409 12th St. SW, Washington, DC 20024-2188; (800) 762-ACOG; http://www.acog.org/

PROGNOSIS

- For nulliparous women with preeclampsia before 30 weeks of gestation, the recurrence rate for the disorder may be as high as 40% in future pregnancies.
- 25% of eclamptic women will have HTN during subsequent pregnancies, but only 5% of these will be severe and only 2% will be eclamptic again.
- Preeclamptic, multiparous women may be at higher risk for subsequent essential HTN; they also have higher mortality during subsequent pregnancies than do primiparous women.

COMPLICATIONS

- Most women do not have long-term sequelae from eclampsia, although many may have transient neurologic deficits.
- A history of preeclampsia is equivalent to traditional risk factors for cardiovascular disease. Women with a history of preeclampsia should be strongly advised to avoid obesity and smoking. Other signs of metabolic syndrome should be closely monitored as well.
- Intrauterine growth restriction (IUGR)
- Maternal and/or fetal death

CODES

ICD10

- O14.90 Unspecified pre-eclampsia, unspecified trimester
- O15.00 Eclampsia in pregnancy, unspecified trimester
- O14.00 Mild to moderate pre-eclampsia, unspecified trimester

CLINICAL PEARLS

- Management of preeclampsia depends on both the severity of the condition and the GA of the fetus.
- Diagnosis no longer requires presence of proteinuria.
- Low-dose ASA starting in early pregnancy in high-risk patients may lower rate of preeclampsia.
- Continue to monitor maternal blood pressures postpartum—still at risk for developing preeclampsia.

PREMENSTRUAL SYNDROME (PMS) AND PREMENSTRUAL DYSPHORIC DISORDER (PMDD)

Courtney I. Jarvis, PharmD • Allison Hargreaves, MD

BASICS

DESCRIPTION

- Premenstrual syndrome (PMS), a complex of physical and emotional symptoms sufficiently severe to interfere with everyday life, occurs cyclically during the luteal phase of menses.
- Premenstrual dysphoric disorder (PMDD) is a severe form of PMS characterized by severe recurrent depressive and anxiety symptoms, with premenstrual (luteal phase) onset, that remits a few days after the start of menses.
- PMDD is now included as a full diagnostic category in the 5th edition of the *Diagnostic and Statistical Manual of Mental Disorders* (*DSM-5*).
- System(s) affected: endocrine/metabolic, nervous, reproductive

EPIDEMIOLOGY

Prevalence

- Many women have some physical and psychological symptoms before menses (this is not PMS).
- 30% of menstruating women suffer from PMS; 3–8% of menstruating women have PMDD.

ETIOLOGY AND PATHOPHYSIOLOGY

Not well understood. Leading theories postulate metabolites of progesterone interact with central neurotransmitter receptors (serotonin and γ-aminobutyric acid [GABA]), provoking downstream effects of decreased GABA-mediated inhibition and decreased serotonin levels. Women with PMS/PMDD have similar levels of progesterone but seem to have an increased sensitivity to its metabolites, compared with women without PMS/PMDD.

Genetics

- Role of genetic predisposition is controversial; however, twin studies do suggest a genetic component.
- Involvement of gene coding for the serotonergic *5HT1A* receptor and allelic variants of the estrogen receptor-*α* gene (*ESR1*) is suggested.

RISK FACTORS

- Age: usually present in late 20s to mid-30s
- History of mood disorder (major depression, bipolar disorder), anxiety disorder, personality disorder, or substance abuse
- Family history
- Low parity
- Tobacco use
- Psychosocial stressors/history of trauma
- High BMI

DIAGNOSIS

HISTORY

- *DSM-5* criteria (1)[A]
- Symptoms occur 1 week before menses, improve in the first few days after menses begin, and are minimal/absent in the week following menses (over most menstrual cycles during the past year).
- ≥5 of the following (1 must be among the first 4):
  - Marked depressed mood, feelings of hopelessness, or self-deprecating thoughts
  - Marked anxiety, tension, and/or feelings of being keyed up or on edge
  - Marked affective lability (mood swings)
  - Marked irritability or anger or increased interpersonal conflicts
  - Decreased interest in usual activities and social withdrawal
  - Lethargy, easy fatigability, or lack of energy
  - Appetite change, overeating, food cravings
  - Hypersomnia or insomnia
  - Feeling out of control or overwhelmed

  - Subjective difficulty concentrating
  - Physical symptoms, such as abdominal bloating, breast tenderness, headaches, weight gain, and joint/muscle pain
- For PMDD, emotional symptoms must be sufficiently severe to interfere with work, school, usual social activities, or relationships with others.
- Symptoms may be superimposed on an underlying psychiatric disorder but may not be an exacerbation of another condition, such as panic disorder/major depression.
- Criteria should be confirmed by prospective patient record of symptoms for a minimum of two consecutive menstrual cycles (without confirmation, "provisional" should be noted with diagnosis).
- Use the Daily Record of Severity of Problems (available online at http://www.aafp.org/afp/2011/1015/p918-fig1.pdf) or similar inventory (2) [A].
- Symptoms should not be attributable to drug abuse, medications, or other medical conditions.

PHYSICAL EXAM

No specific physical exam required; may consider thyroid and pelvic exams if indicated by additional patient symptoms.

DIFFERENTIAL DIAGNOSIS

- Premenstrual exacerbation of underlying psychiatric disorder
- Psychiatric disorders (especially bipolar disorder, major depression, anxiety)
- Thyroid disorders
- Perimenopause
- Premenstrual migraine
- Chronic fatigue syndrome
- Irritable bowel syndrome (painful symptoms)
- Seizures
- Anemia
- Endometriosis (painful symptoms)
- Drug/alcohol abuse

DIAGNOSTIC TESTS & INTERPRETATION

- The repetitive nature of symptoms precludes need for labs if a classic history is present.
- Consider
  - Hemoglobin to rule out anemia
  - 25-OH vitamin D level to exclude deficiency, although precise relationship of deficiency with the disorder is unclear
  - Serum thyroid-stimulating hormone (TSH) to rule out hypothyroidism
- Imaging with pelvic ultrasound to diagnose causes of pelvic pain and dysmenorrhea may be needed.

TREATMENT

GENERAL MEASURES

Although evidence is lacking for aerobic exercise in treating PMS/PMDD, it is often recommended as part of an integrated care plan.

MEDICATION

First Line

- SSRIs show a small to moderate effect in the treatment of physical, functional, and behavioral symptoms of PMS and PMDD compared to placebo (3)[A]:
  - Both intermittent luteal phase dosing and continuous full-cycle dosing are effective with no clear evidence of difference between modes of administration (3)[A].
  - All SSRIs tested appeared effective (3)[A].
  - SSRIs are effective at low doses. Higher doses have increased effect but are accompanied by increased side effects (3)[A].
- Fluoxetine (Prozac, Sarafem) 20 mg/day every day or 20 mg/day only during luteal phase, or 90 mg once a week for 2 weeks in luteal phase
- Sertraline (Zoloft) 50 to 150 mg/day every day or 50 to 150 mg/day only during luteal phase
- Citalopram (Celexa) 10 to 30 mg/day every day or 10 to 30 mg/day only during luteal phase
- Adverse effects (number needed to harm [NNH] with moderate-dose SSRI):

nausea (NNH = 7), asthenia (NNH = 9), somnolence (NNH = 13), fatigue (NNH = 14), decreased libido (NNH = 14), and sweating (NNH = 14) (3)[A].

- Contraindications: patients taking monoamine oxidase inhibitors (MAOIs)
- Precautions
  - Increased risk of suicidal thinking and behavior in children and adolescents with depressive disorders; uncertain if this risk applies to those taking SSRIs for PMDD
  - Bipolar disorder
  - Seizure disorder
  - QTc prolongation (with citalopram)
  - Hepatic dysfunction
  - Renal dysfunction
- Possible interactions
  - MAOIs
  - Selegiline
  - Pimozide
  - Thioridazine
  - Cimetidine, omeprazole, and QTc prolonging agents (with citalopram)

Second Line

Alternative therapies should be considered if no response to SSRIs:

- Spironolactone (Aldactone) 50 to 100 mg/day for 7 to 10 days during luteal phase; helpful for fluid retention. Adverse reactions: lethargy, headache, irregular menses, hyperkalemia
- Oral contraceptive pills (OCPs)
  - OCPs can cause adverse effects similar to PMDD symptoms (4)[B].
  - Extended-cycle use of OCPs (e.g., 12 weeks on and 1 week off) or a shorter placebo interval (e.g., 24 active pills with 4 placebo days [24/4] compared with 21/7 preparations) may be beneficial (4)[B].
  - OCPs containing the progestin drospirenone (structurally similar to spironolactone) may improve physical symptoms and mood changes associated with PMDD (5)[A]. Caution: Risk of venous thromboembolism may be modestly higher than with other OCPs (4)[B].
  - Continuous administration of levonorgestrel/ethinyl estradiol may improve

patient symptoms in PMDD (4)[B].

- Suggested OCP formulations:
  - Ethinyl estradiol 0.02 to 0.03 mg/drospirenone 3 mg (Gianvi/Loryna/Nikki/Ocella/Syeda/Vestura/Yasmin/Yaz Zarah): 1 tablet/day
  - Ethinyl estradiol 0.02 to 0.03 mg/drospirenone 3 mg/levomefolate 0.451 mg (Beyaz/Safyral): 1 tablet/day
  - Levonorgestrel 90 μg/ethinyl estradiol 20 μg (Amethyst/Lybrel): 1 tablet/day

- Anxiolytics
  - Alprazolam (Xanax) 0.25 mg TID–QID only during luteal phase; taper at onset of menses (other benzodiazepines not studied for PMDD). Caution: addictive potential
  - Buspirone (BuSpar) 10 to 30 mg/day divided BID–TID in the luteal phase
- Ovulation inhibitors
  - Gonadotropin-releasing hormone (GnRH) agonists: leuprolide (Lupron) depot 3.75 mg/month IM
    - Precautions: Menopause-like side effects (e.g., osteoporosis, hot flashes, headaches, muscle aches, vaginal dryness, irritability) limit treatment to 6 months; may be first step if considering bilateral oophorectomy for severe, refractory PMDD
  - Danazol (Danocrine) 300 to 400 mg BID; adverse reactions: androgenic and antiestrogenic effects (e.g., amenorrhea, weight gain, acne, fluid retention, hirsutism, hot flashes, vaginal dryness, emotional lability)
  - Estrogen, transdermal preferred, 100 to 200 μg:
    - Precautions: increased risk of blood clot, stroke, heart attack, and breast cancer
    - Requires concomitant progesterone add-back therapy to protect against uterine hyperplasia and endometrial cancer
- Progesterone: insufficient evidence to support use (6)[A]

ISSUES FOR REFERRAL

Referral to psychiatrist may be indicated for mood/anxiety disorders if patient has no symptom-free period.

ADDITIONAL THERAPIES

Cognitive-behavioral therapy (CBT) is theoretically helpful for PMS/PMDD given its application for symptom reduction in other mood disorders, but direct evidence is lacking.

SURGERY/OTHER PROCEDURES

Bilateral oophorectomy, usually with concomitant hysterectomy, is an option for rare, refractory cases with severe, disabling symptoms.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Acupuncture demonstrated superiority to progestins, anxiolytics, and sham acupuncture with no evidence of harm (7)[A].
- Some data support the use of the following (8)[A]:
  - Calcium: 600 mg BID
  - Vitamin B_6: 50 to 100 mg/day
  - Chasteberry (*Vitex agnus-castus*): 4 mg/day of extract containing 6% of agnuside (or 20 to 40 mg/day of fruit extract)
  - Omega-3 fatty acids 2 g/day
- Data insufficient regarding the following (8)[A]:
  - Magnesium: 200 to 400 mg/day
  - Vitamin D: 2,000 IU/day
  - Vitamin E: 400 IU/day
  - Manganese: 1.8 mg/day
  - St. John’s wort: 900 mg/day
  - Soy: 68 mg/day isoflavones
  - Ginkgo: 160 to 320 mg/day
  - Saffron: 30 mg/day
- Evidence supporting efficacy and/or safety of herbal products is lacking; the following products/interventions have *not* been found useful for PMS/PMDD, although not all studies are of high quality and able to eliminate possibility of benefit completely (8)[A]:
  - Evening primrose oil
  - Black currant oil
  - Black cohosh
  - Wild yam root

- Dong quai
- Kava kava
- Light-based therapy

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Increased risk of suicidal thinking and behavior in children and adolescents with depressive disorders on initiation of SSRIs; uncertain if this risk applies to those taking SSRIs for PMDD

DIET

- Reduce consumption of salt, sugar, caffeine, dairy products, and alcohol (anecdotal reports).
- Eat small, frequent portions of food high in complex carbohydrates (limited data).

PATIENT EDUCATION

- Counsel patients to eat a balanced diet rich in calcium, vitamin D, and omega-3 fatty acids and low in saturated fat and caffeine.
- Counsel women that they are not “crazy.” PMDD is a real disorder with a physiologic basis.
- Although incompletely understood, successful treatment is often possible.

PROGNOSIS

- Many patients can have their symptoms adequately controlled. PMS disappears at menopause.
- PMS can continue after hysterectomy, if ovaries are left in place.

CODES

ICD10

N94.3 Premenstrual tension syndrome

CLINICAL PEARLS

- Have the patient keep a daily log of her symptoms and menses. Symptoms beginning in the week before menses and abating before the end of menses, occurring over at least 2 months, and sufficiently severe to interfere with daily functioning are diagnostic of PMS.
- The difference between PMS and PMDD is that PMDD is a severe form of PMS characterized by recurrent depressive and anxiety symptoms with luteal phase onset, sufficiently severe to disrupt social and occupational functioning. These symptoms remit a few days after the onset of menses.
- PMDD is not the same as more generalized depressive/anxiety disorders. PMDD-associated symptoms of depression and anxiety begin to resolve within the first few days of menses.
- Treatment only during the luteal phase is likely as effective as continuous-cycle treatment with SSRIs but has fewer adverse effects.

PRENATAL CARE AND TESTING

Fozia Akhtar Ali, MD • Teny Anna Philip, MD

BASICS

- The goal of prenatal care is to ensure the birth of a healthy baby with minimal risk for the mother by the following:
  - Identifying the patient who is at risk for complications
  - Estimating the gestational age (GA) as accurately as possible
  - Evaluating the health status of mother and fetus
  - Encouraging and empowering the patient to do her part to care for herself and her baby-to-be
  - Intervening when fetal abnormalities are present to prevent morbidity

GENERAL PREVENTION

- A recommended prenatal care schedule consists of the following:
  - Monthly visits to a health care professional for weeks 4 to 28 of pregnancy
  - Visits twice monthly from 28 to 36 weeks
  - Weekly after week 36 (delivery at week 38 to 40)
- Recommendations for use of dietary supplements in pregnancy
  - Folic acid supplementation (0.4 to 0.8 mg) prior to conception; 4 mg for secondary prevention
  - Calcium: 1,000 to 1,300 mg/day; supplement may be beneficial for women with high risk for gestational hypertension or communities with low dietary calcium intake.
  - Iron: Screen for anemia (Hgb/Hct) and treat if necessary. Recommend 30 mg/day of iron in pregnant women.
  - Vitamin A: Pregnant women in industrialized countries should limit to <5,000 IU/day.
  - Vitamin D: Consider supplementation in women with limited exposure to sunlight.
- Routine thyroid screening and vitamin D deficiency during pregnancy is not recommended.

DIAGNOSIS

HISTORY

At the initial visit, a complete medical, obstetrical, family, and psychosocial history should be obtained and updated throughout the pregnancy.

- Assess and counsel as appropriate regarding the following:
  - Lifestyle, nutrition, safety of medications (teratogenicity, category); tobacco, alcohol, and drug use; toxins; relationship issues/domestic violence; stressors/supports; work environment; risk factors
- Domestic violence
  - ACOG guidelines recommend that physicians screen *all* pregnant patients for intimate partner domestic violence.
    - At the first prenatal visit
    - At least once per trimester
    - At the postpartum checkup

PHYSICAL EXAM

- A full physical exam should be performed at the first prenatal appointment.
- At each subsequent prenatal visit, the following should be recorded:
  - Weight: Total weight gain range (lb) should be 25 to 35 lb, except in obese women, for whom weight gain should be <15 lb.
  - BP
    - ACOG defines hypertension as BP >140 mm Hg systolic or >90 mm Hg diastolic (1,2).
    - Monitor BP especially closely in patients with chronic hypertension (predating pregnancy), preeclampsia/eclampsia, or gestational hypertension.
  - UA for glucose and protein; 24-hour protein excretion is the gold standard but not practical.
  - Fundal height
  - Fetal heart rate: usually audible by 12 weeks' GA with a Doppler instrument
  - Routine fetal movement counts *not* recommended
  - Fetal position by abdominal palpation at 36 weeks

- Pelvic/cervical exam if indicated

DIAGNOSTIC TESTS & INTERPRETATION

Cervical cancer screening

- A Pap smear should be obtained when indicated by standard Pap screening guidelines, regardless of gestation (ACOG, USPSTF, ASCCP, ACS, and ASCP guidelines state that women <21 years should not be screened regardless of age of sexual initiation or other risk factors).
- Squamous intraepithelial lesions can progress during pregnancy but often regress postpartum.
- LSIL in pregnancy: colposcopy preferred, but it is acceptable to defer colposcopy to postpartum (3).
- Colposcopy only to exclude the presence of invasive cancer in high-risk women
- Cervical biopsy should be avoided unless a malignancy is suspected. Endocervical sampling is contraindicated.
- First prenatal visit
  - Lab tests
    - Hematocrit or hemoglobin
    - Blood type: A, B, AB, or O
    - Rhesus type and antibody screen: Rh(+) or Rh(−)
    - Hemoglobin electrophoresis for patients at risk for sickle cell disease or thalassemia
    - Urine testing for glucose and protein
    - Urine culture
    - Rubella titer
    - Syphilis test
    - Gonorrhea/chlamydia screening
    - Hepatitis B surface antigen
    - HIV testing (patient may “opt out” if chooses to decline)
    - Routine screening for bacterial vaginosis, toxoplasmosis, CMV, and parvovirus not recommended
    - Cystic fibrosis screening (information should be made available to all couples)
      - Cystic fibrosis carrier screening should be offered before conception or

early in pregnancy when one partner is of Caucasian, European, or Ashkenazi Jewish descent (4).
        - It is reasonable to offer cystic fibrosis carrier screening to all couples regardless of race or ethnicity as an alternative to selective testing.
- Screening tests (for birth defects), noninvasive
  - US nuchal translucency (NT): measures thickness at the back of the neck of the fetus
  - Blood screens: human chorionic gonadotropin (hCG), pregnancy-associated plasma protein A (PAPP-A), quad screen: *α*-fetoprotein (AFP), unconjugated estriol (UE3), hCG, inhibin-A (INH-A)
  - Cell-free DNA testing should be offered as an alternative noninvasive method of screening for fetal aneuploidies to high-risk pregnant women between 10 and 22 weeks' gestation. Women who elect cell-free DNA testing will also need an AFP test for neural tube defects. The assay also allows screening for aneuploidy, rhesus typing in Rh(D) -negative women, and single-gene disorders (limited to detection of paternally inherited mutation). Because of a small but real risk for false-positive results, most experts advise using these assays as screening tests and confirming positive result with invasive prenatal diagnostics.
  - 1st-trimester screening between 11 and 14 weeks' GA using both NT and hCG/PAPP-A blood testing is an effective protocol in the general population and is more effective than NT alone, with an 83% detection rate for Down syndrome, with false-positive rate of 5%. Detects trisomy 21 (Down syndrome) and trisomy 18 (Edward syndrome). May be performed either as a single combined stand-alone test (US NT 1 blood [HCG and PAPP-A]) or as part of a sequential "step-by-step" 1st- and 2nd-trimester screening process (see the following discussion)
  - 2nd-trimester screening protocols
    - Obtain "multiple marker"/quad screen between 15 and 21 weeks' GA, optimally between 16 and 18 weeks; ~84% detection rate for trisomy 21, trisomy 18, and neural tube defects (NTDs), with false-positive rate of 5%, *or*
    - 2-step integrated screening protocol: combines information collected during the 1st and 2nd trimesters of the pregnancy to determine the risk

of Down syndrome, trisomy 18, or open NTD:

- Two options: stepwise sequential integrated screen (~91% detection rate with false-positive rate 3.3%):
  - 1st trimester: NT measurement, plus blood (hCG, PAPP-A):
    - If calculated risk for Down syndrome is ≥1:30, then additional steps are recommended (genetic counseling, US, and chorionic villi sampling [CVS]).
    - If calculated risk for Down syndrome is <1:30 *then*
  - 2nd-trimester quad screen (AFP, UE3, hCG, INH-A) is required, *or*
- Serum integrated screen: 88% detection rate with false-positive rate of 4.5%; requires a 1st-trimester PAPP-A blood test without NT measurement, and a 2nd-trimester (16- to 18-week quad screen)

- Diagnostic tests (for birth defects), invasive
  - ACOG guidelines: All pregnant women, not just women ≥35 years, should be offered invasive prenatal diagnostic testing, such as CVS and amniocentesis to detect possible genetic abnormalities in their fetuses (5) [C].
  - Women found to be at increased risk of having a baby with Down syndrome with 1st-trimester screening should be offered genetic counseling and the option of CVS or midtrimester amniocentesis. If screening tests show increased risk of birth defect, there are two possible diagnostic tests:
    - CVS: 1st trimester: usually done after 10 weeks (10 to 12 weeks). Small sample of the placenta; chorionic tissue sample obtained either transcervical (TC) or transabdominal (TA). Complication: pregnancy loss rate of 1.0–1.5%
    - Amniocentesis
      - 1st trimester: usually at 11 to 13 weeks but higher rate of pregnancy loss and complication than either CVS or early 2nd-trimester procedures; therefore, not recommended
      - 2nd trimester: usually done after 15 weeks (15 to 18 weeks). The prenatal diagnostic technique associated with the lowest risk of pregnancy loss. Small sample of amniotic fluid from the amniotic sac surrounding the developing fetus is obtained by an US-guided TA approach. Complication: pregnancy loss rate of ≤0.5%

- 24 to 28 weeks
  - Obtain diabetes screen (see the following discussion), repeat hematocrit or hemoglobin, and repeat antibody screen in Rh-negative mother prior to receiving prophylactic Rh immunoglobulin.
    - Gestational diabetes mellitus (GDM) screening: universal recommendation for ideal approach for screening and diagnosis of GDM remains elusive. In 2010, the International Association of Diabetes and Pregnancy Study Group proposed a new system in which diabetes in pregnancy is classified as overt versus gestational diabetes. The American Diabetes Association reaffirmed this in 2010 and 2013. Presently, this system is not endorsed by ACOG because there is no evidence that one-step screening using this criteria leads to clinically significant improvements in maternal and fetal outcomes but would lead to significant increase in health care costs.
    - Overt diabetes (test when women first present for prenatal care): fasting blood sugar ≥126 mg/dL or HbA1c ≥6.5%, or random ≥200 mg/dL that is confirmed with subsequent fasting blood sugar or HbA1c. (These thresholds were chosen due to correlation with adverse vascular events, e.g., retinopathy and CAD.)
    - Gestational diabetes: fasting plasma glucose >92 mg/dL but is <126 mg/dL at any GA. At 24 to 28 weeks of gestation, a 75 g 2-hour oral glucose tolerance test with at least 1 abnormal result: FBG ≥92 mg/dL, but <126 mg/dL or 1-hour ≥180 mg/dL, or 2-hour ≥153 mg/dL
    - The prevalence of gestational diabetes in the United States can be 2–25%, greater in African Americans, Hispanics, Native Americans, and Asians than in Caucasians. Using the IADPSG criteria for overt versus gestational diabetes, ~18% of women would be diagnosed with diabetes during pregnancy.
    - The following guidelines for GDM are established by ACOG:
      - Specified cutoffs define GDM
        - A value of >130 mg/dL will identify 90% of women with GDM, but 20–25% of all women screened will need to continue to the 3-hour oral glucose tolerance test (OGTT) (1,2).
        - Raising the value to >140 mg/dL will identify only 80% of women

with GDM but decrease to 14–18% the number of women who will need to continue to the 3-hour OGTT (6).

- Screening test: 1-hour OGTT (nonfasting)
  - 50 g PO glucose load with blood glucose testing 1 hour later
  - Carpenter and Coustan positive screen: >130 mg/dL
  - National Diabetes Data Group (NDDG) positive screen: >140 mg/dL
- Diagnostic test: 3-hour OGTT (fasting)
  - If abnormal 1-hour OGTT screening test, may be followed by a 3-hour OGTT
  - 100 g PO glucose load with blood drawn: fasting, 1, 2, and 3 hours after ingestion of glucose
  - Either the plasma or serum glucose level designated by Carpenter and Coustan or by the NDDG are appropriate to use:
    - *A positive diagnosis of GDM requires that ≥2 thresholds be exceeded.
      - Carpenter and Coustan standard
        - **>95 (fasting), >180 (1-hour), >155 (2-hour), >140 (3-hour)*
      - National Diabetes Data Group standard:
        - **105 (fasting), >190 (1-hour), >165 (2-hour), >145 (3-hour)*

- 35 to 37 weeks
  - Group B Streptococcus (GBS) culture: Universal screening for GBS colonization at 35 to 37 weeks of gestation remains the sole strategy for intrapartum antibiotic prophylaxis.
  - High-risk patients: High-risk patients should be screened again for gonorrhea, chlamydia, HIV, and syphilis.
- Postterm pregnancy
  - Rate of stillbirth increases with GA by 1/3,000 per week at 37 weeks; 3/3,000 per week at 42 weeks; and 6/3,000 at 43 weeks. In one meta-analysis, routine induction of labor at 41 weeks' gestation reduced rates of perinatal death without increased rates of cesarean delivery.
  - For gestational periods beyond 42 weeks, fetal well-being should be assessed with nonstress testing and US assessment of amniotic fluid volume.

TREATMENT

ISSUES FOR REFERRAL

Abnormal screening labs or imaging may prompt referral to maternal–fetal medicine specialist or other medical specialist, as indicated.

ONGOING CARE

PATIENT EDUCATION

- Immunizations during pregnancy. The following vaccines are considered safe per CDC (7):
  - Women should get (Tdap) during each pregnancy. Ideally, the vaccine should be given between 27 and 36 weeks of pregnancy—Hep B, and influenza; possibly include meningococcal, rabies. Contraindicated during pregnancy or safety not established:live vaccines including BCG, MMR, and varicella.
  - Patients should be made aware of the tests that are performed routinely, as well as other tests that might be elected (e.g., CVS or amniocentesis), as well as the choices that would be available if testing were abnormal (pregnancy termination, preparation for the birth of an infant with congenital anomalies, further testing).
- Prevention
  - Preconception counseling offers the opportunity to discuss individualized risks.
- To decrease the risks of NTDs, preconception folate supplementation is indicated.
- Recommendations
  - Airline travel: generally safe until up to 4 weeks from EDD. Lengthy trips associated with increased risk of thrombosis
  - Caffeine: Limit to <200 mg/day. Correlation between IUGR and miscarriage with caffeine is undetermined at this time.
  - Exercise: Healthy women with uncomplicated pregnancies should continue to exercise.

  - Seat belts/air bags: ACOG recommends that pregnant women wear lap and shoulder seatbelts and should not turn off air bags.
  - Sexual activity: Intercourse is not associated with adverse outcomes.
- Alcohol, cigarettes, and illicit drugs are injurious to fetal and maternal health.
  - Pregnancy-safe medications (teratogenicity)

CODES

ICD10

- Z34.90 Encntr for suprvsn of normal pregnancy, unsp, unsp trimester
- Z36 Encounter for antenatal screening of mother

- Z34.00 Encntr for suprvsn of normal first pregnancy, unsp trimester

CLINICAL PEARLS

Prenatal care and screening are best accomplished using standardized flow sheets and checklists to ensure that the complex sequence of evaluations and education is performed consistently and properly.

PREOPERATIVE EVALUATION OF THE NONCARDIAC SURGICAL PATIENT

Andrew Grimes, MD • Stacy L. Jones, MD

BASICS

DESCRIPTION

- Preoperative medical evaluation should determine the presence of established or unrecognized disease or other factors that may increase the risk of perioperative morbidity and mortality in patients undergoing surgery.
- Specific assessment goals include the following:
  - Conducting a thorough medical history and physical exam to assess the need for further testing and/or consultation
  - Recommending strategies to reduce risk and optimize patient condition prior to surgery
  - Encouraging patients to optimize their health for possible improvement of both perioperative and long-term outcomes
- Synonym(s): preoperative diagnostic workup; preoperative preparation; preoperative general health assessment

EPIDEMIOLOGY

Overall patient morbidity and mortality related to surgery is low. One large study of inpatients looking at 30-day mortality in the United States showed a rate of 1.32%. This rate varies by type of procedure and varies by country. Preoperative patient evaluation and subsequent optimization of perioperative care can reduce both postoperative morbidity and mortality.

RISK FACTORS

- Functional capacity (1): Exercise tolerance is one of the most important determinants of cardiac risk:
  - Self-reported exercise tolerance may be an extremely useful predictive tool when assessing risk. Patients unable to meet a 4 metabolic equivalents (MET) demand (defined in the “Diagnosis” section) during daily activities have increased perioperative cardiac and long-term risks.

  - Patients who report good exercise tolerance require minimal, if any, additional testing.
- Levels of surgical risk
  - An increased risk for major adverse cardiac events (MACE) is associated with procedures that are intrathoracic, intra-abdominal, or vascular procedures that are suprainguinal in nature (1).
- Clinical risk factors (1): history of ischemic heart disease, the presence of compensated heart failure or a history of prior congestive heart failure (CHF), cerebrovascular disease, diabetes mellitus (DM), and renal insufficiency; these risk factors plus surgical risk can dictate the need for further cardiac testing.
- Age: Patients >70 years of age are at higher risk for perioperative complications and mortality and have a longer length of stay in the hospital postoperatively (likely attributed to increasing medical comorbidities with increasing age). Age alone should not be a deciding factor in the decision to proceed or not proceed with surgery.

DIAGNOSIS

HISTORY

- Evaluate pertinent medical records and interview the patient. Many institutions provide standard patient questionnaires that screen for preoperative risk factors:
  - History of present illness and treatments
  - Past medical and surgical history
  - Patient and family anesthetic history and associated complications
  - Current medications (including over-the-counter [OTC] medications, vitamins, supplements, and herbals) as well as reasons for use
  - Allergies (including specific reactions)
  - Social history: tobacco, alcohol, drug use, and cessation
  - Family history: prior illnesses and surgeries
- Systems (both history and current status)
  - Cardiovascular: Inquire about exercise capacity.
    - 1 MET: can take care of self, eat, dress, and use toilet; walk around house indoors; walk a block or 2 on level ground at 2 to 3 mph

    - 4 METs: can climb flight of stairs or walk uphill, walk on level ground at 4 mph, run a short distance, do heavy work around house, participate in moderate recreational activities
    - 10 METs: can participate in strenuous sports such as swimming, singles tennis, football, basketball, or skiing
- Note presence of CHF, cardiomyopathy, ischemic heart disease (stable vs. unstable), valvular disease, hypertension (HTN), arrhythmias, murmurs, pericarditis, history of pacemaker or implantable cardioverter defibrillator (ICD):
    - Rhythm management devices (pacemakers and automatic ICDs [AICD]) affect the perioperative course. Most importantly, the following information need to be available for proper management: name of cardiologist who manages the device, type of device, manufacturer, last interrogation, and any problems that have occurred recently. Based on this information and the location and type of surgery, a perioperative plan of management will be made (2).
    - Stents: Patients with coronary stents are maintained on antiplatelet therapy with a thienopyridine, such as clopidogrel, frequently in combination with aspirin. Premature discontinuation of antiplatelet therapy markedly increases the risk of acute stent thrombosis, the results of which can be catastrophic. Elective surgery should be delayed and antiplatelet therapy continued for 4 to 6 weeks after bare-metal stent placement and for at least 12 months after placement of drug-eluting stents. Even after this time period, any perioperative disruption in the patient's antiplatelet regimen should be discussed with the patient's cardiologist and surgeon. The risk of perioperative bleeding must be weighed against the risks associated with discontinuation of antiplatelet drugs prior to surgery.
- Pulmonary: Chronic and active disease processes should be addressed: chronic infections, bronchitis, emphysema, asthma, wheezing, shortness of breath, cough (productive or otherwise):
    - Sleep apnea: Patients with obstructive sleep apnea (OSA) are at increased risk for perioperative adverse events. Screening tools (such as the STOP/BANG) can help risk stratify patients. Additional evaluation

should be considered if a patient has associated significant systemic disease, hypoventilation syndrome, severe pulmonary HTN, or resting hypoxemia (3).
    - Often, patients with an existing diagnosis of OSA who use positive airway pressure (PAP) at night are asked to bring their PAP machine to the hospital or surgery center when they are admitted for surgery. For patients with suspected but previously undiagnosed OSA, PAP therapy should be considered on a case by case basis.
    - Some studies suggest that even short periods (3 weeks) of treatment with PAP can improve some indices of ventilation and therefore may reduce postoperative morbidity.
  - GI: hepatic disease, gastric ulcer, inflammatory bowel disease, hernias (especially hiatal), significant weight loss, nausea, vomiting, history of postoperative nausea and vomiting: Any symptoms consistent with gastroesophageal reflux disease (GERD) should be optimally treated.
  - Hematologic: anemia, serious bleeding, clotting problems, blood transfusions, hereditary disorders
  - Renal: kidney failure, dialysis, infections, stones, changes in bladder function
  - Endocrine: nocturia, parathyroid, pituitary, adrenal disease, thyroid disease
    - Diabetes: Evidence that hyperglycemia in the perioperative period is associated with increased perioperative complications. Although recommendations vary, most experts recommend keeping perioperative blood glucose levels <180.
  - Neurologic/psychiatric: seizures, stroke, paralysis, tremor, migraine headaches, nerve injury, multiple sclerosis, extremity numbness, psychiatric disorders (e.g., anxiety, depression)
  - Musculoskeletal: arthritis, lower back pain
  - Reproductive: possibility of pregnancy in women of childbearing potential
- Mouth/upper airway: dentures, crowns, partials, bridges, teeth (loose, chipped, cracked, capped)

PHYSICAL EXAM

- Assess vital signs, including arterial BP bilaterally.
- Check carotid pulses; auscultate for bruits.

- Examine lungs by auscultating all lung fields and listening for rales, rhonchi, wheezes, or other sounds indicating disease.
- Examine cardiovascular system by auscultating heart and noting any irregular rhythms or murmurs; precordial palpation.
- Palpate abdomen.
- Examine airway and mouth for ease of intubation, neck mobility, and size of tongue; note any lesions or dental deformities.
- If a regional anesthesia technique is being contemplated, perform a relevant, focused neurologic exam.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Laboratory testing should not be obtained routinely prior to surgery unless indicated (4)[C]. Specific tests should be requested if the evaluator suspects findings from the clinical evaluation that may influence perioperative patient management.
- Labs performed within the past 4 months prior to evaluation are reliable unless the patient has had an interim change in clinical presentation or is taking medications that require monitoring of plasma level or effect.
- CBC (4)[C]
  - Hemoglobin: if a patient has symptoms of anemia or is undergoing a procedure with major blood loss; extremes of age; liver or kidney disease
  - WBC count: if symptoms suggest infection or myeloproliferative disorder or the patient is at risk for chemotherapy-induced leukopenia
  - Platelet count: if history of bleeding, myeloproliferative disorder, liver or renal disease, or the patient is at risk for chemotherapy-induced thrombocytopenia
- Serum chemistries (electrolytes, glucose, renal and liver function tests): should be obtained for extremes of age; in known renal insufficiency, CHF, liver dysfunction, or endocrine abnormalities; or the patient is on medications that alter electrolyte levels, such as diuretics
- PT/PTT: if history of a bleeding disorder, chronic liver disease, or malnutrition, or those with recent or chronic antibiotic or anticoagulant use
- Urinalysis: Routine urinalysis is not recommended preoperatively.

- Pregnancy test: controversial; should be *considered* for all female patients of childbearing age
- CXR is not generally indicated. It can be considered in patients with recent upper respiratory tract infection and in those with suspected cardiac or pulmonary disease (because there is a likelihood for unanticipated findings), but these indications are not considered unequivocal.

Diagnostic Procedures/Other

- ECG (1)[C]
  - Preoperative resting 12 lead ECG is reasonable for patients with known coronary disease, known peripheral vascular disease, significant arrhythmia, or known significant structural heart disease.
  - ECGs are not indicated for asymptomatic patients undergoing low-risk procedures.
- The AHA guidelines recommend using the Revised Cardiac Risk Index or the ACS NSQUIP online risk calculator to make an estimate of risk of MACE in the perioperative period. If the risk of MACE is low (<1%), then proceed with surgery. If the risk is >1%, the functional capacity needs to be considered. For patients with a functional capacity of >4 METs, then proceed with surgery. If the functional capacity is <4 METs or unknown, consider pharmacologic stress testing if it will change management (1).
- PFTs: Definitive data regarding the efficacy of preoperative testing are lacking. The most important factor is preoperative optimization of patients with chronic obstructive pulmonary disease (COPD) or reactive airways disease with indicated use of antibiotics, bronchodilators, and inhaled corticosteroids. Spirometry can help guide therapy. Upper abdominal and thoracic surgery have a higher risk of postoperative pulmonary complications.

