pyelonephritis. Oral β-lactams are less effective, with the exception that parental β-lactams may be preferred in cases of complicated urinary tract infections.

PYLORIC STENOSIS

Joshua Scott Will, DO • Jennifer M. Cornwell, DO • Rachel M. Jones, DO

BASICS

DESCRIPTION

- Progressive narrowing of the pyloric canal, occurring in infancy
- Synonym(s): infantile hypertrophic pyloric stenosis (IHPS)

EPIDEMIOLOGY

- Predominant age: infancy
  - Onset usually at 3 to 6 weeks of age; rarely in the newborn period or as late as 5 months of age
- Considered the most common condition requiring surgical intervention in the 1st year of life
- A recent decline in its incidence has been reported in a number of countries.
- Predominant sex: male > female (4 to 5:1)

Incidence

In Caucasian population, 2 to 5:1,000 babies; less common in African American and Asian populations

Prevalence

National prevalence level is 1 to 2:1,000 infants, ranging from 0.5 to 4.21:1,000 live births.

ETIOLOGY AND PATHOPHYSIOLOGY

- Abnormal relaxation of the pyloric muscles leads to hypertrophy.
- Redundant mucosa fills the pyloric canal.
- Gastric outflow is obstructed, leading to gastric distension and vomiting.
- The exact cause remains unknown, but multiple genetic and environmental factors have been implicated (1,2)[B].
- Breast versus bottle feeding—increased vasoactive intestinal peptide in breast milk may mediate pyloric relaxation and increase gastric emptying while

bottle feeding may cause higher serum levels associated with pylorospasm (3) [C].

Genetics

Recent studies have identified linkage to chromosome 11 and multiple loci and chromosome 16 (1,2)[B].

RISK FACTORS

- Incidence higher in firstborn Caucasian boys (lower incidence in African Americans and Asians)
- 5 times increased risk with affected first-degree relative
- Strong familial aggregation and >80% heritability
- Multiple gestation—200 fold increased risk if monozygotic twin diagnosed and 20 fold increased risk if dizygotic twin diagnosed
- Breast feeding protective versus bottle feeding risk increased
- Postnatal macrolide use (i.e., erythromycin, azithromycin)—erythromycin agonist of motilin which might cause continuous contraction of the pyloric muscle (2)[B],(3)[C]
- A recent surveillance study of a population-based birth defects registry identified association between pyloric stenosis and the use of fluoxetine in the 1st trimester, even after adjustment for maternal age and smoking. The adjusted odds ratio was 9.8 (95% CI 1.5–62) (4)[B].

COMMONLY ASSOCIATED CONDITIONS

Associated anomalies present in ∼4–7% of infants with pyloric stenosis.

- Hiatal and inguinal hernias (most commonly)
- Other anomalies include the following:
  - Congenital heart disease
  - Esophageal atresia
  - Tracheoesophageal fistula
  - Renal abnormalities
  - Turner syndrome and trisomy 18
  - Cornelia de Lange syndrome
  - Smith-Lemli-Opitz syndrome
- A common proposed genetic link between breast cancer, endometriosis, and

pyloric stenosis has been observed in families.

DIAGNOSIS

HISTORY

- Nonbilious projectile vomiting after feeding, increasing in frequency and severity
- Emesis may become blood-tinged from vomiting-induced gastric irritation.
- Hunger due to inadequate nutrition
- Decrease in bowel movements
- Weight loss

PHYSICAL EXAM

- Firm, mobile (“olivelike”) mass palpable in the right upper quadrant (historically 70–90% of the time)
- However, this finding has decreased in occurence to about 13% due to earlier diagnosis with US (3)[C]
- Epigastric distention
- Visible gastric peristalsis after feeding
- Late signs: dehydration, weight loss
- Rarely, jaundice when starvation leads to decreased glucuronyl transferase activity resulting in indirect hyperbilirubinemia

DIFFERENTIAL DIAGNOSIS

- Inexperienced or inappropriate feeding
- GERD
- Gastritis
- Congenital adrenal hyperplasia, salt-losing
- Pylorospasm
- Gastric volvulus
- Antral or gastric web

DIAGNOSTIC TESTS & INTERPRETATION

Metabolic disturbances are late findings and are uncommon in present era of early diagnosis and intervention.

- If prolonged vomiting, then check electrolytes for the following:
  - Hypokalemia
  - Hypochloremia
  - Metabolic alkalosis
- Elevated unconjugated bilirubin level (rare)
- Paradoxical aciduria: The kidney tubules excrete hydrogen to preserve potassium in face of hypokalemic alkalosis.
- Abdominal US is the study of choice.
  - US shows thickened and elongated pyloric muscle and redundant mucosa.
- Upper GI series reveals strong gastric contractions; elongated, narrow pyloric canal (string sign); and parallel lines of barium in the narrow channel (double-tract sign or railroad track sign).

Test Interpretation

Concentric hypertrophy of pyloric muscle

TREATMENT

SURGERY/OTHER PROCEDURES

- Ramstedt pyloromyotomy is curative. The entire length of hypertrophied muscle is divided, with preservation of the underlying mucosa.
- Surgical approaches include open (traditional right upper quadrant transverse) incision, more contemporary circumumbilical incision, and laparoscopic techniques.
- A recent review concluded that the laparoscopic approach results in less postoperative pain and can be performed with no increase in operative time or complications (5)[A].
- Conservative approach
  - Conservative management of infantile hypertrophic pyloric stenosis with atropine can be effective in approximately six out of seven cases but has a lower success rate and longer duration of therapy than surgery (6)[B].
  - Atropine therapy may be considered as an alternative to pyloromyotomy for patients unsuitable or at high risk for surgery and in areas of the world where surgery on small infants is unavailable or unsafe (6)[B].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Prompt treatment to avoid dehydration and malnutrition
- Correct acid–base and electrolyte disturbances. Surgery should be delayed until alkalosis is corrected.
- Patients need pre- and postop apnea monitoring. They have a tendency toward apnea to compensate with respiratory acidosis for their metabolic alkalosis.
- IV fluids to correct dehydration and metabolic abnormalities. For optimal resusication in infants, use D5 1/2NS with 20 meq of KCl (3)[C].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Routine pediatric health maintenance
- Postoperative monitoring, including monitoring for pain, emesis, apnea
- If significant emesis present after 1 to 2 weeks, then upper GI studies needed to rule out incomplete pyloromyotomy or duodenal leak (3)[C]

DIET

- No preoperative feeding
- Initiate feeding 4 hours after surgery with adlib feedings thereafter (7)[A].

PROGNOSIS

Surgery is curative.

COMPLICATIONS

- No long-term morbidity
- Incomplete pyloromyotomy
- Mucosal perforation
- Wound infections
- Delayed feeding due to postoperative vomiting
- Serosal tear
- Subcutaneous emphysema
- 4.6–12% complication rate (3)[C]

CODES

ICD10

Q40.0 Congenital hypertrophic pyloric stenosis

CLINICAL PEARLS

- Pyloric stenosis is the most common condition requiring surgical intervention in the 1st year of life.
- The condition classically presents between 1 and 5 months of life, with projectile vomiting after feeds and a firm, mobile mass in the right upper quadrant.
- Abdominal US is the study of choice.
- Surgery (laparoscopic Ramstedt pyloromyotomy is the preferred method) is curative.

RABIES

Alan M. Ehrlich, MD

BASICS

DESCRIPTION

- A rapidly progressive CNS infection caused by a ribonucleic acid (RNA) rhabdovirus affecting mammals, including humans
- Generally considered to be 100% fatal once symptoms develop
- System(s) affected: nervous
- Synonym(s): hydrophobia (inability to swallow water)

EPIDEMIOLOGY

Incidence

- Most cases are in developing countries.
- Estimated 55,000 deaths worldwide per year
- Typically only 1 to 3 cases per year in the United States, with 1/3 of those being due to exposure outside of the United States
- Predominant age: any
- Predominant sex: male = female

ETIOLOGY AND PATHOPHYSIOLOGY

Lyssavirus, an RNA virus in the family *Rhabdoviridae*

- Rabies virus is a neurotropic virus present in saliva of infected animals.
- Transmission occurs via bites from infected animals or when saliva from an infected animal comes in contact with an open wound or mucous membranes.
- Bats are most common reservoir in the United States.

RISK FACTORS

- Professions or activities with exposure to potentially infected (wild or domestic) animals (e.g., animal handlers, lab workers, veterinarians, cave explorers)
- Most U.S. cases are associated with bat exposure.
- Internationally, rabies is widespread in both domestic and feral dogs.

- Human-to-human transmission has occurred through transplantation of cornea, solid organs, and other tissues.
- Travel to countries where canine rabies is endemic.

GENERAL PREVENTION

- Preexposure vaccination for high-risk groups (veterinarians, animal handlers, and certain laboratory workers)
- Consider preexposure vaccination for travelers to areas (such as North Africa) that have increased risk of rabies from domestic animals.
- Immunization of dogs and cats
- Contact animal control and avoid approaching or handling wild (or domestic) animals exhibiting strange behaviors.
- Avoid wild and unknown domestic animals.
- Seek treatment promptly if bitten, scratched, or in contact with saliva from potentially infected animal.
- Prevent infection by prompt postexposure treatment.
- Consider postexposure prophylaxis for individuals in direct contact with bats, unless it is known that an exposure did not occur.
- Hospital contacts of patients infected with rabies do not require postexposure prophylaxis unless there has been exposure through mucous membranes or an open wound (including a bite) to saliva, CSF, or brain tissue from the infect patient.

DIAGNOSIS

HISTORY

- History of animal exposure
- Most patients do not recall exposure.
- Five stages (may overlap)
  - Incubation period: time between bite and first symptoms: usually 10 days to 1 year (average of 20 to 60 days). Incubation is shortest in patients with extensive bites in the head or trunk.
  - Prodrome: lasts 1 to 14 days; symptoms include pain or paresthesia at bite site and nonspecific flulike symptoms, including fever and headache.

- Acute neurologic period: lasts 2 to 10 days. CNS symptoms dominate; generally 1 of 2 forms: (i) furious rabies: brief (~5 minute) episodes of hyperactivity with hydrophobia, aerophobia, hyperventilation, hypersalivation, and autonomic instability; (ii) paralytic rabies: Paralysis dominates; may be ascending (as in Guillain-Barré syndrome) or may affect ≥1 limbs differentially
- Coma: lasts hours to days; may evolve over several days following acute neurologic period; may be sudden, with respiratory arrest
- Death: usually occurs within 3 weeks of onset as result of complications

PHYSICAL EXAM

Findings range from normal exam to severe neurologic findings, including paralysis and coma, depending on the stage of rabies at the time of presentation.

DIFFERENTIAL DIAGNOSIS

- Any rapidly progressive encephalitis; important to exclude treatable causes of encephalitis, especially herpes
- Transverse myelitis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Lumbar puncture. WBC count is normal or shows moderate pleocytosis; protein normal or moderately elevated
- Skin biopsy to detect rabies antigen in hair follicles
  - Available through state and federal reference labs
- Rabies antibody titer of serum and CSF
- Skin biopsy from nape of neck for direct fluorescent antibody examination
- Viral isolation from saliva or CSF
- Corneal smear stains are positive by immunofluorescence in 50% of patients.
- Hyponatremia is common.
- Head CT scan: normal or nonspecific findings consistent with encephalitis
- MRI can help rule out other forms of encephalitis.

Follow-Up Tests & Special Considerations

Submit brain of the biting animal for testing if possible.

Test Interpretation

Encephalitis may be found on brain biopsy. Other abnormal findings (e.g., brainstem, midbrain, cerebellum) often found only postmortem.

TREATMENT

Thorough wound cleansing with soap and water is first line of treatment. Irrigate wound with virucidal agent, such as povidone-iodine, if available.

GENERAL MEASURES

- Evaluate risk based on exposure and consult public health officials about the need for rabies prophylaxis.
- In the United States, raccoons, skunks, bats, foxes, and coyotes are the animals most likely to be infected. Any carnivore can carry the disease.
- Before initiating antirabies treatment, consider:
  - Type of exposure (bite or nonbite)
  - Epidemiology of rabies in species involved
  - Circumstances surrounding exposure (provoked vs. unprovoked bite)
  - Vaccination status of offending animal

MEDICATION

ALERT

- Immunosuppression alters immunity after vaccination. Immunosuppressive drugs should be avoided during postexposure prophylaxis if possible. If postexposure prophylaxis is given to an immunosuppressed patient, check serum samples for the presence of rabies virus–neutralizing antibody to assess response to vaccination (1)[C].
- Clean wounds thoroughly, regardless of postexposure prophylaxis status.
- Assess need for postexposure prophylaxis based on circumstances of possible exposure.
- Increased risk:
  - Bites involving skin puncture are high risk; saliva exposure is a risk only if it comes in contact with an open wound or mucous membranes.
  - Wild or domestic animals unavailable for quarantine

  - Bat exposure
  - Hybrid animals of wild and domestic species (e.g., wolf-dog)
  - Unprovoked attack (Feeding a wild animal is considered a provoked attack.)
- Management:
  - Bites from cats, dogs, and ferrets that can be watched for 10 days do not require prophylaxis unless animal shows signs of illness.
  - Skunks, foxes, bats, raccoons, and most carnivores are high risk, and prophylaxis should begin promptly unless animal can be captured and euthanized for pathologic evaluation.
  - For rodents or livestock, consult local public health authorities before initiating prophylaxis.
- Postexposure prophylaxis (2)[B]
  - Passive vaccination: rabies immunoglobulin (RIG, HyperRAB) 20 IU/kg administered once. Infiltrate RIG around the wound if possible. Administer remaining RIG IM. Do not administer RIG using the same syringe or into the same anatomic site as vaccine.
  - Active vaccination: rabies vaccine, human diploid cell vaccine (HDCV) or rabies vaccine adsorbed (RVA) or purified chick embryo cell vaccine IM in the deltoid. Give the first dose, 1 mL, as soon as possible after exposure. The day of the first dose is designated day 0. Give additional 1-mL doses on days 3, 7, and 14. If immunocompromised, give fifth dose on day 28. For children, use the anterolateral aspect of the thigh and avoid the gluteal area.
- For previously vaccinated patients, administer an initial 1-mL IM dose of vaccine immediately and an additional 1-mL dose 3 days later. RIG is not necessary in these patients (2)[B].
- Preexposure vaccination: for people in high-risk groups, such as veterinarians, animal handlers, certain laboratory workers, and those spending time in foreign countries where rabies is enzootic (3)[B]:
  - Primary preexposure: three IM 1-mL injections of HDCV or RVA in deltoid area on days 0, 7, and 21, or 28
  - Preexposure boosters: For people at risk of exposure to rabies, test serum every 2 years. Administer preexposure booster of 1-mL IM if immunity is

waning. If titer cannot be obtained, a booster can be administered instead.
- Contraindications: none for postexposure treatment

Pregnancy Considerations

- Pregnancy is not a contraindication to postexposure prophylaxis.
- Rabies vaccination is not associated with a higher incidence of spontaneous abortion, premature births, or fetal abnormalities.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Clinical rabies

- Comfort care and sedation for all patients.
- Milwaukee protocol: experimental treatment using ketamine, midazolam, and amantadine (originally included ribavirin but no longer recommended) (1,4) [C]. One patient who did not receive pre- or postexposure prophylaxis recovered from clinical rabies in 2004 after being treated with medically induced coma and amantadine l (1)[C].
- Control cerebral artery vasospasm (with an agent such as nimodipine) (4,5) [C].
- Fludrocortisone and hypertonic saline if needed to maintain normal sodium level (5)[C]

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

After primary vaccination, serologic testing is necessary only if the patient has a disease or takes immunosuppresive medication.

PATIENT EDUCATION

Use screens over ventilation areas in the roof to secure from bats. Avoid exposure to wild mammalian species known to carry rabies and report potential exposures immediately.

PROGNOSIS

- No postexposure failures in the United States since the 1970s.

- If untreated, rabies has the highest case fatality rate of any infectious disease; generally considered to be 100% fatal once symptoms develop.
- There have only been a small number of cases of successful recovery from rabies. Almost all received some form of pre- or postexposure immunization.

COMPLICATIONS

0.6% of people develop mild serum sickness reaction following HDCV boosters. Mild local and systemic reactions are common following vaccination. Do not interrupt immunization series with mild reactions.

SEE ALSO

Bites, Animal and Human

CODES

ICD10

- A82.9 Rabies, unspecified
- Z20.3 Contact with and (suspected) exposure to rabies

CLINICAL PEARLS

- Rabies is rare in the United States but more common in other areas of the world.
- Seek immediate treatment if exposed to scratch, bite, or saliva of potentially infected animal (e.g., feral dog, bat, fox, raccoon, or other wild mammals).
- Postexposure prophylaxis consists of three steps: local wound cleansing, passive immunization with rabies immunoglobulin, and active immunization with HDCV.
- Consider postexposure prophylaxis for those reporting direct contact with bats, unless it can be verified that an exposure did not occur.