TREATMENT

MEDICATION

- Reducing cardiac risk
  - Elective surgery should be delayed or canceled if the patient has any of the following: unstable coronary syndromes (unstable or severe angina), recent

myocardial infarction (MI) (<30 days), decompensated heart failure, significant arrhythmias, or severe valvular disease.
  - Active HF should be treated with diuretics, afterload reduction, and *β*-adrenergic blockers.
  - Perioperative *β*-blockade has been shown to reduce mortality and the incidence of perioperative MIs in high-risk patients. Studies conflict, however, in which patients need to be treated, the dosage and timing of treatment, and for what surgeries. *Patients chronically on β*-blockers should have the medication continued in the perioperative period. When *β*-blockers are discontinued in the perioperative period, 30-day mortality increases. *β*-Blockers are reasonable for vascular surgery patients with at least one clinical risk factor. It is not recommended to start *β*-blockers on the day of surgery in *β*-blocker naïve patients (1).
  - Perioperative statin use may have a protective effect on reducing cardiac complications. Currently, the American Heart Association (AHA) has a class I indication for perioperative statin therapy for patients already on statins prior to their surgery. There is also evidence that vascular surgery patients benefit from perioperative statins.
  - A recent review looked at prophylactic use of aspirin in the perioperative period and did not find a significant effect on perioperative mortality or risk for MI in patients undergoing noncardiac surgery and may be associated with an increased risk of perioperative bleeding. There were important exclusion criteria including patients with recent stent placement.
- Reducing pulmonary risk
  - Recommend cigarette cessation for at least 8 weeks prior to elective surgery.
  - Patients with asthma should not be wheezing and should have a peak flow of at least 80% of their predicted or personal-best value.
  - Treatment of COPD and asthma should focus on maximally reducing airflow obstruction and is identical to treatment of nonsurgical patients.
  - Lower respiratory tract infections (bacterial) should be treated with appropriate antibiotic therapy.

SEE ALSO

Algorithm: Preoperative Evaluation of the Noncardiac Surgical Patient

CODES

ICD10

- Z01.818 Encounter for other preprocedural examination
- Z01.811 Encounter for preprocedural respiratory examination
- Z01.812 Encounter for preprocedural laboratory examination

CLINICAL PEARLS

- The preoperative evaluation should include medical record evaluation, patient interview, and physical exam.
- The minimum for the physical exam includes airway, pulmonary, and cardiovascular exams.
- Functional capacity, the level of surgical risk, and clinical risk factors determine if further cardiac testing is needed.
- No preoperative tests are routine.
- Active cardiac conditions should lead to delay or cancellation of nonemergent surgery.

PRESBYCUSIS

Ronald L. Cook, DO, MBA, FAAFP, FACOFP • Kimberly C. Nelson, MD

BASICS

DESCRIPTION

- May be divided into central and peripheral causes:
  - Central presbycusis: age-related change in the auditory portions of the central nervous system negatively impacting auditory perception, speech-communication performance, or both
  - Peripheral presbycusis: age-related, bilateral sensorineural hearing loss (SNHL) typically symmetric
- Represents a lifetime of insults to the auditory system from toxic noise exposure and natural decline
- Initially presents as high-frequency SNHL with tinnitus (ringing)
- Impacts the "clarity" of sounds (i.e., ability to detect, identify, and localize sounds)
- Due to mild and progressive nature, presbycusis is often treated with amplification alone.
- Can lead to adverse effects on physical, cognitive, emotional, behavioral, and social function in the elderly (e.g., depression, social isolation)

EPIDEMIOLOGY

Incidence

According to an ongoing community-based epidemiologic study, the 10-year cumulative incidence rates of hearing loss (HL) are as follows, approximately:

- Age 48 to 59 years: M (31.7%), F (15.6%); all (21.8%)
- Age 60 to 69 years: M (56.8%), F (40.7%); all (45.5%)
- Age 70 to 79 years: M (87.1%), F (70.6%); all (73.7%)
- Age 80 to 92 years: M (100%), F (100%); all (100%)

Prevalence

- 10% of the population develops SNHL severe enough to impair

communication.

- Increases to 40% in the population >65 years of age
- 80% of HL cases occur in elderly patients.
- Only 10–20% of older adults with HL have ever used hearing aids (HAs).
- Predominant sex: male > female
- Hearing levels are poorer in industrialized societies than in isolated or agrarian societies.

ETIOLOGY AND PATHOPHYSIOLOGY

- The external ear transmits sound energy to the tympanic membrane. The middle ear ossicles amplify and conduct the sound waves into the inner ear (cochlea) via the oval window. The organ of Corti, located in the cochlea, contains hair cells that detect these vibrations and depolarize, producing electrical signals that travel through the auditory nerve to the brain. Toxic noise exposure traumatizes the hair cells and leads to cell death and HL. New research also suggests that overexcitation of the neurosynapses causes increased glutamate, which is also neurotoxic (1).
  - Sensory presbycusis: primary loss of the hair cells in the basal end of the cochlea (high frequency HL)
  - Neural presbycusis: loss of spiral ganglion cells (nerve cells induced by hair cells to produce action potentials to travel to the brainstem)
  - Strial (metabolic) presbycusis: atrophy of the stria vascularis (the cochlear tissue that generates the endocochlear electrical potential)
  - Cochlear conductive (mechanical) presbycusis: no morphologic findings (presumed stiffening of the basilar membrane)
  - Mixed presbycusis: combinations of hair cell, ganglion cell, and stria vascularis loss
  - Indeterminate presbycusis: no morphologic findings (presumed impaired cellular function)
- Presbycusis is caused by the accumulated effects of noise exposure, systemic disease, oxidative damage, ototoxic drugs, and genetic susceptibility.

Genetics

Presbycusis has a clear familial aggregation:

- Heritability estimates show 35–55% of the variance of sensory presbycusis is

from genetic factors; even greater percentage in strial presbycusis
- Heritability is stronger among women than men.

RISK FACTORS

- Noise exposure (military, industrial, etc.)
- Ototoxic substances
  - Organic solvents
  - Heavy metals
  - Carbon monoxide
- Drugs
  - Aminoglycosides
  - Cisplatin
  - Salicylates
  - Diuretics
- Tobacco smoking
- Alcohol
- Lower socioeconomic status
- Family history of presbycusis
- Head trauma (temporal bone fractures)
- Cardiovascular disease (hypertension, atherosclerosis, hyperlipidemia); labyrinthine artery is terminal artery to the cochlea.
- Diabetes mellitus
- Autoimmune disease (autocochleitis/labyrinthitis)
- Metabolic bone disease
- Endocrine medical conditions: levels of aldosterone
- Alzheimer disease
- Otologic conditions (e.g., Ménière disease or otosclerosis)

GENERAL PREVENTION

- Avoid hazardous noise exposure.
- Use hearing protection.
- Maintain healthy diet and exercise.
- Screening
  - In the only published RCT on screening for HL, HA use was significantly higher in three screened groups (4.1% in those using a questionnaire, 6.3%

using handheld audiometry, and 7.4% using both modalities) versus unscreened control participants (3.3%) at 1-year follow-up (2)[B].
  - Based on a 2011 review, according to the USPSTF, there is insufficient evidence to assess the relative benefits and harms of HL screening in adults ≥50 years (3)[A].

DIAGNOSIS

HISTORY

- Reduced hearing sensitivity and speech understanding in noisy/public environments
- Impaired localization of sound sources
- Increased difficulty understanding conversations, especially with women, due to higher frequency of spoken voice
- Presents bilaterally and symmetrically
- If unilateral HL, alternative diagnosis should be pursued.
- Additional history if HL is suspected or detected (4)[B]:
  - Time course of HL
  - Symptoms of tinnitus, otalgia, otorrhea, or vertigo
  - History of noise exposure, ear trauma, or head trauma
  - Presence of any neurologic deficit
- Reports from patient/family/caregiver (4)[B]
  - Confusion in social situations
  - Excessive volume of television/radio/computer
  - Social withdrawal
  - Anxiety in group settings

PHYSICAL EXAM

- Rinne and Weber tests are helpful for determining conductive versus SNHL but not recommended for general screening.
- Pneumatic otoscopy to evaluate for simple middle ear effusion as cause of conductive HL

DIFFERENTIAL DIAGNOSIS

- Complete canal occlusion (cerumen, foreign body)

- Large external ear tumors (e.g., polyp, exostosis, squamous cell)
- Otitis externa
- Chronic otitis media or effusion
- Cholesteatoma
- Otosclerosis
- Osteogenesis imperfecta
- Large middle ear tumors (e.g., facial nerve schwannomas, paragangliomas)
- Perilymph fistula (trauma/iatrogenic)
- Ménière disease
- Acoustic neuroma (usually unilateral)
- Vascular anomaly
- Acute noise-induced traumatic loss (explosion)
- Autoimmune HL

DIAGNOSTIC TESTS & INTERPRETATION

- Central: Synthetic Sentence Identification test with Ipsilateral Competing Message and the Dichotic Sentence Identification test (5)[A]
- Peripheral: Handheld audiometry; insert probe in ear (sealing canal) and have patient indicate if tones can be heard.
  - Positive likelihood ratio (LR) range, 3.1 to 5.8; negative LR range, 0.03 to 0.40
- Screening audiometry
  - Symmetric high-frequency HL in descending slope pattern
  - SNHL frequencies >2 KHz initially
  - Essential to determine global clinical hearing status and if etiology is conductive HL versus SNHL or pseudohypacusis (conversion)

TREATMENT

- HAs
  - Types
    - Analog HA: picks up sound waves through a microphone; converts them into electrical signals; amplifies and sends them through the ear canal to the tympanic membrane

    - Digital HA: programmable; may reduce acoustic feedback, reduce background noise, detect and automatically accommodate different listening environments, control multiple microphones.
  - HAs have an average decibel gain of 16.3 dB.
  - Associated with hypersensitivity to loud sounds (“loudness recruitment”)
- Hearing-assistive technologies (HATs) (6)[A]
  - Can be used alone or in combination with HAs (for difficult listening conditions)
  - Addresses face-to-face communication, broadcast or other electronic media (radio, TV), telephone conversation, sensitivity to alerting signals and environment stimuli (doorbell, baby’s cry, alarm clock, etc.)
  - Includes personal FM systems, infrared systems, induction loop systems, hardwired systems, telephone amplifier, telecoil, TDD (telecommunication device for the deaf), situation-specific devices (e.g., television), alerting devices
- Aural rehabilitation (also known as audiologic orientation or auditory training) (4)[A]
  - Adjunct to HA or HATs
  - Involves education regarding proper use of amplification devices, coaching on how to manage the auditory environment, training in speech perception and communication, and counseling for coping strategies to deal with the difficulties of HAs or HATs

ISSUES FOR REFERRAL

Refer to audiologist for formal evaluation and optimal fitting of HAs and/or HATs.

- Individuals receiving postfitting orientation/education have significantly fewer HA returns.
- Individuals receiving >2 hours of education and counseling report higher levels of satisfaction.

SURGERY/OTHER PROCEDURES

- Cochlear implants (CIs)
  - Works by bypassing the ear canal, middle ear, and hair cells in the cochlea to provide electric stimulation directly to the auditory nerve

- Indications include hearing no better than identifying ≤50% of key words in test sentences in the best aided condition in the worst ear and 60% in the better ear.
- Incoming sounds are received through the microphone in the audio processor component (resembles a small HA), which converts them into electrical impulses and sends them to the magnetic coil (located on the skin). The impulses transmit these across intact skin via radio waves to the implanted component (directly subjacent to the coil). The pulses travel to the electrodes in the cochlea and stimulate the cochlea at high rates.
- Receiving a unilateral CI is most common; some may receive bilateral CIs (either sequentially or in the same surgery). Others may wear a CI in 1 ear and an HA in the contralateral ear (bimodal fit).
- Younger age at CI placement derives greatest benefit.

- Active middle ear implants (AMEIs) (6)[B]
  - Suitable for elderly adults who cannot wear conventional HAs for medical or personal (cosmetic) reasons and whose HL is not severe enough for a CI
  - Comes in different models and may include components that are implantable under the skin
- Electric acoustic stimulation: use of CI and HA together in one ear
  - Addresses the specific needs of patients presenting with good low-frequency hearing (a mild to moderate sensorineural HL in frequencies up to 1,000 Hz) but poorer hearing in the high frequencies (sloping to 60 dB or worse HL above 1,000 Hz)
    - Contraindications: progressive HL, autoimmune disease; HL related to meningitis, otosclerosis, or ossification; malformation of the cochlea; a gap in air conduction and bone conduction thresholds of >15 dB; external ear contraindications, active infection, or unwillingness to use amplification devices

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- During follow-up visits, check for compliance of HA use.
  - 25–40% of adults will either stop wearing them or use them only occasionally.
- Assess perceived benefit of HA and, if ineffective, for indications for possible surgical treatments.
- Annual audiograms
- Can follow up with audiologists for HA fittings if HA becomes uncomfortable
- Asymmetric HL should have evaluation via MRI for acoustic neuroma.
- Sudden SNHL is atypical and warrants urgent otolaryngologic evaluation/audiometry. The most recent recommendations by the American Academy of Otolaryngology recommend steroids empirically.

PATIENT EDUCATION

- Should be face-to-face; spoken clearly and unhurriedly, without competing background noise (e.g., radio, TV); and include a confirmation that the message is received.
- Formal speech reading classes may be beneficial; however, availability may be limited.

CODES

ICD10

- H91.10 Presbycusis, unspecified ear
- H91.13 Presbycusis, bilateral
- H91.11 Presbycusis, right ear

CLINICAL PEARLS

- Presbycusis is an age-related HL, showing increased incidence with age. It is often bilateral and initially begins as high-frequency HL. It presents as difficulty communicating in noisy conditions.
- There are more affected males than females.
- Compliance is only 25–40% for those who own HA. A referral to an audiologist is key for optimal evaluation, fitting for HAs, and other assistive technologies or surgical treatment.
- Indication for CIs include hearing no better than identifying ≤50% key words in test sentences in the best aided condition in the worst ear and 60% in the better ear.
- Early audiology referral for individuals with suspected HL may improve

treatment efficacy.

PRESSURE ULCER

Amy M. Zack, MD, FAAFP

BASICS

DESCRIPTION

- A localized area of soft tissue injury resulting from pressure between an external surface and a bony prominence that causes local tissue breakdown classified in stages according to the National Pressure Ulcer Advisory Panel (NPUAP) classification.
  - Stage I: erythema of localized area, usually nonblanching over bony surface; may be painful, have consistency or temperature difference from surrounding tissue
  - Stage II: partial loss of dermal layer, resulting in pink ulceration; may be fluid-filled blister, or shiny, dry ulcer
  - Stage III: Full dermal loss often exposing subcutaneous tissue and fat.
  - Stage IV: Full-thickness ulceration exposing bone, tendon, or muscle. Osteomyelitis may be present.
- Synonym(s): decubitus ulcer; bed sores

EPIDEMIOLOGY

Incidence

2.5 million pressure ulcers treated yearly in United States in acute care facilities (1)

Prevalence

- Acute care 0.4–38%; long-term care 2.2–23.9%; home care 0–17%
- Majority occur in patients >65 years: 36% with hip fracture, 50% in ICU care (2)

ETIOLOGY AND PATHOPHYSIOLOGY

- Pathophysiology of pressure ulcers is changing, differs depending on stage of ulceration.
- Stages I to II result largely from prolonged moisture and friction and may not

even be related to pressure and hypoxia, as previously believed (3).

- Stages III to IV likely begin with compressive forces, causing muscle damage and tissue hypoxia and leading to reperfusion injury of the deep tissue. The skin ulcer forms after significant deep tissue damage is already under way (3).
- Shearing and friction forces are also components of some ulcer formation, resulting in localized skin damage and early-stage ulcers (3).

RISK FACTORS

- Immobility: greatest risk factor regardless of patient, temporary or permanent immobility (4)
- Urinary and fecal incontinence present in >80% of immobile patients with pressure ulcers
- Poor nutritional status: Hypoalbuminemia and low BMI are markers for poor ulcer outcome (4).
- Poor skin perfusion, including vascular disease, diabetes, anemia, and tobacco use, increases risk.
- Extended stay in hospital/nursing home, inadequate staffing (5)
- Other risks include history of previous ulcer, age-related skin changes, immunocompromise, impaired skin sensation, and impaired awareness.
- Assessment scales commonly used for risk evaluation include Braden and Norton scales. The use of these does not decrease incidence, but they are more accurate than clinical judgment alone (6)[A].

GENERAL PREVENTION

- *Up to 95% are preventable*; identification of at-risk patients within 8 hours of admission, with early multidisciplinary care.
- *Skin assessment*: policy in all health care settings (5)[B]
  - Increase frequency of assessments with decline in clinical condition (5)[C].
  - Include erythema, edema, skin temperature, and consistency in all evaluation (5)[B].
  - Assess around medical devices twice daily (5)[C].
- *Pressure relief*
  - Establish pressure relief schedule.
  - Proper patient positioning and the use of mattresses, cushions, heel protectors, and other devices to minimize pressure and friction

  - Regular turning of patients, including the use of angles and rotation of extremities, helps to minimize pressure.
- *Avoid positioning on area of erythema* (5)[C].
- *Minimize duration of immobility*: adequate physical and occupational therapies when appropriate
- *Aggressive moisture prevention*: management plan for incontinence (5)[C]
- *Nutrition*
  - Complete assessment of nutritional status and form plan, particularly protein intake and albumin levels.
  - Reassess with all changes in condition.
  - Develop individualized nutritional care plan for protein, calories, vitamins, and hydration (5)[C].
- *Manage skin health:* clean and dry with mild cleansers, skin protection where appropriate. Avoid massage or rubbing skin prone to ulcers (5)[C].
- *Microclimate control*: emerging therapy, control moisture, and temperature when selecting support structure. Avoid use of heating devices (5)[C].
- *Prophylactic dressings*: emerging therapy, apply foam dressing to bony prominences to avoid friction and shear (5)[B].
- *Textiles and fabrics*: Sheets and clothing should be silk-like rather than cotton or other abrasives.

COMMONLY ASSOCIATED CONDITIONS

See "Risk Factors."

DIAGNOSIS

HISTORY

- Risk factors
- Date of ulcer diagnosis
- Treatment course

PHYSICAL EXAM

- Do full skin examination on admission to hospital or extended-care facility and repeatedly throughout admission, best with bathing/bed changes.
- 83% of hospitalized patients with decubitus ulcers develop them in first 5 days

of hospitalization.

- Classify ulcer based on NPUAP stages (see "Description").
  - Focus on skin color, consistency, and temperature changes when classifying ulcer.
  - Assess and document location, category, size, tissue, color, edges, sinus tracts, exudate, odor.
  - Assess pain (5)[B].

DIFFERENTIAL DIAGNOSIS

- Venous stasis ulcers
- Arterial ulcers resulting from poor vascular supply
- Diabetic ulcers
- Pyoderma gangrenosum, cancers, vasculitides, and other dermatologic conditions

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Wound culture: Do not culture surface drainage. If culture necessary, do deep tissue culture/bone biopsy.
- If systemic infection or that of bone, muscle is suspected, add infectious workup, including inflammatory markers, CBC, blood cultures, x-ray. MRI may be necessary to confirm osteomyelitis.
- Nutritional assessment: BMI, protein and calorie intake, albumin, prealbumin, CBC for anemia. No clear evidence in support of specific nutritional supplements including zinc and vitamin C (7)[A],(8)[B].

Follow-Up Tests & Special Considerations

Additional tests may be indicated when additional medical illness complicates assessment. This may include testing for diabetes, vascular disease, and other dermatologic diagnoses.

TREATMENT

GENERAL MEASURES

- Pressure reduction, minimize immobility, manage incontinence, and improve

nutritional status and skin health (as described in “Prevention”)

- Wound management by stage of ulcer
  - Stage I: aggressive preventive measures, thin film dressings for protection
  - Stage II: occlusive dressing to maintain healing, transparent films, hydrocolloids
  - Stages III to IV: débridement of necrotic tissue. Exudative ulcers will benefit from absorptive dressings such as calcium alginates, foams, hydrofibers. Dry ulcers require occlusive dressing to maintain moisture, including hydrocolloids, and hydrogels.
  - Débridement: type depends on extent of necrosis or eschar, or presence of biofilm; incisional with scalpel when extensive dry. Mechanical with wet-dry dressings; enzymatic débridement is also frequently used. Débride only when there is adequate perfusion to wound.
  - Surgical closure may be necessary in advanced wounds.
- Vacuum-assisted closure
  - Negative pressure reduces wound edema and improves local tissue perfusion.
  - Removes necrotic debris and reduces bacterial load
  - Literature review demonstrates the efficacy of negative-pressure wound therapy (9)[A].
- Dressings: mixed evidence for improvement (10)[B]
  - Select based on wound, exudate, ulcer stage.
  - Gauze: Avoid use, if no other options, wet-to-dry only.
  - Hydrocolloid: clean, shallow Stage II, not infected
  - Transparent: autolytic débridement, not for use on heavy exudate or over enzymatic debriding agents
  - Hydrogel: Stage II, shallow, minimal exudate, not infected
  - Alginate: Stage II to III, shallow with heavy exudate, infected, long duration dressing
  - Foam: Stage II to III, shallow with heavy exudate
  - Collagen-matrix: nonhealing Stage III to IV
  - Silver impregnated: infected or heavily colonized, high risk infection, short duration only
  - Honey impregnated: Stage II/III

- Cadexomer iodine: Stage II/III with heavy exudate

MEDICATION

First Line

- See "General Measures" for first-line treatment.
- Pain control
- Aggressive management of contributing medical conditions
- Infection: If suspected, treat appropriately for cellulitis or osteomyelitis.
  - High index of suspicion for infection: poor healing, odor, pain, warmth, drainage, necrosis, diabetes, malnutrition, poor perfusion, immunosuppression, culture with $>10^5$ cfu/g or GBS presence
- Topical therapy
  - Débride as indicated
  - Nontoxic topical anesthetics including iodine, silver sulfadiazine, chlorhexidine (avoid hydrogen peroxide, Dakin solution) (5)[C]

Second Line

Nutritional interventions as determined by nutritional assessment. Weak evidence to support protein supplementation to reduce wound size (10)[C]

ISSUES FOR REFERRAL

- Vascular surgery is a consideration for improvement of blood flow to wound via vascular bypass.
- Plastic surgery is a consideration for skin graft/flap.

ADDITIONAL THERAPIES

- Alternative therapies
  - Light, laser, acoustic have little shown benefit.
  - Whirlpool contraindicated (5)[B]
  - Electrical stimulation shows some benefit (10)[B].

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Nutritional support as needed
- Ultrasound and electrical stimulation create new vasculature in affected region (9)[C].

ADMISSION, INPATIENT, AND NURSING

CONSIDERATIONS

- Admission criteria/initial stabilization: refractory cellulitis, osteomyelitis, systemic infection, advanced nutritional decline, suspected patient mistreatment, inability to care for self
- Dressing changes 1 to 3 times daily based on wound assessment and plan of care
- Assess risk factors according to scales.
- Assess for new or changing wounds.
- Discharge criteria: clinical improvement in wound and systemic illness; when applicable, safe, and appropriate location for discharge

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Weekly assessment by nurse with wound experience; biweekly assessment by physician

Patient Monitoring

- Home health nursing
- Change in plan of care if no improvement in 2 to 3 weeks

DIET

- 1 to 1.5 kg/day of protein
- Good glycemic control
- Include supply of micronutrients in diet or as supplements.

PATIENT EDUCATION

- Check skin regularly.
- Signs and symptoms of infection
- Report new or increased pain.
- Prevention of new wound where old wound healed
- Skin care, moisture prevention

PROGNOSIS

Variable, depending on the following:

- Removal of pressure
- Nutrition
- Wound care

COMPLICATIONS

- Infection
- Amputation

CODES

ICD10

- L89.95 Pressure ulcer of unspecified site, unstageable
- L89.91 Pressure ulcer of unspecified site, stage 1
- L89.92 Pressure ulcer of unspecified site, stage 2

CLINICAL PEARLS

- Create assessment and prevention protocols for all patients.
- Identify risk, reduce pressure, maximize nutrition, regular skin checks, and assess and treat wound appropriately.
- All care needs to be done in time-sensitive, patient-centered fashion.

PRETERM LABOR

Kara M. Coassolo, MD • John C. Smulian, MD, MPH

BASICS

DESCRIPTION

Contractions occurring between 20 and 36 weeks' gestation at a rate of 4 in 20 minutes or 8 in 1 hour with at least one of the following: cervical change over time or dilation ≥2 cm (1)

EPIDEMIOLOGY

Preterm birth is the leading cause of perinatal morbidity and mortality in the United States.

Incidence

10–15% of pregnancies experienced at least one episode of preterm labor.

Prevalence

~12% of all births in the United States are preterm (9% spontaneous preterm births and 3% indicated preterm births).

ETIOLOGY AND PATHOPHYSIOLOGY

- Premature formation and activation of myometrial gap junctions
- Inflammatory mediator–stimulated contractions
- Weakened cervix (structural defect or extracellular matrix defect)
- Abnormal placental implantation
- Systemic inflammation/infections (e.g., UTI, pyelonephritis, pneumonia, sepsis)
- Local inflammation/infections (intra-amniotic infections from aerobes, anaerobes, *Mycoplasma*, *Ureaplasma*)
- Uterine abnormalities (e.g., cervical insufficiency, leiomyomata, müllerian anomalies, diethylstilbestrol exposure)
- Overdistension (by multiple gestation or polyhydramnios)
- Preterm premature rupture of membranes
- Trauma

- Placental abruption
- Immunopathology (e.g., antiphospholipid antibodies)
- Placental ischemic disease (preeclampsia and fetal growth restriction)

Genetics

Familial predisposition

RISK FACTORS

- Demographic factors, including single parent, poverty, and black race
- Short interpregnancy interval
- No prenatal care
- Prepregnancy weight <45 kg (100 lb), body mass index <20
- Substance abuse (e.g., cocaine, tobacco)
- Prior preterm delivery (common)
- Previous 2nd-trimester dilation and evacuation (D&E)
- Cervical insufficiency or prior cervical surgery (cone biopsy or loop electrosurgical excision procedure [LEEP])
- Abdominal surgery/trauma during pregnancy
- Uterine structural abnormalities such as large fibroids or müllerian abnormalities
- Serious maternal infections/diseases
- Bacterial vaginosis
- Bacteriuria
- Vaginal bleeding during pregnancy
- Multiple gestation
- Select fetal abnormalities
- Intrauterine growth restriction
- Placenta previa
- Premature placental separation (abruption)
- Polyhydramnios
- Ehlers-Danlos syndrome

GENERAL PREVENTION

- Patient education at each visit in 2nd and 3rd trimesters for those at risk and periodically in the last two trimesters for the general population

- If previous preterm birth, evaluate if etiology is likely to recur and target intervention to specific condition.
  - Weekly injections of 17α-hydroxyprogesterone (250 mg IM every week) from 16 to 36 weeks if previous spontaneous preterm birth
  - Consider cerclage placement before 24 weeks' gestation for those at high risk because of cervical insufficiency or significant or progressive cervical shortening (2)[A].
- For women with a short cervix in the 2nd trimester (<20 mm on transvaginal US), progesterone 200 mg/day per vagina for 24 to 34 weeks may decrease the risk of preterm delivery (3)[A].

DIAGNOSIS

Diagnosis is generally based on a combination of significant cervical changes (such as dilation, effacement) with regular contractions. However, there is no single test that will reliably diagnose or predict true preterm labor. The diagnosis is based on a combination of physical findings and diagnostic tests that are interpreted in the context of the degree of risk to the patient.

HISTORY

- Address risk factors, especially etiologies of previous preterm birth.
- Regular uterine contractions or cramping
- Dull, low backache or pain
- Intermittent lower abdominal pain
- Increased low pelvic pressure
- Change in vaginal discharge
- Vaginal bleeding
- Fluid leakage

PHYSICAL EXAM

- Sterile speculum exam for membrane rupture evaluation, cultures, and cervical inspection
- Bimanual cervical exam if intact membranes: dilation of the cervix >1 cm and/or effacement of the cervix >50%

ALERT
Avoid bimanual examination when possible if rupture of the membranes is suspected.

DIFFERENTIAL DIAGNOSIS

- Braxton-Hicks contractions/false labor
- Round ligament pain
- Lumbosacral muscular back pain
- Urinary tract or vaginal infections
- Adnexal torsion
- Degenerating fibroid
- Appendicitis
- Dehydration
- Viral gastroenteritis
- Nephrolithiasis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- In symptomatic women from 22 to 34 weeks' gestation with intact membranes and no intercourse or bleeding in past 24 hours, obtain a fetal fibronectin (FFN) swab from the posterior vaginal fornix. FFN must be obtained prior to digital cervical exam.
  - If results are positive (≥50 ng/mL), patient is at a modest increased risk of preterm birth (positive predictive value [PPV] 13–30% for delivery within 2 weeks).
  - If results are negative, >97% of patients will not deliver in 14 days, so can consider avoiding complicated or high-risk interventions.
- Urinalysis and urine culture
- Cultures for gonorrhea and chlamydia
- Wet prep for bacterial vaginosis evaluation (although evidence for improved outcomes with treatment is weak)
- Vaginal introitus and rectal culture for group B *Streptococcus*
- pH and ferning test of vaginal fluid to evaluate for rupture of membranes
- CBC with differential
- Drug screen when appropriate

- US to identify number of fetuses and fetal position, confirm gestational age, estimate fetal weight, quantify amniotic fluid, and look for conditions making tocolysis contraindicated.
- Transvaginal US to evaluate cervical length, funneling, and dynamic changes after obtaining FFN (if clinical assessment of the cervix is uncertain or if the cervix is closed on digital exam)

Follow-Up Tests & Special Considerations

- Repeat FFN as indicated by symptoms.
- After successful treatment, progressive changes of the cervix on repeat examination or US (in 1 to 2 weeks) may indicate need for hospitalization.

Diagnostic Procedures/Other

- Monitor contractions with external tocodynamometer.
- Consider amniocentesis at any preterm gestational age to evaluate for intra-amniotic infection (cell count with differential, glucose, Gram stain, aerobic, anaerobic, *Mycoplasma, Ureaplasma* cultures).

Test Interpretation

- Placental inflammation
  - Acute inflammation usually caused by infection
  - Chronic inflammation caused by immunopathology
- Abruption

TREATMENT

GENERAL MEASURES

- Treat underlying risk factors (e.g., antibiotics for infections, hydration for dehydration).
- Liquids only or NPO if delivery is imminent
- Hospitalization is necessary if the patient is on IV tocolysis.

MEDICATION

Tocolysis may allow time for interventions such as transfer to tertiary care facility and administration of corticosteroids but may not prolong pregnancy significantly (4)[A].

First Line

- Tocolysis
  - Nifedipine: 30 mg PO loading dose; then 10 to 20 mg q6h for 24 hours; then 10 to 20 mg PO q8h (do not use sublingual route); check BP often and avoid hypotension. Concurrent use with magnesium sulfate should be avoided to avoid theoretic risk of neuromuscular blockade.
  - Indomethacin: 50 to 100 mg PO initial dose; then 25 to 50 mg q6–8h for 24 hours (or, if available, 100-mg suppository per rectum q12h for 2 doses); then 25 mg q6–8h; use for no longer than 72 hours due to risk of premature closure of ductus arteriosus, oligohydramnios, and possibly neonatal necrotizing enterocolitis. Use with caution in patients with platelet dysfunction, liver dysfunction, or allergy to aspirin.
  - Contraindications to tocolysis: severe preeclampsia, hemorrhage, chorioamnionitis, advanced labor, intrauterine growth retardation, fetal distress, or lethal fetal abnormalities
- Antibiotics: antibiotics for group B *Streptococcus* prophylaxis if culture is positive or unknown
- Steroids: If mother is at 23 to 34 weeks' gestation with no evidence of systemic infection, give glucocorticoids to decrease neonatal respiratory distress, intraventricular hemorrhage, necrotizing enterocolitis, and overall perinatal mortality. Betamethasone 12 mg IM × 2 doses 24 hours apart (preferred choice) *or* dexamethasone 6 mg IM q12h for 4 doses (5)[A]
- Steroids may reduce the risk of respiratory morbidities in infants born in the late preterm period (34+0 to 36+6 weeks gestation). If delivery is likely during this time period, administration of steroids may be considered as above. Tocolysis is not recommended (6)[A].

Second Line

- Magnesium sulfate by IV infusion has not been shown to be superior to placebo in prolonging pregnancy beyond 48 hours. The side effects are generally greater compared with calcium channel blockers or NSAIDs. Therefore, this agent should be used cautiously if at all (standard dosages for tocolysis start with a 4- to 6-g IV bolus over 20 minutes followed by 2 to 3 g/hr infusion until contractions stop).

  - Magnesium may decrease the risk of cerebral palsy when 12-hour course is given prior to an anticipated preterm birth.
  - Relative contraindications to magnesium sulfate include myasthenia gravis, hypocalcemia, renal failure, or concurrent use of calcium channel blockers.
- Terbutaline 0.25 mg SC q30min for up to 3 doses until contractions stop and then 0.25 mg SC q6h for 4 doses (optional); if contractions persist or pulse >120 bpm, change to another tocolytic agent (may be poorly tolerated by mothers).
- Terbutaline PO or by infusion pump has been used in the past for treatment or prevention of preterm labor. Due to reports of serious cardiovascular events and maternal deaths, PO or long-term SC administration of terbutaline should not be given.
- Significant possible interactions include pulmonary edema from crystalloid fluids and tocolytic agents, especially magnesium sulfate.
- PO maintenance therapy with any agent is ineffective and is not recommended.

ISSUES FOR REFERRAL

- If delivery is inevitable but not immediate, consider transport to a tertiary care center or hospital equipped with a neonatal ICU.
- Consider consultation with maternal–fetal medicine specialist.

ADDITIONAL THERAPIES

- Pelvic rest (e.g., no douching or intercourse) and activity restriction are often recommended; however, data to prove the efficacy are lacking. Some reduction in physical activity may be reasonable; this should be individualized.
- Strict bed rest has not been demonstrated to be effective in most situations.

SURGERY/OTHER PROCEDURES

- For malpresentation or fetal compromise, consider cesarean delivery if labor is progressing.
- Cerclage for cervical insufficiency (until 24 weeks' gestation)

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Suspected/threatened preterm labor

- IV access
- Continuous fetal and contraction monitoring
- Assess cervix for dilatation and effacement.
- Hydrate with 500 mL 5% dextrose normal saline solution or 5% dextrose lactated Ringer solution for first half hour; then at 125 mL/hr.
- Monitor for fluid overload (input/output monitoring, symptoms, lung auscultation, pulse oximetry), especially with tocolysis and multiple gestations.

Discharge Criteria

- Regular contractions and cervical change resolve.
- If cervix is dilated ≥3 cm or FFN is positive, individualize decision to discharge by gestational age and patient circumstances.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Weekly office visits with contraction monitoring, cervical checks, or cervical US if at high risk for recurrence
- Routine use of maintenance tocolysis is ineffective in preventing preterm birth.

DIET

Regular

PATIENT EDUCATION

Call physician or proceed to hospital whenever regular contractions last >1 hour, bleeding, increased vaginal discharge or fluid, decreased fetal movement.

PROGNOSIS

- If membranes are ruptured and no infection is confirmed, delivery often occurs within 3 to 7 days.
- If membranes are intact, 20–50% deliver preterm.

COMPLICATIONS

Labor resistant to tocolysis, pulmonary edema, infection with preterm rupture of membranes

CODES

ICD10

- O60.00 Preterm labor without delivery, unspecified trimester
- O60.02 Preterm labor without delivery, second trimester
- O60.03 Preterm labor without delivery, third trimester

CLINICAL PEARLS

- Treatment of preterm labor may delay delivery to facilitate short-term interventions.
- Steroids improve neonatal outcomes.
- Progesterone therapy can prevent recurrence of preterm birth in next pregnancy.

PRIAPISM

Shenelle Wilson, MD • Kelvin A. Moses, MD, PhD

BASICS

DESCRIPTION

- Penile erection that lasts for >4 hours and is unrelated to sexual stimulation or excitement
- Classified into ischemic and nonischemic types
- Ischemic (low-flow) priapism is painful and requires urgent clinical intervention.
- Stuttering priapism is recurrent episodes of short-lived, self-limiting ischemic priapism over an extended period.
- Nonischemic (high-flow) priapism is painless, could be related to prior trauma, and does not require urgent treatment.
- Malignant priapism is a rare condition resulting most commonly from penile metastases from primary bladder, prostatic, rectosigmoid, and renal tumors.
- System(s) affected: reproductive

Pediatric Considerations

In children, nearly all priapism is caused by either sickle cell anemia or trauma (1).