RAPE CRISIS SYNDROME

Ravin V. Patel, MD • Dustin Creech, MD

BASICS

DESCRIPTION

- Definitions (legal definitions may vary from state to state)
  - Sexual contact: intentional touching of a person's intimate parts (including thighs) or the clothing covering such areas, if it is construed as being for the purpose of sexual gratification
  - Sexual conduct: vaginal intercourse between a male and female, or anal intercourse, fellatio, or cunnilingus between persons, regardless of sex
  - Rape (which is a legal term, physician should use the phrase alleged sexual assault): any sexual penetration, however slight, using force or coercion against the person's will
  - Sexual imposition: similar to rape but without penetration or the use of force (i.e., nonconsensual sexual contact, stalking)
  - Gross sexual imposition: nonconsensual sexual contact with the use of force
  - Corruption of a minor: sexual conduct by an individual age ≥18 years with an individual <16 years of age
- Most states have expanded rape statutes to include marital rape, date rape, and shield laws.
- System(s) affected: nervous; reproductive; GI

EPIDEMIOLOGY

- In the United States, 25% of women and 7.6% of men report being target of the definition of rape crisis syndrome listed above. The cost of this are estimated to exceed $5.8 billion annually.
- Anyone can be sexually assaulted, but some populations are especially vulnerable.
  - Adolescents and young children
  - People with disabilities
  - Elderly
  - Low socioeconomic status and homeless people

  - Sex workers
  - Those living in institutions/areas of conflict
- Predominant age
  - The incidence of sexual assault peaks in those 16 to 19 years of age, with the mean occurring at 20 years of age
    - Adolescent sexual assault has a greater frequency of anogenital injuries.
- Predominant sex: female > male
  - For males
    - 69% of male victims were first raped before age 18 years.
    - 41% of male victims were raped before age 12 years.

INCIDENCE

- In the United States, approximately 1.5 million women and 834,700 men are sexually assaulted annually (1).
- Estimated that only a fraction of sexual assaults are reported to law enforcement.
- 18% of American women will be sexually assaulted during their lifetime (2).
  - Between 20% and 25% of females will experience rape/attempted rape during their college years.
- 2–3% of American men will be sexually assaulted during their lifetime.
- Most rape victims either know or have some acquaintance with their attacker.

RISK FACTORS

- Chronologic age of adolescent and young adults 16 to 24 years incur sexual assault. Children living in household of sexual assault are increase risk of maltreatment and lifelong poor health.
- Previous history of victimization (sexually or physically)
- Alcohol consumption is estimated to be involved in 1/2 of sexual assault.
- Illicit drug may also contribute to sexual assault.

GENERAL PREVENTION

- The public health approach should include both prevention and avoidance of vulnerability factors and implementation of protective factors.
- Females may benefit from assertiveness training and self-defense training.
- U.S. Preventive Services Task Force found insufficient evidence to support

general screening in all their patient (no evidence of harm in screening), but physician should discuss sexual assault and family violence with their patient in nonjudgement manner.

DIAGNOSIS

- In adults
  - History of sexual penetration
  - Sexual contact/conduct without consent and/or with the use of force
- In children
  - Actual observation/suspicion of sexual penetration, sexual contact, or sexual conduct
  - Signs include evidence of the use of force and/or evidence of sexual contact (e.g., presence of semen and/or blood).

HISTORY

- Avoid questioning that implies the patient is at fault.
- Record answers in patient's own words insofar as possible. Include date, approximate time, and general location as best as possible. Document physical abuse other than sexual. Describe all types of sexual contact, whether actual/attempted. Take history of alcohol and/or drug use before or after alleged incident; note that some states require specific forms for documenting history.
- Document time of last activity that could possibly alter specimens (e.g., bath, shower, douche).
- Thorough gynecologic history is mandatory, including last menstrual period, last consenting sexual contact, contraceptive practice, and prior gynecologic surgery (3)[C].

PHYSICAL EXAM

- Use of drawings and/or photographs is encouraged; note that some states require specific forms for documenting physical exam.
- Document all signs of trauma/unusual marks.
- Document mental status/emotional state.
- Use UV light (Wood lamp) to detect seminal stains on clothing/skin.

- Obtaining the patient's consent at each step of examination helps the patient regain a sense of control.

ALERT

- A forensic kit or "rape kit" contains swabs that are collected from the vagina and rectum, and instructions are given with the kit regarding proper collection.
- Many states and emergency departments across the country are using a Sexual Assault Nurse Examiner (SANE) when available. This has led to more consistent and more accurate collection of evidence in alleged rape cases.
- Complete genital–rectal exam, including evidence of trauma, secretions, or discharge.
  - Use of a nonlubricated, water-moistened speculum is mandatory because commonly used lubricants may destroy evidence.
  - Testing and/or specimen collection, as indicated, and in compliance with state requirements (4)

DIFFERENTIAL DIAGNOSIS

Consenting sex among adults

DIAGNOSTIC TESTS & INTERPRETATION

- In females, obtain a serum or urine pregnancy test.
- Record results of wet mount, screening for vaginitis, but also note the presence/absence of sperm and, if present, whether it is motile/immotile.
- Drug/alcohol testing as indicated by history and/or physical findings

TREATMENT

GENERAL MEASURES

- Providing health care to victims of sexual assault/abuse requires special sensitivity and privacy.
- All such cases *must* be reported immediately to the appropriate law enforcement agency.
- With the victim's permission, enlist the help of personnel from local support

agencies (e.g., rape crisis center). When available, use of in-house social services is extremely helpful to victim and family.

- SANE programs have been shown to be beneficial, especially in large cities and metropolitan areas with multiple emergency departments of varying capability and staff training/experience.
- Give sedation and tetanus prophylaxis when indicated.
- Discuss possible pregnancy and pregnancy termination with the victim. If hospital policy precludes such as discussion, then information about this option should be offered to the victim via follow-up mechanisms.
- Discuss suspected HIV and hepatitis B exposure and testing with the victim in accordance with hospital, regional, and state policies/protocols. The initial HIV test should be completed within 7 days of the suspected exposure.

MEDICATION

First Line

- Controversy exists regarding empiric antibiotic prophylaxis for victims of sexual assault. However, the Centers for Disease Control and Prevention (CDC) recommends empiric antibiotic prophylaxis of potential sexually transmitted infections (specifically, gonorrhea, chlamydia, trichomoniasis, and potentially syphilis), as many patients will not return for a follow-up visit and many patients prefer immediate treatment (5)[C].
- Cultures are *not* required before initiating treatment but can be considered as part of routine evidence collection.
- Gonorrhea: ceftriaxone 250 mg IM once. Note: Be aware that drug resistance is on the rise in several major cities. Quinolones are no longer recommended for treatment of gonorrhea.
- Chlamydia: azithromycin 1 g PO single dose, or doxycycline 100 mg PO BID for 7 days, *or* erythromycin base 500 mg PO QID for 7 days, *or* erythromycin ethylsuccinate 800 mg PO QID for 7 days
- Syphilis: benzathine penicillin G 2 to 4 million units IM once, or doxycycline 100 mg PO BID for 14 days. Some suggest ceftriaxone 1 g/day, either IM/IV, for 8 to 10 days, but treatment failures have been reported in several geographic areas.
- Trichomoniasis and bacterial vaginosis, if present (if cultures/wet mount were

collected): metronidazole 2 g PO once, *or* metronidazole 500 mg PO BID for 7 days (consider single dose to maximize compliance), *or* metronidazole gel 0.75% 1 full applicator (5 g) intravaginally every day for 5 days; *or* clindamycin cream 2% 1 full applicator (5 g) intravaginally at bedtime for 7 days (considered less efficacious than PO metronidazole)

- If pregnancy prophylaxis is indicated, use levonorgestrel 1.5 mg once (Plan B, progestin-only), efficacious for up to 5 days after the incident.
  - Levonorgestrel alone has proved more effective than the Yuzpe regimen, a method of emergency contraception.
  - *Alternatively*, ethinyl estradiol/levonorgestrel (Yuzpe) 100 μg/0.5 mg once and repeated in 12 hours can be used.
  - Alternatively, ulipristal acetate (Ella) 30 μg once can be used.
  - Alternatively, a copper intrauterine device can be inserted up to 5 days after the earliest predicted date of ovulation in that cycle (6)[C].
- HIV: Currently, there is a low likelihood of HIV transmittance, but the CDC still recommends postexposure prophylaxis (PEP) for victims of sexual assault. Regimen is PEP for 3 to 7 days, with short-term follow-up for further counseling, with a specialist familiar with PEP regimens.
  - Most effective if started within 4 hours and could reduce transmission by as much as 80%; unlikely to be beneficial if started after 72 hours.
- Hepatitis B: if prevalent in area or assailant known to be high risk: hepatitis B immunoglobulin 0.06 mL/kg IM, single dose, and initiate 3-dose hepatitis B virus immunization series. No treatment if the victim has had a complete hepatitis B vaccine series, with documented levels of immunity (7)[C].

Second Line

Pregnancy Considerations

Conduct baseline pregnancy test; discuss pregnancy prevention and termination with patient.

Pediatric Considerations

Assure the child that she or he is a good person and was not the cause of the incident.

ADMISSION, INPATIENT, AND NURSING

CONSIDERATIONS

- Contact appropriate social services agency.
- Most adult victims can be treated as outpatients, unless associated trauma (physical/mental) requires admission.
- Most pediatric sexual assault/abuse victims will require admission/outside placement until appropriate social agency can evaluate home environment (8) [C].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Patient should be seen in 7 to 10 days for follow-up care, including pregnancy testing and counseling.
- Close exam for vaginitis and treatment if necessary.
- Follow-up test for gonorrhea should occur in 1 to 2 weeks.
- Follow-up testing for syphilis, HIV, and hepatitis B should occur at 6 weeks, 3 months, and 6 months.
- Provide telephone numbers of counseling agency(ies) that can provide counseling/legal services to the patient.
- Strongly consider SANE, if available (9)[C].

PATIENT EDUCATION

- Local rape crisis support organizations
- National Sexual Violence Resource Center, 123 Enola Drive, Enola, PA 17025; (877) 739-3895; www.nsvrc.org
- National Domestic Violence Hotline at (800) 799-SAFE(7233) or TTY (800) 787-3224 or www.thehotline.org

PROGNOSIS

- Acute phase (usually 1 to 3 weeks following rape): shaking, pain, wound healing, mood swings, appetite loss, crying. Also feelings of grief, shame, anger, fear, revenge, or guilt
- Late/chronic phase (also called “reorganization”): Female victim may develop

fear of intercourse, fear of men, anxiety or increase discomfort during Pap smears, nightmares, sleep disorders, daytime flashbacks, fear of being alone, loss of self-esteem, anxiety, depression, posttraumatic stress syndrome, and somatic complaints (e.g., nonspecific abdominal pain).

- Recovery may be prolonged. Patients who are able to talk about their feelings seem to have a faster recovery. It is unclear if pharmaco- or psychotherapy results in better outcomes.

COMPLICATIONS

Sequelae include the following:

- Trauma (physical and or mental)
- STIs, including HIV
- Unwanted pregnancy (with the possibility of abortion)
  - The rape-related pregnancy rate in the United States is 5% per rape among victims of reproductive age, resulting in >32,000 unwanted pregnancies each year.
  - Adolescents are at highest risk of pregnancy.
- Medical: chronic pain, fibromyalgia, headaches, irritable bowel syndrome, sexual dysfunction
- Psychological: anxiety, depression, posttraumatic stress disorder, eating disorder, substance abuse

CODES

ICD10

- T74.21XA Adult sexual abuse, confirmed, initial encounter
- T74.22XA Child sexual abuse, confirmed, initial encounter

- Z04.41 Encounter for exam and obs following alleged adult rape

CLINICAL PEARLS

- *Rape* is a legal term, and the examining physician is encouraged to use terminology such as *alleged rape* or *alleged sexual conduct*.
- Marital rape is a federal offense in all 50 states and the District of Columbia; in some states, also applies to unmarried cohabiting couples.
- Because “consent defense” is common, documentation of evidence supporting the use of force or the administration of drugs/alcohol is imperative.
- Use of a protocol is encouraged to assure every victim a uniform, comprehensive evaluation, regardless of the expertise of the examiner. The protocol must ensure that all evidence is properly collected and labeled, chain of custody is maintained, and the evidence is sent to the most appropriate forensic laboratory.
- All medical records must be well documented and legible.
- All medical personnel must be willing and able to testify on behalf of the patient.

RAYNAUD PHENOMENON

Herbert L. Muncie, Jr., MD • Kelsey E. Phelps, MD

BASICS

DESCRIPTION

- Idiopathic intermittent episodes of vasoconstriction of digital arteries, precapillary arterioles, and cutaneous arteriovenous shunts in response to cold, emotional stress, or blunt trauma
  - A triphasic color change of the fingers (occasionally the toes, rarely nipples) is the principal physical manifestation.
    - The initial color is *white* from extreme pallor, then *blue* from cyanosis, and finally with warming and vasodilatation the skin appears *red*.
    - Thumbs are rarely involved.
  - Swelling, throbbing, and paresthesias are associated symptoms.
  - Primary
    - 80% of patients have primary disease.
    - Episodes are bilateral and nonprogressive.
    - Diagnosis confirmed if after 2 years of symptoms, no underlying connective tissue disease develops.
  - Secondary
    - Progressive and asymmetric
    - Vascular spasm is more frequent and more severe over time. Ulceration is rare; gangrene does not develop; 13% progress to digital fat pad atrophy and ischemic changes of the fingertips.
    - Typically associated with an underlying connective tissue disorder
- System(s) affected: hematologic, lymphatic, immunologic, musculoskeletal, dermatologic, exocrine

Pregnancy Considerations

- Raynaud phenomenon can appear as breast pain in lactating women (1).
- Positive breast milk bacterial culture distinguishes mastitis from Raynaud phenomenon.

Geriatric Considerations

Initial appearance of Raynaud phenomenon after age 40 years often indicates underlying connective tissue disease.

Pediatric Considerations

Associated with systemic lupus erythematosus (SLE) and scleroderma

EPIDEMIOLOGY

Incidence

- Primary
  - Predominant age: 14 years; ~1/4 begin >40 years
  - Predominant sex: female > male (4:1)
- Secondary
  - Predominant age: >40 years
  - Predominant sex: no gender predilection

Prevalence

- Primary: 3–12.5% of men; 6–20% of women (based on clinical history)
- Secondary: ~1% of population

ETIOLOGY AND PATHOPHYSIOLOGY

Unknown. Dysregulation of vascular control mechanisms leads to imbalance between vasodilation and vasoconstriction. There is a reduced endothelin-dependent vasodilation activity and an increased vasoconstriction in peripheral vessels by overproduction of endothelin-1. 5-HT_2 serotonin receptors may be involved in secondary Raynaud phenomenon. Platelet and blood viscosity abnormalities in secondary contribute to ischemic pathology.

Genetics

Some studies suggest dominant inheritance pattern. ~1/4 of primary patients have a first-degree relative with Raynaud phenomenon.

RISK FACTORS

- Existing autoimmune or connective tissue disorder
- End-stage renal disease with hemodialysis may increase risk if a steal phenomenon associated with the arterial-venous shunt develops.

- Primary and secondary disease associated with elevated homocysteine levels.
- Smoking is not associated with increased risk of Raynaud phenomenon but may worsen symptoms.

GENERAL PREVENTION

- Avoid cold exposure.
- Tobacco cessation
- No relationship has been established between Raynaud phenomenon and vibratory tool use.