EPIDEMIOLOGY

Incidence

In the United States, one study estimates 1,868 to 2,960 cases of priapism each year. They also noted an increasing incidence from 1998 to 2006, specifically in those from nonhematologic causes:

- Mean age: 33.7 years. There has been an age shift in recent years toward men in their 40s.
- Other studies have found the incidence of priapism to double in men aged >40 years (2.9 vs. 1.5/100,000 person-years).
- Race: 61.1% black, 30% white, 6.3% Hispanic
- Associations: sickle cell anemia (41.9%), drug abuse (7.9%), sickle cell trait

(2.5%)

- Anatomy and physiology
  - The penis consists of three longitudinally oriented corpora: two dorsolaterally paired corpora cavernosa that are responsible for penile erection and a single ventral corpus spongiosum that surrounds the glans penis and extends distally to form the glans penis.
  - In general, the penile artery (which is a branch of the internal pudendal artery that, in turn, is a branch from the internal iliac artery) supplies the penis. It divides into three branches: dorsal artery, bulbar artery (supplies the corpus spongiosum), and cavernosal artery (the main blood supply to the erectile tissue).
  - During an erection, smooth muscle relaxation of the cavernosal arterioles results in high-volume inflow to the sinusoids, resulting in compression of the exiting venules. This leads to significant volume expansion of the corpora cavernosa.
  - During the flaccid resting state, the sympathetic nervous system is predominantly in control. Penile tumescence and erection are driven by the parasympathetic nervous system through the generation of nitric oxide (NO).
  - Smooth muscle relaxation occurs via usage of the phosphodiesterase type 5 (PDE-5A) pathway, which generates cyclic guanosine monophosphate (cGMP).

ETIOLOGY AND PATHOPHYSIOLOGY

- In ischemic priapism, decreased venous outflow results in increased intracavernosal pressure. This leads to erection, decreased arterial inflow, blood stasis, local hypoxia, and acidosis (a compartment syndrome). Eventually, penile tissue necrosis and fibrosis may occur. The exact mechanism is unknown and may involve trapping of erythrocytes in the veins, draining the erectile bodies.
- In nonischemic priapism, there is increased arterial flow without decreased venous outflow. There is increased inflow and outflow, which results in a sustained, nonpainful, partially rigid erection.
- Aberrations in the PDE-5A pathway have been proven in mice to be one mechanism of priapism.

- Ischemic priapism
  - Idiopathic, estimated to about 50% (1)
  - Intracavernosal injections of vasoactive drugs for erectile dysfunction
  - Oral agents for erectile dysfunction
  - Pelvic vascular thrombosis
  - Prolonged sexual activity
  - Sickle cell disease and trait
  - Leukemia and other malignancies that can infiltrate the corpora
  - Other blood dyscrasias (G6PD deficiency, thrombophilia)
  - Pelvic hematoma or neoplasia (penis, urethra, bladder, prostate, kidney, rectal)
  - Cerebrospinal tumors
  - Asplenism
  - Fabry disease
  - Tertiary syphilis
  - Total parenteral nutrition, especially 20% lipid infusion (results in hyperviscosity)
  - Bladder calculus
  - Trauma to penis
  - UTIs, especially prostatitis, urethritis, cystitis
  - Several drugs suspected as causing priapism (e.g., chlorpromazine, prazosin, cocaine, trazodone, and some corticosteroids), anticoagulants (heparin and warfarin), phosphodiesterase inhibitors (sildenafil, others), immunosuppressants (tacrolimus); and antihypertensives (hydralazine, propranolol, guanethidine)
  - Intracavernous fat emulsion
  - Hyperosmolar IV contrast
  - Spinal cord injury
  - General or spinal anesthesia
  - Heavy alcohol intake or cocaine use
- Nonischemic priapism
  - The most common cause is penile or perineal trauma resulting in a fistula between the cavernous artery and the corpora.
  - Acute spinal cord injury

- Rarely, iatrogenic causes for the management of ischemic priapism can result in nonischemic priapism.
- Certain urologic surgeries have also resulted in nonischemic priapism.

RISK FACTORS

- Sickle cell anemia, lifetime risk of ischemic priapism 29–42% (1)
- Dehydration

GENERAL PREVENTION

- Avoid dehydration.
- Avoid excessive sexual stimulation.
- Avoid causative drugs (see "Etiology and Pathophysiology") when possible.
- Avoid genital and pelvic trauma.

COMMONLY ASSOCIATED CONDITIONS

- Sickle cell anemia or sickle cell trait
- Drug abuse
- G6PD deficiency
- Leukemia
- Neoplasm

DIAGNOSIS

HISTORY

- Penile erection that is persistent, prolonged, painful, and tender (ischemic).
- Duration of erection, degree of pain
- Perineal or penile trauma
- Prior episodes of priapism
- Urination difficult during erection
- History of any hematologic abnormalities
- Cardiovascular disease
- Medications
- Recreational drugs
- Loss of erectile function if treatment is not prompt and effective

PHYSICAL EXAM

- Ischemic priapism
  - Penis is fully erect, corpora cavernosa are rigid and tender, and corpora spongiosum and glans are flaccid. Usually associated with tenderness and pain
- Nonischemic priapism
  - Penis is partially erect and the corpora cavernosa are semirigid and nontender, with the glans and corpora spongiosum flaccid. Usually not tender or painful
- Perineum, abdomen, and lymph node exam also valuable to rule out underlying condition
- A complete penile and scrotal exam is necessary. Determine if a penile prosthesis is present.

DIAGNOSTIC TESTS & INTERPRETATION

- CBC with reticulocyte count to detect leukemia or platelet abnormalities
- Sickling hemoglobin (Hgb) solubility test and Hgb electrophoresis
- Coagulation profile
- Platelet count
- Urinalysis
- Urine toxicology if illicit drugs suspected
- Corporal blood gas (CBG) should be used to distinguish ischemic from nonischemic priapism.
- A color duplex ultrasound of the penis and perineum may be necessary to differentiate ischemic from nonischemic priapism. In ischemic priapism, there is no blood flow in the cavernosal arteries, whereas in nonischemic patients, there is high blood flow (1); may also see fistulas or pseudoaneurysms suggestive of nonischemic priapism
- Penile arteriography can be used to identify the presence and site of fistulas in patients with nonischemic priapism.

Diagnostic Procedures/Other

A physical exam is usually able to distinguish ischemic from nonischemic priapism; however, CBG is the most definitive method.

Test Interpretation

- Pelvic vascular thrombosis
- Partial thrombosis of corpora cavernosa of the penis
- Corpus spongiosum, glans penis: no involvement
- Arterial priapism will show arteriocavernous fistula.

TREATMENT

- Ischemic priapism requires immediate treatment to preserve future erectile function (a longer delay in treatment means a higher chance of future impotence).
  - Cavernosal aspiration with a large bore needle with irrigation (success rate ~30%) (1,2)
  - Cavernosal injection of phenylephrine (α-adrenergic sympathomimetic) with monitoring of patient's BP and pulse (success rate ~65%) (2). Inject q5–10min until detumescence.
  - Continue aspiration, irrigation, and phenylephrine for several hours. If this fails, shunt procedures are considered (first a distal shunt).
- Nonischemic priapism
  - Initial observation
  - If this fails, arteriography and embolization with absorbable materials (5% rate of impotence vs. 39% with permanent materials) or surgical ligation as a last resort (2)
- Treat the underlying condition (i.e., sickle cell disease). Do not delay intracavernous treatment.

GENERAL MEASURES

- Reassure the patient about the outcome, if warranted.
- Provide continuous caudal or spinal anesthesia if the etiology is neurogenic.
- Treat any underlying cause.
- In sickle cell anemia: IV hydration; supplemental oxygen; partial exchange or repeated transfusions to reduce percentage of sickle cells to <50%
- Relieve the patient's pain.
- Initiating proper management depends on whether the priapism is ischemic or nonischemic.

MEDICATION

- Opioids for pain, if needed
- Intracavernous injection of phenylephrine is recommended by the American Urological Association for ischemic priapism (2).
- Phenylephrine minimizes risk of cardiovascular side effects that are more common with other sympathomimetics; terbutaline has been studied and may be effective (uncontrolled trials showed a 65% resolution rate) for priapism caused by self-injection of agents to treat erectile dysfunction (2).
- Ketoconazole 200 mg TID and prednisone 5 mg daily for 2 weeks; then tapering to ketoconazole 200 mg nightly for 6 months has been shown to prevent recurrent ischemic priapism.
- For stuttering priapism, a trial of gonadotropin-releasing hormone (GnRH) agonists or antiandrogens is effective; self-injection of phenylephrine is also effective.
- PDE-5 inhibitors also have a role in the prevention of priapism in patients suffering from stuttering priapism.

ISSUES FOR REFERRAL

A urologist should be consulted in all cases of suspected priapism to ensure the highest likelihood of preserved erectile function.

SURGERY/OTHER PROCEDURES

- For ischemic priapism, introduction of 18- or 19-gauge needle into corpora cavernosa (best done by urologist if available) at 9 o'clock and 3 o'clock positions with aspiration of 20 to 30 mL of blood from corpus cavernosum. May follow with intracavernous injection of 100 to 500 μg phenylephrine (mix 0.2 mL [200 μg]) of 1% phenylephrine in 9.8 mL of normal saline. 1-mL injections given every 3 to 5 min for ~1 hour before determining if treatment is successful. If this fails, consider shunts.
- Distal shunts
  - Percutaneous: Ebbehoj, Winter, or T-shunt
  - Open: Al-Ghorab or corporal snake
- Proximal shunts
  - Open: Quackles or Sacher
  - Saphenous vein shunt

– Deep dorsal vein shunt

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Bed rest until priapism resolves

Patient Monitoring

Close follow-up with a urologist is required after surgical treatments for priapism.

PATIENT EDUCATION

- Information about long-term outlook, referral for counseling
- Reduction of vasoactive drug therapy if responsible for priapism and elimination of offending drugs if causal

PROGNOSIS

- Even with excellent treatment for a prolonged priapism, detumescence may require several weeks secondary to edema (1).
- Impotence due to irreversible corporal fibrosis is likely in ischemic priapism and is up to 90% if the priapism lasts >24 hours.
- Despite early intervention, ischemic priapism is likely to result in impotence in up to 50% of men.

COMPLICATIONS

Erectile dysfunction (i.e., impotence)

CODES

ICD10

- N48.30 Priapism, unspecified
- N48.39 Other priapism
- N48.31 Priapism due to trauma

CLINICAL PEARLS

- Priapism is a prolonged penile erection that lasts >4 hours and is unrelated to sexual stimulation.
- In evaluating priapism, the clinician must distinguish ischemic from nonischemic priapism by history and physical exam, as well as blood gas and possibly ultrasound, if needed.
- Ischemic priapism is an emergent condition that requires immediate urologic evaluation and treatment.
- The most common causes of ischemic priapism are idiopathic, related to treatments for erectile dysfunction, or related to use of substances (medicinal or recreational).
- If an underlying medical condition is identified (sickle cell anemia), proper concomitant treatment is necessary to increase the efficacy of treatment.

PROSTATE CANCER

Sara L. Valente, MD • Jason K. Frankel, MD • Joseph R. Wagner, MD

BASICS

DESCRIPTION

- The prostate is a male reproductive organ that contributes seminal fluid to the ejaculate.
- The prostate gland is about the size of a walnut, averaging 20 to 25 g in volume in an adult male; tends to enlarge after age 50 years
- Three distinct zones delineate the functional anatomy of the prostate: peripheral zone (largest, neighbors rectal wall, palpable on DRE, most common location for prostate cancer), central zone (contains the ejaculatory ducts), and transition zone (located centrally, adjacent to the urethra).
- Prostatic epithelial cells produce prostate-specific antigen (PSA), which is used as a tumor marker and in screening.

EPIDEMIOLOGY

Incidence

According to the National Cancer Institute SEER data, an estimated 180,890 men in the United States will be newly diagnosed with carcinoma of the prostate (CaP) in 2016 (1).

Prevalence

- About 2.8 million men are living with CaP in the United States (1).
- An estimated 26,120 men in the United States will die of CaP in 2016 (1).
- Mean age at diagnosis is 66 years.
- Prostate cancer is the most commonly diagnosed nonskin cancer in men in the United States (~14.0% lifetime risk) and second leading cause of cancer death in men (only ~3% of all CaP results in CaP-related death) (1).
- Autopsy studies find foci of latent CaP in 50% of men in their 8th decade of life.
- Probability of clinical CaP 10.9% (1 in 9) in men aged ≥70 years

ETIOLOGY AND PATHOPHYSIOLOGY

- Adenocarcinoma: >95%; nonadenocarcinoma: <5% (most common transitional cell carcinoma)
- Cells generally stain positive for PSA and prostatic acid phosphatase (PAP)
- Location of CaP: 70% peripheral zone, 20% transitional zone, 5–10% central zone

Genetics

Elevated risk if first-degree relative diagnosed with CaP suggesting genetic component. Specifics unclear

RISK FACTORS

- Age >50 years
- African American race
- Positive family history
- Poorly understood environmental factors

GENERAL PREVENTION

There are no FDA-approved drugs or diet modifications to prevent CaP.

- Finasteride has been studied for this purpose in a phase III trial called the Prostate Cancer Prevention Trial. A moderate risk reduction associated with an increased risk of high-grade disease was encountered. Therefore, it has not been FDA approved for prevention (2)[A].

ALERT

Screening for prostate cancer is controversial:

- U.S. Preventive Services Task Force (USPSTF) recommends against PSA-based screen for prostate cancer, concluding the harm of screening outweighs benefit (3)[A].
- For men ages 55 to 69 years, the AUA panel recommends shared decision making between physician and patient regarding PSA screening.
- PSA screening is not recommended in men under age 40 years, over age 70 years, or any man with <10 years of estimated life expectancy.

DIAGNOSIS

HISTORY

- Inquire about family history of CaP, symptoms of bladder outlet obstruction, and other voiding symptoms.
- Anorexia and weight loss, bone pain or neurologic deficits from spinal cord compression (with metastasis), hematuria, hematospermia (rare)

PHYSICAL EXAM

- DRE to assess for prostatic masses, firmness, or asymmetry
- Evaluate lumbar spine and lymph nodes for evidence of metastasis.

DIFFERENTIAL DIAGNOSIS

Benign prostatic hyperplasia, prostatitis, prostatic intraepithelial neoplasia (PIN), prostate stones, atypical small acinar proliferation (ASAP)

- The high predictive value of ASAP for subsequent adenocarcinoma warrants repeat biopsy within 3 months.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

PSA, DRE, and clinical history primarily determine need for prostate biopsy:

- In general, total PSA ≥4 ng/mL is concerning for CaP (sensitivity 21%, specificity 91%).
  - Other benign conditions can elevate PSA (infection, inflammation, normal growth, natural PSA fluctuations, normally high variants).
  - Rectal manipulation will not significantly elevate PSA.
- Age-/race-adjusted "normal" PSA values (ng/mL) (4):

Age	Asians	Blacks	Whites
40–49	0–2.0	0–2.0	0–2.5
50–59	0–3.0	0–4.0	0–3.5
60–69	0–4.0	0–4.5	0–4.5
70–79	0–5.0	0–5.5	0–6.5

- 5-α-Reductase inhibitors decrease PSA by ~50% (2).
- Other PSA metrics used to aid in CaP diagnosis: PSA velocity, PSA doubling

time, PSA density, percentage free PSA
  - Total PSA velocity: ≥0.75 ng/mL/year or >20% baseline for higher values increases CaP risk.
  - Free PSA and age/race-adjusted PSA helpful in evaluating risk. For patients with PSA between 4 and 10 ng/mL, a low percent free PSA is associated with higher risk of CaP.
  - PSAD (PSA density) ≥0.15 associated with higher prevalence of CaP.
  - Screening tests that utilize serum biomarkers in conjunction with clinical information to predict CaP risk are also available (e.g., 4Kscore, PHI).
- Prostate biopsy
  - Decision to biopsy involves PSA, DRE findings, and overall clinical suspicion of CaP with consideration of comorbidities and life expectancy.
  - Standard biopsy includes systematic random cores from the peripheral zone-base, mid, and apex, generally 8 to 12 cores.
  - The Gleason Grade is the standard pathologic grading system:
    - Ranks specimens from 1 (most differentiated) to 5 (least differentiated) based on architectural pattern identified
    - Primary and secondary patterns are identified and reported, and the sum is the Gleason score (e.g., 3 + 4 = 7).
    - Most prostate cancer are scored 6 to 10, with 10 having the worst prognosis.
- Staging (5)
  - TNM (tumor, node, and metastasis) staging is used to generate a clinical and pathologic stage, which primarily directs treatment. Clinical staging is as follows:
    - T1: cancer found incidentally on TURP or found on biopsy for elevated PSA
    - T2: cancer found on DRE but confined to the prostate
    - T3: cancer found to be extended locally outside of the prostate and/or the seminal vesicle
    - T4: invading adjacent organs
    - N1: denotes local lymph node spread
    - M1: distant metastasis

Follow-Up Tests & Special Considerations

- Bone scan and/or CT scan and/or MRI may be indicated for high-risk cancers.
- Biopsy if suspicious nodal findings
- Alkaline phosphatase associated with bony mets
- Genetic testing (e.g., Prolaris, Oncotype Dx, Decipher) is emerging as a prognostic modality.

TREATMENT

Treatment options include:

- Watchful waiting: monitoring with expectation to provide palliation with symptoms
- Active surveillance: close monitoring of PSA, DRE, and repeat biopsy at regular intervals (6)
- Radical prostatectomy: ± pelvic lymph node dissection (PLND)
- Radiation therapy: external beam (EBRT)
- ProtecT trial (2016) found watchful waiting had equal cancer-specific and all-cause mortality compared to surgery or radiotherapy. In the treatment arms, there was approximately 50% less disease progression (including metastatic disease) but resulted in significantly more morbidity (urinary and bowel dysfunction, erectile dysfunction) (7)[B].
- Brachytherapy: radioactive implants placed in prostate; option for early clinical stage localized to the prostate
- Androgen deprivation therapy (ADT) may be surgical or nonsurgical:
  - Bilateral orchiectomy (surgical castration)
  - Gonadotropin-releasing hormone (GnRH) agonist, antagonist, or antiandrogen (medical castration)
- Chemotherapy: includes multiple chemotherapeutic agents used to treat castrate-resistant prostate cancer

RISK STRATIFICATION

- Treatment options based on risk: low-, intermediate-, and high-risk categories; this is based on risk of recurrence after definitive treatment. Must meet all three criteria to be low risk; any one criterion moves patient to a higher risk group (5,8)[A]:

Risk Category	Clinical Stage	Serum PSA (ng/ml)	Gleason Score
Low	T1–T2a	<10	≤6
Intermediate	T2b–T2c	>10 and ≤20	7
High	T3a	>20	8–10

- Localized CaP
  - Low risk:
    - Mainstay of therapy is active surveillance.
    - Radical prostatectomy and radiation therapy may be offered.
  - Intermediate risk:
    - Mainstay of therapy is radical prostatectomy or radiation therapy.
    - Radical prostatectomy has shown a possible survival benefit in intermediate- and high-risk prostate cancer (9)[A].
  - High risk:
    - Mainstay of therapy is radical prostatectomy or radiation therapy.
    - Adjuvant radiation may be considered based on adverse pathologic findings after prostatectomy.

ALERT

Life expectancy determination as well as educating the patient of the risks and benefits of surveillance and treatment options is critical.

- Locally advanced CaP:
  - Mainstay of therapy is ADT and radiation. Surgery and adjuvant radiation may also play a role.
- Metastatic CaP:
  - Mainstay of therapy is RT and ADT.
  - Early chemotherapy (docetaxel) may be considered for high-volume disease.
  - ADT specifics:
    - GnRH agonists include leuprolide or goserelin.
    - GnRH antagonists include degarelix: an alternative to GnRH agonists; suppresses testosterone production and avoids flare phenomenon observed with GnRH agonists
    - Side effects of ADT: osteoporosis, gynecomastia, erectile dysfunction

(ED), decreased libido, obesity, lipid alterations, greater risk of diabetes, and cardiovascular disease
    - Flare phenomenon (disease flare: hot flashes, fatigue) can occur owing to transient increase in testosterone levels on initiation of GnRH agonist therapy.
    - If spinal cord metastases are present, the concern for cord compression with a testosterone flare can be avoided by starting antiandrogen therapy prior to initiation of a GnRH agonist.
    - Combined androgen blockade with GnRH agonist and antiandrogen (e.g., bicalutamide, nilutamide, or flutamide) may be used to prevent flare.
- Castration-resistant prostate cancer (CRPC)
  - CRPC is defined as progression of disease following ADT. Treatment includes the following:
    - Nonmetastatic
      - Continue ADT, no further treatment has been shown to increase overall survival.
      - Antiandrogen or androgen synthesis inhibitor (e.g., ketoconazole) may be added.
    - Asymptomatic metastatic: no previous therapy with docetaxel:
      - Abiraterone: inhibitor of CYP17A (adrenal androgen production), used with prednisone
      - Enzalutamide: androgen receptor inhibitor
      - Docetaxel: chemotherapeutic that inhibits microtubules
      - Sipuleucel-T: immunotherapy
    - Symptomatic metastatic: no previous therapy with docetaxel
      - Abiraterone, enzalutamide, docetaxel
      - Radum-223 (radiopharmaceutical) for patients with symptomatic bony metastases and no visceral metastasis
    - Symptomatic metastatic: previous therapy with docetaxel:
      - Good performance status: abiraterone, enzalutamide, cabazitaxel
      - Poor performance status: Mainstay is palliative care; may attempt further therapy based on patient wishes

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Prostatectomy: PSA and DRE are recommended at regular intervals. PSA threshold-defining biochemical recurrence is evolving; however, recent data suggests a cutoff of 0.2 ng/mL (8). A CT and bone scan are usually obtained. If the PSA recurrence is thought to be from local disease, salvage radiation is considered. For metastatic disease, androgen deprivation is considered (5).
- XRT: PSA and DRE are recommended at regular intervals. Biochemical recurrence is defined as PSA increase ≥2 ng/mL above nadir; a CT and bone scan is usually obtained. If the PSA recurrence is thought to be from local disease, salvage prostatectomy or cryosurgery is considered. For metastatic disease, androgen deprivation is considered (5).

PROGNOSIS

- Localized disease is frequently curable; advanced disease has a favorable prognosis if lesions are hormone sensitive.
- 5-year CaP survival by stage: local 100%, regional 100%, distant 29.3% (1)
- Recurrence risk increased if adverse pathologic features are present: extraprostatic extension, seminal vesicle invasion, positive surgical margins

COMPLICATIONS

- Prostatectomy: Urinary incontinence and ED are the most common long-term issues.
- Radiation therapy: urinary incontinence, ED, radiation cystitis, and radiation proctitis
- Treatment options for ED: PDE5 inhibitors, intracavernosal injections, intraurethral suppositories, vacuum pump, penile prosthesis
- Treatment options for incontinence: oral medications, urethral sling, artificial sphincter

CODES

ICD10

C61 Malignant neoplasm of prostate

CLINICAL PEARLS

- Prostate cancer is clinically diverse, ranging from low-risk/indolent disease to high-risk/aggressive disease.
- Most men with CaP are asymptomatic.
- The use of PSA for CaP screening is controversial and necessitates an open conversation between medical provider and patient regarding benefits/risks.
- Active surveillance is an important treatment option to consider for low-risk patients.
- Care must be taken when interpreting PSA levels in patients taking 5-α-reductase inhibitors

PROSTATIC HYPERPLASIA, BENIGN (BPH)

Sara M. DeSpain, MD • James E. Hougas, III, MD, FAAFP

BASICS

- Benign prostatic hyperplasia (BPH) is due to proliferation of both the smooth muscle and epithelial cell lines of the prostate which causes increased volume and may cause compression of the urethra and obstructive symptoms.
- Clinically presents with storage and/or voiding symptoms collectively referred to as lower urinary tract symptoms (LUTS). These include difficulty initiating stream, frequency, or dysuria.
- Symptoms do not directly correlate to prostate volume. It is estimated that half of all men with histologic evidence of BPH experience moderate to severe LUTS.
- Progression may result in upper and lower tract infections and may progress to direct bladder outlet obstruction and acute renal failure (ARF).

EPIDEMIOLOGY

Age related, nearly universal development in men

Incidence

Incidence increases with age; wide variety of estimates of prevalence ranging from 70% to 90% by the age of 80 years (estimated at 8–20% by age 40 years).

ETIOLOGY AND PATHOPHYSIOLOGY

- Develops in prostatic periurethral or transition zone
- Hyperplastic nodules of stromal and epithelial components increase glandular components.
- Etiology is unknown.

COMMONLY ASSOCIATED CONDITIONS

- LUTS
  - LUTS can be divided into two groups: filling/storage symptoms and voiding symptoms.

    - Filling/storage symptoms include frequency, nocturia, urgency, and urge incontinence.
    - Voiding symptoms include difficulty initiating stream, incomplete voiding, or weak stream.
    - Can lead to acute or chronic obstructive symptoms
- Sexual dysfunction, including erectile dysfunction and ejaculatory disorders.
- LUTS can also be secondary to cardiovascular, respiratory, or renal disease (1).

RISK FACTORS

- Most significant risk factor is age.
- Increased risk with higher free prostate-specific antigen (PSA) levels, heart disease, and use of β-blockers
- Low androgen levels from cirrhosis/chronic alcoholism can reduce the risk of BPH
- Obesity and lack of exercise can cause LUTS to be more significant.
- No evidence of increased or decreased risk with smoking, alcohol, or any dietary factors.

GENERAL PREVENTION

- The disease appears to be part of the aging process.
- Symptoms can be managed through weight loss, regulation of fluid intake, decreased intake of caffeine, and increased physical activity.

DIAGNOSIS

HISTORY

- Evaluate symptom severity with the American Urological Society Symptom Index or the International Prostate Symptom Score (IPSS).
- Screen for other causes of symptoms such as infection, procedural history, or neurologic causes. Evaluate for comorbid conditions which may produce similar symptoms such as diabetes, congestive heart failure (CHF), or Parkinson disease.
- Review medication list. Particularly diuretics and anticholinergic medications. Also, decongestants (increased sphincter tone), opiates (impaired autonomic

function), or tricyclic antidepressants (anticholinergic effects)

- Review family history for BPH and prostate cancer.
- Screen for gross hematuria.
- IPSS scoring of LUTS (patient survey tracking severity) (2):
  - Questionnaire: Over the past month, how often have you:
    - 1. Had the sensation of not emptying your bladder completely after you finished urinating?
    - 2. Had to urinate again <2 hours after you finished urinating?
    - 3. Found you stopped and started again several times when you urinated?
    - 4. Found it difficult to postpone urination?
    - 5. Had a weak urinary stream?
    - 6. Had to push or strain to begin urination?
    - 7. Been up to urinate from the time you went to bed at night until the time you got up in the morning?
    - 8. How would you feel if you were to spend the rest of your life with your current symptoms?
  - Scoring of the questionnaire:
    - Questions 1 to 6: no symptoms = 0 points, 1 in 5 times = 1 point, less than half = 2 points, about half = 3 points, more than half = 4 points, most of the time = 5 points
    - Question 7: no occurrence = 0 points, 1 time = 1 point, 2 times = 2 points, 3 times = 3 points, 4 times = 4 points, and 5 times or more = 5 points
    - Question 8: 0 = delighted, 1 = pleased, 2 = mostly satisfied, 3 = mixed, 4 = mostly dissatisfied, 5 = unhappy, 6 = terrible
    - Symptoms are classified as mild (total score 0 to 7), moderate (total score 8 to 19), and severe (total score 20 to 35).
- Nocturia >2 times per night, warrants a frequency/volume chart for 2 to 3 days to detect urinary patterns.

PHYSICAL EXAM

- Digital rectal exam (DRE) finding of symmetrically enlarged prostate, but *size does not always correlate with symptoms*.
- Signs of renal failure due to obstructive uropathy (edema, pallor, pruritus, ecchymosis, nutritional deficiencies)
- If DRE is suggestive of prostate cancer, or if there is hematuria, recurrent

infections, concern for stricture, or evidence of neurologic disease, the patient should be referred to urology.

DIFFERENTIAL DIAGNOSIS

- Obstructive
  - Prostate cancer
  - Urethral stricture or valves
  - Bladder neck contracture (usually secondary to prostate surgery)
  - Inability of bladder neck or external sphincter to relax appropriately during voiding
- Neurologic
  - Spinal cord injury
  - Stroke
  - Parkinsonism
  - Multiple sclerosis
- Medical
  - Poorly controlled diabetes mellitus
  - CHF
- Pharmacologic
  - Diuretics
  - Decongestants
  - Anticholinergics
  - Opioids
  - Tricyclic antidepressants
- Other:
  - Bladder carcinoma
  - Overactive bladder
  - Nocturnal polyuria (>33% of the 24-hour urine volume occurs at night)
  - Bladder calculi
  - UTI
  - Prostatitis
  - Urethritis/sexually transmitted infections
  - Obstructive sleep apnea (OSA) (nocturia)
  - Caffeine
  - Polyuria (either isolated nocturnal polyuria or 24-hour polyuria)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Urinalysis (UA) in all patients presenting with LUTS can help rule out other etiologies such as bladder/kidney stones, cancer, UTI, or urethral strictures
- Discuss PSA should with men with a life expectancy of 10 years and who would be surgical candidates if prostate cancer was identified.
- PSA levels also correlate with prostate volume which can help guide treatment choice.
- With bladder cancer risk factors (smoking history or hematuria), obtain urine cytology.
- If nocturia is the main concern, consider using a frequency volume chart for urine output.
- Sleep study if OSA or primary nocturnal polyuria is suspected.
- Serum creatinine measurement is not recommended (AUA recommendation).

Follow-Up Tests & Special Considerations

- No further testing is recommended in uncomplicated LUTS; further testing if symptoms do not respond to medical management or if initial evaluation suggests underlying disease.
- Uroflow: volume voided per unit time (peak flow <10 mL/s is abnormal)
- Postvoid residual (PVR): either with catheterization or bladder ultrasound (>100 mL = incomplete emptying)
- Transrectal ultrasound: assessment of gland size; not necessary in the routine evaluation
- Abdominal ultrasound: can demonstrate increased PVR or hydronephrosis; not necessary in the routine evaluation

Diagnostic Procedures/Other

- Pressure-flow studies (urine flow vs. voiding pressures) to determine etiology of symptoms
  - Obstructive pattern shows high voiding pressures with low flow rate.
- Cystoscopy
  - Demonstrates presence, configuration, cause (stricture, stone), and site of obstructive tissue
  - May help determine therapeutic option

- Not recommended in initial evaluation unless other factors, such as hematuria, are present.

TREATMENT

GENERAL MEASURES

- Treatment ranges from watchful waiting to lifestyle modifications, medications, or surgical management.
- Mild symptoms (score of <7) or moderate symptoms (score 8 to 15) that are non-bothersome require no treatment. Reevaluate annually.
- For moderate to severe symptoms, try lifestyle interventions regulation of fluid intake, avoidance of alcohol and caffeine, exercise, diet, and eliminating/reducing contributing medications.
- Medical treatment requires interval follow-up of 2 to 4 weeks for α-blockers and 3 months for 5-α-reductase inhibitors until symptoms improved and then annually.
- Patients with complications including obstruction and urinary retention require bladder drainage.

MEDICATION

- Should be used as additive therapy, lifestyle modifications are still encouraged.
- Two main classes of medications: α-adrenergic antagonists and 5-α-reductase inhibitors.
- The combination of these two medication classes is effective for long-term management of BPH and demonstrated large prostates.
  - **α-Adrenergic antagonists**
    - First-line option for moderate/severe and bothersome LUTS. Affect contraction of smooth muscle in the prostatic urethra and bladder neck. Show benefit over placebo. Typically take 2 to 4 weeks to show improvement. May affect blood pressure; requires dose titration and blood pressure monitoring. AUA recommends alfuzosin (Uroxatral), doxazosin (Cardura), and tamsulosin (Flomax) as they are thought to be more selective and have less effect on blood pressure. Prazosin

(Minipress) and phenoxybenzamine (Dibenzyline) have insufficient evidence and are not recommended. Most common adverse effect is dizziness. May cause orthostatic hypotension.
        - Doxazosin (Cardura): 1 to 8 mg/day PO. May delay the occurrence of acute urinary retention but does not decrease incidence.
        - Tamsulosin (Flomax): 0.4 to 0.8 mg/day PO
        - Alfuzosin (Uroxatral): 10 mg/day PO
        - Terazosin (Hytrin): Start at 1 mg PO daily at bedtime, max 20 mg daily.
    - **Contraindications:**
        - Use caution in patients who are also using phosphodiesterase type 5 inhibitors for erectile dysfunction.
        - Do not use in men pursuing cataract surgery until they are postoperative due to the risk for perioperative floppy iris syndrome.
- **5-*α*-Reductase inhibitors**
    - Block conversion of testosterone to dihydrotestosterone, gradually reduce prostatic volume therefore are of most benefit when prostate volume exceeds 40 mL. Require 6 months to show clinical benefit. Two equally effective options:
        - Finasteride (Proscar): 5 mg/day PO
        - Dutasteride (Avodart): 0.5 mg/day PO
    - Should not be used in patients without evidence of enlarged prostates
    - Show reduced risk of acute urinary retention, less need for surgical intervention and less overall incidence of prostate cancer.
    - Used in patients with refractory hematuria after other causes have been ruled out
    - Side effects include decreased libido and erectile dysfunction.

- A PSA value in a patient taking a **5-*α*-reductase inhibitors will be artificially low**.
- Combination therapy of *α*-blocker plus 5-*α*-reductase inhibitor is superior to monotherapy with an *α*-blocker only in men with evidence of enlarged prostates.
- Combination therapy is superior to monotherapy to prevent progression but increase risk of drug-related adverse events.

- Anticholinergic agents are appropriate for irritative LUTS without an elevated PVR. Options include solifenacin (Vesicare), tolterodine (Detrol LA), or oxybutynin (Ditropan XL). Should be avoided in patients with PVR >250 mL.
- If patient also experiences erectile dysfunction phosphodiesterase-5 inhibitors have been shown to have mild improvement of LUTS. Can use Tadalafil (Cialis): 5 mg/day PO but avoid use in combination with α-blockers or in those with CrCl <30 mL/min.

Geriatric Considerations

Use caution with anticholinergics, antihistamines, sympathomimetics, tricyclic antidepressants, opioids.

ISSUES FOR REFERRAL

- Moderate or severe LUTS that does not respond to medical management.
- BPH-related complications such as recurrent UTIs or hematuria, renal insufficiency, and urinary retention.
- Abnormal PSA or prostate exam
- Any history of urethral trauma or stricture, or neurologic disease of the bladder/urinary system

SURGERY/OTHER PROCEDURES

- Indications for surgery:
  - Urinary retention due to prostatic obstruction, recurrent, no improvement with medications
  - Intractable symptoms due to prostatic obstruction AUA score >8 and symptoms
  - Obstructive uropathy (renal insufficiency)
  - Recurrent or persistent UTIs due to prostatic obstruction
  - Recurrent gross hematuria due to enlarged prostate
  - Bladder calculi
- Surgical procedures: TURP remains the gold standard of surgical procedures; however, for select patient populations, there are other options available.
- Common complications of TURP:
  - Bleeding can be significant.
  - TURP syndrome: hyponatremia secondary to absorption of hypotonic

irrigation fluid
  - Retrograde ejaculation
  - Urinary incontinence
- Other options include transurethral needle ablation (TUNA) and transurethral microwave thermotherapy (TUMT), or transurethral incision of the prostate (TUIP). Open prostatectomy is more common when prostate exceeds 100 g. Transurethral laser ablation is an alternative option for patients on anticoagulants.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Saw palmetto (*Serenoa repens*) has been thoroughly studied in a subject in Cochrane review, and did not improve LUTS. Other agents including pygeum, Cernilton, and herbs with *β*-sitosterols have been studied less; however, no current evidence to support their use. Acupuncture failed to show improvement in LUTS in one clinical trial as well. There are no recommended complementary or alternative treatments for BPH.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Symptom index (IPSS) monitored every 3 to 12 months.
- DRE yearly
- PSA yearly: should not be checked while patient is in retention, recently catheterized, or within a week of any surgical procedure to the prostate.
- Consider monitoring PVR, if elevated.

DIET

Avoid large boluses of oral or IV fluids or alcohol intake, caffeine may exacerbate symptoms as well.

PATIENT EDUCATION

National Kidney and Urologic Diseases Information Clearinghouse, Box NKUDIC, Bethesda, MD 20893; 301-468-6345

PROGNOSIS

- Symptoms improve or stabilize in 70–80% of patients.
- 25% of men with LUTS will have persistent storage symptoms after prostatectomy.
- Of men with BPH, 11–33% have occult prostate cancer.

COMPLICATIONS

- Urinary retention (acute or chronic)
- Bladder stones
- Prostatitis
- Hematuria

CODES

ICD10

- N40.0 Enlarged prostate without lower urinary tract symptoms
- N40.1 Enlarged prostate with lower urinary tract symptoms

CLINICAL PEARLS

- Although medical therapy has changed the management of BPH, it has only delayed the need for TURP by 10 to 15 years, not eliminated it.
- Urinary retention, obstructive uropathy, recurrent UTIs, elevated PSA, bladder calculi, hematuria, and failure of medical therapy are indications for surgical management of BPH.