COMMONLY ASSOCIATED CONDITIONS

Secondary Raynaud

- Scleroderma; SLE; polymyositis
- Sjögren syndrome; occlusive vascular disease
- Cryoglobulinemia

DIAGNOSIS

HISTORY

- Primary
  - Symmetric attacks involving fingers
  - Family history of connective tissue disorder
  - Absence of tissue necrosis, ulceration, or gangrene
  - If after ≥2 years of symptoms, no abnormal clinical or laboratory signs have developed, secondary disease is highly unlikely.
- Secondary
  - Onset typically after 40 years of age
  - Asymmetric episodes more intense and painful
  - Arthritis, myalgias, fever, dry eyes and/or mouth, rash, or cardiopulmonary symptoms
  - History of medication and/or recreational drug use
  - Exposure to toxic agents
  - Repetitive trauma

PHYSICAL EXAM

Pallor (whiteness) of fingertips with cold exposure, then cyanosis (blue), then redness and pain with warming

- Ischemic attacks evidenced by demarcated or cyanotic skin limited to digits; usually starts on one digit and spreads symmetrically to remaining fingers of both hands.The thumb is typically spared.
- May rarely involve other peripheral tissues (e.g., tongue) (2).
- Beau lines: transverse linear depressions in nail plate on most or all fingernails that occurs after exposure to cold or any insult that disrupts normal nail growth.
- Livedo reticularis: mottling of the skin of the arms and legs; benign and reverses with warming
- Primary
  - Normal physical exam
  - Nail bed capillaries have normal appearance: Place 1 drop of grade B immersion oil on skin at base of fingernail and view capillaries with handheld ophthalmoscope at 10 to 40 diopters.
- Secondary
  - Skin changes, arthritis, and abnormal lung findings suggest connective tissue disease,
  - Ischemic skin lesions: ulceration of finger pads (autoamputation in severe, prolonged cases)
  - Nail bed capillary distortion including giant loops, avascular areas, and increased tortuosity
  - Abnormal Allen test: conducted by having the patient open and close his or her hand several times and then squeezing his or her hand tightly into a fist. The examiner sequentially occludes the ulnar and radial arteries while the patient opens his or her hand to reveal the return of color as a measure of circulation.

DIFFERENTIAL DIAGNOSIS

- Thromboangiitis obliterans (Buerger disease): primarily affects men; smoking-related
- Rheumatoid arthritis (RA)
- Progressive systemic sclerosis (scleroderma): Raynaud phenomenon precedes other symptoms.

- SLE
- Carpal tunnel syndrome; thoracic outlet syndrome
- Hypothyroidism
- CREST syndrome (calcinosis cutis, Raynaud phenomenon, esophageal dysmotility, sclerodactyly, and telangiectasias)
- Cryoglobulinemia; Waldenström macroglobulinemia
- Acrocyanosis
- Polycythemia
- Occupational (e.g., especially from vibrating tools, masonry work, exposure to polyvinyl chloride)
- Drug-induced (e.g., clonidine, ergotamine, methysergide, amphetamines, bromocriptine, bleomycin, vinblastine, cisplatin, cyclosporine)

DIAGNOSTIC TESTS & INTERPRETATION

Provocative test (e.g., ice water immersion) unnecessary

- Primary
  - Antinuclear antibody: negative
  - ESR: normal
- Secondary
  - Tests for secondary causes (e.g., CBC, ESR)
  - Positive autoantibody has low positive predictive value for connective tissue disease (30%).
  - Antibodies to specific autoantigens (e.g., scleroderma with anticentromere or antitopoisomerase antibodies)
  - Videocapillaroscopy is gold standard (200 times magnification).

Follow-Up Tests & Special Considerations

Periodic assessments for a connective tissue disorder

Diagnostic Procedures/Other

Diagnosis is determined by history and physical exam.

TREATMENT

Assess using a Raynaud Condition Score.

GENERAL MEASURES

- Dress warmly, wear gloves, and avoid cold temperatures.
- During attacks, rotate the arms in a windmill pattern or placing the hands under warm water or in a warm body fold to alleviate symptoms.
- Tobacco cessation
- Avoid β-blockers, amphetamines, ergot alkaloids, and sumatriptan.
- Temperature-related biofeedback may help patients increase hand temperature. 1-year follow-up is no better than control.
- Finger guards to protect ulcerated fingertips

MEDICATION

First Line

- Calcium channel blockers (CCBs). Nifedipine is the best studied and most frequently used.
- Nifedipine: 30 to 180 mg/day (sustained-release form); seasonal (winter) use is effective with up to 75% of patients experiencing improvement.
- Is compatible with breastfeeding
- Contraindications: allergy to drug, pregnancy, CHF
- Precautions: may cause headache, dizziness, lightheadedness, edema, or hypotension
- Significant possible interactions
  - Increases serum level of digoxin

Second Line

- Amlodipine (5 to 10 mg/day) and nicardipine are effective and may have fewer adverse effects.
- No data exist to support switching CCB if initial drug is ineffective.
- Small studies support benefit from losartan and fluoxetine.
- Phosphodiesterase type-5 inhibitors (sildenafil, vardenafil) may reduce symptoms without increasing blood flow.
- Parenteral iloprost, a prostacyclin, in low doses (0.5 ng/kg/min over 6 hours), has improved ulcerations with severe Raynaud phenomenon when CCBs failed. Oral prostacyclin has not proven useful.
- Nitroglycerin patches may be helpful, but use is limited by the incidence of severe headache. Nitroglycerin gel has shown promise as a topical therapy.

- Prazosin (1 to 2 mg TID) is the only well-studied α_1-adrenergic receptor blocker with modest effect, but adverse effects may outweigh any benefit.
- ACE inhibitors are no longer recommended.

ISSUES FOR REFERRAL

If an underlying disease is suspected, consider rheumatology consultation for evaluation and treatment.

ADDITIONAL THERAPIES

- Botulinum toxin has shown some effect in reducing vasospastic episodes, frequency of attacks, rest pain, and helping to promote digital ulcer healing (3) [C].
- Aspirin
- Digital or wrist block with lidocaine or bupivacaine (without epinephrine) for pain control
- Short-term anticoagulation with heparin if persistent critical ischemia, evidence of large-artery occlusive disease, or both

SURGERY/OTHER PROCEDURES

Surgical intervention is rarely indicated or used for Raynaud phenomenon. Effect of cervical sympathectomy is transient; symptoms return in 1 to 2 years. Digital fat grafting is a novel modality that has shown improved symptomatology and evidence of measurably increased perfusion in several cases; further study is needed (4)[C].

COMPLEMENTARY & ALTERNATIVE MEDICINE

- *Ginkgo biloba* may reduce the frequency of attacks.
- Well-designed studies have not been done yet (5)[B].
- Fish oil supplements may increase digital systolic pressure and time to onset of symptoms after exposure to cold; not proven in controlled trials
- Vitamin D supplementation led to improvement in self-reported symptoms in vitamin D–deficient patients with Raynaud phenomenon (6)[B].
- Evening primrose oil reduced severity of attacks in one study.
- Oral arginine is no better than placebo.
- Biofeedback is not helpful.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Avoid exposure to cold; reassess for secondary causes.

Patient Monitoring

Manage fingertip ulcers and rapidly treat infection.

DIET

No special diet.

PATIENT EDUCATION

- Tobacco cessation.
- Avoid triggers (e.g., trauma, vibration, cold).
- Dress warmly; wear gloves.
- Warm hands when experiencing vasospasm.

PROGNOSIS

- Attacks may last from several minutes to a few hours.
- 2/3 of attacks resolve spontaneously.
- ~13% of Raynaud patients develop a secondary disorder, typically connective tissue diseases.

COMPLICATIONS

- Primary: very rare
- Secondary: gangrene, autoamputation of fingertips

SEE ALSO

Algorithm: Raynaud Phenomenon

CODES

ICD10

- I73.00 Raynaud's syndrome without gangrene
- I73.01 Raynaud's syndrome with gangrene

CLINICAL PEARLS

- The diagnosis of Raynaud phenomenon is based on clinical symptoms.
- Provocative testing is not recommended.
- Initial presentation of Raynaud phenomenon after age 40 years suggests underlying (secondary) disease.
- Raynaud phenomenon is a cause of breast pain in lactating women.
- Primary Raynaud phenomenon is symmetric; secondary Raynaud phenomenon is asymmetric.
- Primary Raynaud phenomenon is treated with handwarming and avoiding cold exposure.
- Digital ulcers are not normal and always merit a workup for secondary disease.

REACTIVE ARTHRITIS (REITER SYNDROME)

Douglas W. MacPherson, MD, MSc–CTM, FRCPC

BASICS

Reiter syndrome is a seronegative, multisystem, inflammatory disorder classically involving joints, the eye, and the lower genitourinary (GU) tract. Axial joint (e.g., spine, sacroiliac joints) and dermatologic manifestations are common (1)[C].

DESCRIPTION

The classic triad include arthritis, conjunctivitis/iritis, and either urethritis or cervicitis ("can't see; can't pee; can't bend my knee").

- The epidemiology is similar to other reactive arthritides, characterized by sterile joint inflammation associated with infections originating at nonarticular sites. A fourth feature (dermatologic involvement) may include buccal ulceration, balanitis, or a psoriaform skin eruption. (Having only two features does not rule out the diagnosis.)
- Two forms of Reiter syndrome:
  - Sexually transmitted: Symptoms emerge 7 to 14 days after exposure to *Chlamydia trachomatis* and other sexually acquired pathogens.
  - Postenteric infection (including traveler's diarrhea)
- In individuals with new or frequent sexual partners, the triggering infection is likely sexually transmitted (rather than enteric).
- In individuals with a history of recent enteric illness, the triggering event is more likely to be a bacterial enteric infection than sexually transmitted.
- System(s) affected: musculoskeletal, renal/urologic, dermatologic/exocrine
- Synonym(s): idiopathic blennorrheal arthritis; arthritis urethritica; urethro-oculosynovial syndrome; Fiessinger-Leroy-Reiter disease; reactive arthritis

Pediatric Considerations

Juvenile rheumatoid arthritis has many of the same clinical features as Reiter syndrome.

Pregnancy Considerations

No special considerations; usual drug precautions

EPIDEMIOLOGY

Incidence

- Predominant age: 20 to 40 years
- Predominant sex: male > female
- 0.24–1.5% incidence after epidemics of bacterial dysentery
- Complicates 1–2% of nongonococcal urethritis cases

ETIOLOGY AND PATHOPHYSIOLOGY

- The pathophysiology of all the seronegative reactive arthritis syndromes and the immunologic role of infectious diseases as precipitants for clinical illness are incompletely understood.
- Avoiding precipitant infections and early management of multiorgan inflammation is important. Antibiotic treatment following onset of syndrome does not appear to benefit inflammatory joint, eye, or urinary tract symptoms.
- *C. trachomatis* is the most common sexually transmitted infection associated with Reiter syndrome.
- Dysentery-associated Reiter syndrome follows infection with *Shigella*, *Salmonella*, *Yersinia*, and *Campylobacter* spp. Enteric-associated Reiter syndrome is more common in women, children, and the elderly than the postvenereal form.

Genetics

HLA-B27 tissue antigen present in 60–80% of patients, suggesting a genetic predisposition.

RISK FACTORS

- New or high-risk sexual contacts 7 to 14 days before the onset of clinical presentation; the primary infection may be subclinical and undiagnosed.
- Food poisoning or bacterial dysentery

GENERAL PREVENTION

- The immune-response characteristics of this syndrome make specific avoidance of infectious precipitants the most important general precaution (and potentially the most difficult to achieve).

- Safe sexual practices; proper food and water hygiene

COMMONLY ASSOCIATED CONDITIONS

- Enteric disease
  - Shigellosis; Salmonellosis; Campylobacteriosis
  - Enteric infection with *Yersinia* spp.
- Urogenital infection
  - *Chlamydia* urethritis/cervicitis (2)[C]
  - *Mycoplasma* or *Ureaplasma* spp.
- HIV/AIDS

DIAGNOSIS

- Based on clinical presentation with joint, eye, and GU inflammation ("classic triad") and negative serologic testing for rheumatoid factor
- Classic symptoms not always present at the same time
- HLA-B27 testing is not required for diagnosis.

HISTORY

The presence of the clinical syndrome plus

- Diarrhea, dysentery, urethritis, or genital discharge and appropriate exposure history
- Exposure risks, including travel or migration history and potential infectious exposure
- Arthritis associated with urethritis for >1 month (84% sensitive; 98% specific for diagnosis)
- Urethritis occurs 1 to 15 days after sexual exposure.
- Reiter syndrome onset within 10 to 30 days of either enteric infection or STI
- Mean duration of symptoms is 19 weeks.

PHYSICAL EXAM

- Musculoskeletal
  - Asymmetric arthritis (especially knees, ankles, and metatarsophalangeal joints)
  - Enthesopathy (inflammation at tendinous insertion into bone, such as

plantar fasciitis, digital periostitis, and Achilles tendinitis)
  - Spondyloarthropathy (spine and sacroiliac joint involvement)
- Urogenital tract
  - Urethritis; prostatitis; cystitis (rare)
  - Balanitis
  - Cervicitis: usually asymptomatic
- Eye
  - Conjunctivitis of one or both eyes
  - Occasionally, scleritis, keratitis, and corneal ulceration
  - Rarely, uveitis and iritis
- Skin
  - Mucocutaneous lesions (small, painless superficial ulcers on oral mucosa, tongue, or glans penis)
  - Keratoderma blennorrhagica (hyperkeratotic skin lesions of palms and soles and around nails—can be mistaken for psoriasis)
- Cardiovascular: occasionally, pericarditis, murmur, conduction defects, and aortic incompetence
- Nervous system: rarely, peripheral neuropathy, cranial neuropathy, meningoencephalitis, and neuropsychiatric changes
- Constitutional
  - Fever, malaise, anorexia, and weight loss
  - Patient can appear seriously ill (e.g., fever, rigors, tachycardia, and exquisitely tender joints).

DIFFERENTIAL DIAGNOSIS

- Rheumatoid arthritis (RA)
- Ankylosing spondylitis
- Arthritis associated with inflammatory bowel disease
- Psoriatic arthritis
- Juvenile RA
- Bacterial arthritis, including gonococcal

DIAGNOSTIC TESTS & INTERPRETATION

- Blood
  - Negative rheumatoid factor

  - Leukocyte count: 10,000 to 20,000 cells/mm^3
  - Neutrophil predominance
  - Elevated ESR and/or CRP
  - Moderate normochromic anemia
  - Hypergammaglobulinemia
- Synovial fluid
  - Leukocyte count: 1,000 to 8,000 cells/mm^3
  - Bacterial culture negative
- Supportive tests
  - Cultures, antigens, or PCR positive for *Chlamydia trachomatis* or stool test positive for *Salmonella*, *Shigella*, *Yersinia*, or *Campylobacter* species
  - HIV serology positive (acute retroviral syndrome)
  - HLA-B27-positive (*not required for diagnosis*)
  - Drugs that may alter lab results: Antibiotics may affect isolation of the bacterial pathogens.
- X-ray
  - Periosteal proliferation, thickening
  - Articular bony spurs; erosions at articular margins
  - Residual joint destruction
  - Syndesmophytes (spine); sacroiliitis

Diagnostic Procedures/Other

HLA-B27 histocompatibility antigen: positive result in 60–80% of cases in non–HIV-related Reiter syndrome; HLA testing is not required or recommended for diagnosis. Rheumatoid factor is negative.

- Screen for STI if clinically indicated.
- Screening for enteric infections is rarely useful and generally not indicated.

Test Interpretation

- Seronegative spondyloarthropathy (similar to ankylosing spondylitis, enteric arthritis, and psoriatic arthritis)
- Villous formation within joints; hyperemia, and inflammation
- Prostatitis and seminal vesiculitis
- Skin biopsy similar to psoriasis

TREATMENT

GENERAL MEASURES

Treatment is determined by symptoms.

- Conjunctivitis does not require specific treatment.
- Iritis requires treatment.
- Mucocutaneous lesions do not require treatment.
- Physical therapy (PT) aids recovery.
- Arthritis may become prominent and disabling during the acute phase.

MEDICATION

First Line

- Symptomatic management: NSAIDs, including indomethacin, naproxen, and others; intra-articular or systemic corticosteroids for refractory arthritis and enteritis
  - Contraindications
    - GI bleeding
    - Peptic ulcer, gastritis, or ulcerative colitis
    - Renal insufficiency
- Specific treatment of isolated microorganism (3)[A]:
  - *C. trachomatis*: doxycycline 100 mg PO BID for 7 to 14 days (*Note*: All STIs should be treated whether associated with Reiter syndrome or not.)
  - *Salmonella*, *Shigella*, *Yersinia*, and *Campylobacter* infections: ciprofloxacin 500 mg PO BID for 5 to 10 days (*Note*: Emerging antimicrobial resistance may limit the effectiveness of ciprofloxacin. Antibiotic treatment does not reduce GI symptoms or duration of infection or prevent carrier state.)
  - Trials of antibiotic treatment for reactive arthritis have produced mixed results, rendering the efficacy of antibiotics uncertain.
- GI upset: antacids
- Iritis: intraocular steroids
- Keratitis: topical steroids

Second Line

- Aspirin or other NSAIDs

- Sulfasalazine is promising but not approved by the FDA for this indication.
- Methotrexate or azathioprine in severe cases (experimental, not approved or known to be effective); immunosuppressive therapy is relatively contraindicated in HIV-related Reiter syndrome.
- Consultation with specialist is recommended, particularly when considering immunomodulatory agents such as sulfasalazine, methotrexate, or azathioprine or for treatment with anti-TNF medications (etanercept and infliximab) which have shown benefit in isolated case reports.
- Role of antibiotics under investigation—currently unproven effectiveness in seronegative arthritides.
- No published evidence supports the beneficial effect of antibiotics on the long-term outcome in patients with Reiter syndrome.