PROSTATITIS

Kyle B. Stephens, DO • Vincent Lo, MD, FAAFP

BASICS

DESCRIPTION

- Painful or inflammatory condition affecting the prostate gland with or without bacterial etiology, often characterized by urogenital pain, voiding symptoms, and/or sexual dysfunction
- Significant impact on quality of life
- <10% bacteria-proven infection
- National Institutes of Health's classification
  - *Class I*: *Acute bacterial prostatitis*: symptomatic with fever, perineal pain, dysuria, and obstructive symptoms; polymorphonuclear leukocytes (PMNL) and bacteria in urine
  - *Class II*: *Chronic bacterial prostatitis*: symptomatic chronic or recurrent bacterial infection with pain and voiding disturbances; PMNL and bacteria in expressed prostatic secretions (EPS), or urine after prostate massage, or in semen
  - *Class III*: *Chronic prostatitis/chronic pelvic pain syndrome (CP/CPPS)*
    - Inflammatory (Subtype IIIA): chronic symptoms with PMNL in EPS/urine after prostate massage or in semen
    - Noninflammatory (Subtype IIIB): chronic symptoms without presence of PMNL in EPS/urine after prostate massage or in semen
  - *Class IV*: *Asymptomatic inflammatory prostatitis*: incidental finding during prostate biopsy for infertility, cancer workup; presence of PMNL and/or bacteria in EPS/urine after prostatic massage or in semen
- System(s) affected: genitourinary, renal, reproductive

EPIDEMIOLOGY

Incidence

- Two million cases annually in the United States
- Predominant age: 30 to 50 years old, sexually active; chronic is more common

in those >50 years.
- Bacterial prostatitis occurs more frequently in patients with HIV.

Prevalence
- Affects approximately 8.2% of males
- Lifetime probability of diagnosis >25%
- Accounts for 8% of visits to urologists and 1% of visits to primary care physicians
- Percentage of cases by class: Class I: <1%, Class II: 5–10%, Class III: 80–90%, Class IV: 10%

ETIOLOGY AND PATHOPHYSIOLOGY
- Acute bacterial prostatitis (Class I)
  - Likely, etiology from ascending urethral infection with intraprostatic reflux of infected urine into prostatic ducts, often associated with cystitis
  - Can occur after instrumentation of prostate
  - Usually gram-negative bacteria (*Escherichia coli* (most common); *Proteus*, *Klebsiella*, *Serratia*, and *Enterobacter* species; *Pseudomonas aeruginosa*)
  - Rarely, gram-positive bacteria (*Staphylococcus aureus*, *Streptococcus*, and *Enterococcus* species)
  - Confirmed staphylococcal prostatitis should warrant evaluation for hematogenous spread, including endovascular source.
  - Atypical bacteria include *Chlamydia trachomatis*, *Trichomonas vaginalis*, and *Ureaplasma urealyticum*.
  - Consider *Neisseria gonorrhoeae* or *C. trachomatis* in sexually active men <35 years.
- Chronic bacterial prostatitis (Class II)
  - Similar pathogens as discussed earlier
  - Often occurs as recurrent episodes of infection by same organism
  - Progression from acute to chronic prostatitis is poorly understood but could result from inadequate treatment of acute prostatitis.
- CP/CPPS (Class III)
  - Unclear etiology, possibly due to difficult-to-culture infection
  - Inciting agent may cause inflammation or neurologic damage in or around the prostate and lead to pelvic floor neuromuscular and/or neuropathic pain.

RISK FACTORS

- Urinary tract infections
- HIV infection
- Prostatic calculi
- Urethral stricture
- Urinary catheterization: indwelling, intermittent
- Genitourinary instrumentation including prostate biopsy (especially in patients with prior quinolone intake), transurethral resection of prostate, cystoscopy
- Urinary retention
- Benign prostatic hypertrophy
- Unprotected sexual intercourse
- Trauma (e.g., bicycle, horseback riding)

GENERAL PREVENTION

Antibiotic prophylaxis for genitourinary instrumentation and prostatic biopsy

COMMONLY ASSOCIATED CONDITIONS

- Benign prostatic hypertrophy
- Cystitis
- Urethritis
- Sexual dysfunction, including erectile dysfunction and premature ejaculation

DIAGNOSIS

HISTORY

- Acute prostatitis (Class I):
  - Acutely ill with fever, chills, malaise
  - Low back pain, myalgias
  - Frequency, urgency, dysuria, nocturia
  - Prostatodynia, pelvic pain, perineal pain
  - Cloudy urine
  - Obstructive voiding symptoms: poor stream, hesitancy
- Chronic prostatitis (Classes II and III):
  - More insidious presentation than Class I
  - Symptoms for 3 of 6 previous months

- Low-grade fever (Class II only)
- Prostatodynia, perineal pain
- Dysuria, frequency, urgency
- Lower abdominal pain
- Low back, testicular, and/or penile pain
- Hematospermia
- Sexual dysfunction/painful ejaculation

PHYSICAL EXAM

- Vital signs (unstable vitals suggest sepsis)
- Back exam (CVA tenderness)
- Abdominal exam (bladder distension)
- Prostate exam
  - Class I: Prostate is very tender, warm, firm, and edematous.
  - Class II: Often normal but enlarged, tender, edematous, nodular prostate also encountered
  - Class III: Often normal prostate

ALERT

Avoid vigorous massage of the prostate in acute bacterial prostatitis; may induce iatrogenic bacteremia; safe if done gently

DIFFERENTIAL DIAGNOSIS

- Lower urinary tract infection
- Pyelonephritis
- Cystitis (bacterial, interstitial)
- Urethritis
- Prostatic abscess
- Acute/chronic urinary retention
- Benign prostatic hypertrophy malignancy (prostate, bladder)
- Obstructive calculi
- Foreign body

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Suspected acute prostatitis (Class I)

- Urinalysis; urine Gram stain/culture and sensitivity
- CBC with differential; blood culture if fever, chills, or signs of sepsis are present

- Suspected chronic bacterial prostatitis (Class II)
  - Urinalysis; urine/EPS/semen: Gram stain/culture and sensitivity
  - Review previous urine culture results.
  - National Institutes of Health—Chronic Prostatitis Symptom Index (NIH-CPSI): 9-question symptom survey (http://www.prostatitis.org/symptomindex.html)
  - Diagnostic gold standard: Meares-Stamey 4-glass test (not performed often)
  - 2-glass test (pre- and postmassage urine testing) more common and easier with equivalent sensitivity and specificity
    - Cultures of midstream preprostate massage urine and EPS/postmassage urine
  - Consider urinary flow rate and postvoid residual volume if urinary retention is present.
- Suspected CP/CPPS (Class III)
  - Diagnosis of exclusion
  - Urinalysis; urine/EPS/semen: Gram stain/culture and sensitivity
  - Hematuria if present: urine cytology, cystoscopy, CT urography with or without contrast
  - PSA is not indicated unless malignancy is suspected.
  - Concomitant abdominal pain: CT abdomen
  - Testicular pain: scrotal US
  - Sensation of incomplete bladder emptying: postvoid residual volume with bladder US or catheterization
  - Lumbar radiculopathy: MRI spine

Follow-Up Tests & Special Considerations

- Failure to respond to initial antibiotic therapy: US, CT, or MRI to image prostate and urology referral
- US or CT or MRI if prostatic calculi, malignancy, or abscess is suspected
- Acute bacterial: urinalysis and culture 30 days after initiating treatment
- Chronic bacterial: urinalysis and culture every 30 days (may take several months of treatment to clear)

Diagnostic Procedures/Other

- Needle biopsy or aspiration for culture
- Urodynamic testing (prostatodynia) if indicated
- Cystoscopy (in persistent nonbacterial prostatitis to rule out bladder cancer, interstitial cystitis)

TREATMENT

GENERAL MEASURES

- Analgesics/antipyretics/stool softeners
- Hydration
- Sitz baths to relieve pain and spasm
- Suprapubic catheter for urinary retention
- Anxiolytics, antidepressants if anxiety and/or depression are present

MEDICATION

First Line

- Acute bacterial (Outpatient) (1)[A]
  - Fluoroquinolone (ciprofloxacin 500 mg PO q12h or levofloxacin 500 mg PO once daily) for 2 to 4 weeks *or*
  - Trimethoprim-sulfamethoxazole 1 double-strength tab PO q12h for 2 to 4 weeks *or*
  - If gram-positive cocci are seen in initial urine Gram stain, start with amoxicillin 500 mg PO q8h. Adjust antibiotics once culture and sensitivities report is available.
  - Local sensitivity pattern should guide therapy.
  - If at risk for sexually transmitted infection (STI) pathogens: Ceftriaxone 250 mg IM for 1 dose plus doxycycline 100 mg PO q12h daily for 1 week or azithromycin 1 g PO single dose
- Acute bacterial (Inpatient) (1)[A]
  - Ampicillin 2g IV q6h or fluoroquinolone (ciprofloxacin 400 mg IV q12h or levofloxacin 500 mg q24h); begin oral therapy after afebrile for 24 to 48 hours.
- Chronic bacterial (Class II) (1,2,3)[A],(4)[C]

- Fluoroquinolone (e.g., levofloxacin 500 mg PO) once daily for 4 weeks or ciprofloxacin 500 mg PO q12h for 4 to 12 weeks
- Combination therapy with azithromycin may help to eradicate atypical pathogens.
- Anti-inflammatory agents for pain symptoms and α-blockers for urinary symptoms

- CP/CPPS (Class III) (4)[C],(5,6)[A]
  - Heterogeneous condition with no universally effective treatment
  - Treatment choice is patient centered, focusing on symptoms relief of four domains: pain, lower urinary tract symptoms (LUTS), psychological stress, and sexual dysfunction.
    - α-Blockers, antibiotics, and combinations of these therapies achieve greatest improvement in clinical symptoms scores compared to placebo.
    - Tamsulosin 0.4 mg PO once daily at bedtime for 4 to 6 weeks; continue if there is a positive response.

Second Line

- Piperacillin or ticarcillin with aminoglycoside, erythromycin, tetracycline, cephalexin, fluoroquinolones, dicloxacillin, nafcillin IV, vancomycin IV
- Finasteride (in patients >45 years, class IIIA, and enlarged prostate glands)
- Atypical: may benefit from erythromycin, doxycycline

ISSUES FOR REFERRAL

Urology referral if antibiotic treatment fails, symptoms persist (especially obstructive voiding symptoms), hematuria, elevated PSA, or for surgical drainage if an abscess persists after ≥1 week of therapy

ADDITIONAL THERAPIES

- Psychotherapy if sexual dysfunction is present
- 5-α-Reductase inhibitors, nonsteroidal anti-inflammatory medications, pelvic floor physical therapy, transurethral microwave thermotherapy, circumcision

SURGERY/OTHER PROCEDURES

Surgical resection can be considered for refractory cases of recurrent bacterial prostatitis or to drain an abscess, when necessary.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Class III: Acupuncture, electro-acupuncture, phytotherapies (pollen extract, quercetin), heat therapy, low-intensity pulsed US, and myofascial release have limited data to support.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Proven or suspected abscess
- Unstable vital signs (sepsis)
- Immunocompromised
- Failed outpatient treatment

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Negative urine culture at 7 days predictive of cure after completion of treatment course
- Consider prostatic abscess in patients who do not respond well to therapy.

Patient Monitoring

NIH-CPSI: 9 questions, which can be used to evaluate severity of patient symptoms and response to treatment within three domains:

- Pain
- Urinary symptoms
- Quality of life

PROGNOSIS

- Fever and dysuria usually resolve in 2 to 6 days.
- Acute infection usually improves in 3 to 4 weeks.
- Course of chronic prostatitis is often prolonged and difficult to cure; 55–97% cure rate depending on population and drug used
- 20% have reinfection or persistent infection.

COMPLICATIONS

- Prostatic abscess (common in HIV infected)

- Pyelonephritis
- Gram-negative sepsis, bacteremia
- Urinary retention
- Epididymitis
- Infertility
- Chronic bacterial prostatitis (following acute prostatitis)
- Metastatic infection (spinal, sacroiliac)

SEE ALSO

- Prostate Cancer; Prostatic Hyperplasia, Benign (BPH); Urinary Tract Infection (UTI) in Males
- Algorithm: Hematuria

CODES

ICD10

- N41.9 Inflammatory disease of prostate, unspecified
- N41.0 Acute prostatitis
- N41.1 Chronic prostatitis

CLINICAL PEARLS

- Vigorous prostatic massage is contraindicated in acute prostatitis.
- Fluoroquinolones are recommended first-line antibiotic for bacterial prostatitis, both acute and chronic (Class I and Class II).
- At least 14 to 30 days of antibiotic therapy is required for acute prostatitis; longer for chronic bacterial prostatitis
- Antibiotic therapy is not proven to be effective in CP/CPPS (Class III).
- Imaging is often not needed.

PROTEIN C DEFICIENCY

Elie Chalhoub, MD • Dalia Hammoud, MD • Maissaa Janbain, MD

BASICS

DESCRIPTION

- Protein C is a vitamin K–dependent factor made by the liver that becomes activated when thrombin binds to the endothelial receptor thrombomodulin.
- Activated protein C, with protein S as a cofactor, inactivates factors Va and VIIIa.
- Patients with protein C deficiency have a thrombotic disorder that primarily affects the venous system but can also affect the arterial system.
- System(s) affected: cardiovascular, hemic/lymphatic/immunologic, pulmonary

EPIDEMIOLOGY

Prevalence

- 0.3% of normal individuals
- 4–5% of persons with venous thrombosis (VT)
- Predominant age: Mean age of first thrombosis is 45 years.
- Predominant sex: male = female

ETIOLOGY AND PATHOPHYSIOLOGY

- Polymorphisms in the promoter region of the protein C gene can affect antigen levels. At least 150 mutations have been described in the protein C gene that can lead to functional deficiency.
- New mutations have been described associated with later-onset cerebral thrombosis (1).
- Acquired protein C deficiency can occur with liver disease, ARDS, DIC, chemotherapy with L-asparaginase, 5-FU, methotrexate, and cyclophosphamide, as well as postoperative state and severe infections, especially meningococcemia. Also, rare patients can develop inhibitors to activated protein C. Neonates have lower levels of protein C than adults.

Genetics

Patients heterozygous for protein C deficiency who start warfarin without concomitant heparin can develop warfarin-induced skin necrosis because the half-life of other vitamin K–dependent clotting factors, prothrombin, factor IX, and factor X is much longer than that of protein C (4 to 8 hours). These patients develop extremely low levels of protein C and subsequently increased thrombin generation, leading to necrosis of the skin over central areas of the body such as the breast, abdomen, buttocks, and genitalia (2)[A].

GENERAL PREVENTION

Because protein C deficiency is a congenital disease, there are no preventive measures.

COMMONLY ASSOCIATED CONDITIONS

- Deep and superficial VT, often spontaneous
- Up to 50% of homozygotes will have thrombosis.
- Homozygosity is associated with catastrophic thrombotic complications at birth (e.g., *purpura fulminans*).
- Sites of thrombosis can be unusual, including the mesentery and cerebral veins, especially when combined with other risk factors such as oral contraceptives.
- Arterial thrombosis is rare.
- Skin necrosis can be seen in patients on warfarin.
- Recurrent pregnancy losses

DIAGNOSIS

HISTORY

- VT at <40 years of age without another etiology
- Thrombosis in unusual locations (e.g., mesentery, sagittal sinus, portal vein)
- Family history of thrombosis or spontaneous abortion

PHYSICAL EXAM

Normal

DIFFERENTIAL DIAGNOSIS

- Factor V Leiden (causes resistance to activated protein C, not a deficiency of protein C)
- Protein S deficiency
- Antithrombin deficiency
- Dysfibrinogenemia
- Dysplasminogenemia
- Homocystinemia
- Prothrombin 20210 mutation
- Elevated factor VIII levels

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- For evaluation of new clot in patient at risk (see "History"): CBC with peripheral smear, PT/INR, aPTT, thrombin time, lupus anticoagulant, antiphospholipid antibodies, factor VIII, anticardiolipin antibody, anti-β_2-glycoprotein I antibody, activated protein C resistance, protein S antigen and resistance, antithrombin III assay, fibrinogen, factor V Leiden, prothrombin G20210A, homocysteine
- Protein C activity assay using a snake venom protease to activate protein C
- Immunoassay for quantitative assessment of protein C level
- Drugs that may alter lab results
  - Oral contraceptives can raise protein C levels.
  - Warfarin reduces protein C levels.
  - Patients should be off warfarin for 2 to 3 weeks before reliable testing (3) [C].
- Disorders that may alter lab results
  - Liver disease reduces protein C levels.

ALERT

Acute thrombosis can lower protein C levels. Repeat confirmatory test of low protein C level at a separate time is advisable. If a normal level of protein C is obtained at presentation, then deficiency can be excluded.

TREATMENT

Treat active thrombosis; follow-up.

GENERAL MEASURES

- Routine anticoagulation for asymptomatic patients with protein C deficiency is not recommended (2)[A].
- Anticoagulation for 6 to 12 months is recommended for patients with protein C deficiency and a first thrombosis.
- Some argue for lifetime anticoagulation; data are limited.
- Anticoagulation for life is indicated for patients with protein C deficiency and recurrent thromboses.
- The role of family screening for protein C deficiency is unclear because most patients with this mutation do not have thrombosis. Screening should be considered for women considering using oral contraceptives or pregnancy and who have a family history of protein C deficiency (4)[B].
- Treatment with low-molecular-weight heparin (LMWH) is recommended over unfractionated heparin, unless the patient has severe renal failure (5)[B].
- Treat as outpatient, if possible (5)[B].
- Initiate warfarin together with LMWH on the first treatment day and discontinue LMWH after minimum of 5 days and two consecutive INRs >2 (5)[A].
- For pregnant women with no prior history of venous thromboembolism (VTE), we suggest antepartum and postpartum clinical vigilance. Postpartum prophylaxis for 6 weeks with prophylactic- or intermediate-dose LMWH is reserved only for patients with positive family history of VTE (3)[C],(5).
- Severe congenital protein C deficiency may be treated with protein C concentrates.

MEDICATION

First Line

- LMWH (2)[A]: initially for a minimum of 5 days and two consecutive INRs between 2 and 3
  - Enoxaparin (Lovenox) 1 mg/kg SC BID or enoxaparin 1.5 mg/kg/day SC

  - Tinzaparin (Innohep): 175 anti-Xa IU/kg/day SC
  - Dalteparin (Fragmin) 200 U/kg/day
- Factor Xa inhibitors
  - Fondaparinux (Arixtra) <50 kg: 5 mg/day SC; 50 to 100 kg: 7.5 mg/day SC; >100 kg: 10 mg/day SC; contraindicated if CrCl <30 mL/min
- Oral vitamin K antagonist: warfarin (Coumadin), per the most recent chest guidelines, 5 mg/day PO and then adjusted to an INR of 2 to 3 for at least 3 to 6 months (2)[A] ,(5)
- Novel oral anticoagulants (NOACs):
  - Dabigatran 150 mg PO BID (after 5 to 10 days of parenteral anticoagulation)
  - Rivaroxaban 15 mg PO BID for 21 days and then 20 mg PO QD
  - Apixaban 10 mg PO BID for 7 days and then 5 mg PO BID
  - Edoxaban 60 mg PO QD (after 5 to 10 days of parenteral anticoagulation)
- Contraindications
  - Active bleeding precludes anticoagulation; risk of bleeding is a relative contraindication to long-term anticoagulation.
  - Warfarin is contraindicated in patients with a prior history of warfarin-induced skin necrosis.
- Precautions
  - Observe patient for signs of embolization, further thrombosis, or bleeding.
  - Avoid IM injections.
  - Periodically, check stool and urine for occult blood; monitor CBC, including platelets.
  - Heparin: thrombocytopenia and/or paradoxical thrombosis with thrombocytopenia
  - Warfarin: necrotic skin lesions (typically breasts, thighs, and buttocks)
  - LMWH: Adjust dose in renal insufficiency.
- Significant possible interactions
  - Agents that intensify the response to oral anticoagulants: alcohol, allopurinol, amiodarone, anabolic steroids, androgens, many antimicrobials, cimetidine, chloral hydrate, disulfiram, all NSAIDs, sulfinpyrazone, tamoxifen, thyroid hormone, vitamin E, ranitidine, salicylates, acetaminophen

- Agents that diminish the response to oral anticoagulants: aminoglutethimide, antacids, barbiturates, carbamazepine, cholestyramine, diuretics, griseofulvin, rifampin, oral contraceptives

Second Line

- Heparin 80 U/kg IV bolus followed by 18 U/kg/hr; adjust dose depending on PPT.
- In patients requiring large daily doses of heparin, measure an anti-Xa level for dose guidance.
- Alternatively, and for outpatients, unfractionated heparin can be given at 333 U/kg and then 250 U/kg SC, without monitoring (5)[C].

ISSUES FOR REFERRAL

- Patients with suspected protein C deficiency should be seen by a hematologist.
- However, screening and therefore prophylactic treatment of asymptomatic family members is not justified.

SURGERY/OTHER PROCEDURES

- Anticoagulation must be held for surgical interventions.
- In patients with acute proximal DVT of the leg *and* an absolute contraindication to anticoagulation, inferior vena cava (IVC) filters are recommended; otherwise, the use of an IVC filter in addition to anticoagulants is not recommended in most patients with acute DVT of the leg (2)[B],(5).

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Life-threatening VT
- Significant bleeding while on anticoagulant therapy
- Look for signs of bleeding while on anticoagulation therapy.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Warfarin requires periodic (monthly after initial stabilization) monitoring of

the INR to maintain a range of 2 to 3.
- LMWH is the treatment of choice in pregnancy. Periodic monitoring with anti-Xa levels is recommended in these patients.

DIET

Unrestricted (except if on warfarin—avoid food with significant amounts of vitamin K)

PATIENT EDUCATION

- Patients should be educated about the use of oral anticoagulant therapy if taking such.
- Avoid NSAIDs while on warfarin.
- Avoid OCPs, as they increase risk of thrombosis.

PROGNOSIS

- When compared with normal individuals, persons with protein C deficiency have normal life spans.
- By age 45 years, 50% of the people heterozygous for protein C deficiency will have VT; half will be spontaneous.

COMPLICATIONS

Recurrent thrombosis (requires indefinite anticoagulation)

CODES

ICD10

D68.59 Other primary thrombophilia

CLINICAL PEARLS

- Asymptomatic patients with protein C deficiency do not need prophylactic anticoagulation because the risk of thrombosis is low (6).
- Patients with protein C deficiency who have DVT should be anticoagulated for at least 6 months.

PROTEIN S DEFICIENCY

Dalia Hammoud, MD • Elie Chalhoub, MD • Maissaa Janbain, MD

BASICS

DESCRIPTION

- Protein S is a vitamin K–dependent factor produced mainly by the liver and acts as a cofactor for protein C.
- Protein C becomes activated when thrombin binds to the endothelial receptor, thrombomodulin.
- Activated protein C, with protein S as a cofactor, inactivates clotting factors Va and VIIIa, and it enhances fibrinolysis.
- Protein S is also able to directly inhibit factors Va, VIIa, and Xa independently of activated protein C.
- Patients with protein S deficiency have a thrombotic disorder that primarily affects the venous system.
- System(s) affected: cardiovascular; hematologic/lymphatic/immunologic; pulmonary

EPIDEMIOLOGY

Incidence

- Predominant age: Mean age of first thrombosis is the 2nd decade of life.
- Predominant sex: male = female

Prevalence

- 0.3% of normal individuals
- Found in 3% of persons with venous thrombosis (VT)

ETIOLOGY AND PATHOPHYSIOLOGY

- >131 mutations in the protein S gene leading to an inherited protein S deficiency have been described.
- Protein S reversibly binds to the C4b-binding protein. Only the free form (40%) acts as a cofactor for activated protein C. This leads to conditions in

which free protein S is low, but total protein S is normal. These individuals are prone to thrombosis.
- Acquired protein S deficiency from decreased free protein S can occur during pregnancy; in patients taking oral contraceptives or warfarin; and in DIC, liver disease, nephrotic syndrome, inflammation, L-asparaginase chemotherapy, and acute thrombosis.
- Transient autoantibodies can develop to protein S in patients with acute varicella (1)[C].

Genetics

- Autosomal dominant
- Considered one of the highest risk thrombophilias
- Heterozygotes have an odds ratio (OR) of VT of 1.6 to 11.5. Arterial thrombosis is more frequent in patients with protein S deficiency who smoke.
- Homozygotes can have a fulminant thrombotic event in infancy, termed *neonatal purpura fulminans*. Homozygosity or compound heterozygosity, if untreated, is usually incompatible with adult life.

RISK FACTORS

- Oral contraceptives, pregnancy, and the use of HRT increase the risk of VT in patients with protein S deficiency (2)[A].
- Patients with protein S deficiency and another prothrombotic state, such as factor V Leiden, have further increased rate of thrombosis (2)[A].
- Patients heterozygous for protein S deficiency who are initiated on warfarin without concomitant heparin can develop warfarin-induced skin necrosis because the half-life of other vitamin K–dependent clotting factors (e.g., prothrombin, factor IX, and factor X) is much longer than the anticoagulant protein S (4 to 8 hours), leading to a transient hypercoagulable state when protein S becomes depleted. These patients develop extremely low levels of protein S and develop necrosis of the skin over central areas of the body such as the breast, abdomen, buttocks, and genitalia (2)[A].

Pregnancy Considerations

Increased thrombotic risk in patients with protein C deficiency

GENERAL PREVENTION

Because protein S deficiency is a congenital disease, there are no preventive measures.

COMMONLY ASSOCIATED CONDITIONS

- Deep and superficial VT, often unprovoked
- Up to 50% of homozygotes will have thrombosis.
- Homozygosity is associated with catastrophic thrombotic complications at birth: *neonatal purpura fulminans*.
- Sites of thrombosis can be unusual, including the mesentery, cerebral veins, and axillary veins.
- Arterial thrombosis is rare, but reported in several case reports.
- Skin necrosis can be seen in patients on warfarin.
- Recurrent pregnancy losses (3)

DIAGNOSIS

HISTORY

Order testing for patients with VT at age <40 years without another etiology; thrombosis in unusual locations (e.g., mesentery, sagittal sinus, portal vein) with a family history of thrombosis or spontaneous abortion

PHYSICAL EXAM

Normal

DIFFERENTIAL DIAGNOSIS

- Factor V Leiden
- Protein C deficiency
- Antithrombin deficiency
- Dysfibrinogenemia
- Dysplasminogenemia
- Homocysteinemia
- Prothrombin 20210 mutation
- Elevated factor VIII levels

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- For evaluation of new clot in patient at risk: CBC with peripheral smear, PT/INR, aPTT, thrombin time, lupus anticoagulant, antiphospholipid antibodies, factor VIII, anticardiolipin antibody, anti-β_2-glycoprotein I antibody, activated protein C resistance, protein S antigen and resistance, antithrombin III assay, fibrinogen, factor V Leiden, prothrombin G20210A, homocysteine
- Protein S activity assay (mainly after obtaining APC resistance)
- Immunoassay for quantitative assessment of total and free protein S levels. Test off vitamin K antagonists.
- Disorders that may alter lab results: liver disease and pregnancy-reduce protein S levels.
- Total protein S levels are markedly decreased in newborns and young infants; use age-adjusted norms.

TREATMENT

GENERAL MEASURES

- Routine anticoagulation for asymptomatic patients with protein S deficiency is not recommended (2)[A].
- Anticoagulation for 6 to 12 months is recommended for patients with protein S deficiency and a first thrombosis.
- Some argue for lifetime anticoagulation; data are limited.
- Anticoagulation for life is indicated for patients with protein S deficiency and recurrent thrombosis.
- The role of family screening for protein S deficiency is unclear because most patients with this mutation do not have thrombosis. Screening should be considered for women considering oral contraceptives or pregnancy and who have a family history of protein S deficiency (4)[B].
- Treatment of thrombosis with low-molecular-weight heparin (LMWH) is recommended over unfractionated heparin, unless the patient has severe renal failure (5)[B].
- Treat as outpatient, if possible (5)[B].
- Initiate warfarin together with LMWH on the first treatment day and

discontinue LMWH after a minimum of 5 days and two consecutive INRs >2 (5)[A].

- For pregnant women with no prior history of VTE, we suggest antepartum and postpartum clinical vigilance. Postpartum prophylaxis is reserved for patients with positive family history only; in that case, we suggest prophylactic- or intermediate-dose LMWH for 6 weeks (1)[C],(5).

MEDICATION

First Line

- LMWH (2)[A] initially for a minimum of 5 days and two consecutive INRs between 2 and 3, at which time it can be stopped
  - Enoxaparin (Lovenox) 1 mg/kg SC BID:
    - Alternatively, 1.5 mg/kg/day SC
  - Tinzaparin (Innohep) 175 anti-Xa IU/kg/day SC
  - Dalteparin (Fragmin) 200 IU/kg/day
- Factor Xa Inhibitor
  - Fondaparinux (Arixtra) <50 kg: 5 mg/day SC; 50 to 100 kg: 7.5 mg/day SC; >100 kg: 10 mg/day SC; contraindicated if CrCl <30 mL/min
- Oral anticoagulant: warfarin (Coumadin): 5 mg/day PO then adjusted to an INR of 2 to 3 for at least 6 months (5)[A]
- Novel oral anticoagulants (NOACs) (6):
  - Dabigatran 150 mg PO BID (after 5 to 10 days of parenteral anticoagulation)
  - Rivaroxaban 15 mg PO BID for 21 days then 20 mg PO QID
  - Apixaban 10 mg PO BID for 7 days then 5 mg PO BID
  - Edoxaban 60 mg PO QID (after 5 to 10 days of parenteral anticoagulation)
- Contraindications
  - Active bleeding precludes anticoagulation; risk of bleeding is a relative contraindication to long-term anticoagulation.
  - Warfarin is contraindicated in patients with a prior history of warfarin-induced skin necrosis.
- Precautions
  - Observe patient for signs of embolization, further thrombosis, or bleeding.
  - Avoid IM injections.

  - Periodically, check stool and urine for occult blood; monitor CBC, including platelets.
  - Heparin: thrombocytopenia and/or paradoxical thrombosis with thrombocytopenia
  - Warfarin: necrotic skin lesions (typically breasts, thighs, and buttocks)
  - LMWH: Adjust dose in renal insufficiency.
- Significant possible interactions
  - Agents that intensify the response to oral anticoagulants: alcohol, allopurinol, amiodarone, anabolic steroids, androgens, many antimicrobials, cimetidine, chloral hydrate, disulfiram, all NSAIDs, sulfinpyrazone, tamoxifen, thyroid hormone, vitamin E, ranitidine, salicylates, acetaminophen
  - Agents that diminish the response to oral anticoagulants: aminoglutethimide, antacids, barbiturates, carbamazepine, cholestyramine, diuretics, griseofulvin, rifampin, oral contraceptives

Second Line

Heparin 80 U/kg IV bolus, followed by 18 U/kg/hr; adjust dose depending on aPTT:

- In patients requiring large daily doses of heparin, measure an anti-Xa level for dose guidance.
- Alternatively, in outpatients, unfractionated heparin can be given at 333 units/kg and then 250 units/kg SC, without monitoring (5)[C].
- It does not alter plasma protein S concentration.

ISSUES FOR REFERRAL

- Patients with suspected protein S deficiency should be seen by a hematologist.
- Screening and prophylactic treatment of asymptomatic family members is not justified (7).

SURGERY/OTHER PROCEDURES

- Anticoagulation must be held for surgical interventions.
- For most patients with DVT, recommendations are against routine use of vena cava filter in addition to anticoagulation; IVC filter is only recommended in case of contraindication to anticoagulation (5)[A].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Life-threatening VT
- Significant bleeding while on anticoagulant therapy
- Look for signs of bleeding while on anticoagulation therapy.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Warfarin requires periodic (monthly after initial stabilization) monitoring of the INR.
- Periodic measurement of INR to maintain a range of 2 to 3
- LMWH is the treatment of choice in pregnancy. Periodic monitoring with anti-Xa levels is recommended in some cases, such as overweight and borderline renal failure.

DIET

Unrestricted

PATIENT EDUCATION

- Patients should be educated about use of oral anticoagulant therapy if taking such.
- Patients undergoing warfarin therapy should avoid drinking alcohol on a daily basis.
- Avoid NSAIDs while on warfarin.

PROGNOSIS

- Persons with protein S deficiency have normal lifespan.
- By age 45 years, 50% of the people heterozygous for protein S deficiency will have VT; half will be spontaneous.

COMPLICATIONS

Recurrent thrombosis (requires indefinite anticoagulation)

CODES

ICD10

D68.59 Other primary thrombophilia

CLINICAL PEARLS

- Asymptomatic patients with protein S deficiency do not require prophylactic anticoagulation because the risk of thrombosis is low; asymptomatic patients do not require anticoagulation (6).
- Patients with protein S deficiency and DVT should be anticoagulated for at least 6 months, especially if first episode.

PROTEINURIA

Andrew S. Allegretti, MD

BASICS

DESCRIPTION

Urinary protein excretion of >150 mg/day

- Nephrotic-range proteinuria: urinary protein excretion of >3.5 g/day; also called *heavy proteinuria*
- Three pathologic types:
  - Glomerular proteinuria: increased permeability of proteins across glomerular capillary membrane
  - Tubular proteinuria: decreased proximal tubular reabsorption of proteins
  - Overflow proteinuria: increased production of low-molecular-weight proteins

Pediatric Considerations

- Proteinuria: Normal is daily excretion of up to 100 mg/m^2 (body surface area).
- Nephrotic-range proteinuria: daily excretion of >1,000 mg/m^2 (body surface area)

Pregnancy Considerations

- Proteinuria in pregnancy beyond 20 weeks' gestation is a hallmark of preeclampsia/eclampsia and demands further workup.
- Proteinuria in pregnancy before 20 weeks' gestation is suggestive of underlying renal disease.

ETIOLOGY AND PATHOPHYSIOLOGY

- Glomerular proteinuria: increased filtration/larger proteins (albumin) due to the following:
  - Increased size of glomerular basement membrane pores and
  - Loss of proteoglycan negative charge barrier
- Tubular proteinuria: Tubulointerstitial disease prevents proximal tubular reabsorption of smaller proteins (β_2-microglobulin, immunoglobulin [Ig] light

chains, retinol-binding protein, amino acids).

- Overflow proteinuria: proximal tubular reabsorption overwhelmed by increased production of smaller proteins
- Glomerular proteinuria
  - Primary glomerulonephropathy
    - Minimal-change disease
    - Idiopathic/primary membranous glomerulonephritis
    - Focal segmental glomerulonephritis
    - Membranoproliferative glomerulonephritis
    - IgA nephropathy
  - Secondary glomerulonephropathy
    - Diabetic nephropathy
    - Autoimmune/collagen vascular disorders (e.g., lupus nephritis, Goodpasture syndrome)
    - Amyloidosis
    - Preeclampsia
    - Infection (HIV, hepatitis B and C, poststreptococcal, endocarditis, syphilis, malaria)
    - Malignancy (GI, lung, lymphoma)
    - Renal transplant rejection
    - Structural (reflux nephropathy, polycystic kidney disease)
    - Drug-induced (NSAIDs, penicillamine, lithium, heavy metals, gold, heroin)
- Tubular proteinuria
  - Hypertensive nephrosclerosis
  - Tubulointerstitial disease (uric acid nephropathy, hypersensitivity, interstitial nephritis, Fanconi syndrome, heavy metals, sickle cell disease, NSAIDs, antibiotics)
  - Acute tubular necrosis
- Overflow proteinuria
  - Multiple myeloma (light chains; also tubulotoxic)
  - Hemoglobinuria
  - Myoglobinuria (in rhabdomyolysis)
  - Lysozyme (in acute monocytic leukemia)

- Benign proteinuria
  - Functional (fever, exercise, cold exposure, stress, CHF)
  - Idiopathic transient
  - Orthostasis (postural)

RISK FACTORS

- Hypertension
- Diabetes
- Obesity
- Strenuous exercise
- CHF
- UTI
- Fever

Genetics

No known genetic pattern

GENERAL PREVENTION

Control of weight, BP, and blood glucose reduces the risk of proteinuria.

COMMONLY ASSOCIATED CONDITIONS

- Hypertension (common)
- Diabetes mellitus (common)
- Preeclampsia (common)
- Multiple myeloma (rare)

DIAGNOSIS

HISTORY

- Frothy/foamy urine
- Change in urine output
- Blood- or cola-colored urine
- Recent weight change
- Swelling
- Rule out systemic illness: diabetes, heart failure, autoimmune, poststreptococcal infection

PHYSICAL EXAM

- BP
- Weight
- Peripheral edema
- Periorbital/facial edema
- Ascites
- Palpation of kidneys
- Check lungs, heart for signs of CHF

DIFFERENTIAL DIAGNOSIS

Includes all causes listed under “Etiology and Pathophysiology”

DIAGNOSTIC TESTS & INTERPRETATION

Screening for proteinuria is not cost-effective unless directed at groups with hypertension/diabetes, older persons, and so forth.

Initial Tests (lab, imaging)

- Urinalysis (UA) quantitatively estimates proteinuria:
  - Only sensitive to albumin; will not detect smaller proteins of overflow/tubular etiologies
  - False-positive finding if urine pH >7, highly concentrated (specific gravity [SG] >1.015), gross hematuria, mucus, semen, leukocytes, iodinated contrast agents, penicillin analogues, sulfonamide metabolites
  - False-negative finding if urine is dilute (SG 1.005), albumin excretion <20 to 30 mg/dL, protein is nonalbumin
  - Sensitivity, 32–46%; specificity, 97–100%
  - Also can perform sulfosalicylic acid test to detect nonalbumin protein
- If UA positive, perform urine microscopy. Refer to nephrologist if positive for signs of glomerular disease.
- If UA shows trace to 2+ protein, rule out transient proteinuria with repeat UA at another visit:
  - More common than persistent proteinuria
  - Causes include exercise, fever, CHF, UTI, and cold exposure
  - Reassure patient that transient proteinuria is benign and requires no further workup.

- If initial UA shows 3+ to 4+ protein or repeat UA is positive, measure creatinine clearance and quantify proteinuria with 24-hour urine collection (gold standard) or spot urine protein-to-creatinine (P/C) ratio (acceptable practice) (1)[A]:
  - Numerical P/C ratios correlate with total protein excreted in grams per day (i.e., ratio of 0.2 correlates with 0.2 g during a 24-hour collection).
  - Patients age <30 years with 24-hour urine excretion of <2 g/day and normal creatinine clearance should be tested for orthostatic proteinuria:
    - Benign condition is present in 2–5% of adolescents.
    - Diagnosed with a normal urine P/C ratio in first morning void and an elevated urine P/C ratio in a second specimen taken after standing for several hours
- If protein excretion >2 g/day, consider nephrology referral and begin workup for systemic/renal disease.
- Patients with persistent proteinuria not explained by orthostatic changes should undergo renal ultrasound to rule out structural abnormalities (e.g., reflux nephropathy, polycystic kidney).

Follow-Up Tests & Special Considerations

Renal/systemic disease workup can include the following:

- CBC, ferritin, ESR, serum iron
- Electrolytes, LFTs
- Lipid profile (ideally, fasting)
- Prothrombin time/international normalized ratio
- Anti-phospholipase A2 receptor antibody: positive in ∼70% of primary membranous nephropathy
- Antinuclear antibodies: elevated in lupus
- Antistreptolysin O titer: elevated after streptococcal glomerulonephritis
- Complement C3/C4: low in most glomerulonephritis
- HIV, syphilis, and hepatitis serologies: all associated with glomerular proteinuria
- Serum and urine protein electrophoresis: abnormal in multiple myeloma
- Blood glucose: elevated in diabetes
- All patients with diabetes should be screened for microalbuminuria.
- Patients with nephrotic-range proteinuria are at increased risk for

hypercholesterolemia and thromboembolic events (~25% of adult patients) with highest risk in membranous nephropathy. Optimal duration of prophylactic anticoagulation is unknown but may extend for the duration of the nephrotic state (2).

- Proteinuric pregnant patients beyond 20 weeks' gestation should be examined for other signs/symptoms of preeclampsia (e.g., hypertension, thrombocytopenia, elevated liver transaminases).

TREATMENT

- BP goals for both diabetic and nondiabetic adults is ≤140/90 mm Hg (3)[C].
- Proteinuria goal is <0.5 g/day (4)[A].

GENERAL MEASURES

- Limit protein intake to 0.8 g/kg/day in adults with DM or without DM and glomerular filtration rate (GFR) <30 mL/min/1.73 m^2. Soy protein may be renoprotective. Monitor protein intake with 24-hour urine urea excretion (4)[A].
- Limit sodium chloride intake to <2 g/day to optimize antiproteinuric medications (3)[B]. Effect on BP is further protective (4)[A].
- Limit fluid intake for urine output goal of <2 L/day. Larger urine volumes are associated with increased proteinuria and later GFR decline (4)[B].
- Smoking cessation: Smoking is associated with increased proteinuria and faster kidney disease progression (4)[B].
- Encourage supine posture (up to 50% reduction vs. upright) (4)[B].
- Discourage severe exertion (4)[B].
- Encourage weight loss (4)[B].

MEDICATION

First Line

- ACE inhibitors: first choice; use maximally tolerated doses; use even if normotensive (4)[A]
- Angiotensin receptor blockers (ARBs): proven antiproteinuric and renoprotective; ARBs are first choice if ACE inhibitors are not tolerated (4)

[A].

- Combination ACE inhibitor and ARB should not be used. Although shown to reduce proteinuria, combination does not reduce poor CV outcomes and does increase risk of adverse drug reactions (5)[A].

Second Line

- *β*-Blockers: antiproteinuric and cardioprotective (4)[A]
- Dihydropyridine calcium channel blockers (DHCCBs): should be avoided unless needed for BP control; not antiproteinuric (4)[A]
- Non-DHCCB: antiproteinuric, may be renoprotective (4)[B]
- Aldosterone antagonists: antiproteinuric independent of BP control (4)[B]
- NSAIDs: antiproteinuric, but also nephrotoxic; generally should be avoided (4)[C]

ISSUES FOR REFERRAL

Consider nephrology referral for possible renal biopsy if

- Impaired creatinine clearance
- Nephrotic-range proteinuria
- Unclear etiology of non-nephrotic-range proteinuria
- Diabetics with microalbuminuria

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Corticosteroids: No proven benefit in mortality or need for renal replacement in adults with nephrotic syndrome, although steroids are recommended in some patients who do not respond to conservative treatment. Classically, children with nephrotic syndrome respond better than adults, especially those with minimal-change disease (6)[A].
- Estrogen/progesterone replacement: may be renoprotective in premenopausal women but should be avoided in postmenopausal women (4)[B]
- Antioxidant therapy: may be antiproteinuric in diabetic nephropathy (4)[C]
- Sodium bicarbonate: not antiproteinuric but may block tubular injury caused by proteinuria; correcting metabolic acidosis may decrease protein catabolism (4)[C].
- Avoid excessive caffeine consumption: antiproteinuric in diabetic rat models (4)[C]

- Avoid iron overload (4)[C].
- Pentoxifylline: prevents progression of renal disease by unclear mechanisms (4)[C]
- Mycophenolate mofetil: antiproteinuric and renoprotective in animal models (4)[C]

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

All patients with persistent proteinuria should be followed with serial BP checks, UA, and renal function tests in the outpatient setting. Intervals depend on underlying etiology.

PROGNOSIS

- Transient and orthostatic proteinuria are benign conditions that do not convey a poor prognosis.
- Clinical significance of persistent proteinuria varies greatly and depends on underlying etiology.
- Degree of proteinuria is associated with disease progression in chronic kidney disease.
- Independent of GFR, higher levels of proteinuria likely convey an increased risk of mortality, myocardial infarction, and progression to kidney failure (7).

COMPLICATIONS

- Progression to chronic renal failure and the need for dialysis/renal transplant
- Hypercholesterolemia
- Hypercoagulable state

CODES

ICD10

- R80.9 Proteinuria, unspecified
- R80.2 Orthostatic proteinuria, unspecified
- R80.1 Persistent proteinuria, unspecified

CLINICAL PEARLS

- Transient and orthostatic proteinuria are benign conditions that do not convey a poor prognosis.
- Proteinuria >2 g/day likely represents glomerular malfunction and warrants a nephrology consultation.
- Clinical course varies greatly but, in general, the degree of proteinuria correlates with kidney disease progression.
- First-line therapy for persistent proteinuric patients is a high-dose ACE

inhibitor.

PROTHROMBIN 20210 (MUTATION)

Dalia Hammoud, MD • Elie Chalhoub, MD • Maissaa Janbain, MD

BASICS

DESCRIPTION

- Prothrombin 20210 mutation is the second most common inherited risk factor for venous thromboembolism (VTE) after factor V Leiden mutation.
- Polymorphism (replacement of G by A) in the 3' untranslated end of the prothrombin gene causes increased translation, resulting in elevated synthesis and secretion of prothrombin. This leads to a 2.8-fold increased risk for venous thrombosis.
- Heterozygous carriers have 30% higher plasma prothrombin levels than normal.
- System(s) affected: cardiovascular; hemic/lymphatic/immunologic; nervous; pulmonary; reproductive
- Synonym(s): prothrombin G20210A mutation; prothrombin G20210 gene polymorphism; prothrombin gene mutation; FII A^{20210} mutation

EPIDEMIOLOGY

- Found largely in Caucasian population. Found in 2–5% of European and Middle Eastern population but rarely in nonwhites. Found in 4–8% of persons with VTE and in up to 18% of patients with recurrent thrombosis.
- Predominant age: Mean age of first thrombosis is in the 2nd decade of life.
- Predominant gender: male = female

Prevalence

3–5% of the population

ETIOLOGY AND PATHOPHYSIOLOGY

- Replacement of G for A in the 3′ untranslated region of the prothrombin gene resulting in relatively higher plasma prothrombin activity, leading to increased risk for venous thrombosis.

- Prothrombin Yukuhashi (Arg596Leu) was described in a Japanese thrombophilic family. The mutant prothrombin had moderately lower, but adequate, activity than wild-type prothrombin. The thrombin molecule generated is resistant to inactivation by antithrombin, thereby conferring an increased susceptibility to thrombosis.
- Gene mutation

Genetics

Autosomal dominant

RISK FACTORS

- Patients with prothrombin 20210 and another prothrombotic state, such as factor V Leiden, have increased rates of thrombosis (1).
- The risk of venous thrombosis in patients with prothrombin 20210 mutation increases when added to the use of oral contraceptives, pregnancy, and the use of hormone replacement therapy as well as prolonged immobilization (1).
- Heterozygosity for the prothrombin 20210 mutation is mildly thrombophilic.

Pregnancy Considerations

- Increased thrombotic risk in patients with prothrombin 20210.
- A new mutation C20209T has been described recently in women with recurrent pregnancy loss; the clinical and biochemical implications of this mutation are not fully understood yet (2).

GENERAL PREVENTION

Patients with prothrombin 20210 without thrombosis do not require prophylactic anticoagulation (3)[A], except for pregnant women with family history of VTE, who require antepartum and 6-week postpartum prophylaxis with low-molecular-weight heparin (LMWH) (4)[B].

COMMONLY ASSOCIATED CONDITIONS

Venous thromboembolism

DIAGNOSIS

HISTORY

- Previous thrombosis
- Family history of thrombosis
- Family history of factor prothrombin 20210 mutation

PHYSICAL EXAM

Arterial thrombosis is rare in adults with prothrombin 20210 gene mutation.

DIFFERENTIAL DIAGNOSIS

- Factor V Leiden mutation
- Protein C deficiency
- Protein S deficiency
- Antithrombin deficiency
- Other causes of activated protein C resistance (e.g., antiphospholipid antibodies)
- Dysfibrinogenemia
- Dysplasminogenemia
- Homocystinemia
- Elevated factor VIII levels

DIAGNOSTIC TESTS & INTERPRETATION

Test patients with thrombosis at age <50 years, history of recurrent idiopathic thrombosis, those with thrombosis in unusual locations, or those with strong family history.

Initial Tests (lab, imaging)

- For evaluation of a new clot in patients at risk: CBC with peripheral smear, PT/INR, aPTT, thrombin time, lupus anticoagulant, antiphospholipid antibodies, factor VIII, anticardiolipin antibody, anti-β_2 glycoprotein I antibody, activated protein C resistance, protein S antigen and resistance, antithrombin III assay, fibrinogen, factor V Leiden, prothrombin G20210A, homocysteine
- DNA analysis for mutation
- Testing is reliable during acute thrombosis and on anticoagulation, as is gene analysis (4).
- As appropriate for suspected site of thrombosis: US, CT scan, and V/Q scan

Follow-Up Tests & Special Considerations

Although prothrombin levels are elevated, this is not a sensitive test to make the diagnosis.

Diagnostic Procedures/Other

MR angiography (MRA), venography, or arteriography to detect thrombosis

Test Interpretation

Venous thrombus

TREATMENT

For acute thrombosis

GENERAL MEASURES

- Patients with prothrombin 20210 mutation and a first thrombosis should receive anticoagulation medication initially with heparin or LMWH (1)[A].
- Treatment with LMWH is recommended over unfractionated heparin, unless the patient has severe renal failure (3)[A].
- Treat as outpatient, if possible (3)[B].
- Initiate warfarin on day 1 or 2 of LMWH therapy; discontinue LMWH after minimum of 5 days and 2 consecutive INRs >2 (3)[A].
- Patients should be maintained on warfarin with an INR of 2 to 3 for at least 3 months (4)[A].
- Recurrent thrombosis requires indefinite anticoagulation (1)[B].

MEDICATION

First Line

- LMWH (3)[A]
  - Enoxaparin (Lovenox): 1 mg/kg SC BID; tinzaparin (Innohep): 175 anti-Xa IU/kg SC daily; dalteparin (Fragmin): 200 IU/kg SC daily
  - Initiate warfarin on day 1 or 2 of LMWH therapy; continue LMWH for a minimum of 5 days and 2 consecutive INRs >2.
  - Fondaparinux (Arixtra): <50 kg: 5 mg SC daily; 50 to 100 kg: 7.5 mg SC daily; >100 kg: 10 mg SC daily

- Oral anticoagulant
  - Warfarin (Coumadin) 5 mg PO daily and then adjusted to an INR of 2 to 3 (4)
- Contraindications
  - Active bleeding precludes anticoagulation (3)[A].
  - Risk of bleeding is a relative contraindication to long-term anticoagulation (3)[A].
  - Warfarin is contraindicated in patients with history of warfarin skin necrosis (3)[A].
  - Fondaparinux: severe renal impairment (CrCl <30 mL/min)
- Precautions
  - Observe patient for signs of embolization, further thrombosis, or bleeding.
  - Avoid IM injections. Periodically check stool and urine for occult blood; monitor CBCs, including platelets.
  - Heparins: thrombocytopenia
  - Warfarin: necrotic skin lesions (typically breasts, thighs, or buttocks)
  - LMWH: Adjust dosage in renal insufficiency.
- Significant possible interactions
  - Agents that intensify the response to oral anticoagulants: alcohol, allopurinol, amiodarone, anabolic steroids, androgens, many antimicrobials, cimetidine, chloral hydrate, disulfiram, all NSAIDs, sulfinpyrazone, tamoxifen, thyroid hormone, vitamin E, ranitidine, salicylates, acetaminophen
  - Agents that diminish the response to anticoagulants: aminoglutethimide, antacids, barbiturates, carbamazepine, cholestyramine, diuretics, griseofulvin, rifampin, oral contraceptives

Second Line

- Heparin 80 U/kg IV bolus followed by 18 U/kg/hr continuous infusion
- Adjust dose, depending on aPTT.
- In patients requiring large daily doses of heparin, measure an anti-Xa level for dose guidance.
- Alternatively, unfractionated heparin can be given for outpatients at 333 U/kg then 250 U/kg SC (4)[A].

ISSUES FOR REFERRAL

- Recurrent thrombosis on anticoagulation
- Difficulty anticoagulating
- Genetic counseling

SURGERY/OTHER PROCEDURES

- Anticoagulation must be held for surgical interventions.
- For most patients with deep venous thrombosis (DVT), recommendations are against routine use of vena cava filter in addition to anticoagulation, except in case with contraindication to anticoagulation (4)[A].
- Thrombectomy may be necessary in some cases.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Admission criteria/initial stabilization: complicated thrombosis, such as pulmonary embolus; heparin
- Discharge criteria: stable on anticoagulation

ONGOING CARE

Compression stockings for prevention

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Warfarin use requires periodic (monthly after initial stabilization) INR measurements, with a goal of 2 to 3 (3)[A].
- Heterozygosity for the prothrombin 20210 mutation increase the risk for recurrent VTE only slightly, thus its presence does not alter the length of anticoagulation treatment decision.

DIET

- No restrictions
- Food rich in vitamin K may interfere with warfarin anticoagulation.

PATIENT EDUCATION

- Patients should be educated about:

  - Use of oral anticoagulant therapy
  - Avoidance of NSAIDs while on warfarin
- The role of family screening is unclear, as most patients with this mutation do not have thrombosis. In a patient with a family history of prothrombin 20210 mutation, consider screening during pregnancy or if considering oral contraceptive use.

PROGNOSIS

- When compared with normal individuals, persons with prothrombin 20210 have normal lifespan.
- Carriage of the PT20210 mutation has been linked to an increased rate of liver fibrosis in HCV patients (5).

COMPLICATIONS

- Recurrent thrombosis
- Bleeding on anticoagulation

CODES

ICD10

D68.52 Prothrombin gene mutation

CLINICAL PEARLS

- Prothrombin 20210 mutation is the second most common inherited risk factor for VTE after factor V Leiden mutation.
- Asymptomatic patients with prothrombin 20210 mutation do not need anticoagulation.
- Testing for the prothrombin G20210 mutation may be done while the patient is anticoagulated, as it is a genetic assay.
- For pregnant women homozygous for factor V Leiden, or heterozygous for factor V and prothrombin G20210 mutation, but no prior history of VTE, postpartum prophylaxis with prophylactic or intermediate-dose LMWH or vitamin K antagonists with target INR 2 to 3 for 6 weeks is recommended. Antepartum prophylaxis is added if there is positive family of VTE.

PRURITUS ANI

Sonia Taneja, MD • Marie L. Borum, MD, EdD, MPH

BASICS

DESCRIPTION

- Intense, unpleasant anal/perianal itching and/or burning
- Usually acute
- Can be classified as idiopathic (primary) pruritus ani (~75% of cases) or secondary to anorectal pathology (1)

EPIDEMIOLOGY

Incidence

- Uncommon, 1–5% of the general population (1)
- Predominant age: 30 to 60 years (1)
- Predominant sex: male > female (4:1) (1)

Prevalence

Difficult to estimate as often unreported, one study found present in 2.4% of patients visiting PCPs (2).

ETIOLOGY AND PATHOPHYSIOLOGY

- Pruritus ani may be considered idiopathic (primary) or secondary to anorectal pathology with over 100 etiologies categorized by cutaneous, neuropathic, neurogenic, and psychogenic causes (3,4).
- Pruritus may create an irresistible desire to scratch the perianal area leading to a self-perpetuating itch-scratch-itch cycle.
- Consider primary pruritus ani when no other demonstrable causes can be found. This includes:
  - Poor anal hygiene
  - Loose or leaking stool that makes hygiene difficult. Patients with abdominal ostomy bags typically do not complain of pruritus (1).
  - Internal sphincter laxity
- Etiologies of secondary pruritus ani:

- Inflammatory dermatologic diseases:
  - Allergic contact dermatitis (soaps, perfumes, or dyes in toilet paper, topical anesthetics, oral antibiotics)
  - Atopic dermatitis ± lichen simplex chronicus (patients also have asthma and/or eczema)
  - Psoriasis (lesions tend to be poorly demarcated, pale, and nonscaling)
  - Seborrheic dermatitis
  - Lichen planus (may be seen in patients with ulcerative colitis and myasthenia gravis)
  - Radiation dermatitis (3)
- Colorectal/anorectal diseases: rectal prolapse, hemorrhoids, fissures or fistulas, chronic diarrhea/constipation, polyps
- Infectious etiologies, may be sexually transmitted: bacteria (gonorrhea, chlamydia, syphilis), viruses (herpes simplex virus [HSV], condyloma acuminate from human papillomavirus [HPV], molluscum), parasites (pinworms, lice, scabies, or bed bugs), fungal (*Candida*, or dermatophytes like *Tinea*). Other bacteria (*Staphylococcus aureus*, *β*-hemolytic *Streptococcus*, *Corynebacterium minutissimum* [Erythrasma]) (3)
- Malignancies: melanoma, basal cell/squamous cell carcinoma, colorectal cancer, or (uncommon) the presenting symptom of Bowen or Paget disease
- Mechanical factors: vigorous cleaning and scrubbing, tight-fitting clothes, synthetic undergarments
- Systemic diseases: diabetes mellitus (most common), chronic liver disease, renal failure, leukemia or lymphoma, hyperthyroidism, anemia
- Chemical irritants: chemotherapy, diarrhea (often from antibiotic use)
- Dietary elements (citrus, milk products, coffee, tea, cola, chocolate, beer, wine, tomatoes, nuts)
- Psychogenic factors: anxiety–itch–anxiety cycle

RISK FACTORS

- Obesity
- Excess perianal hair growth, and/or perspiration
- Underlying anorectal pathology
- Underlying anxiety disorder
- Caffeine intake has been correlated with symptoms.

GENERAL PREVENTION

- Good perianal hygiene
- Avoid mechanical irritation of skin (vigorous cleaning or rubbing with dry toilet paper or baby wipes, harsh soaps or perfumed products, excessive scratching with fingernails, or wearing tight/synthetic undergarments).
- Minimize moisture in perianal area (absorbent cotton in anal cleft may help keep area dry).
- Avoid laxative use (loose stool is an irritant).

DIAGNOSIS

HISTORY

- Patient presents with complaint of anal and/or perianal itching, burning, or excoriations present.
- Inquire about:
  - Timing (when it started, when it is worse)
  - Frequency of cleansing and products used on affected area
  - Change in bowel habits
  - Melena or hematochezia
  - Recent antibiotic use
  - Skin disorders (psoriasis, eczema)
  - Rectal or vaginal discharge, menstrual cycle
  - Dietary history: Focus on the “C”s: caffeine, coffee, cola, chocolate, citrus, calcium (dairy) (3).
  - Medical history (hepatitis, iron deficiency anemia, and diabetes in particular)
  - Family history of colorectal cancer
  - Anal receptive intercourse
  - Change in toiletry products
  - Household members (particularly children) with itching (possible pinworms)
  - Clothing preference (tight, synthetic) (1)

PHYSICAL EXAM

- Perianal visual inspection for erythema, hemorrhoids, anal fissures, maceration, lichenification, warts, polyps, excoriations, neoplasia, stool seepage
- Classification based on gross appearance
  - Stage 1: erythema, inflamed appearance
  - Stage 2: lichenification
  - Stage 3: lichenification, coarse skin, potential fissures or ulcerations (1)[C]
- Digital rectal exam to evaluate for masses, internal sphincter tone, pain. Valsalva to evaluate for prolapse
- Anoscopy to evaluate for hemorrhoids, fissures, other internal lesions

DIFFERENTIAL DIAGNOSIS

- "ITCHeS" acronym (4)
  - **I**nfection: *Candida*, parasites (scabies, pinworms), HPV, HSV, bacterial (gram-positive bacteria, gonorrhea, chlamydia, syphilis)
  - **T**opical irritants: soaps/detergents, garments, deodorants, perfumes, stool leakage
  - **C**utaneous/**C**ancer/**C**olorectal: eczema, psoriasis, lichen planus, lichen sclerosus, seborrhea, skin cancer, extramammary Paget disease, Bowen disease, fistula, fissure, prolapse, hemorrhoids, colorectal cancer
  - **H**ypersensitivity: foods (the "C's" above), medications (colchicine, quinidine, mineral oil)
  - e**S**ystemic: diabetes, iron deficiency anemia, uremia, cholestasis, hematologic malignancy

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (labs, imaging)

Depending on history and exam, consider the following:

- Pinworm tape test; stool for ova and parasites
- CBC, comprehensive metabolic panel, A1c, thyroid studies to identify underlying systemic disease
- Wood lamp examination will show coral-red fluorescence in erythrasma (1).
- Skin scraping with potassium hydroxide (KOH) prep for dermatophytes or candidiasis (as etiology or as superinfection) and mineral oil prep for scabies
- Perianal skin culture (bacterial superinfection)

- Hemoccult testing of stool

Pediatric Considerations

Pinworms are common in children; consider perianal Crohn disease (5).

Follow-Up Tests & Special Considerations

Anal DNA polymerase chain reaction (PCR) probe for gonorrhea and chlamydia, and anal Pap smear for HPV if receptive anal intercourse

Diagnostic Procedures/Other

- Biopsy suspicious lesions (e.g., lichenification, ulcerated epithelium, refractory cases) to exclude neoplasia; evaluate etiology.
- Consider colonoscopy if history, exam, or testing suggests colorectal pathology (family history of colorectal disease, especially if age >40 years, weight loss, rectal bleeding, change in bowel habits).

Geriatric Considerations

- Stool incontinence may be a predisposing factor.
- Consider systemic disease.
- Higher likelihood of colorectal pathology

TREATMENT

GENERAL MEASURES

- Educate patients regarding proper anal hygiene and to avoid chemical and mechanical irritants (1).
- High-fiber diet and/or bowel regimen to maintain regular bowel movements (1)
- Avoid tight-fitting clothing. Use cotton undergarments.
- Absorbent cotton, talcum powder, or cornstarch if excess moisture (1)
- Wear cotton gloves at night to control nocturnal scratching (1).

MEDICATION

First Line

- Treat underlying infections: fungal or dermatophyte infection with topical imidazoles, bacterial infection with topical antibacterials.

- Treat underlying anorectal anatomic pathology: banding of prolapsing internal hemorrhoids, treat fistulas, or fissures.
- Break itch–scratch cycle with low-potency steroid cream such as hydrocortisone 1% ointment applied sparingly up to 4 times daily (1)[A]. Discontinue when itching subsides. Avoid use >12 weeks due to risk of skin atrophy.
- If no response with low-potency steroid, consider high-potency steroid cream.
- Antihistamines, witch hazel may be useful until local measures take effect, particularly sedating antihistamines, which will reduce nighttime itching (4).
- Tricyclic antidepressants may reduce nighttime scratching
- Zinc oxide can be used after completing steroid course for barrier protection (3)[C]; petroleum jelly is another barrier treatment (mineral oil can worsen pruritus).
- Low-dose topical capsaicin cream in combination with steroid cream if refractory symptoms (1)[A]
- 0.1% tacrolimus ointment may be a good option for patients at risk for atrophy from prolonged steroid use.
- Several small case series have shown symptomatic benefit with methylene blue injection—this may be an additional option for patients with refractory itch.

Second Line

Radiation may be used to destroy nerve endings (create permanent anesthesia) in intractable cases. This is almost never indicated but is very effective.

ISSUES FOR REFERRAL

- Intractable pruritus: Consider referral to gastroenterology (for colonoscopy) or dermatology (for additional treatment, possibly injections, or biopsies). Refractory or persistent symptoms should signal the possibility of underlying neoplasia, as pruritus ani of long duration is associated with a greater likelihood of colorectal pathology.
- Refer for colonoscopy if at risk for colon cancer.

SURGERY/OTHER PROCEDURES

As above, especially if concern for malignancy identified

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

See patient every 2 weeks if not improving. Ensure proper hygiene, and avoidance of irritants. Work up for systemic disease, and check for persistent lichenification. If refractory pruritus or lichenification does not resolve, consider underlying malignancy.

DIET

- Trial elimination of foods and beverages known or suspected to exacerbate symptoms: coffee, tea, chocolate, beer, cola, vitamin C tablets in excessive doses, citrus fruits, tomatoes, or spices.
- Eliminate foods or drugs contributing to loose bowel movements or dermatitis.
- Add fiber supplementation to bulk stools and prevent fecal leakage in patients who have fecal incontinence or partially formed stools.

PATIENT EDUCATION

- Review proper anal hygiene:
  - Resist overuse of soap and rubbing.
  - Avoid products with irritating perfumes and dyes.
  - Avoid use of ointments and mineral oil.
  - Wear loose, light cotton clothing.
  - If moisture is a problem, use cotton, unmedicated talcum powder, or cornstarch to keep the area dry.
  - Cleanse perianal area after bowel movements with water-moistened cotton.
  - Dry area after bathing by patting with a soft towel or by using a hair dryer (1).
- Avoid medications that cause diarrhea or constipation.
- Avoid caffeine, cola, chocolate, citrus, tomatoes, tea, beer/wine, nuts, milk products (3)[C].
- Evaluate for underlying medical disease.
- Use barrier protection if engaging in anal intercourse.
- If unable to completely empty rectum with defecation, use small plain-water enema (infant bulb syringe) after each bowel movement to prevent soiling and

irritation.

PROGNOSIS

- Conservative treatment successful in ~90% of cases
- Idiopathic pruritus ani often is chronic, waxing and waning.

COMPLICATIONS

- Bacterial superinfection at site of excoriations and potential abscess formation or penetrating infection via self-inoculation with colonic pathogens
- Lichenification
- Significant effect on quality of life

SEE ALSO

Pinworms; Pruritus Vulvae

CODES

ICD10

L29.0 Pruritus ani

CLINICAL PEARLS

- Pruritus ani is characterized by intense anal/perianal itching and/or burning.
- Usually idiopathic or related to skin irritation with itch–scratch–itch cycle
- Conservative treatment with good perianal hygiene and reassurance is successful in 90% of patients.
- Evaluate for systemic disease, and treat underlying anorectal pathology or other secondary causes.
- Consider trial of dietary elimination of “C”s—citrus, vitamin C supplements, calcium products, caffeine, coffee, cola, chocolate.
- Rule out infection (viral, bacterial, parasitic) in immunosuppressed patients.
- Consider underlying malignancy if refractory.

PRURITUS VULVAE

Maeve K. Hopkins, MA, MD • Michael P. Hopkins, MD, MEd

BASICS

DESCRIPTION

- Pruritus vulvae is a symptom, as well as a primary diagnosis:
  - The symptom may indicate an underlying pathologic process.
  - Only when no underlying disease is identified may this be used as a primary diagnosis.
- Pruritus vulvae as a primary diagnosis may also be more appropriately documented as vulvodynia (see "Vulvodynia" topic) or burning vulva syndrome.

EPIDEMIOLOGY

Symptoms may occur at any age during a woman's lifetime.

- Young girls most commonly have infectious or hygiene etiology.
- The primary diagnosis is more common in postmenopausal women.

Incidence

The exact incidence is unknown, although most women complain of vulvar pruritus at some point in their lifetime.

ETIOLOGY AND PATHOPHYSIOLOGY

Vulvar tissue is more permeable than exposed skin due to differences in structure, occlusion, hydration, and susceptibility to friction. It is particularly vulnerable to irritants (1)

- Perfumes
- Soaps
- Laundry detergent
- Douches
- Toilet paper
- Sanitary napkins

RISK FACTORS

- High-risk sexual behavior
- Immunosuppression
- Obesity

GENERAL PREVENTION

- Attention should be paid to personal hygiene and avoidance of possible environmental factors.
- Tight-fitting clothing should be avoided.
- Only cotton underwear should be worn.

COMMONLY ASSOCIATED CONDITIONS

- Infectious etiology
  - Vaginal or vulvar candida
  - *Gardnerella vaginalis*
  - *Trichomonas*
  - Human papillomavirus
  - Herpes simplex virus
- Vulvar vestibulitis
- Lichen sclerosis
- Lichen planus
- Lichen simplex chronicus (squamous cell hyperplasia)
- Malignant or premalignant conditions
- Psoriasis
- Fecal or urinary incontinence
- Dermatophytosis
- Parasites: scabies, phthrius pubis
- Extrammmary Paget’s
- Dietary: methylxanthines (e.g., coffee, cola), tomatoes, peanuts
- Autoimmune progesterone dermatitis: perimenstrual eruptions
- Irritant or allergic contact dermatitis
- Atopic dermatitis

DIAGNOSIS

Pruritus vulvae is a diagnosis of exclusion.

HISTORY

- Persistent itching
- Persistent burning sensation over the vulva or perineum
- Change in vaginal discharge
- Postcoital bleeding
- Dyspareunia

PHYSICAL EXAM

- Visual inspection of the vulva, vagina, perineum, and anus
  - Superior surfaces of the labia majora—extending from mons to the anal orifice are most involved.
  - Vulvar skin is leathery or lichenified in appearance.
  - Papillomatosis may be a sign of chronic inflammation.
- Light touch identification of affected areas
- Cotton swab–applied pressure to vestibular glands

DIAGNOSTIC TESTS & INTERPRETATION

- Sodium chloride: *Gardnerella* or *Trichomonas*
- 10% potassium hydroxide: *Candida*
- Viral culture or polymerase chain reaction (PCR): herpes simplex virus
- Directed biopsy: human papillomavirus, lichen, malignancy
- Colposcopy with acetic acid or Lugol solution of vagina and vulva

Follow-Up Tests & Special Considerations

- A patch test may be performed by a dermatologist to assist in identifying a causative agent if contact dermatitis is suspected.
- Exam-directed tissue biopsies are essential in the postmenopausal population to rule out malignancy.

Diagnostic Procedures/Other

Biopsies should be collected from any ulceration, discoloration, raised areas, macerated areas, and the area of most intense pruritus.

Test Interpretation

- Only in the absence of pathologic findings can the primary diagnosis of

pruritus vulvae be made.
- In one study, a specific clinicopathologic diagnosis was obtained in 89% of patients by using the most recent 2006 International Society for the Study of Vulvar Diseases (ISSVD) classifications (2).

TREATMENT

Identify the underlying cause or disease to target treatment
- Stop all potential irritants.
- Eliminate bacterial and fungal infection.
- Cool the affected area: Use cool gel packs (not ice packs, which may cause further injury).
- Sitz baths and bland emollients to soothe fissured or eroded skin

MEDICATION

First Line

- 1st-generation antihistamines (3)[C]
  - Hydroxyzine: Initiate with 10 mg before bedtime (slow increase up to 100 mg).
  - Doxepin: Initiate with 10 mg before bedtime (slow increase up to 100 mg).
  - 2nd-generation antihistamines are of little benefit.
- SSRIs (3)[C]
  - Citalopram 20 to 40 mg in the morning may be helpful for daytime symptoms.
- Topical steroids (4)[C]
  - Triamcinolone 0.1% applied daily for 2 to 4 weeks, then twice weekly
  - Hydrocortisone 1–2.5% cream applied 2 to 4 times daily (5)
  - Avoid long-term use due to risk of atrophy.
  - One randomized, controlled trial showed no difference between topical triamcinolone and placebo cream (6).

Second Line

Calcineurin inhibitors such as topical pimecrolimus 1% cream applied BID for 3 weeks (7)[B]
- May lead to an 80% reduction of pruritus

ISSUES FOR REFERRAL

- Persistent symptoms should prompt additional investigation and referral to a gynecologist or gynecologist oncologist.
- Gynecology oncology referral for proven or suspected malignancy
- Dermatology referral for patch testing to evaluate for contact dermatitis

ADDITIONAL THERAPIES

- SC triamcinolone injections (8)[B]
- Alcohol nerve block (9)[B]
- Laser therapy (10)[B]
- GnRH analogue

ONGOING CARE

- Frequent evaluation, repeat cultures, and biopsies are necessary for cases resistant to treatment.
- Refractory cases may require referral to gynecologist or gynecology oncology for further management.

DIET

Dietary alterations include avoidance of the following:

- Coffee and other caffeine-containing beverages
- Tomatoes
- Peanuts

PATIENT EDUCATION

- American Congress of Obstetricians and Gynecologists: www.acog.org
- National Vulvodynia Foundation: www.nva.org

PROGNOSIS

Conservative measures and short-term topical steroids control most patients' symptoms.

COMPLICATIONS

Malignancy

CODES

ICD10

- L29.2 Pruritus vulvae
- N94.819 Vulvodynia, unspecified

CLINICAL PEARLS

- Most women complain of pruritus vulvae at some point in their lifetime.
- Pruritus vulvae is a diagnosis of exclusion once other causes of itching have been ruled out.
- Exam-directed biopsies from any ulceration, discoloration, raised areas, macerated areas, and the area of most intense pruritus are essential to rule out malignancy.
- Initial treatment is conservative.

PSEUDOFOLLICULITIS BARBAE

Maurice Duggins, MD

BASICS

DESCRIPTION

- Foreign-body inflammatory reaction from an ingrown hair resulting in the appearance of papules and pustules. This is found mainly in the bearded area (*barbae*) but may occur in other hairy locations such as the scalp, axilla, or pubic areas where shaving is done (1).
- A mechanical problem: extrafollicular and transfollicular hair penetration
- System(s) affected: skin/exocrine
- Synonym(s): chronic sycosis barbae; pili incarnate; folliculitis barbae traumatica; razor bumps; shaving bumps; tinea barbae; pseudofolliculitis barbae (PFB)

EPIDEMIOLOGY

- Predominant age: postpubertal, middle age (14 to 25 years) (2)
- Predominant sex: male > female (can be seen in females of all races who wax/shave)

Incidence

- Adult male African Americans: unknown
- Adult male whites: unknown

Prevalence

- Widespread in Fitzpatrick skin types IV–VI (darker complexions) who shave
- 45–83% of African American soldiers who shave (1)

ETIOLOGY AND PATHOPHYSIOLOGY

- Transfollicular escape of the low-cut hair shaft as it tries to exit the skin is accompanied by inflammation and often an intraepidermal abscess.
- As the hair enters the dermis, more severe inflammation occurs, with downgrowth of the epidermis in an attempt to sheath the hair.
- A foreign-body reaction forms at the tip of the invading hair, followed by

abscess formation.
- Shaving too close
- Plucking/tweezing or wax depilation of hair may cause abnormal hair growth in injured follicles.

Genetics

- People with curly hair have an asymmetric accumulation of acidic keratin hHa8 on hair shaft.
- Single-nucleotide polymorphism (disruption Ala12Thr substitution) affects keratin of hair follicle.