ISSUES FOR REFERRAL

Joint and eye complications; complex cases—consider reconsultation with rheumatology; ophthalmology

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Based on severity of disease and associated complications
- Inpatient care may be needed during acute phase.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Activity modification until joint inflammation subsides

Patient Monitoring

Monitor clinical response to anti-inflammatory drugs. Observe for complications, particularly with sulfasalazine and immunosuppressive drugs.

PATIENT EDUCATION

- Educate on risk factors for exposure and recurrence.
- Home physical therapy
- Arthritis Foundation, 1314 Spring Street NW, Atlanta, GA 30309, 404-872-

7100

- National Institute of Arthritis and Musculoskeletal and Skin Diseases: http://www.niams.nih.gov/

PROGNOSIS

Prognosis is poor in cases involving the heel, eye, or heart.

COMPLICATIONS

- Chronic or recurrent disease in 5–50% of patients
- Ankylosing spondylitis develops in 30–50% of patients who test positive for HLA-B27 antigen.
- Urethral strictures
- Cataracts and blindness
- Aortic root necrosis

Ankylosing Spondylitis; Arthritis, Psoriatic; Behçet Syndrome

CODES

ICD10

- M02.30 Reiter’s disease, unspecified site
- M02.39 Reiter’s disease, multiple sites

CLINICAL PEARLS

- Diagnosis of Reiter syndrome is based on the clinical presentation of the classic triad of joint, eye, and GU inflammation and negative serologic testing for rheumatoid factor (signs and symptoms may not all be present at the same time).
- Screen for STI (including HIV) if sexually acquired. Enteric studies are rarely clinically indicated.
- Refer patients with a chronic or recurrent course or those who have clinical complications.

REFRACTIVE ERRORS

Robert M. Kershner, MD, MS, FACS

BASICS

DESCRIPTION

- Refraction is the bending of a wave of light as it passes through the optical system of the eye. The degree of bending is dependent on the index of refraction through the air, cornea, and lens and is described quantitatively by Snell law. A refractive error refers to the inability of the eye to produce a focused image on the fovea or central part of the retina.
- Emmetropia: When light rays are in perfect focus, the image being viewed is seen clearly.
- Ametropia: any refractive error of the eye that prevents normal focusing of the image
- Hyperopia: When the cornea of the eye is too flat or the eye is too short, light rays fall in focus behind the retina, and the individual is “farsighted.”
- Myopia: When the cornea is too steep or the length of the eyeball is too long, the focal point for light rays lies short of the retina, and the individual is “nearsighted.”
- Presbyopia: The natural tendency of the crystalline lens to harden/become sclerotic with age, limiting the focusing of the eye on near objects (accommodation). By the age of 40 years, most people do not have enough room within the eye to allow normal excursion of the lens and accommodation; viewing of near objects is blurred, and reading glasses are required.
- Astigmatism: When the cornea is steeper in one meridian more than the other or the globe is not round (i.e., is oval or almond shaped), visual blurriness occurs due to the absence of a single point of focus.
- Anisometropia: an unequal refractive error between the two eyes
- System(s) affected: nervous

Geriatric Considerations

Presbyopia occurs after the age of 40 years.

Pediatric Considerations

Refractive errors can be detected early in life.

EPIDEMIOLOGY

- Predominant age: Refractive errors may be present at birth and can increase in magnitude with age until the eye is fully developed. Often they are not detected until puberty.
- Predominant gender: male = female
- Individuals >40 years of age are more likely to experience presbyopia/the normal loss of accommodation that occurs with age, necessitating the use of reading glasses for close work.

Prevalence

Of the general U.S. population, 70% have some form of ametropia.

ETIOLOGY AND PATHOPHYSIOLOGY

- Developmental (most common)
- Ocular trauma
- Iatrogenic (e.g., post refractive surgery or cataract removal)

Genetics

Inherited

GENERAL PREVENTION

No exercises; optical lenses can correct the refractive error.

COMMONLY ASSOCIATED CONDITIONS

- Patients with diabetes mellitus have fluctuating myopia as a result of poorly controlled blood glucose and concomitant swelling of the crystalline lens.
- Those who have a pathologic steepening of the cornea due to structural weakness (keratoconus) may have increasing myopia and astigmatism throughout life.

DIAGNOSIS

HISTORY

- Difficulty seeing objects at a distance
- Difficulty focusing on near objects
- Difficulty reading
- Squinting
- Headaches (from squinting)
- In children:
  - Rubbing of the eyes
  - Sitting close to TV/computer screen
  - Problems in sports, particularly declining performance
  - Declining grades
  - Preference for front-row seating
  - Covering of an eye while reading

PHYSICAL EXAM

Snellen eye chart (developed by Dr. Hermann Snellen in 1862)

- Test each eye separately.
- The smallest row of letters that the patient can read determines visual acuity in the uncovered eye.
- The standard convention is visual acuity measured at 20 feet with a Snellen chart. A person with "normal" acuity will see letters clearly at 20 feet as recorded 20/20 (6/6 in meters). A person with 20/200 vision would be considered legally blind and able only to see a letter at 20 feet that a person with normal vision could see clearly at 200 feet.

DIAGNOSTIC TESTS & INTERPRETATION

- Pinhole vision test: To distinguish a refractive error from an organic cause of visual blurring, have the patient look through a pinhole in a card without a corrective lens.
- Patients with a pure refractive error have improved vision because the pinhole blocks nonparallel and unfocused rays of light.
- There are no lab tests for measuring visual acuity.
- A number of digital imaging systems exist for measuring refractive error.
  - Ultrasound or Laser Interferometry can determine the length of the eye (A-Scan or Laser Biometry).
  - Autorefractors can measure myopia, hyperopia, and astigmatism using a

projected light into the eye and measuring the quality of its image upon its return.
  - Corneal topography or Orbscan quantitatively and qualitatively measures the amount of curvature on the surface of the cornea that affects the bending and focusing of light on the retina.
  - Wavefront corneal analysis measures the reflected rays of light as they pass into and out of the entire optical system (cornea, lens, and retina).
- Most corneal and refractive imaging techniques are reserved for individuals who are contemplating refractive surgical correction (intraocular lenses or excimer laser surgery "LASIK").

Follow-Up Tests & Special Considerations

Corneal and refractive imaging are used to monitor changing refractive errors postsurgically and to follow pathologic changes such as in keratoconus.

Diagnostic Procedures/Other

- Methods
  - Objective streak retinoscopy may be used to measure the degree of refractive error in spherocylinder correction for the proper spectacle/contact lens.
  - Antimuscarinic agents, such as cyclopentolate (Cyclogyl) or tropicamide (Mydriacyl), applied topically paralyze the ciliary body, preventing accommodation. Cycloplegic refraction can then be performed.
  - *α*-Adrenergic agents, such as phenylephrine (Neo-Synephrine), can be used concomitantly to stimulate and dilate the pupillary dilator muscle, making measurements easier. They have no effect on cycloplegia.
- Age-related testing
  - Newborns should be examined for general eye health; ophthalmologic evaluation is indicated for any problems discovered.
  - Vision screening should occur at each well-child visit.
  - Visual acuity testing and motility testing should be performed at ~3 to 5 years of age or at any time that a malposition of the eyes, squinting, or difficulty following objects is observed.
  - Visual acuity must be performed by age 5 years or prior to the child entering school to screen for and pick up refractive errors early before they

lead to amblyopia.
  - Visual acuity should be retested prior to obtaining a driver's license, at age 40 years, and every 2 to 4 years until age 65 years, after which age evaluations are recommended every 1 to 2 years.

DIFFERENTIAL DIAGNOSIS

- Corneal disease
- Cataract
- Retinal abnormalities
- Diseases of the optic nerve
- Neuromuscular disorders
- Neurologic impairment

TREATMENT

GENERAL MEASURES

- Spectacle lenses (glasses)
- Soft/hard contact lenses
- Surgery

MEDICATION

Precaution: Antimuscarinic agents may induce acute glaucoma via acute-angle closure in susceptible individuals. The elderly and those with high hyperopia or a history of angle closure should not be tested with these agents.

First Line

No medical treatment for refractive error exists.