RISK FACTORS

- Curly hair
- Shaving too close or shaving with multiple razor strokes
- Plucking/tweezing hairs
- South Mediterranean/American, Middle Eastern, Asian, or African descent (skin types IV–VI)

GENERAL PREVENTION

- Prior to shaving, rinse face with warm water to hydrate and soften hairs.
- Use adjustable hair clippers that leave very low hair length above skin.
- Shave with either a manual adjustable razor at coarsest setting (avoids close shaves), a single-edge blade razor (e.g., Bump Fighter), a foil-guarded razor (e.g., PFB razor), or electric triple “O-head” razor.
- Empty razor of hair frequently.
- Shave in the direction of hair growth. Do not overstretch skin when shaving.
- Use a generous amount of the correct shaving cream/gel (e.g., Ef-Kay Shaving Gel, Edge Shaving Gel, Aveeno Therapeutic Shave Gel, Easy Shave Medicated Shaving Cream).
- Daily shaving reduces papules/pruritus.
- Regular use of depilatories

COMMONLY ASSOCIATED CONDITIONS

- Keloidal folliculitis
- Pseudofolliculitis nuchae

DIAGNOSIS

HISTORY

Pain on shaving; pruritus of shaved areas, irritated “razor bumps”

PHYSICAL EXAM

- Tender, exudative, erythematous follicular papules or pustules in beard area (less commonly in scalp, axilla, and pubic areas); range from 2 to 4 mm
- Hyperpigmented “razor or shave bumps”
- Alopecia
- Lusterless, brittle hair

DIFFERENTIAL DIAGNOSIS

- Bacterial folliculitis
- Impetigo
- Acne vulgaris
- Tinea barbae
- Sarcoidal papules

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Clinical diagnosis
- Culture of pustules: usually sterile; may show coagulase-negative *Staphylococcus epidermidis* (normal skin flora)
- Additional hormonal testing may be indicated in females with hirsutism and/or polycystic ovary syndrome: dehydroepiandrosterone sulfate, luteinizing hormone (LH)/follicle-stimulating hormone (FSH), and free and total testosterone (3)[C].

Test Interpretation

Follicular papules and pustules

TREATMENT

- Mild cases

  - Stop shaving or avoid close shaving for 30 days while keeping beard groomed and clean (1,2)[C].
  - Consider 5% benzoyl peroxide after shaving and application of 1% hydrocortisone cream at bedtime (or LactiCare HC lotion after shaving) (2)[C].
  - Tretinoin 0.025% cream; apply daily(1)[C]
- Moderate cases
  - Chemical depilatories (barium sulfide; Magic Shave powder); first test on forearm for 48 hours (for irritation) (1–3)[B]
  - Consider eflornithine HCl cream (Vaniqa) to reduce hair growth and stiffness in combination with other therapies (1,4)[B].
- Severe cases
  - Laser therapy: Longer wavelength laser (e.g., neodymium [Nd]:YAG) is safer for dark skin (5)[B].
  - Avoid shaving altogether; grow beard (1–3)[C].

GENERAL MEASURES

Acute treatment

- Dislodge embedded hair with sterile needle/tweezers.
- Discontinue shaving until red papules have resolved (minimum 3 to 4 weeks; longer if moderate or severe); can trim to length >0.5 cm during this time.
- Massage beard area with washcloth, coarse sponge, or a soft brush several times daily.
- Hydrocortisone 1–2.5% cream to relieve inflammation
- Selenium sulfide if seborrhea is present and to help reduce pruritus
- Systemic antibiotics if secondary infection is present

Pregnancy Considerations

Do not use tretinoin (Retin-A), tetracycline, or benzoyl peroxide.

MEDICATION

First Line

- Topical or systemic antibiotic for secondary infection
  - Application of clindamycin (Cleocin T) solution BID or topical erythromycin

  - Low-dose erythromycin or tetracycline 250 to 500 mg PO BID for more severe inflammation
  - Benzoyl peroxide 5%– clindamycin 1% gel BID: Administer until papule/pustule resolves.
- Mild cases: tretinoin 0.025% cream at bedtime; combination of the above therapies
- Moderate disease/chemical depilatories
  - Disrupt cross-linking of disulfide bonds of hair to produce blunt (less sharp) hair tip.
  - Apply no more frequently than every 3rd day: 2% barium sulfide (Magic Shave) or calcium thioglycollate (Surgex); calcium hydroxide (Nair)
- Contraindications
  - Clindamycin: hypersensitivity history; history of regional enteritis or ulcerative colitis; history of antibiotic-associated colitis
  - Erythromycin, tetracycline, tretinoin: hypersensitivity history
- Precautions
  - Clindamycin: colitis, eye burning and irritation, skin dryness; pregnancy Category B
  - Erythromycin: Use cautiously in patients with impaired hepatic function; GI side effects, especially abdominal cramping; pregnancy Category B (erythromycin base formulation).
  - Chemical depilatories: Use cautiously; frequent use and prolonged application may lead to irritant contact dermatitis and chemical burns.
  - Tetracycline: Avoid in pregnancy.
  - Tretinoin: Severe skin irritation; avoid in pregnancy.
  - Benzoyl peroxide: skin irritation and dryness, allergic contact dermatitis
  - Hydrocortisone cream: local skin irritation, skin atrophy with prolonged use, lightening of skin color
- Significant possible interactions
  - Erythromycin: increases theophylline and carbamazepine levels; decreases clearance of warfarin
  - Tetracycline: depresses plasma prothrombin activity

Second Line

Chemical peels with either glycolic acid or salicylic acid

ISSUES FOR REFERRAL

- Worsening or poor response to the above therapies after 4 to 6 weeks should prompt dermatology consultation.
- Occupational demands may also prompt earlier referral to dermatology for more aggressive therapy.

SURGERY/OTHER PROCEDURES

Laser treatment with long-pulsed Nd:YAG is helpful for severe cases.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- As needed
- Educate patient on curative and preventive treatment.

DIET

- No restrictions
- No dietary studies available

PATIENT EDUCATION

- https://medlineplus.com/
- http://www.uptodate.com/home

PROGNOSIS

- Good, with preventive methods
- Prognosis is poor in the presence of progressive scarring and foreign-body granuloma formation.

COMPLICATIONS

- Scarring (occasionally keloidal)
- Foreign-body granuloma formation
- Disfiguring postinflammatory hyperpigmentation (use sunscreens; can treat with hydroquinone 4% cream, Retin A, clinical peels)
- Impetiginization of inflamed skin
- Epidermal (erythema, crusting, burns with scarring) and pigmentary changes

with laser

SEE ALSO

Folliculitis; Impetigo

CODES

ICD10

- L73.1 Pseudofolliculitis barbae
- B35.0 Tinea barbae and tinea capitis
- L73.8 Other specified follicular disorders

CLINICAL PEARLS

- Electrolysis is not recommended as a treatment. It is expensive, painful, and often unsuccessful.
- Combination of laser therapy with eflornithine is more effective than laser alone.
- Use Bump Fighter razor from American Safety Razor Company (http://www.asrco.com/).
- Men may prefer the convenience of the Bump Fighter razor over depilatory products.
- The aversive smell of sulfur could be a problem with some depilatory products.
- Have patient test for skin sensitivity with a small (coin-sized) amount of the depilatory on the bearded area or forearm.

PSEUDOGOUT (CALCIUM PYROPHOSPHATE DIHYDRATE)

Caitlyn M. Rerucha, MD

BASICS

DESCRIPTION

- Autoinflammatory disease triggered by calcium pyrophosphate dihydrate (CPPD) crystal deposition in the joints
- One of many diseases associated with pathologic deposition of crystal, mineralization, and ossification
  - CPPD crystal deposition = chondrocalcinosis, pseudogout
  - Monosodium urate crystal deposition = gout
  - Hydroxyapatite deposition associated with ankylosing spondylitis, osteoarthritis, and vascular calcification
- Suspect pseudogout in arthritis cases with a pattern of joint involvement not usually affected by degenerative joint disease (e.g., metacarpophalangeal joints, wrists)
- Clinical presentation is broad:
  - Asymptomatic CPPD (incidentally identified on radiograph by chondrocalcinosis with or without additional findings of osteoarthritis)
  - Acute CPPD arthritis (acute onset, self-limiting, synovitis)
  - Chronic CPPD crystal inflammatory arthritis (1)[C]
- Chronic CPPD crystal deposition may cause a progressive degenerative arthritis in numerous joints:
  - Primarily affects the elderly
  - Usually involves large joints
- Symptom onset is usually insidious.
- Definitive diagnosis requires the identification of CPPD crystals in synovial fluid.
- System(s) affected: endocrine/metabolic; musculoskeletal
- Synonyms: pseudogout; CPPD; pyrophosphate arthropathy; chondrocalcinosis —when calcification visibly seen within tissues on imaging

EPIDEMIOLOGY

Prevalence

- Predominant age: 80% of patients >60 years
- Predominant sex: male > female 1.4:1
- Prevalence varies on method of identification (chondrocalcinosis on radiograph vs. CPPD crystals in synovial fluid)
- Chondrocalcinosis is present in 1:10 adults age 60 to 75 years and 1:3 by >80 years; however, only a small percentage develop arthropathy.
- 20–43% prevalence of CPPD cyrstals in synovial fluid of osteoarthritic joints at time of joint replacement

ETIOLOGY AND PATHOPHYSIOLOGY

- Arthropathy results from an acute autoinflammatory reaction to CPPD crystals in the synovial cavity.
- CPPD crystal deposition occurs in three general stages:
  - CPPD crystals first develop in the pericellular matrix of the articular cartilage via overproduction of anionic pyrophosphate (PPi).
  - PPi binds calcium to form CPPD crystals that are released from cartilage surface and elicit an inflammatory response. Neutrophils engulf CPPD crystals, inducing the formation of extracellular traps.
  - Increased deposition of CPPD crystals in and around cartilage causes inflammation and damage. Cartilage degeneration is accelerated through mechanical wear and tear of the joint (2)[C].

Genetics

Uncommonly seen in familial pattern with autosomal dominant inheritance (<1% of patients); most cases are sporadic. Mutation in ANKH gene increased risk for calcium crystal formation.

RISK FACTORS

- Advanced age
- Traumatic injury
- CPPD often may occur as a complication in patients hospitalized for other medical and surgical illnesses.

GENERAL PREVENTION

Colchicine 0.6 mg BID may be used prophylactically to reduce frequency of episodes in recurrent CPPD.

COMMONLY ASSOCIATED CONDITIONS

- Hyperparathyroidism
- Hemochromatosis
- Gout
- Hypophosphatasia
- Hypothyroidism
- Ochronosis
- Wilson disease
- Amyloidosis
- Hypomagnesemia
- Familial hypocalciuric hypercalcaemia
- X-linked hypophosphatemic rickets
- Acromegaly

DIAGNOSIS

HISTORY

- Presentation often mimicks gout (“pseudogout”).
- Acute CPPD: pain and swelling of ≥1 or more joints; knee involved in 50% of cases; ankle, wrist, toe, and shoulder are also common.
- Can present in proximal joints (mimicking polymyalgia rheumatica), often accompanied by tibiofemoral and ankle arthritis and tendinous calcifications
- Multiple symmetric joint involvement (mimicking RA) in <5% of cases
- May develop after intra-articular injection of hyaluronic acid (Hyalgan, Synvisc)
- Chronic CPPD: progressive degenerative arthritis with superimposed acute inflammatory attacks

PHYSICAL EXAM

- Inflammation (erythema, warmth, tender to touch), joint effusion, decreased range of motion of joint
- 50% associated with fever

- Any synovial joint may be involved.

DIFFERENTIAL DIAGNOSIS

- Illnesses that may cause acute inflammatory arthritis in a single or multiple joint(s):
  - Gout
  - Septic arthritis
  - Trauma
- Other illnesses that may present with an acute inflammatory arthritis:
  - Reiter syndrome
  - Lyme disease
  - Acute RA

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

Synovial fluid analysis shows an inflammatory effusion:

- Cell count 2,000 to 100,000 WBCs/mL
- Differential predominantly neutrophils (80–90%)
- >50,000 WBC count increases likelihood of septic arthritis, 11% prevalence; number needed to treat (NNT) = 9; >100,000 WBCs/mL, 22% prevalence
- Wet prep with polarized microscopy may demonstrate small numbers of crystals. False-negative rate is high.

ALERT

Rhomboid-shaped weakly positively birefringent crystals in the fluid and within neutrophils is pathognomonic. In contrast, gout crystals are needle-shaped and negatively birefringent.

- Obtain the following metabolic studies in patients <50 years of age and consider in the elderly to exclude underlying disease:
  - Serum calcium, phosphorus, and magnesium
  - Serum alkaline phosphatase
  - Serum parathormone (i-PTH)
  - Serum iron, total iron-binding capacity, and serum ferritin
  - Serum thyroid-stimulating hormone (TSH) level
- Plain radiograph

  - Radiographic findings in pseudogout are neither sensitive nor specific.
  - Punctate and linear calcifications may be visualized in articular hyaline or fibrocartilage (e.g., menisci).
  - Knees, hips, symphysis pubis, and wrists are most commonly affected.
  - Patients with chronic CPPD may demonstrate subchondral cysts and loose bodies (osseous fragmentation with formation of intra-articular radiodense bodies) in joints not typically affected by degenerative joint disease.
- Ultrasound (US)
  - US may be more useful than plain radiography for the diagnosis of pseudogout in peripheral joints, with a positive predictive value of 92% and negative predictive value of 93% (3)[C].
  - US imaging characteristics include joint effusion, synovial thickening, and hyperechoic deposits.
- MRI
  - Chondrocalcinosis may be evident as hypointense lesions on MRI, particularly in association with the menisci of the knee.

Diagnostic Procedures/Other

ALERT

Aspiration of joint fluid with synovial fluid analysis and demonstration of CPPD crystals is required for diagnosis; aspiration may relieve symptoms and speed resolution of the inflammatory process.

Test Interpretation

CPPD crystal deposition in articular cartilage, synovium, ligaments, and tendons

TREATMENT

GENERAL MEASURES

Target symptom relief (reduce inflammation):

- Rest and elevate affected joint(s).
- Apply ice/cool compresses to affected joints.
- Nonweight bearing on affected joint while painful; use crutches or a walker.

MEDICATION

First Line

- A combination of pharmacologic and nonpharmacologic measures is recommended.
- Acute attacks should be treated with cool packs, rest, and joint aspiration with or without steroid injection.
- Chronic inflammatory CPPD arthropathy should be managed prophylactically with oral NSAIDs and/or colchicine (3)[C].
- Oral NSAIDs
  - Ibuprofen 600 to 800 mg PO TID–QID with food; maximum 3.2 g/day
  - Naproxen 500 mg PO BID with food
  - Other NSAIDs at anti-inflammatory doses are effective, although indomethacin has higher complication rates (relative risk [RR] = 2.2) compared with ibuprofen (RR = 1.2).
- Contraindications:
  - History of hypersensitivity to NSAIDs or aspirin
  - Active peptic ulcer disease or history of recurrent upper GI lesions
  - Avoid in renal insufficiency.
  - Serious GI bleeding can occur without warning; patient should be instructed on signs/symptoms. Administer proton pump inhibitor (PPI) or misoprostol 200 μg PO QID in patients at risk for NSAID-induced gastric ulcers.
- Oral colchicine
  - 0.6 mg QID or 0.6 mg hourly until symptoms relieved or vomiting/diarrhea develops; maximum dose per attack 4 to 6 mg; alternatively 0.5 to 1 mg/day may be used; avoid cholchicine with significant renal insufficiency.
- Intra-articular steroid injection
  - Prednisolone–sodium phosphate 4 to 20 mg or triamcinolone diacetate 2 to 40 mg with local anesthetic

ALERT

Significant adverse effects of NSAIDs:

- May elevate BP in patients on antihypertensive therapy
- May blunt antihypertensive effects of ACE inhibitors
- May prolong prothrombin time (PT) in patients taking oral anticoagulants

- Avoid concomitant aspirin use.
- May blunt diuretic effect of furosemide and hydrochlorothiazide
- May increase plasma lithium level in patients taking lithium carbonate

Second Line

- Oral prednisone: 30 to 50 mg/day for 7 to 10 days
- IM triamcinolone acetonide 40 mg; may repeat in 1 to 4 days
- Consider referring patients with large space-occupying tophaceous lesions for surgical removal.
- Alternative therapies for chronic CPPD
  - ACTH, Anakinra (anti-IL1), hydroxychloroquine, infliximab, probenecid, magnesium, ethyldiamine tetracetic acid (EDTA) have all been suggested. Large scale studies are needed to evaluate effectiveness (4)[C].

ALERT

Recent randomized trial showed no significant effect of methotrexate in chronic-recurrent CPPD (5)[B].

ISSUES FOR REFERRAL

Consider consultation with orthopedist or rheumatologist if septic joint or patient is not responding.

ADDITIONAL THERAPIES

Physical therapy

- Isometric exercises to maintain muscle strength during the acute stage (e.g., quadriceps isometric contractions, leg lifts if knee affected)
- Begin joint range-of-motion (ROM) exercises as inflammation and pain subside.
- Resume weight bearing when pain subsides.

SURGERY/OTHER PROCEDURES

Perform arthrocentesis and joint fluid analysis.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Consider admission for septic arthritis if:

- Synovial fluid WBC count >50,000/mL

- Treat with appropriate antibiotics pending culture results.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Reevaluate response to therapy 48 to 72 hours after beginning treatment; reexamine in 1 week then as needed.

DIET

No known relationship to diet

PATIENT EDUCATION

- Rest affected joint.
- Symptoms usually resolve in 7 to 10 days.

PROGNOSIS

- Acute attack usually resolves in 10 days; prognosis for resolution of acute attack is excellent.
- Patients may experience progressive joint damage and functional limitation.

COMPLICATIONS

- Recurrent acute attacks
- Osteoarthritis

Geriatric Considerations

Elderly patients treated with NSAIDs require careful monitoring and are at higher risk for GI bleeding and acute renal insufficiency. No loading dose for colchicine due to high rates of renal insufficiency in elderly patients.

CODES

ICD10

- M11.20 Other chondrocalcinosis, unspecified site

- M11.269 Other chondrocalcinosis, unspecified knee
- M11.29 Other chondrocalcinosis, multiple sites

CLINICAL PEARLS

- Suspect CPPD if arthritis case doesn’t follow a pattern typical of degenerative joint disease (e.g., metacarpophalangeal joints, wrists).
- Perform arthrocentesis to confirm diagnosis.
- If septic arthritis is considered, treat presumptively with antibiotics until culture results are available.
- NSAID therapy is the preferred treatment for acute flare.
- Oral steroids are useful if NSAIDs are contraindicated.
- Intra-articular steroids can be used *if* septic arthritis has been excluded.

PSORIASIS

Edwin A. Farnell, IV, MD • Michael O. Needham, MD • Rebecca Matz, MD

BASICS

DESCRIPTION

- A chronic, multisystem inflammatory disorder most commonly characterized by cutaneous erythematous papules and plaques with silvery scale. A complex genetic and immune-mediated disorder with flares related to systemic, psychological, infectious, and environmental factors. Skin disease with multiple different phenotypic variations and degrees of severity
- Clinical phenotypes
  - Plaque (vulgaris): most common variant (>80% of cases); well-demarcated, red plaques with thick, silvery scale; symmetrically distributed most commonly on the scalp, extensor surfaces of extremities, and trunk
  - Guttate: <2% of psoriasis patients, usually in patients <30 years of age; presents abruptly with 1- to 10-mm droplet-shaped pink erythematous papules and fine scale over trunk and extremities; often preceded by group A β-hemolytic streptococcal infection 2 to 3 weeks earlier
  - Inverse: affects intertriginous areas and flexural surfaces; pink-to-red plaques with minimal scale; absence of satellite pustules distinguishes it from candidiasis although may coexist.
  - Erythrodermic: ~1–2.25% of psoriasis patients; generalized erythema and scaling, affecting >75% of BSA; associated with desquamation; hair loss; nail dystrophy; and systemic symptoms such as fever, chills, malaise, or high-output cardiac failure; may require hospital admission for management of dehydration, electrolyte abnormalities, and high risk of infection
  - Pustular: sterile pustules; several forms including generalized pustular psoriasis, annular pustular psoriasis, and impetigo herpetiformis; generalized type can result in life-threatening bacterial superinfections, sepsis, and dehydration if left untreated.
  - Nail disease: pitting, oil spots, and onycholysis; nails involved in up to 50%

of patients with psoriasis with lifetime incidence of 80–90%
  - Psoriatic arthritis: 5–30% of patients. Most commonly asymmetrical oligoarthritis involving the hands and feet

EPIDEMIOLOGY

Incidence

Predominant sex: male = female. Predominant age: two peaks in incidence between the ages of 20 to 30 years and 50 to 60 years.

Prevalence

- 2–4.7%—similar prevalence in all races
- ~80% of patients have mild to moderate disease (1).

ETIOLOGY AND PATHOPHYSIOLOGY

Psoriasis is a complex immune-mediated disorder with interactions between dendritic cells, T-lymphocytes, neutrophils, and keratinocytes. It is considered a TH1- and TH17-driven disease with numerous cytokines including TNF-α, interferon-γ, IL-12, IL-17, and IL-23 playing pathogenic roles resulting in an inflammatory, hyperproliferative state.

Genetics

- Genetic predisposition (probably polygenic)
- 40% have psoriasis in a first-degree relative
- Increased incidence of specific human leukocyte antigens (e.g., HLA-Cw6)
- Multiple susceptibility loci contain genes involved in immune system regulation (e.g., psoriasis susceptibility [*PSORS1*] locus on chromosome 6p21; polymorphisms in the IL-12/IL-13 receptor, the p40 subunit of IL-12 and IL-23, and the p19 subunit of IL-12) (2)

RISK FACTORS

- Family history
- Local trauma; local irritation (Koebner phenomenon)
- HIV; streptococcal infection
- Mental stress (exacerbation)
- Medications (lithium, antimalarials, β-blockers, interferon, withdrawal of steroids)

- Smoking

GENERAL PREVENTION

Avoid triggers, including trauma, sunburns, smoking, and exposure to certain medications (as mentioned earlier), alcohol, and stress; weight loss if obese

COMMONLY ASSOCIATED CONDITIONS

- Psoriatic arthritis
- Seborrheic dermatitis
- Obesity, metabolic syndrome, diabetes, CKD
- Cardiovascular disease; atherosclerotic disease
- Nonalcoholic fatty liver disease (NAFLD)
- Autoimmune: Crohn disease, ankylosing spondylitis
- Psychiatric/psychological: depression, suicide, emotional burden/anxiety, alcohol abuse
- Malignancy: lymphoma, nonmelanoma skin cancer with psoralen-UVA (PUVA) therapy

DIAGNOSIS

HISTORY

- May include sudden onset of clearly demarcated, erythematous plaques with overlying silvery scales; exacerbation of chronic plaques, especially on extensor surfaces and scalp; typically no or mild pruritus; triggers may include streptococcal/viral infection or trauma.
- Family history of similar condition

PHYSICAL EXAM

- Well-demarcated salmon pink-to-red erythematous papules and plaques; silvery scale
- Distribution favors scalp, auricular conchal bowls, and postauricular area; extensor surface of extremities, especially knees and elbows; umbilicus, lower back, intergluteal cleft, and nails
- Nail findings: pitting, oil spots, onycholysis, splinter hemorrhages, subungual hyperkeratosis

- Auspitz sign: pinpoint bleeding with removal of scale
- Koebner phenomenon: new psoriatic lesions arising at sites of skin injury/trauma
- Genitals affected up to 40% of patients
- Sebopsoriasis: Psoriasis can overlap with seborrheic dermatitis as greasy scales on the eyebrows, nasolabial folds, and postauricular and presternal areas.

DIFFERENTIAL DIAGNOSIS

- Plaque: seborrheic dermatitis (may coexist), nummular eczema, atopic dermatitis, contact dermatitis, lichen simplex chronicus (may coexist), tinea, pityriasis rubra pilaris, dermatomyositis, squamous cell carcinoma in situ, reactive arthritis
- Guttate: pityriasis rosea, pityriasis lichenoides chronica, secondary syphilis, small plaque parapsoriasis
- Inverse: cutaneous candidiasis, tinea, seborrheic dermatitis, contact dermatitis
- Pustular: subcorneal pustulosis, acute generalized exanthematous pustulosis, folliculitis
- Erythrodermic: cutaneous T-cell lymphoma, drug-induced erythroderma, pityriasis rubra pilaris

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

Clinical diagnosis based on history and physical exam. Labs generally not helpful, although KOH to rule out tinea helpful. Consider x-rays if complaints of joint pain to evaluate for psoriatic arthritis.

Diagnostic Procedures/Other

- Psoriasis Area and Severity Index (PASI) evaluates overall severity and body surface area (BSA) involvement.
- Dermatology Life Quality Index (DLQI)

Test Interpretation

Biopsy: thickening of the stratum corneum (hyperkeratosis) with retention of nuclei (parakeratosis); elongation, thickening, and clubbing of rete ridges; dilated tortuous capillary loops in the dermal papillae; perivascular lymphocytic

infiltrate, Munro microabscesses: neutrophils in stratum corneum

TREATMENT

GENERAL MEASURES

Adequate topical hydration (emollients), sun exposure (avoid sunburns), stress relief

MEDICATION

First Line

- Mild-to-moderate disease
  - Emollients BID: petrolatum/ointments to maintain skin hydration and minimize pruritus and risk of koebnerization
  - Topical corticosteroids
    - Anti-inflammatory, antiproliferative, immunosuppressive, and vasoconstrictive effects; tachyphylaxis may develop over time, may alternate to prevent.
    - Local side effects: skin atrophy, hypopigmentation, striae, acne, folliculitis, and purpura. Systemic side effects: Risk is higher, with higher potency formulations used over a large surface for a prolonged period; pregnancy Category C
    - Applications are typically twice daily until lesions flatten/resolve, then taper to PRN use for maintenance.
    - Scalp: strong potency in solution/foam vehicle; shampoos and sprays also available
    - Face, intertriginous areas, infants: low-potency corticosteroids: 1% hydrocortisone
    - Adult initial therapy: medium-potency corticosteroids daily 0.1% mometasone or triamcinolone (you don’t do, e.g., for the other ones); strong-potency corticosteroids: 0.05% betamethasone or fluocinonide daily; superpotency corticosteroids: clobetasol, halobetasol; caution with use over 2 to 4 weeks; avoid occlusive dressings; reserved for recalcitrant plaques
  - Vitamin D analogues: calcipotriene 0.005% ointment daily to BID; limits

keratinocyte hyperproliferation; may be highly effective for short-term control in combination with a superpotent corticosteroid; should not be used with products that can alter pH, such as topical lactic acid; local side effects: burning, pruritus, edema, peeling, dryness, and erythema; pregnancy Category C

- Topical retinoids: tazarotene 0.05% or 0.1% (Tazorac) daily; normalizes abnormal keratinocyte differentiation and diminishes hyperproliferation; may be combined with corticosteroids; side effects: local irritation, photosensitivity; pregnancy Category X
- Topical calcineurin inhibitors: Tacrolimus 0.1% or pimecrolimus 1% may be used as steroid-sparing agents, especially in facial and intertriginous areas.
- Comparison of topical therapies: vitamin D analogues have slower onset of action than topical corticosteroids but longer disease-free periods for body plaques. For scalp, potent and superpotency steroids more effective (3)[A]
- Combination of superpotent steroids and vitamin D analogs has better efficacy than either as monotherapy or come in combination compounds (4) [A].

- Severe disease: may need combination therapy
  - Light therapy: locally immunosuppressive and antiproliferative. Natural sunlight; UVB (broad/narrow band [BB, NB]) or PUVA: Treatment protocols are skin type dependent: PUVA most effective, followed by NB-UVB, then BB-UVB; well tolerated but increased risk of nonmelanoma skin cancers with >350 treatments
  - Systemic therapies
    - Methotrexate: blocks DNA synthesis and inhibits proliferation and migration of T cells; start 7.5 to 15 mg/week IV, PO, IM, or SC, then increase 2.5 mg every 2 to 3 weeks, up to 25 mg; contraindicated in pregnancy; supplement with folic acid 1 to 5 mg/day to protect against side effects : hepatotoxicity, pulmonary toxicity, bone marrow suppression; baseline chest x-ray, monitor LFTs, renal function, CBC, testing for latent tuberculosis (TB); consider liver biopsy when cumulative dose reaches 1 to 1.5 g; avoid alcohol and medications that interfere with folic acid metabolism, including Bactrim, NSAIDS,

sulfamethoxazole, or hepatotoxic agents (e.g., retinoids).

- Cyclosporine: inhibits T-cell activation; start 2.5 mg/kg/day; if insufficient response after 4 weeks, increase by 0.5 mg/kg/day; additional dosage increases every 2 weeks (max dose: 5 mg/kg/day pregnancy Category C; side effects: renal toxicity and hypertension, limit use to 6 months to 1 year: Monitor renal function, with Mg^{2+} and K^{+}, CBC, lipids, and BP.
- Acitretin (Soriatane): systemic retinoid; onset ranges from 3 to 6 months; start at 10 to 25 mg/day given with the main meal; effective for pustular psoriasis and as a maintenance therapy after stabilization with other agents; sometimes combined with UVB/PUVA; pregnancy Category X: pregnancy test before starting; two forms of contraception 1 month before, during, and for at least 3 years after treatment; avoid alcohol (may convert acitretin to etretinate); side effects: alopecia, xerosis, cheilitis, hepatotoxicity, hyperlipidemia, cataracts; monitor LFTs, renal function, lipid profile, CBC, regular eye exams.

– Biologics: general guidelines: Screen for latent TB at baseline and yearly, hepatitis panel at baseline, avoid live vaccines; monitor CBC with differential, signs/symptoms of infections, heart failure, malignancy, drug-induced lupus, inflammatory bowel disease, demyelinating disorder. Some concern for “biologic fatigue” phenomenon, or loss of PASI 75 over time, likely due to antidrug antibodies. Each has been shown to be effective at 24 weeks with an NNT between 1 and 3. All should be considered effective first-line treatments (5)[A]. Pregnancy Category B

- TNF-α inhibitors: etanercept (Enbrel): Begin at 50 mg SC twice a week for 3 months then maintenance of 50 mg/week. Adalimumab (Humira): Dosing starts at 80 mg SC for 1 week, then 40 mg SC every other week. Infliximab (Remicade): 5 mg/kg IV at weeks 0, 2, and 6; maintenance doses of 5 mg/kg every 8 weeks thereafter; adjust interval, as needed; anaphylaxis-like infusion reaction occurs in <1% of patients.
- IL-12/IL-23 antagonist: ustekinumab (Stelara): patients <100 kg: 45 mg SC at weeks 0 and 4, then every 12 weeks; >100 kg: 90 mg can be given.
- IL-17a antagonist: secukinumab (Cosentyx). 150 mg SC on weeks 0, 1, 2, 3, and 4 then every 4 weeks

- Phosphodiesterase-4 enzyme inhibitor: apremilast (Otezla): 10 mg PO, titrate up by 10 mg per day on days 2 to 5 to maintenance dose of 30 mg BID starting on day 6. Routine lab monitoring not required. Most common SE are GI symptoms. Pregnancy Category C

Second Line

Immunosuppressives: azathioprine, hydroxyurea, 6-thioguanine, fumaric acid esters, and topicals: salicylic acid; anthralin; coal tar

ISSUES FOR REFERRAL

Psoriasis >20% of BSA, psoriatic arthritis, severe extremity involvement, particularly hands and feet

SURGERY/OTHER PROCEDURES

Psoriasis and psoriatic medications can affect wound healing postoperatively; methotrexate: Monitor for postoperative infections; hold cyclosporine for 1 week before and after; some surgeons may prefer to hold therapy with biologics for up to 1 month before and after surgery.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Generalized pustular psoriasis/erythrodermic psoriasis: Rule out sepsis; restoration of barrier function of skin with cleaning and bandaging; intensive topical corticosteroid therapy, phototherapy, systemic therapy, particularly medications with a quick onset such as oral cyclosporine; management of electrolytes

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Measure BSA involvement to determine if therapy is working; change therapy or add agent if no improvement is seen.

DIET

Well-balanced diet and exercise to limit cardiovascular risk factors and decrease risk of associated conditions, including obesity, metabolic syndrome, diabetes,

and atherosclerosis

PATIENT EDUCATION

National Psoriasis Foundation: www.psoriasis.org; 800-723-9166

PROGNOSIS

Guttate form may be self-limited and remit after 4 months; chronic plaque type is lifelong, with intermittent spontaneous remissions and exacerbations; erythrodermic and generalized pustular forms may be severe and persistent.

COMPLICATIONS

Psoriatic arthritis, generalized pustular psoriasis, erythrodermic psoriasis

Arthritis, Psoriatic

CODES

ICD10

- L40.9 Psoriasis, unspecified
- L40.50 Arthropathic psoriasis, unspecified
- L42 Pityriasis rosea

CLINICAL PEARLS

Chronic lifelong inflammatory skin condition with remissions and exacerbations; set realistic expectations with patient. Disease burden not limited to skin. If one medication does not work, use/combine with another agent.

PSYCHOSIS

Alan J. Anderson, DO • Bernadette M. Stevenson, MD, PhD

BASICS

DESCRIPTION

Syndrome seen with schizophrenia, schizoaffective disorder, mood disorder, substance use, medical problems, delirium, and dementia; symptoms include the following:

- Positive symptoms: hallucinations and delusions (fixed false and often paranoid beliefs created as the patient loses the ability to correct errors in thinking)
- Negative symptoms: anhedonia, poverty of speech, lack of motivation, social withdrawal, affective blunting
- Disorganized speech/behavior
- Cognition: decreased working memory, difficulty with attention, poor and slow information processing

EPIDEMIOLOGY

Prevalence

- Schizophrenia: peak onset 18 to 25 years in men; women peak onset 25 to 35 years
  - 1% of the U.S. population; similar percentage worldwide
- Delusional disorder: 0.03% of population
- Bipolar type I: 1% of population
- Prevalence in major depression not known

ETIOLOGY AND PATHOPHYSIOLOGY

- Neurodevelopmental predisposition plus 1st/3rd trimester in utero insult (e.g., 1st trimester infection or 3rd trimester birth hypoxia) leads to exaggerated neuronal apoptosis in late adolescence with subsequent thalamic sensory overload. Increased dopaminergic mesolimbic transmission may contribute to delusions and hallucinations in schizophrenia. Dopamine deficiency in

mesocortical pathways may contribute to frontal lobe hypoactivity often associated with apathy and withdrawal in schizophrenia. Glutamate, neurosteroids, inflammation, and neurodevelopmental abnormalities are active areas of research.
- Postulated stress-diathesis model: Individuals biologically at risk develop psychosis when under stress.

Genetics

Schizophrenia: 50% concordance for monozygotic twins, little or no shared environmental effect; multiple candidate genes involved

RISK FACTORS

Substance abuse (particularly cannabis or synthetic cannabinoids), family history of psychosis, lower socioeconomic status (SES)

GENERAL PREVENTION

Community interventions for early detection and treatment of prodromal symptoms show promise. Research currently exploring use of omega-3 fatty acids/fish oil and anti-inflammatories which may prevent prodromal progression to schizophrenia.

COMMONLY ASSOCIATED CONDITIONS

- Serious mental illness is associated with metabolic syndrome, autonomic dysfunction, and sudden cardiac death.
- Cancer mortality: particularly breast and lung cancer
- Substance abuse disorders, including nicotine dependence

DIAGNOSIS

First, rule out delirium: Psychosis should not have fluctuating consciousness/reduced clarity of awareness.

HISTORY

- Delusions (fixed false beliefs): persecutory (being monitored), bizarre (involving impossible states), somatic (fixed belief in nonexistent serious illness), referential (getting messages from TV, radio, or thoughts

inserted/deleted by others), grandiose (belief that one has special powers)
- Hallucinations: auditory, visual, tactile
- Bipolar illness, depression, and dementia are all associated with psychosis, so screen for symptoms of depression, mania, and memory loss.
- Screen for toxidromes of drugs of abuse.
- Screen for history of epileptiform activity.
- Suicidality: higher risk with comorbid depression/mania, previous suicide attempts, drug abuse, agitation/akathisia, poor compliance

PHYSICAL EXAM

- Mental status exam: disorganized idea sequencing and/or error correction, not incorrect thought content, is the *conditio sine qua non* of schizophrenia. Patients often have negative symptoms (e.g., social withdrawal, lack of initiative, poverty of thought) and disorganized behavior.
- Attention to neurologic focalities, antipsychotic-induced parkinsonism, tardive dyskinesia, and akathisia
- May rarely present with catatonia: extreme excitement/lack of movement; posturing, mutism, grimacing, waxy flexibility

DIFFERENTIAL DIAGNOSIS

- Schizophrenia: positive symptoms (psychosis) and negative symptoms (flat affect), prodrome of social withdrawal, cognitive impairment; schizophreniform disorder: psychotic/prodromal symptoms in <6 months; schizoaffective disorder: manic/depressive mood disorder with hallucinations/delusions that persist even when euthymic; schizotypal personality disorder: no true psychosis but distance in relationships and odd beliefs; delusional disorder: nonbizarre delusion (e.g., erotomanic, grandiose, jealous, persecutory, somatic), no negative/mood symptoms
- Mood disorder with psychotic features: can occur in mania/depression. Delusions often mood-congruent; psychosis remits when mood improves.
- Substance-induced psychosis: alcohol and benzodiazepine withdrawal, intoxication with cocaine, bath salts, PCP, cannabis, synthetic cannabinoids, amphetamines, hallucinogens, and alcohol. May persist beyond acute intoxication
- Borderline personality disorder: During extreme stress, patients often

experience auditory/visual hallucinations (psychosis NOS).

- Posttraumatic stress disorder: psychosis associated with traumatic recollections. Often visual hallucinations (vs. more auditory in schizophrenia)
- Psychosis due to general medical condition: delirium, stroke, infection, collagen vascular disease, head injury, tumor, interictal, porphyria, syphilis, etc.
- Medication-induced psychosis: common causes: steroids, L-dopa, anticholinergic medication, antidepressants in bipolar patients, interferon, digoxin, stimulants

DIAGNOSTIC TESTS & INTERPRETATION

Test for causes of delirium mimicking psychosis, if uncertain.

- Broad screen for medical causes: CBC, metabolic panel, LFTs, thyroid-stimulating hormone (TSH), rapid plasma reagin (RPR), HIV, ANA, ESR, vitamin B_{12}, U/A, and screens for subclinical infection in elderly
- Screen for drugs of abuse.
- No imaging necessary for diagnosis. Consider MRI/CT to evaluate for medical cause of symptoms, especially if new onset or in elderly. In research studies, schizophrenia is associated with enlarged lateral ventricles and decreased frontal activity.

Follow-Up Tests & Special Considerations

Because of elevated risk related to schizophrenia and psychotropic medications, screen for metabolic syndrome.

- Consider Wilson disease, porphyria, metachromatic leukodystrophy, inflammatory conditions.
- Consider ECG: All antipsychotics can prolong corrected QT (QTc) interval, particularly ziprasidone, thioridazine, droperidol, IV haloperidol.
- Consider lumbar puncture if unable to distinguish from delirium and/or unexplained rapid-onset psychosis.
- Consider electroencephalogram (EEG) for partial complex seizures and psychosis associated with preictal and postictal events.

TREATMENT

- Before antipsychotic treatment: Obtain baseline fasting lipid panel and glucose, HgbA1c, CBC, LFTs, metabolic panel, weight, waist circumference. Continue monitoring with long-term use (1)[B].
- Clinical Practice Guidelines: https://www.psychiatry.org/psychiatrists/practice/clinical-practice-guidelines

MEDICATION

- Antipsychotics are the mainstay of treatment (1)[B].
- Classified as typical versus atypical. Dopamine-2 (D_2) antagonists with varied affinity for the receptor. Atypicals also block serotonin 5-HT2A receptors. Help positive symptoms more than negative. Nonspecific effect on agitation begins early; antipsychotic effect takes 1 to 6 weeks.
- For mania with psychotic features, a mood stabilizer may be used with an antipsychotic.
- For major depression with psychotic features, antidepressant and antipsychotic medications yield better response rate than either medication alone.
- In delirium, must treat underlying cause
- Risks of antipsychotic medications include the following:
  - Acute dystonia: Use 1 to 3 mg IM/IV benztropine initially and then 0.5 to 2 mg BID–TID or diphenhydramine 50 to 100 mg IM/IV BID–TID max 400 mg/day.
  - Parkinsonism: Lower antipsychotic dose; switch to atypical (particularly, quetiapine, olanzapine, or clozapine) or add benztropine 0.5 to 2 mg PO BID–TID, diphenhydramine 25 to 50 mg BID–TID.
  - Akathisia: intense restlessness, especially legs. Lower antipsychotic dose; treat with β-blocker, anticholinergic, or benzodiazepine; may switch to antipsychotic with lower risk for akathisia such as quetiapine, olanzapine, iloperidone, or clozapine
  - Tardive dyskinesia: 20% of those treated long-term with typicals. Switch to clozapine or quetiapine. If cannot, minimize dose.
  - Neuroleptic malignant syndrome: potentially fatal; rigidity, tremor, fever, autonomic instability, mental status changes; discontinue neuroleptic; ICU; volume resuscitation; cooling blankets; no anticholinergics/antihistaminics;

consider dantrolene, amantadine, bromocriptine electroconvulsive therapy (ECT).
  - Metabolic syndrome, sudden cardiac death (risk higher IM/IV droperidol, IV haloperidol), stroke (elderly), QTc prolonged, pulmonary embolus

First Line

- Benefits of some of the atypical antipsychotics include low risk of extrapyramidal symptoms (quetiapine, olanzapine, iloperidone, or clozapine) and tardive dyskinesia (clozapine, quetiapine); possibly more effective for negative symptoms
- Greater risk of weight gain, new-onset diabetes, and hyperlipidemia with olanzapine and clozapine compared with typicals and some of the other atypicals (ziprasidone, aripiprazole)
- Acute psychotic agitation: olanzapine 5 to 10 mg IM with up to three 10-mg injections over a 24-hour period, do not administer concurrently with benzodiazepines; ziprasidone 10 mg IM q2h or 20 mg q4h; max 40 mg over a 24-hour period; aripiprazole IM has been discontinued; haloperidol/lorazepam 5 mg/2 mg IM often with 1 mg IM benztropine, max 20 mg haloperidol, and 8 mg lorazepam over a 24-hour period
- Psychosis in schizophrenia
  - Olanzapine: Start 5 to 10 mg at bedtime, target dose 5 to 20 mg/day within 2 days and up to 40 mg/day in treatment-refractory schizophrenia. More likely weight gain, hyperlipidemia, and hyperglycemia than other oral atypicals except clozapine; may have lower rates of discontinuation and rehospitalization than several other atypicals but likely not more efficacy than clozapine. Sedation initially
  - Quetiapine: Start 25 mg BID 25 to 50 mg BID–TID on days 2 and 3, up to 300 to 400 mg in divided doses by day 4. Within 2 weeks, up to 400 to 800 mg/day divided BID–TID; less parkinsonism, useful in Parkinson disease psychosis; more weight gain than others; sedation, restless legs syndrome; more gradual titration tolerated better. Quetiapine XR can start 300 mg/day. Dose increases can be within 1 day and up to 300 mg/day, but slower start and titration may be better; target dose 300 to 800 mg at bedtime
  - Risperidone: Start 1 to 2 mg/day; target dose of 2 to 6 mg/day to be reached over 1 to 2 weeks; doses >6 mg rarely more effective and higher risk of

parkinsonism; higher risk of prolactinemia/parkinsonism due to D2 blockade

- Paliperidone: Start 3 to 6 mg/day target dose 6 to 12 mg/day; titrate over 1 to 2 weeks. Higher risk of prolactinemia/parkinsonism than others; excreted unchanged in urine, ideal for hepatic impairment
- Ziprasidone: Start 20 to 40 mg PO BID, with target dose of 100 to 200 mg/day in divided doses over 2 weeks; prolongs QTc; less likely to cause weight gain than other atypicals; higher risk of akathisia/parkinsonism. Requires meal for optimal absorption; often activating at lower doses
- Aripiprazole: Start 10 to 15 mg/day, may increase up to 30 mg/day over a week or 2; less weight gain but higher rates of akathisia/parkinsonism
- Asenapine: Start 5 mg at bedtime or BID sublingually, increase to 10 mg BID if needed over a week or 2; less weight gain than some, higher rates of akathisia/parkinsonism; sedation, orthostatic hypotension, numb tongue, nausea, bad taste
- Lurasidone: Start 20 to 40 mg once daily with food (at least 350 calories), increase up to max of 160 mg at bedtime if needed over 2 to 4 weeks. Less weight gain than some but higher rates of akathisia/parkinsonism; not antihistaminic but α-blocking sedation and serotonergic nausea
- Iloperidone: Start 1 mg BID, may increase by 2 mg BID each day, but slower can be better due to significant orthostasis. Increase to max 12 mg BID; little akathisia/parkinsonism, less weight gain but slower efficacy due to long titration, orthostasis, sedation
- Brexpiprazole: Start 1 mg qd for first 4 days, 2 mg qd days 5 to 7, can dose up to 4 mg/day based on response and tolerability. Lower rates of akathisia/parkinsonism than aripiprazole but higher rates than others; less weight gain than others
- Cariprazine: Start at 1.5 mg qd, can be increased to 3 mg qd on day 2, dosed up to 6 mg daily based on tolerability and response. In 6-week study, similar to placebo in changes of fasting glucose, cholesterol, triglycerides and showed 0.8 to 1.0 kg weight increase.

Geriatric Considerations

Increased risk of death compared to placebo when antipsychotics are used in the elderly with dementia 3[B]

Second Line

- Clozapine: more effective for reducing symptoms, preventing relapse, decreasing tardive dyskinesia, and decreasing suicidality than other antipsychotics but second line given risk of fatal agranulocytosis. Single national registry (clozapine REMS) for all patients on clozapine, updated guidelines in 2015 requiring CBC to monitor absolute neutrophil count (ANC) weekly for first 6 months, then every 2 weeks for 6 months, and then every 4 weeks. More weight gain, hyperlipidemia, hyperglycemia, seizures, myocarditis, pulmonary embolus, and sedation but low rate of parkinsonism, tardive dyskinesia; useful in treatment-refractory psychosis and in Parkinson disease psychosis
- Despite association with more weight gain than other antipsychotics, clozapine and olanzapine do not appear to increase risk of cardiac and all-cause mortality (2,3)[B].
- Long-acting preparations: available for 2 typicals (haloperidol and fluphenazine) and 4 atypicals (risperidone, paliperidone, olanzapine, aripiprazole; olanzapine requires registration due to rare delirium syndrome). Test tolerability with oral medication first. Long-acting antipsychotics promote compliance.
- Long-acting haloperidol, paliperidone, olanzapine, aripiprazole administered every 4 weeks; aripiprazole has formulation with better oral equivalence conversion; paliperidone also has every 3-month injection, long-acting risperidone and fluphenazine administered every 2 weeks.

ISSUES FOR REFERRAL

Encourage contact with advocacy groups for families and patients (National Alliance for the Mentally Ill).

ADDITIONAL THERAPIES

Cognitive-behavioral therapy (CBT) is an effective adjuvant to antipsychotics (1)[B].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Admission criteria/initial stabilization: at risk for harm to self or others;

extreme functional impairment; unable to care for self; new-onset psychosis
- Discharge criteria: no longer a danger to self or others and adequate outpatient treatment in place

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Close follow-up for inpatient discharge (high risk for suicide), use CBT, exercise, teach smoking cessation

PATIENT EDUCATION

National Alliance on Mental Illness: www.nami.org/

PROGNOSIS

Schizophrenia: Fluctuating course, 70% first-episode psychosis patients improve in 3 to 4 months; 7% will die of suicide; 20–40% will attempt suicide.

SEE ALSO

Delirium; Schizophrenia

CODES

ICD10

- F29 Unsp psychosis not due to a substance or known physiol cond
- F20.9 Schizophrenia, unspecified
- F39 Unspecified mood [affective] disorder

CLINICAL PEARLS

- Antipsychotics are the mainstay of treatment; evidence corroborates decreased all-cause mortality in patients who are adherent to these medications.
- Clozapine and long-acting preparations may increase adherence, whereas newer atypicals quetiapine, lurasidone, aripiprazole, olanzapine-fluoxetine combination) may help with depressive symptoms in psychosis.

PULMONARY ARTERIAL HYPERTENSION

J. Todd Vassalli, MD • David Navel, MD

BASICS

DESCRIPTION

- Pulmonary arterial hypertension (PAH) is a category of pulmonary hypertension (PH) characterized by abnormalities in the small pulmonary arteries (precapillary PH) that produce increased pulmonary arterial pressure (PAP) and vascular resistance, eventually resulting in right-sided heart failure. PAH is a progressive disorder associated with increased mortality.
  - Previously, PH was classified as primary PH (without cause, now idiopathic pulmonary arterial hypertension [IPAH]) or secondary PH (with cause or associated condition); now, it is clear that some types of secondary PH closely match primary PH (IPAH) in their histology, natural history, and response to treatment. Therefore, WHO classifies PH into five groups based on mechanism, with PAH as group 1 in this classification.
- PAH is diagnosed by right-heart catheterization and defined by:
  - Mean PAP ≥25 mm Hg at rest
  - Pulmonary capillary wedge pressure ≤15 mm Hg (to exclude PH owing to left heart disease; i.e., group 2 PH)
  - Mild or absent chronic lung disease or other causes of hypoxemia (excludes PH owing to lung disease or hypoxemia; i.e., group 3 PH)
  - Absent venous thromboembolic disease (excludes chronic thromboembolic PH; i.e., group 4 PH)
  - Absent systemic disorder (like sarcoidosis), hematologic disorders (like myeloproliferative disease), and metabolic disorders (like glycogen storage disease). Purpose is to exclude group 5 PH.
- PAH is divided into following main categories:
  - Idiopathic: sporadic, with no family history or risk factors
  - Heritable: IPAH with mutations or familial cases with or without mutations
  - Drug or toxin induced: mostly associated with anorectics (e.g., fenfluramine), rapeseed oil, L-tryptophan, and illicit drugs such as

methamphetamine and cocaine
  - Associated: connective tissue diseases (e.g., systemic lupus erythematosus, rheumatoid arthritis, scleroderma), HIV infection, portal hypertension, congenital heart disease, schistosomiasis (chronic hemolytic anemia added to group 5 PH—unclear/multifactorial mechanisms (1)
  - Pulmonary veno-occlusive disease (PVOD) and/or pulmonary capillary hemangiomatosis (PCH) and persistent pulmonary hypertension of the newborn (PPHN) are classified as separate categories due to more differences than similarities with PAH.
    - PVOD and/or PCH: rare cause of PH characterized by extensive diffuse occlusion of the pulmonary veins (unlike PAH which involves the small muscular pulmonary arterioles)
    - PPHN: 2 per 1,000 live births; maternal SSRI use may correlate.
- System(s) affected: pulmonary, cardiovascular

EPIDEMIOLOGY

- Age: can occur at any age; mean age 37 years
- Sex (IPAH): female > male (~4:1)

Incidence

- Overall PAH: 5 to 52 cases/million
- IPAH: low, ~2 to 6 per million
- Drug-induced PAH: 1/25,000 with >3 months of anorectic use
- HIV associated: 0.5/100
- Portal hypertension associated: 1 to 6/100
- Scleroderma associated: 6–60%

Prevalence

- PAH: ~15 to 50 cases per million
- IPAH: ~6 cases per million

ETIOLOGY AND PATHOPHYSIOLOGY

- Pulmonary: Inflammation, vasoconstriction, endothelial dysfunction, and remodeling of pulmonary arteries produced by increased cell proliferation and reduced rates of apoptosis lead to obstruction.
- Cardiovascular: right ventricular hypertrophy (RVH), eventually leading to

right-sided heart failure

- IPAH: by definition, unknown. True IPAH is mostly sporadic or sometimes familial in nature.
- Pulmonary arteriolar hyperactivity and vasoconstriction, occult thromboembolism, or autoimmune (high frequency of antinuclear antibodies)

Genetics

- 75% of heritable pulmonary arterial hypertension (HPAH) cases and 25% of IPAH cases have mutations in *BMPR2* (autosomal dominant).
- Mutations in *ALK1* and endoglin (autosomal dominant) also are associated with PAH.

RISK FACTORS

- Female sex
- Previous anorectic drug use
- Recent acute pulmonary embolism
- First-degree relatives of patient with familial PAH

COMMONLY ASSOCIATED CONDITIONS

See associated PAH, earlier discussed.

DIAGNOSIS

Symptoms of PAH are nonspecific, which can lead to missed or delayed diagnosis of this serious disease.

HISTORY

Dyspnea, weakness, syncope, dizziness, chest pain, palpitations, lower extremity edema

PHYSICAL EXAM

- Pulmonary component of S_2 (at apex in >90% of patients)
- Right ventricular (RV) lift
- Early systolic click of pulmonary valve
- Pansystolic murmur of tricuspid regurgitation
- Diastolic murmur of pulmonic insufficiency (Graham-Steell murmur)

- RV S_3 or S_4
- Edema as jugular vein distention, ascites, hepatomegaly, or peripheral edema

DIFFERENTIAL DIAGNOSIS

Other causes of dyspnea:

- Pulmonary parenchymal disease such as chronic obstructive pulmonary disease
- Pulmonary vascular disease such as pulmonary thromboembolism
- Cardiac disease such as cardiomyopathy
- Other disorders of respiratory function such as sleep apnea

DIAGNOSTIC TESTS & INTERPRETATION

- ECG: RVH and right axis deviation
- Pulmonary function testing and/or arterial blood gas: arterial hypoxemia, reduced diffusion capacity, hypocapnia
- Ventilation–perfusion ratio (V/Q) scan: must rule out proximal pulmonary artery emboli and chronic thromboembolic PH (CTEPH)
- Exercise test: reduced maximal O_2 consumption, high-minute ventilation, low anaerobic threshold, increased PO_2 alveolar–arterial gradient; correlation to severity of disease with 6-minute walk test (6MWD)
- Antinuclear antibody positive (up to 40% of patients)
- LFTs to evaluate for portopulmonary HTN, a complication of chronic liver disease
- HIV test, thyroid function tests, sickle cell disease screening
- Elevated brain natriuretic peptide (BNP) and N-terminal-proBNP may be useful for early detection of PAH in young, otherwise healthy patients with mild symptoms. It can also be used to assess disease severity and prognosis.
- Chest radiograph
  - Prominent central pulmonary arteries with peripheral hypovascularity of pulmonary arterial branches
  - RV enlargement is a late finding.
- Echo Doppler
  - Should be performed with suspicion of PAH; recent studies show some inaccuracy compared with right-sided heart catheterization.
  - Most commonly used screening tool

    - Estimates mean PAP and assesses cardiac structure and function, excludes congenital anomalies
    - Echo suggests, but does not diagnose, PAH. Invasive hemodynamic evaluation confirms PAH diagnosis.
- Right atrial and ventricular enlargement; tricuspid regurgitation
- Important to rule out underlying cardiac disease such as atrial septal defect with secondary PH or mitral stenosis
- Cardiac magnetic resonance is not commonly used.

Diagnostic Procedures/Other

- Pulmonary angiography
  - Should be done if V/Q scan suggests CTEPH
  - Use caution; can lead to hemodynamic collapse; use low osmolar agents, subselective angiograms.
- Right-sided cardiac catheterization (gold standard for diagnosis of PAH)
  - Essential first step to confirm diagnosis and determine severity and prognosis by measuring pulmonary arterial pressures and hemodynamics
  - Rule out underlying cardiac disease (e.g., left-sided heart disease) and response to vasodilator therapy.
- Lung biopsy: not recommended unless primary pulmonary parenchymal disease exists
- 6MWD: classifies severity of PAH and estimates prognosis

TREATMENT

- Treat underlying diseases/conditions that may cause PAH to relieve symptoms and improve quality of life and survival.
- Reasonable goals of therapy include the following:
  - Modified NYHA FC I or II
  - Echocardiography/CMR of normal/near-normal RV size and function
  - Hemodynamic parameters showing normalization of the RV function (RAP <8 mm Hg and CI >2.5 to 3.0 L/min/m^2
  - 6MWD of >380 to 440 m
  - Cardiopulmonary exercise testing, including peak oxygen consumption of

>15 mL/min/kg and EqCO2 <45 L/min
  - Normal BNP levels (2)[C]

GENERAL MEASURES

- Supervised exercise training (3)[A]
- Psychosocial support (3)[C]
- Avoid strenuous physical activity (3)[C].
- Avoid pregnancy (3)[C].
- Influenza and pneumococcal immunization (3)[C]
- Oxygen—maintain arterial blood O2 pressure >60 mmHg (3)[C]

MEDICATION

- Acute vasodilator test (performed during cardiac catheterization) for all PAH patients who are potential candidates for long-term oral calcium channel blocker (CCB) therapy (3)[C]
  - Screens for pulmonary vasoreactivity/responsiveness using inhaled nitrous oxide; epoprostenol (IV) or adenosine (IV): Positive response may be a prognostic indicator.
  - Contraindicated in right-sided heart failure or hemodynamic instability
- Chronic vasodilator therapy
  - If IPAH with positive response to acute vasodilator test (a fall in mean PAP of ≥10 mm Hg and to a value <40 mm Hg, with unchanged/increased cardiac output), use CCBs.
    - Adequate response confirmed after 3 to 4 months of treatment
    - ~13% will initially respond. Long-term clinical response to CCB therapy is small (~7%) (3)[C].
    - CCBs include nifedipine (long acting), diltiazem, amlodipine.
    - Avoid verapamil due to its significant negative inotropic effect.
  - CCBs are contraindicated in patients with a cardiac index of <2 L/min/m^2 or a right atrial pressure >15 mm Hg if PAH with negative response to acute vasodilator test or worsening on therapy; specific vasodilator choice based on risk stratification (3)[C].
    - Nonresponders to acute vasoreactivity who are in WHO-FC II should be treated with an oral compound (3)[B].
    - Nonresponders who remain or progress to WHO-FC III should be

considered for treatment with any approved PAH drugs (3)[B].
    - Continuous IV epoprostenol is recommended as first-line therapy for WHO-FC IV PAH due to survival benefit (NNT = 5) (3)[A].
    - In case of inadequate clinical response, sequential combination therapy should be considered. Therapy includes ERA plus a phosphodiesterase type 5 inhibitor (PDE-5i) or a prostanoid plus ERA or a prostanoid plus a PDE-5i (3)[A]
    - WHO-FC II PAH–approved drugs: ambrisentan, bosentan, macitentan, riociguat, sildenafil, tadalafil (3)[B]
    - WHO-FC III PAH–approved drugs: ambrisentan, bosentan, epoprostenol (IV), macitentan, riociguat, sildenafil, tadalafil, treprostinil (SC, inhaled) (3)[B]
    - WHO-FC IV PAH–approved drugs—epoprostenol (IV) (3)[A]
  - Drug classes:
    - Prostacyclins: improve exercise capacity, cardiopulmonary hemodynamics: epoprostenol (IV), treprostinil (IV, SC, or inhaled), iloprost, beraprost
    - Prostacyclin IP: receptor agonist—selexipag
    - Endothelin receptor antagonists: improve exercise capacity; reducing mortality has been noted (4)[A]: bosentan (PO); ambrisentan (PO), macitentan. Pregnancy Category X; monitor LFTs monthly.
    - PDE-5i: suggested improvement in exercise capacity, cardiopulmonary hemodynamics, and symptoms (3)[C]: sildenafil (PO), tadalafil (PO), vardenafil
    - Guanylate cyclase stimulant: stimulators of the nitric oxide receptor, improves exercise capacity (5)[B]: riociguat (PO)
- Anticoagulation
  - Improved survival originally suggested in patients with IPAH only. Newer studies show some evidence for favorable effects of anticoagulation on survival in IPAH, HPAH, or PAH associated with anorexigens (3)[C].
  - Warfarin with international normalized ratio of 1.5 to 2.5
    - Contraindications: Avoid in patients with syncope or significant hemoptysis; consider drug interactions.
- Diuretics indicated in patients with RV volume overload (e.g., peripheral

edema or ascites) (3)[B]

- Digoxin has little long-term data in PAH: used in RV failure and/or atrial dysrhythmias, increases cardiac output and preserves RV contractility

ISSUES FOR REFERRAL

Refer to a pulmonologist and/or a cardiologist for further evaluation/treatment if PAH is suspected.

SURGERY/OTHER PROCEDURES

- Patients with documented large-vessel thromboembolic disease should be considered for pulmonary thrombectomy.
- Balloon atrial septostomy for severe PAH with right-sided heart failure despite optimized medical therapy to relieve symptoms prior to lung transplant or as a treatment on its own
- Heart–lung or lung transplantation

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Medical therapy is primarily palliative.
- Hospitalization with invasive monitoring is needed to screen vasodilator responsiveness and initiate vasodilator therapy.
- National registry has been established by the National Heart, Lung, and Blood Institute.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Pneumococcal and influenza vaccines
- Exercise: walking or low-level aerobic activity, as tolerated, once stable; respiratory training

Patient Monitoring

Frequently evaluate disease progression and therapeutic efficacy. Tests to measure treatment response include 6-minute walk test and cardiopulmonary exercise test.

DIET

Fluid and salt restrictions, especially with RV failure

PATIENT EDUCATION

Discuss disease, prognosis, lifestyle changes, and all therapeutic options (including transplant).

PROGNOSIS

- Median survival is 2 to 3 years from diagnosis; 5-year survival rate is 34% (NIH registry); newer data show 5-year survival ~70% with new treatment.
- Mode of death: right-sided heart failure (most common), pneumonia, sudden death, cardiac death
- Poor prognostic factors
  - Rapid symptom progression
  - Clinical evidence of RV failure
  - WHO functional PAH class 4 (or NYHA functional class III or IV)
  - 6MWD <300 m
  - Peak VO_2 during cardiopulmonary exercise testing <10.4 mL/kg/min
  - Echocardiography with pericardial effusion, significant RV enlargement/dysfunction, right atrial enlargement
  - Mean right atrial pressure >20 mm Hg
  - Cardiac index <2 L/min/m^2
  - Elevated mean PAP
  - Significantly elevated BNP and NT-proBNP; other markers also show promise in predicting survival: RDW, GDF-15, interleukin-6, creatinine.
  - Scleroderma spectrum of diseases

COMPLICATIONS

- Thromboembolism, heart failure, pleural effusion, and sudden death
- Pregnancy should be avoided due to high maternal mortality (30–50%) and fetal wastage.

SEE ALSO

Cor Pulmonale; Pulmonary Embolism

CODES

ICD10

- I27.0 Primary pulmonary hypertension
- I27.2 Other secondary pulmonary hypertension

CLINICAL PEARLS

- PAH involves abnormalities in the small pulmonary arteries (precapillary PH) that produce increased PAP and vascular resistance, eventually resulting in right-sided heart failure.
- For positive vasodilator test, CCBs are the first-line agents to manage IPAH.
- For nonresponders, treatment depends on WHO-FC.

PULMONARY EDEMA

Timothy R. Takagi, MD

BASICS

DESCRIPTION

- Pulmonary capillaries leak fluid into the lung interstitium and alveoli, leading to hypoxia and respiratory distress.
- Fluid accumulation results from cardiogenic causes (e.g., heart failure), leading to imbalanced hydrostatic and oncotic pressures within pulmonary capillaries or from noncardiogenic causes (e.g., acute lung injury) that increase alveolar membrane permeability.

EPIDEMIOLOGY

Incidence

- Annual heart failure incidence: 650,000 cases
- Heart failure incidence increases with age.
  - Age 35 to 64 years: 2 cases per 1,000
  - Age 65 to 69 years: 20 cases per 1,000
  - Age >85 years: >80 cases per 1,000
- Disparities in heart failure incidence by race and sex
  - Blacks (16.3/1,000) versus whites (11.9/1,000)
  - Men (15.8/1,000) versus women (11.7/1,000)
- Acute respiratory distress syndrome (ARDS): 190,000 cases annually in United States

Prevalence

Heart failure syndromes: 5.8 million U.S. adults

ETIOLOGY AND PATHOPHYSIOLOGY

- Cardiogenic causes increase large vessel (and subsequently) pulmonary capillary hydrostatic pressure, leading to increased transvascular filtration of a protein-poor fluid into lung interstitium.
- Systolic dysfunction is due to decreased contractility of the left ventricle (LV),

leading to decreased cardiac output, which in turn stimulates the renin–angiotensin system and increases fluid retention. Diastolic dysfunction is often due to decreased LV compliance secondary to hypertrophy.

- Cardiogenic (left-sided heart failure)
  - Impaired contractility
    - Ischemic heart disease
    - Dilated cardiomyopathy
    - Myocarditis
    - Volume overload
    - Alcoholic cardiomyopathy
  - Increased LV afterload
    - Systemic hypertension (HTN)
    - Aortic stenosis
    - Cocaine abuse
  - Poor diastolic filling
    - LV hypertrophy
    - Hypertrophic cardiomyopathy
    - Mitral stenosis
    - Atrial fibrillation
  - Valvular dysfunction
    - Mitral regurgitation
    - Acute papillary muscle rupture
  - High cardiac output states
    - Thyrotoxicosis
    - Systemic arteriovenous fistulas
    - Anemia
  - Noncompliance with medications or diet
  - Medications with negative inotropic effects
- Noncardiogenic causes will increase permeability of the lung vasculature, leading to accumulation of protein-rich fluid in the lung interstitium and air spaces. Many causes of this vascular permeability are associated with ARDS.
- Noncardiogenic
  - ARDS
  - Acute lung injury

- Transfusion-related acute lung injury
- Preeclampsia
- Rapid ascent to high altitude (>2,500 m)
- Drug toxicity (salicylates, opiates)
- Embolism (thrombus, fat, air, amniotic fluid)
- Neurogenic (after head trauma/surgery)
- Reexpansion (after pneumothorax/thoracentesis)

Genetics

Multifactorial

RISK FACTORS

- Cardiogenic: HTN, valvular disease, hyperlipidemia, atherosclerosis, diabetes mellitus, obesity, excessive alcohol intake, physical inactivity, dietary choices, and smoking
- Noncardiogenic: sepsis, aspiration, pneumonia, trauma, inhaled toxins, DIC

GENERAL PREVENTION

Early detection and treatment of risk factors, including high blood pressure, diabetes, alcohol intake, obesity, and tobacco abuse (1)[A]

COMMONLY ASSOCIATED CONDITIONS

See "Etiology and Pathophysiology."

DIAGNOSIS

HISTORY

- Past medical history
  - Underlying comorbidities, including prior heart failure or prior myocardial infarction (MI)
  - Recent trauma
  - Drug (illicit opiate, cocaine) or alcohol abuse
  - Dietary or medication noncompliance
  - Recent weight gain or increasing edema
  - Recent use of negative inotropic agents
  - Recent use of NSAIDs (increase water retention)

- Symptoms
  - Fever or other symptoms of infection
  - Progressive dyspnea
  - Orthopnea and paroxysmal nocturnal dyspnea
  - Cough
  - Fatigue and generalized weakness
  - Pink frothy sputum
  - Chest pain

PHYSICAL EXAM

- Vital signs: tachypnea, tachycardia, and hypoxemia. Patients may be hypotensive or hypertensive.
- General: respiratory distress, diaphoresis
- HEENT (head, eyes, ears, nose, throat): frothy oral secretions, cyanosis
- Cardiac: S3 or S4, jugular venous distension, murmurs suggestive of valvular disease
- Pulmonary: rales, crackles, or wheezing
- Extremities: edema, cyanosis, mottled skin

DIFFERENTIAL DIAGNOSIS

- COPD
- Pneumonia
- Pulmonary embolism
- Asthma/reactive airway disease
- Pneumothorax
- Cardiac tamponade
- Asphyxiant or toxic gas exposure
- Inhalational burns

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- CBC/differential to screen for anemia or infection
- Chemistry panel to screen for acute kidney injury, hyponatremia (associated with severe heart failure), or electrolyte disturbances leading to dysrhythmias
- Troponin may be elevated from recent infarction causing acute heart failure or

from myocardial ischemia secondary to elevated ventricular strain. Elevated cardiac enzymes carry a strongly negative prognosis in heart failure.

- In settings of clinical uncertainty, B-type natriuretic peptide (BNP), or N-terminal pro-BNP, can add to clinical judgment in patients with symptoms suggestive of heart failure (1,2)[A]. BNP >500 pg/mL suggests heart failure, and BNP <100 pg/mL suggests alternative causes. BNP may also be elevated due to atrial fibrillation, renal failure, severe valvular disease, or pulmonary HTN.
- Liver function tests (LFTs) to check for elevated transaminases, which can suggest hepatic congestion from heart failure or may indicate heavy alcohol use contributing to cardiomyopathy
- Drug levels (aspirin, opiates, cocaine, alcohol)
- Arterial blood gas to measure PO_2 and A-a gradient
- Serum lipase, if suspecting pancreatitis
- TSH, if suspecting thyrotoxicosis
- Blood/urine cultures and lactic acid if concerned for sepsis or septic shock
- Urinalysis to check for nephrotic syndrome or UTI
- Chest x-ray to evaluate for the following:
  - Pneumothorax
  - Cardiomegaly
  - Infiltrate suggestive of pneumonia
  - Increased interstitial markings, perihilar alveolar edema, or pleural effusion
- CT pulmonary angiography if concerned for pulmonary emboli
- ECG to evaluate for ischemia or dysrhythmias
- Echocardiography to assess ventricular systolic and diastolic function, size, valve function, and for presence of a pericardial effusion or wall motion abnormalities (2)[C].

Follow-Up Tests & Special Considerations

Perform echocardiography emergently, if suspecting cardiogenic shock, tamponade, or papillary muscle rupture.

Diagnostic Procedures/Other

- If cause of pulmonary edema is unknown, a pulmonary artery catheter (or Swan-Ganz) can be inserted to measure the pulmonary artery capillary wedge

pressure. A wedge pressure <18 mm Hg favors acute lung injury over cardiogenic pulmonary edema.

- Patients with new-onset or worsening heart failure (without determined cause) should have further evaluation for myocardial ischemia. The pretest probability of underlying ischemic cardiomyopathy should guide the decision on which testing modality to use (1)[C].

TREATMENT

GENERAL MEASURES

- The mainstay of therapy, in all cases, is to address the suspected cause/condition.
- Ensure adequate reversal of hypoxia.

MEDICATION

Cardiogenic pulmonary edema

First Line

- Diuretics: reduce preload for acute cardiogenic edema; used in low doses daily for chronic heart failure to manage volume overload. If on chronic diuretics, start IV dose at or above home dose and titrate for acute cardiogenic edema. Onset is 15 to 30 minutes for IV loop diuretics. Monitor for electrolyte derangement and renal dysfunction. Use very carefully in patients with aortic stenosis.
  - Acute: furosemide 40 to 80 mg IV, torsemide 10 mg IV, or bumetanide 1 mg IV
  - Chronic: furosemide 20 to 80 mg q6–8h, torsemide 20 mg/day, or bumetanide 1 mg q12h
- ACE inhibitors or angiotensin receptor blockers (ARBs): reduce afterload for systolic heart failure. Maintenance therapy may be cautiously continued during exacerbation. Avoid in acutely ill patients with hypotension, acute kidney insult, hyperkalemia, or poor diuresis. Use ARBs in patients who are ACE inhibitor–intolerant.
  - Target dose for chronic heart failure: lisinopril 20 to 40 mg/day, enalapril 10 to 20 mg q12h, captopril 50 mg q8h, candesartan 32 mg/day, valsartan 160

mg q12h, losartan 100 mg/day

- β-Blockers: reduce afterload for systolic heart failure. Maintenance therapy may be continued for mild decompensation; hold or reduce dose for moderate to severe decompensation. Avoid if patients are hypotensive or recently received inotropic therapy. Do not initiate until recovery from acute exacerbation of heart failure.
  - Target dose for chronic heart failure: carvedilol 25 mg q12h, metoprolol ER 200 mg/day, bisoprolol 10 mg/day
- Inotropes: improve contractility in hypotensive patients with severe systolic heart failure and signs of systemic hypoperfusion (2)[B]. Inotropes increase myocardial oxygen demand and may damage the ischemic myocardium.
  - Dobutamine: 5 to 10 μg/kg/min IV, titrate
  - Milrinone: loading dose (optional): 50 μg/kg IV over 10 minutes and then infuse 0.375 to 0.750 μg/kg/min, titrate
  - Dopamine: 5 to 10 μg/kg/min IV, titrate
  - Norepinephrine: 2 to 4 μg/min IV for acute cardiogenic shock following acute MI; not for use in acute decompensated heart failure
- Nitrates: Acute cardiogenic pulmonary edema use IV nitrate vasodilators. Rapid onset. Nitroglycerin IV 5 to 10 μg/min, titrate 5 to 10 μg/min q3–5min to max 200 μg/min until distress resolved or onset of hypotension. For severe HTN, consider IV nitroprusside 5 to 10 μg/min, titrate. Max 400 μg/min. Use <48 hours due to risk of cyanide toxicity.
  - For patients who are not tolerant of ACE inhibitors or ARBs, hydralazine and an oral nitrate should be started (1)[C].
- Precaution: Monitor the additive hypotensive effects of diuretics, nitrates, and afterload reducers.

Second Line

- Thiazide diuretics: metolazone 2.5 to 10 mg/day PO, added to loop diuretics
- Spironolactone: 25 to 50 mg/day PO; recheck renal function and electrolytes in 7 to 10 days.
- Digoxin: 125 μg/day PO, titrate to serum concentration of 0.5 to 0.8 ng/mL
- Noncardiogenic pulmonary edema
  - High-altitude pulmonary edema

- Descent is the single best treatment (3)[A].
- Adjunctive therapy: supplemental oxygen. Consider nifedipine ER 30 mg PO q12h or sildenafil 50 mg PO q8h or tadalafil 10 mg PO q12h (3)[C].

ISSUES FOR REFERRAL

- Cardiology referral for underlying cardiac disease
- Patients with ARDS should be carefully monitored in an ICU setting.

ADDITIONAL THERAPIES

- Noninvasive positive pressure ventilation (NPPV) should be considered early for emergency department patients with acute respiratory distress from cardiogenic pulmonary edema/congestive heart failure (CHF). NPPV decreases preload and afterload, thereby alleviating symptoms and potentially avoiding intubation by allowing time for medications to work. Use cautiously if patients are hypotensive (4)[A].
- Early invasive ventilation should be considered for patients with noncardiogenic pulmonary edema secondary to ARDS.

SURGERY/OTHER PROCEDURES

- Extracorporeal membrane oxygenation (ECMO) for severe refractory hypoxia/ARDS
- Intra-arterial balloon pump for cardiogenic shock
- Implantable cardioverter defibrillator (ICD) for sudden cardiac death prevention in patients with prior cardiac arrest or ischemic/dilated cardiomyopathy and LVEF <30% (2)[B]
- Cardiac resynchronization therapy (CRT) may be useful for LVEF ≤35%, sinus rhythm, and QRS >0.15 m/s (2)[B].
- LV assist device (LVAD) for severe systolic dysfunction as bridge to a heart transplant (2)[B]

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Hypotension
- Acute kidney injury
- Altered mental status
- Dyspnea at rest

- O_2 saturation <90%
- Acute coronary syndromes
- Arrhythmias (i.e., new-onset atrial fibrillation)
- Mild distress: oxygen by nonrebreather mask
- Significant hypoxia
- Intubation for patients with apnea, altered mental status, or hypoxia despite NPPV
- Use crystalloid infusions cautiously. Limit free water.
- Daily weights, strict input/output
- Assess for functional improvement.
- Discharge criteria
  - Underlying condition treated, fluid status optimized
  - Started β-blocker and ACE inhibitor in patients with CHF (1)[B]
  - Patient and family educated about diet/medications

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Strict input/output measurement, daily weights
- Posthospitalization appointment in 7 to 10 days

DIET

Low-sodium diet (<2 g/day), fluid restriction (<2 L/day) (2)[C]

PATIENT EDUCATION

- Dietary precautions
- Early signs and symptoms of fluid overload
- Adjust diuretic dose based on recent weight gain.

PROGNOSIS

Mortality: 30–60% for noncardiogenic edema/ARDS; up to 80% for cardiogenic causes

COMPLICATIONS

- Acute hypoxic respiratory failure
- CHF increases long-term risk for dysrhythmias and sudden cardiac death.
- ARDS increases short-term risk for pneumonia and pneumothorax. Long-term complications include risks of pulmonary HTN and fibrosis.

SEE ALSO

Altitude Illness; Congestive Heart Failure: Differential Diagnosis; Respiratory Distress Syndrome, Acute (ARDS)

CODES

ICD10

- J81.1 Chronic pulmonary edema

- J81.0 Acute pulmonary edema

CLINICAL PEARLS

- Diagnosis of the underlying etiology is essential.
- Initial treatment of acute cardiogenic edema among hypertensive/normotensive patients includes IV diuretics, IV nitrates, and NPPV.
- Hypotensive patients with pulmonary edema due to CHF will require careful use of inotropes and vasopressor to improve hemodynamic stability.

PULMONARY EMBOLISM

Karla A. Oliveros, MD • Alfonso Tafur, MD, MS, RPVI

BASICS

DESCRIPTION

- Pulmonary embolism (PE) is the most serious presentation of venous thromboembolism (VTE).
- Mortality exceeds 15% during the first 3 months. In 25% of patients, first manifestation is sudden death.

EPIDEMIOLOGY

Case fatality rate 1–60%. For patients with intermediate risk, mortality rate is 3–15% if right ventricular (RV) dilation or dysfunction. If hemodynamically unstable, mortality is >15% due to worsening RV failure and cardiogenic shock.

Incidence

- Approximately 60 to 70 per 100,000, with >100,000 cases annually in the United States
- Incidence increases with age, most occurring at 60 to 70 years of age.
- 250,000 hospitalizations per year in the United States, 10–60% in hospitalized patients
  - Highest risk for orthopedic patients
  - 1:1,000 pregnancies (including postpartum)

ETIOLOGY AND PATHOPHYSIOLOGY

- Venous stasis, endothelial damage, and changes in coagulation properties trigger formation of thrombus (1).
- Causes increased pulmonary vascular resistance, impaired gas exchange, and decreased pulmonary compliance. RV failure due to pressure overload is usually the primary cause of death (1).
- DVT in the proximal veins is the most common source of PE, up to 85% of the cases.

Genetics

- Factor V Leiden: Most common thrombophilia. +5.5% in Caucasian, 2.2% in Hispanics, 1.2% in African American, 0.5% in Asian. Associated with 20% of all VTE
- Prothrombin G20210A: 3% of Caucasians, rare in African American, Asian, and Native American; 6% in patients with VTE
- Deficiencies in protein C, S, and antithrombin

RISK FACTORS

- Acquired: age, immobilization, surgery, major trauma, lower limb fractures, joint replacement, spinal cord injury, cancer, hormonal replacement therapy, pregnancy/puerperium, previous thrombosis, paroxysmal nocturnal hemoglobinuria, antiphospholipid syndrome, prolonged travel
- Oral contraceptives is the most frequent medication (1).
- Inherited: antithrombin deficiency, protein C or S deficiency, factor V Leiden, prothrombin gene mutation *G20210A* (1)

GENERAL PREVENTION

- Mechanical thromboprophylaxis: early ambulation after surgery, compression stockings, and intermittent pneumatic compression
- Intermediate risk: general, gynecologic, or urologic surgery; prophylaxis is recommended with low-molecular-weight heparin (LMWH), unfractionated heparin (UFH), or fondaparinux.
- High risk: 10 or more days prophylaxis in hip or knee arthroplasty, with LMWH, fondaparinux, apixaban, dabigatran, rivaroxaban, or low-dose UFH. 28 to 35 days with LMWH, fondaparinux, UFH, or vitamin K antagonists (VKA) in hip fracture surgery. LMWH or UFH in major trauma, spinal cord injury
- Long-distance travel (>8 hours): hydration, walking, avoidance of constrictive clothing and frequent calf exercises; if additional risk factors, then compression stockings below knee
- Patients with factor V Leiden, prothrombin *G20210A* with no previous thrombosis do not need long-term daily prophylaxis.

DIAGNOSIS

- Establish a pretest probability based on clinical criteria (2).
  - Wells score
    - Clinical signs and symptoms of DVT +3
    - Alternative diagnosis is less likely than PE +3
    - Heart rate >100 +1.5
    - Immobilization previous 4 weeks +1.5
    - Previous DVT/PE +1.5
    - Hemoptysis +1
    - Malignancy +1
    - <2 points, low clinical probability; 2 to 6 points, moderate; >7 points, high
- Recently, Wells and revised Geneva score were simplified (2).
  - Wells score: Each predictor is +1. PE unlikely if 0 to 1, PE likely if >2.
  - Geneva score: Each predictor is +1 except for heart rate >95 which is +2. PE unlikely if 0 to 2 and PE likely if >3.

HISTORY

- Determine if the presentation is provoked or idiopathic. Approximately 30% of cases develop without identifiable risk factor.
- Presence of risk factors and family history
- Bleeding risk (previous anticoagulation, history of bleeding, recent interventions/surgeries, liver disease)
- Sudden onset dyspnea (>85%), chest pain (>50%), cough (20%), syncope (14%), hemoptysis (7%).

PHYSICAL EXAM

- Dyspnea, syncope, hemoptysis, tachycardia, tachypnea, accentuated S^2. Pleuritic chest pain, pleural friction rub, rales (1)
- Signs of DVT: leg swelling, tenderness, visible collateral veins (1)
- Signs of RV failure: jugular vein distention, third or fourth sound, systolic murmur at left sternal edge, hepatomegaly (1)

ALERT

- Massive PE: mortality rate exceeding 20%. Hemodynamic instability with sustained hypotension, pulselessness, or persistent bradycardia, cardiogenic

shock, acute manifesting RV failure (1)

- Submassive PE: hemodynamically stable. Mortality rate of 5–25%. No systemic hypotension but there is either RV dysfunction or myocardial necrosis (1,3).
  - RV dysfunction: RV dilation or systolic dysfunction on echocardiography, RV dilation on CT, elevation of brain natriuretic peptide (BNP) or N-terminal pro-BNP (500 pg/mL), or consistent ECG changes
- Low-risk PE: acute and absence of clinical markers of adverse prognosis

DIFFERENTIAL DIAGNOSIS

- Pulmonary: pneumonia, bronchitis, pneumothorax, pneumonitis, chronic obstructive pulmonary disease (COPD) exacerbation, pulmonary edema, pneumothorax
- Cardiac/vascular: myocardial infarction, pericarditis, congestive heart failure (CHF), aortic dissection
- Musculoskeletal: rib fracture(s), musculoskeletal chest wall pain

DIAGNOSTIC TESTS & INTERPRETATION

- D-dimer ELISA: In patients with low pretest probability, it can rule out PE if it is negative (high negative predictive value [NPV]) (1)[A]. It is not diagnostic if positive (low positive predictive value [PPV]) and it is not helpful if pretest probability is intermediate or high (1)[B].
- CBC, creatinine, aPTT and PT, ABG: In young patients with idiopathic, recurrent, or significant family history of VTE, consider testing for hypercoagulable tests.
  - Do not test for protein C, S, factor VIII, or antithrombin in the acute setting or while on treatment, as may be falsely abnormal.
  - Patients with intermediate or high pretest probability and low probability with elevated D-dimer need further diagnostic testing.
- Chest x-ray (CXR): Westermark sign (lack of vessels in an area distal to the embolus), Hampton hump (wedge-shaped opacity with base in pleura), Fleischner sign (enlarged pulmonary arteries), atelectasis, pleural effusion, pulmonary infarct, hemidiaphragm elevation (1)
- ECG: right heart strain, nonspecific rhythm abnormalities, S1Q3T3
- CT pulmonary angiography: sensitivity 96–100%, specificity 86–89%; NPV

99.8%. If normal, it safely excludes PE if low or intermediate clinical probability (1)[A].

- Ventilation/perfusion scintigraphy (V/Q scan): safe with few allergic reactions. Use if CT angiography is not available or contraindicated. A high-probability V/Q scan makes the diagnosis of PE; normal V/Q scan excludes PE (1)[B].
- Pulmonary angiography: gold standard but invasive and technically difficult: 2% morbidity and <0.01 mortality risk (1)[C]
- Echocardiogram: Assess RV function, found in 25% of patients with PE.
- Magnetic resonance angiography: lower sensitivity and specificity than CT angiography
- Compression venous ultrasound (CUS): noninvasive. Sensitivity >90%, specificity approximately 95%. It confirms the diagnosis of PE in patients with clinical suspicion (1)[B].
- CT venography: can be done at the same time as CT angiography; increases diagnostic yield (1)

ALERT

If your preclinical probability is intermediate or high and the patient has a low bleeding risk, start treatment while waiting for the diagnostic results (3)[C].

Follow-Up Tests & Special Considerations

Elevated troponin I or T and elevated BNP are markers for higher risk patients.

TREATMENT

MEDICATION

- If clinical suspicion is high and no contraindications, start treatment immediately.
- Start LMWH, fondaparinux, UFH, as initial therapy for first 5 to 10 days. VKA can be started the 1st day and must overlap with parenteral treatment for minimum of 5 days, until international normalized ratio (INR) is 2 to 3 for 24 hours.
- Following 5 to 10 days of parenteral therapy, dabigatran or edoxaban are also approved (1).

- An oral option for initial and long-term treatment is rivaroxaban or apixaban (1).
- Patients with massive PE with low bleeding risk: Consider systemic thrombolytics if no contraindications. Also in patients <75 years old with submassive PE. Greater benefit if initiated within 48 hours of symptoms onset (1)

First Line

- UFH (3)[A]:
  - IV bolus of 80 U/kg or 5,000 U followed by continuous infusion (initially 18 U/kg/hr or 1,300 U/hr) with dose adjustments to maintain aPTT that corresponds to anti-Xa levels of 0.3 to 0.7
  - SC injection: 2 options:
    - Monitored: 17,500 U or 250 U/kg BID with dose adjustments to maintain an aPTT that corresponds to anti-Xa levels of 0.3 to 0.7 measured 6 hours after a dose
    - Fixed dose: 333 U/kg initial dose, followed by 250 U/kg BID
- LMWH: preferred due to lower risk of major bleeding and heparin-induced thrombocytopenia (HIT) (1),(3)[A]
  - Enoxaparin (Lovenox) 1 mg/kg/dose SC q12h
  - Dalteparin (Fragmin 200 U/kg SC q24h
  - Fondaparinux (Arixtra): 5 mg (body weight <50 kg), 7.5 mg (body weight 50 to 100 kg), or 10 mg (body weight >100) SC q24h
- Maintenance therapy: Warfarin on day 1, if possible; 5 mg/day for 3 days in hospitalized or older patients, and at a dose of 10 mg in <60 years of aged patients; adjust dose to maintain an INR of 2 to 3. Needs to overlap with UFH, LMWH, or fondaparinux: 5 to 7 days, until 2 consecutive days of therapeutic INR (1).
- Rivaroxaban: 15 mg BID for 3 and then 20 mg once daily to complete treatment. Compared to warfarin, it has less major bleeding side effects while having same efficacy (1)[B].
- Edoxaban: 60 mg once daily (reduced to 30 mg once daily if CrCl 30 to 50 mL/min or body weight <60 kg). Patients require initial treatment with LMWH at least 5 days before starting edoxaban. Less bleeding risk compared

to warfarin (1)[B]

- Apixaban: 10 mg BID for 7 days, followed by 5 mg once daily was compared to conventional therapy. Compared to warfarin, noninferior against recurrent symptomatic VTE or death related to VTE, with less frequently major bleeding episodes (1)[B]
- Dabigatran: Require initial treatment with LMWH. Compared to warfarin, 150 mg BID had noninferior efficacy and no differences in major bleeding and fewer episodes of any bleeding (1)[B].

ALERT

Contraindications

- Active bleeding
- Heparin: HIT
- LMWH: HIT, renal failure
- Warfarin: pregnancy
- Rivaroxaban and Fondaparinux: renal failure (1)[A]
- Edoxaban: severe kidney or liver failure (1)[A]
- Apixaban: renal impairment and nonvalvular atrial fibrillation (1)[A]
- Dabigatran: severe kidney problems. Use of dronedarone or ketoconazole increase risk.

Pregnancy Considerations

- Warfarin is teratogenic and should not be used in pregnant patients (especially in 1st trimester); safe while breastfeeding
- **LMWH**: Dalteparin, enoxaparin, and fondaparinux are Category B; heparin is Category C, use if the benefit overweight risks.
- **UFH**: Require aPTT monitoring. Can cause osteoporosis if used for prolonged period
- Rivaroxaban is Category C.
- Edoxaban and Apixaban: Category B; increases risk of hemorrhage
- Dabigatran: Category C; use it only if benefit overweight side effects.

Second Line

Massive PE: Consider thrombolytics if the patient has hemodynamic compromise and low bleeding risk, intracranial hemorrhage risk: 0.7–6.4%: (1),

(3)[B]

- Tissue plasminogen activator (tPA) 100 mg infused over 2 hours. Absolute contraindications:
  - Intracranial hemorrhage, known intracranial cerebrovascular or malignant disease, ischemic stroke within 3 months, suspected aortic dissection, bleeding diathesis, active bleeding, recent neurosurgery, or major trauma

SURGERY/OTHER PROCEDURES

- Inferior vena cava (IVC) filter placement if absolute contraindication for anticoagulation or recurrent PE despite adequate anticoagulation treatment (3) [B].
- PREPIC2 trial showed that retrievable IVC filters at 3 months plus anticoagulation compared to anticoagulation alone among patients with severe PE had no benefit reducing the risk of symptomatic recurrent PE (3%, 95% CI 1.1–6.5% vs. 1.5%, 95% CI 0.3–4.3%) (3)[C].
- Emergency embolectomy can be considered in patients with massive PE with contraindications for thrombolysis (3)[C].
- Consider catheter-based interventions if massive PE and thrombolytic contraindications (3)[C].
- Consider ultrasound-assisted catheter-directed thrombolysis (USAT) in patients with intermediate risk of death or submassive PE, superior than heparin alone in reversing RV dilation at 24 hours without increase in bleeding complications.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

ICU-level care if hemodynamically unstable

ONGOING CARE

Duration of anticoagulation

- Provoked PE (trigger no longer present): 3 months (1)[B]
- Unprovoked PE: Minimum of 3 months, consider long-term or prolonged secondary prophylaxis if bleeding risk is low (1)[B].

- Cancer-related PE: LMWH first 3 to 6 months. Consider secondary prophylaxis as long as the patient has active cancer (1)[B].
- Recurrent PE: long-term anticoagulation

FOLLOW-UP RECOMMENDATIONS

- If concomitant DVT, knee-height compression stockings, 30 to 40 mm Hg knee height
- If an IVC filter was placed, follow-up for retrieval.

Patient Monitoring

- INR should be checked regularly; target is 2 to 3 (1).
- aPTT needs to be monitored in SC UFH (1).
- Anti-Xa can be checked in special circumstances if treated with LMWH, including pregnancy, younger patients, renal disease.

DIET

Warfarin use; recommend a vitamin K diet.

PROGNOSIS

- Massive PE 50% versus nonmassive PE 8–14%
- Simplified Pulmonary Embolism Severity Index score predicts acute mortality (any one of the following defines high-risk: age >80 years, history of cancer, chronic cardiopulmonary disease, heart rate 110/min, systolic blood pressure <100 mm Hg, O_2 saturation <90%) (1)[B].
- High early mortality risk: shock or hypotension, +SPESI index >1+ RV dysfunction signs by imaging and cardiac laboratory biomarkers (1)
- Intermediate high early mortality risk: no shock or hypotension + SPESI >1 + RV dysfunction signs by imaging and cardiac laboratory biomarkers (1)
- Intermediate low early mortality risk: no shock or hypotension + SPESI >1 + either RV dysfunction by imaging or cardiac laboratory biomarkers (1)
- Low early mortality risk: no shock or hypotension, no SPESI; imaging is optional (if assessed is negative) (1).

COMPLICATIONS

- 1 in 25 patients will develop chronic thromboembolic pulmonary hypertension, recurrent DVT, or PE.

- Younger age, previous PE, and larger perfusion defect were significantly associated with increased risk of CTPH found in 5.2% of 58 patients with previous DVT, and 33.3% of 24 patients with previous PE.
- Incidence of major hemorrhage associated with thrombolytics is 8%; intracerebral bleed is 2% (fatal in 1/2 of cases).

CODES

ICD10

- I26.99 Other pulmonary embolism without acute cor pulmonale
- I27.82 Chronic pulmonary embolism

CLINICAL PEARLS

- PE can be excluded in patients who have low pretest probability and negative D-dimer testing.
- Perform cancer-oriented review of systems and age/gender-appropriate cancer screening in patients >40, recurrent VTE, upper extremity DVT (not related to catheter or lines), bilateral lower extremity DVT, intra-abdominal DVT, resistance to treatment.
- In patients with prolonged baseline aPTT, adjust heparin dose with anti-Xa levels (therapeutic range 0.3 to 0.7).

PULMONARY FIBROSIS

Azfar S. Syed, DO • Zachary Prather, MD

BASICS

DESCRIPTION

- Characterized by fibrosis of the lung parenchyma
- Chest CT shows reticular pattern and honeycombing, with subpleural and lower lobe predominance.
- Lung biopsy shows “usual interstitial pneumonia” pattern.
- Classified based on etiology
  - Idiopathic
  - Nonidiopathic

EPIDEMIOLOGY

Incidence

- Incidence of IPF is 7 to 16/100,000 person-years.
- Idiopathic pulmonary fibrosis (IPF) is more common in men.
- Most patients with IPF are >60 years.
- Incidence of nonidiopathic pulmonary fibrosis is unknown.

Prevalence

- Prevalence of IPF is 2 to 39 cases/100,000 people.
- Prevalence of nonidiopathic pulmonary fibrosis is unknown.

ETIOLOGY AND PATHOPHYSIOLOGY

- Postulated that microinjury to alveolar epithelial cells causes release of cytokines that activates fibroblasts, which in turn leads to excess production of extracellular matrix
- Causes of the nonidiopathic form include:
  - Occupational exposure
  - Environmental exposure
  - Drugs
  - Systemic connective tissue diseases

– Granulomatous diseases

Genetics

- <5% of IPF is familial and may involve mutations in surfactant protein A2 and C and/or abnormal telomere shortening.
- Most likely mode of transmission is autosomal dominant with variable penetrance.

RISK FACTORS

- Family history of pulmonary fibrosis
- Gastroesophageal reflux disease (GERD)
- Smoking
- Exposure to birds, livestock, dust from metals or wood, solvents

GENERAL PREVENTION

Avoid the risk factors mentioned earlier, such as smoking, certain occupational exposures, or drugs that induce pulmonary fibrosis.

COMMONLY ASSOCIATED CONDITIONS

- Pulmonary hypertension: occurs in 30–80% of patients with IPF, likely as a result of hypoxemic vasoconstriction
- GERD
- Nonidiopathic pulmonary fibrosis may be associated with connective tissue diseases (e.g., rheumatoid arthritis and scleroderma).

DIAGNOSIS

HISTORY

- Slowly progressive dyspnea
- Dry nonproductive cough

PHYSICAL EXAM

- Tachypnea
- Fine inspiratory bibasilar crackles
- Possible clubbing

DIFFERENTIAL DIAGNOSIS

- Asbestosis
- Berylliosis
- Coal worker pneumoconiosis
- Chronic hypersensitivity pneumonitis
- Sarcoidosis
- Silicosis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Increased reticular markings on initial chest x-ray, nonspecific finding
- High-resolution chest computed tomography (HRCT) is needed to make diagnosis. Characteristic findings include a reticular pattern, traction bronchiectasis, and honeycombing. There is a subpleural and lower lobe predominance. There is minimal to no evidence of active inflammation (1,2).
- If the patient has characteristic findings of pulmonary fibrosis on chest CT, then lung biopsy may not necessarily be required (1).
- Initial lab work including CBC, CMP, urinalysis to check for other causes of interstitial lung disease

Follow-Up Tests & Special Considerations

- Surgical lung biopsy should be considered if clinical presentation and HRCT are not entirely characteristic of pulmonary fibrosis (1).
- Blood work to rule out associated collagen vascular disease (1)
- Bronchoscopy with bronchoalveolar lavage has limited role but may help rule out other types of interstitial lung disease and concurrent infection (1).

Diagnostic Procedures/Other

- Pulmonary function testing (PFT): initially, may see only decrease in diffusing capacity; later in disease, may develop decrease in lung volumes as well
- Echocardiogram to evaluate for concomitant pulmonary hypertension
- Resting and exercise pulse oximetry to determine need for supplemental oxygen

Test Interpretation

Usual interstitial pneumonitis: shows interstitial scarring, honeycombing, and fibroblastic foci. There is temporal heterogeneity, meaning there may be areas of

normal lung adjacent to fibrosed or inflamed lung.

TREATMENT

GENERAL MEASURES

- Pulmonary rehabilitation (1)[C]
- Consider treating for GERD, even if asymptomatic (1)[B].
- Consider lung transplant evaluation.

MEDICATION

First Line

- Supplemental oxygen, if needed (1)[C]
- Treat exacerbation with high-dose glucocorticoids (3)[C].

ISSUES FOR REFERRAL

- Patients should be evaluated and cared for longitudinally by a pulmonologist.
- If any uncertainty in diagnosis, then consider referral to thoracic surgery for lung biopsy (4).
- Depending on patient age, comorbidities, and preference, may consider referral for lung transplant

ADDITIONAL THERAPIES

- Recent studies have shown a benefit with the antifibrotic agent pirfenidone and the tyrosine kinase inhibitor nintedanib for slowing the progression of IPF (4,5). These drugs were approved by the FDA in 2014.
- Pirfenidone and nintedanib slowed decline in fixed volume capacity (FVC) more so than *N*-acetylcysteine (6).
- Many other clinical trials are currently under way. Some of the targets being studied include TGF-β; connective tissue growth factor; IL-13; CCL2; CXCR4; and CXCL12, ACE, and angiotensin II (7).

SURGERY/OTHER PROCEDURES

Lung transplant carries a 5-year survival rate of 40–50%.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Recommend pneumococcal vaccine and yearly influenza vaccine.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Worsening shortness of breath and/or increased oxygen requirements:

- Provide adequate supplemental oxygen.
- Workup for other possible causes of respiratory decompensation
- If no other cause for respiratory decompensation is found, then consider administration of high-dose steroids.
- Supplemental oxygen to keep saturations >90%

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient should follow-up with a pulmonologist.

Patient Monitoring

Disease progression can be monitored by periodic PFTs and HRCT.

DIET

No specific dietary requirements

PATIENT EDUCATION

- Patients should be counseled extensively regarding the prognosis of this diagnosis and given as much support as possible. Information about support groups in the local community and online may be helpful.
- American Lung Association: http://www.lung.org/lung-health-and-diseases/lung-disease-lookup/pulmonary-fibrosis/
- Pulmonary Fibrosis Foundation: http://www.pulmonaryfibrosis.org/ which includes information about active pulmonary fibrosis clinical trials

PROGNOSIS

- Median survival time was thought to be 2 to 3 years from time of diagnosis. However, recent data from clinical trials suggest that this may be an underestimate.
- Some patients may deteriorate quickly, whereas others can remain stable for an extended period of time. Acute exacerbations carry a high mortality, and

ICU treatment (mechanical ventilation) is mostly unsuccessful.
- A higher extent of fibrosis increases the risk of death, whereas a higher percentage-predicted diffusing capacity of lung for carbon monoxide reduced the risk of death.

COMPLICATIONS

- Respiratory failure
- Infection
- Pulmonary hypertension
- Rib fractures secondary to prolonged coughing (especially in elderly patients with decreased bone density)

CODES

ICD10

- J84.10 Pulmonary fibrosis, unspecified
- J84.112 Idiopathic pulmonary fibrosis

CLINICAL PEARLS

- Pulmonary fibrosis can usually be diagnosed based on characteristic chest CT findings, which include a reticular pattern, traction bronchiectasis, and honeycombing with a peripheral and basilar predominance.
- There are idiopathic and nonidiopathic forms of pulmonary fibrosis.
- Treatment options for pulmonary fibrosis are very limited and, at best, serve to

slow the progression of disease.

PYELONEPHRITIS

Katelin M. Lisenby, PharmD, BCPS • Dana G. Carroll, PharmD, BCPS, CDE, CGP • Catherine Scarbrough, MD, MSc, FAAFP

BASICS

DESCRIPTION

- Acute pyelonephritis is a syndrome caused by an infection of the renal parenchyma and renal pelvis, often producing localized flank/back pain combined with systemic symptoms, such as fever, chills, and nausea. It has a wide spectrum of presentation, from mild illness to septic shock.
- Chronic pyelonephritis is the result of progressive inflammation of the renal interstitium and tubules, due to recurrent infection, vesicoureteral reflux, or both.
- Pyelonephritis is considered uncomplicated if the infection is caused by a typical pathogen in an immunocompetent patient who has normal urinary tract anatomy and renal function.
- System(s) affected: renal; urologic
- Synonym: acute upper urinary tract infection (UTI)

Geriatric Considerations

- May present as altered mental status; absence of fever is common in this age group.
- Elderly patients with diabetes and pyelonephritis are at higher risk of bacteremia, longer hospitalization, and mortality.
- The high prevalence of asymptomatic bacteriuria in the elderly makes the use of urine dipstick less reliable for diagnosing UTI in this population (1)[A].

Pregnancy Considerations

- Most common medical complication requiring hospitalization
- Affects 1–2% of all pregnancies. Morbidity does not differ between trimesters.
- Urine culture as test of cure 1 to 2 weeks after therapy

Pediatric Considerations

- UTI is present in ~5% of patients age 2 months to 2 years with fever and no apparent source on history and physical exam.
- Treatment (oral or IV; inpatient or outpatient) should be based on the clinical situation and patient toxicity.

EPIDEMIOLOGY

Incidence

Community-acquired acute pyelonephritis: 28/10,000/year

Prevalence

Adult cases: 250,000/year, with 200,000 hospitalizations

ETIOLOGY AND PATHOPHYSIOLOGY

- *Escherichia coli* (>80%)
- Other gram-negative pathogens: *Proteus*, *Klebsiella*, *Serratia*, *Clostridium*, *Pseudomonas*, and *Enterobacter*
- *Enterococcus*
- *Staphylococcus*: *Staphylococcus epidermis*, *Staphylococcus saprophyticus* (number 2 cause in young women), and *Staphylococcus aureus*
- *Candida*

RISK FACTORS

- Underlying urinary tract abnormalities
- Indwelling catheter/recent urinary tract instrumentation
- Nephrolithiasis
- Immunocompromise, including diabetes
- Elderly, institutionalized patients (particularly women)
- Prostatic enlargement
- Childhood UTI
- Acute pyelonephritis within the prior year
- Frequency of recent sexual intercourse; spermicide use; new sex partner within the prior year
- Stress incontinence in the previous 30 days
- Pregnancy
- Hospital-acquired infection

- Symptoms >7 days at time of presentation

COMMONLY ASSOCIATED CONDITIONS

- Indwelling catheters
- Renal calculi
- Benign prostatic hyperplasia

DIAGNOSIS

HISTORY

- In adults
  - Fever
  - Flank pain
  - Nausea ± vomiting
  - Malaise, anorexia
  - Myalgia
  - Dysuria, urinary frequency, urgency
  - Suprapubic discomfort
  - Mental status changes (elderly)
- In infants and children
  - Fever
  - Irritability and poor feeding
  - GI symptoms

PHYSICAL EXAM

- In adults
  - Fever: ≥38°C (100.4°F)
  - Costovertebral angle tenderness
  - Presentation ranges from no physical findings to septic shock.
  - Mental status changes common in the elderly
  - A pelvic exam may be necessary in female patients to exclude pelvic inflammatory disease.
- In infants and children
  - Sepsis
  - Fever

- Poor skin perfusion
- Inadequate weight gain/weight loss
- Jaundice to gray skin color

DIFFERENTIAL DIAGNOSIS

- Obstructive uropathy
- Acute bacterial pneumonia (lower lobe)
- Cholecystitis
- Acute pancreatitis
- Appendicitis
- Perforated viscus; aortic dissection
- Pelvic inflammatory disease; ectopic pregnancy
- Kidney stone
- Diverticulitis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Urinalysis: pyuria ± leukocyte casts, hematuria, nitrites (sensitivity 35–85%; specificity 92–100%), and mild proteinuria
- Urine leukocyte esterase positive (sensitivity 74–96%; specificity 94–98%)
- Urine Gram stain; urine culture (>100,000 colony-forming units/mL or >100 colony forming units/mL + symptoms) and sensitivities
- CBC, BUN, Cr, GFR, and pregnancy test (if indicated)
- C-reactive protein levels have been shown to correlate with prolonged hospitalization and recurrence; serum albumin <3.3 g/dL also associated with risk for hospital admission.
- Imaging not necessary in routine cases
- Pediatrics: Recent guidelines recommend renal/bladder US (not voiding cystourethrogram), after first UTI.

Follow-Up Tests & Special Considerations

- Catheterization/suprapubic aspirate should be used to obtain samples from non–toilet-trained children.
- Catheterization may also be necessary for some geriatric patients.
- Blood culture(s): indicated if diagnostic uncertainty, immunosuppression, or a suspected hematogenous source

- Recent antibiotic use may alter lab results.
- If patient's condition does not improve within 72 hours, if obstruction/anatomic abnormality suspected, or if certain lab abnormalities are present (urine pH >7, GFR <40, 50% decline in renal function), consider:
  - CT scan of abdomen and pelvis ± contrast
  - US of kidneys, ureter, bladder
  - Cystoscopy with ureteral catheterization

Test Interpretation

- Acute: abscess formation with neutrophil response
- Chronic: fibrosis with reduction in renal tissue

TREATMENT

- ≤7 days of treatment is equivalent to longer regimens in adults (including those with bacteremia) without urogenital abnormalities (2)[A].
- IV antibiotics are indicated for inpatients who are toxic appearing or unable to tolerate oral antibiotics.

GENERAL MEASURES

- Broad-spectrum antibiotics initially, tailor therapy to culture and sensitivity results
- Analgesics and antipyretics
- Consider urinary analgesics (e.g., phenazopyridine 200 mg q8h) for dysuria.

MEDICATION

- For empiric oral therapy, a fluoroquinolone is recommended. Should fluoroquinolone resistance exceed 10% or the patient has nausea/vomiting, a single initial IV dose of a long-acting antibiotic such as ceftriaxone 1 g is additionally recommended.
- For parenteral therapy, fluoroquinolone, aminoglycoside ± ampicillin, an extended-spectrum cephalosporin with or without a β-lactamase inhibitor, an extended-spectrum penicillin with or without an aminoglycoside, or a carbapenem are recommended.
- Contraindications:

  - Known drug allergy
  - Fluoroquinolones are not recommended in children, adolescents, and pregnant women unless other alternatives are not available.
  - Nitrofurantoin does not achieve reliable tissue levels for treatment of pyelonephritis.
- Precautions
  - Most antibiotics require adjustments in dosage for patients with renal insufficiency.
  - Monitor aminoglycoside levels and renal function.
  - If *Enterococcus* is suspected based on Gram stain, ampicillin ± gentamicin is a reasonable empiric choice; unless patient is penicillin-allergic, then use vancomycin. If outpatient, add amoxicillin to fluoroquinolone, pending culture results and sensitivity. Do not use a 3rd-generation cephalosporin for suspected/proven enterococcal infections.
  - >20% *E. coli* strains are resistant to ampicillin and TMP-SMX in community-acquired infections.

First Line

- Adults
  - Oral (initial outpatient treatment)
    - Ciprofloxacin: 500 mg q12h for 7 days
    - Ciprofloxacin XR: 1,000 mg/day for 7 days
    - Levofloxacin: 750 mg/day for 5 days
  - Trimethoprim-sulfamethoxazole (TMP-SMX) (160/800 mg): 1 tab q12h for 14 days provided uropathogen known to be susceptible ± ceftriaxone 1 g initial IV dose given IV (assuming normal creatinine clearance [CrCl])
    - Ciprofloxacin: 400 mg q12h
    - Levofloxacin: 750 mg/day
    - Cefotaxime: 1 g q8–12h up to 2 g q4h
    - Ceftriaxone: 1 to 2 g/day
    - Cefepime: 1 to 2 g q12h
    - Gentamicin: 5 to 7 mg/kg of body weight daily
    - Ampicillin: 2 g q6h ± gentamicin for *Enterococcus*
  - Severe illness: IV therapy until afebrile 24 to 48 hours and tolerating oral hydration and medications, then oral agents to complete up to a 2-week

course

- Pediatric
  - Oral: cefdinir: 14 mg/kg/day for 10 to 14 days; ceftibuten 9 mg/kg/day for 10 to 14 days; cefixime 8 mg/kg/day for 10 to 14 days
  - IV (general indication for IV therapy is age <2 months or clinical concern in other ages)
    - Ceftriaxone: 75 mg/kg/day (also can be used IM in outpatient setting)
    - Cefotaxime: 150 mg/kg/day divided in 3 to 4 doses
    - Ampicillin: 100 mg/kg/day divided in 4 doses + gentamicin 7.5 mg/kg/day divided in 3 doses

Second Line

Adults

- Oral
  - Oral β-lactams should be used with caution due to inferior efficacy and higher relapse rates; if used, provide an initial IV dose of ceftriaxone or a consolidated 24-hour dose of an aminoglycoside; longer courses of therapy (10 to 14 days) recommended
  - Cefpodoxime (Proxetil): 200 mg q12h
  - Amoxicillin–clavulanate: 875/125 mg q12h or 500/125 mg q8h
- IV
  - Piperacillin–tazobactam: 3.375 g q6–8h
  - Ticarcillin–clavulanate: 3.1 g q4–6h
  - Meropenem: 500 mg q12h
  - Ceftolazone–tazobactam: 1.5 g q8h

Pediatric Considerations

- Treat children <2 years of age and children with febrile or recurrent UTI for 10 to 14 days.
- Initial empiric antibiotic choice should cover *E. coli*. Add ampicillin if *Enterococcus* is suspected.
  - Oral antibiotics (ceftibuten, cefixime, and amoxicillin/clavulanic acid) may be used alone, *or*
  - IV antibiotics (single daily dosing if an aminoglycoside is chosen) for 2 to 4 days, followed by oral antibiotics for a total of 10 to 14 days (3)[A]

- Complete outpatient antibiotic course in entirety

ISSUES FOR REFERRAL

- Acute pyelonephritis unresponsive to therapy
- Chronic pyelonephritis
- Abnormal urogenital anatomy

SURGERY/OTHER PROCEDURES

Perinephric abscess may require surgical drainage.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Inpatient therapy for severe illness (e.g., high fevers, severe pain, marked debility, intractable vomiting, inability to tolerate oral intake, possible sepsis), risk factors for complicated pyelonephritis, pregnancy, or extremes of age
- Outpatient therapy if mild to moderate illness (not pregnant, no nausea/vomiting; fever and pain not severe), uncomplicated, and tolerating oral hydration and medications. Many patients can be treated as outpatients.
- IV fluids as indicated for dehydration or renal calculi
- Discharge on oral agent after patient is afebrile 24 to 48 hours to complete up to 2 weeks of therapy.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Women: Routine follow-up cultures not recommended unless symptoms recur after 2 weeks; then, urologic evaluation is necessary.
- Men, children, adolescents, patients with recurrent infections, patients with risk factors: repeat cultures 1 to 2 weeks after completing therapy; urologic evaluation after first episode of pyelonephritis and with recurrences

Patient Monitoring

- No response within 48 hours (5% of patients): Reevaluate and review cultures, CT scan, or US to review anatomy; adjust therapy as needed; urologic consult. The two most common causes of failure to respond are a resistant organism

and nephrolithiasis.
- Work with parents to monitor response in children.

DIET
Encourage fluid intake.

PROGNOSIS
95% of treated patients respond within 48 hours.

COMPLICATIONS
- Kidney abscess
- Metastatic infection: skeletal system, endocardium, eye, meningitis with subsequent seizures
- Septic shock and death
- Acute/chronic renal failure

CODES

ICD10

- N12 Tubulo-interstitial nephritis, not spcf as acute or chronic
- N10 Acute tubulo-interstitial nephritis
- N11.9 Chronic tubulo-interstitial nephritis, unspecified

CLINICAL PEARLS

- Pyelonephritis can present with isolated confusion or mental status changes (no fever) in the elderly.
- The most common causes of poor response to treatment are antibiotic resistance and coexisting nephrolithiasis.
- Fluoroquinolones are generally the initial drugs of choice for treating