Second Line

Cycloplegia is sometimes used to "fog/blur" the better seeing eye in cases of amblyopia.

ISSUES FOR REFERRAL

Any individual who fails a basic screening visual acuity test should be promptly referred to an eye care professional for evaluation. Children do not outgrow refractive errors. Left untreated, refractive errors can lead to permanent visual

loss.

ADDITIONAL THERAPIES

Eye exercises and visual training may improve hand-to-eye coordination and visual awareness but do not treat refractive error.

SURGERY/OTHER PROCEDURES

- Astigmatic keratotomy with a surgical diamond blade has been performed either as an isolated procedure or as a part of the cataract surgical procedure to effectively flatten the steep corneal meridian (1,2)[C].
- Manual astigmatic keratotomy is being superseded by the femtosecond laser whereby the surgeon applies the laser to perform the limbal corneal relaxing incisions (LRIs) instead of the surgical diamond blade (3)[C].
- Laser-assisted in-situ keratomileusis (LASIK) was approved by the FDA in 1997. A superficial corneal flap is created with a mechanical keratome/femtosecond laser, under which the excimer laser removes a small amount of tissue corresponding to the correction of refractive error, thus reshaping the cornea. LASIK can be used for all refractive errors but not in all patients. Healing is rapid because reepithelialization is not required. Surgery is reserved for those with a stable refractive error and a cornea that is thick enough to allow safe removal of tissue. The procedure is permanent.
- Implantable contact lens (ICL): A thin plastic lens is permanently implanted either in the anterior chamber and anchored to the iris (FDA approved in 2005, VERISYSE) or in the posterior chamber (Visian ICL, FDA approved in 2006) between the iris and the human crystalline lens. All refractive errors can be corrected. Risks include damage to the natural lens during surgery, cataract formation, and intraocular inflammation/infection.
- Excimer laser photorefractive keratectomy: The laser photoablates corneal tissue from the central visual axis, flattening it. Following the procedure, the cornea must reepithelialize. Healing takes several months, during which there is a mild haze and blurring of vision; FDA approved in October 1995.
- Other modifications:
  - LASIK (laser in-situ keratomileusis), which involves removing of the superficial epithelium before laser application (Epi-LASIK).
  - IntraLASIK is a femtosecond laser that is used to create the flap as an

alternative to a mechanical keratome.
  - Custom ablation: uses the information from a wavefront map of the cornea and eye to tailor the ablation to remove higher orders of refractive errors
- Older methods now superseded by LASIK:
  - Radial keratotomy: With topical anesthesia, a surgical keratome is used to incise multiple (4 to 8) radial incisions into the peripheral cornea to a depth of ≥85%. The incisions cause gaping and thus flatten the central, optical zone of the cornea. Radial keratotomy is safe and effective, corrects nearsightedness and astigmatism, but has been replaced by excimer laser surgery for its improved accuracy and stability of correction.
  - Photorefractive keratectomy: Surface corneal tissue is removed with the excimer laser to reshape the cornea, correcting nearsightedness, farsightedness, or astigmatism. Risks and disadvantages include pain, keratitis, and potential scarring. Healing requires 3 months with topical antibiotics and steroids, with associated risks of glaucoma, cataract, chronic inflammation, and scarring.
- Several scleral expansion procedures have been under investigation to attempt to increase the space within the ciliary body by surgical means to restore lens movement and accommodation. The results have been unsatisfactory.
- Bifocal intraocular lenses (several types have been approved by the FDA: AcrySof IQ ReSTOR, ReZOOM-AMO, TECNIS-AMO) are implanted in the posterior chamber. They increase the depth of field to allow viewing objects both at near and at distance. Side effects include decreased contrast, glare, ghosting of images, and problems with night vision.
- Accommodative intraocular lenses (Crystalens): first FDA-approved intraocular lens; several others under clinical investigation. The accommodative intraocular lens moves in response to ciliary body movement to allow focusing at different focal lengths. Side effects are minimal. Present lenses have limited range of focus.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Exams recommended when starting school, entering college, with any change in vision quality, and at the age of onset of presbyopia (the need for reading glasses)
- Individuals with any of the known risks of eye disease or conditions that could affect the eyes (e.g., diabetes, thyroid disease, hypertension, macular degeneration) need annual ocular examinations.
- Family history of eye diseases/refractive errors necessitates annual reexam.

DIET

Although refractive error is unaffected by diet, diet has been shown to be important for retinal health. Diets high in fats, cholesterol, along with cigarette smoking or diabetes can lead to an increased risk of age-related macular degeneration (AMD), a potentially blinding disease of the retina. Diets high in vegetables, low in meats, and high in antioxidants (e.g., lutein, β-carotene, vitamins A, C, and E, zinc, and omega-3 fatty acids) have been shown to be protective for retinal degeneration. The age-related eye disease study (AREDS) formulation, which has been proven effective in numerous clinical trials, includes a specific daily amount of 500-mg vitamin C, 400 IU of vitamin E, 15 mg of β-carotene (often labeled as the equivalent of 25,000-IU vitamin A), 80 mg of zinc as zinc oxide, and 2 mg of copper as cupric oxide to prevent copper deficiency anemia and is taken with meals in two equally divided doses in the morning and evening. This therapy has been superseded by the AREDS2 formulation, which eliminated vitamin E due to its associated increased risk of lung cancer in smokers and replacing β-carotene with lutein and zeaxanthin.

PATIENT EDUCATION

- All patients should have their eyes examined when starting school and periodically thereafter.
- The options of eyeglasses, contact lenses, and permanent surgical correction of refractive errors can be considered.
- Encourage aggressive control of diabetes mellitus and annual exams by an ophthalmologist. These individuals are at increased risk of blindness from their disease and should not undergo refractive corrective surgery.

PROGNOSIS

- Good, if discovered early and corrected appropriately.
- It is not unusual for refractive errors to be temporarily worsened during pregnancy because of hormonal changes in tear function and corneal swelling.
- It is common that refractive errors worsen as a child ages until complete adult growth has been achieved (this is around age 18 to 20 years for girls and 20 to 25 years for boys). This is a common source of concern for parents. Reassurance that refractive change is often seen with growth spurts, especially at puberty, is advised.
- Any refractive change that is increasing/worsening each year should prompt further investigation by an ophthalmologist.

COMPLICATIONS

- Amblyopia or permanent loss of vision that is not correctable with glasses or contact lenses
- Poor school performance
- Inability to pass a drivers license examination

CODES

ICD10

- H52.7 Unspecified disorder of refraction
- H52.00 Hypermetropia, unspecified eye
- H52.10 Myopia, unspecified eye

CLINICAL PEARLS

- Vision screening should occur at each well-child visit.
- Visual acuity testing should be performed at ~3.5 years of age or at any time that the physician or parent is concerned about the child's eye movements, ability to see, or track objects.
- Children *never* grow out of a refractive error. All suspected refractive errors should be referred to the appropriate eye care professional for evaluation to prevent permanent loss of vision from amblyopia.

RENAL TUBULAR ACIDOSIS

Jason Kurland, MD

BASICS

DESCRIPTION

- Renal tubular acidosis (RTA) is composed of a group of disorders characterized by an inability of the kidney to resorb bicarbonate/secrete hydrogen ions, resulting in normal anion gap metabolic acidosis. Renal function (glomerular filtration rate [GFR]) must be normal or near normal.
- Several types have been identified:
  - Type I (distal) RTA: inability of the distal tubule to acidify the urine due to impaired hydrogen ion secretion, increased back leak of secreted hydrogen ions, or impaired sodium reabsorption (interfering with the generation of negative luminal charge required for hydrogen/potassium secretion). Urine pH >5.5.
  - Type II (proximal) RTA: defect of the proximal tubule in bicarbonate (HCO_3) reabsorption. Proximal tubular HCO_3 reabsorption is absent; plasma HCO_3 concentration stabilizes at 12 to 18 mEq/L due to compensatory distal HCO_3 reabsorption. Urine pH <5.5 unless plasma HCO_3 brought above reabsorptive threshold.
  - Type III RTA: extremely rare autosomal recessive syndrome due to carbonic anhydrase II deficiency; causes mixed type I and type II RTA, osteopetrosis, cerebral calcification, mental retardation
  - Type IV RTA (hypoaldosteronism): due to aldosterone resistance/deficiency that results in hyperkalemia. Urine pH usually is <5.5.

EPIDEMIOLOGY

Incidence

- Predominant age: all ages
- Predominant sex: male > female (with regard to type II RTA with isolated defect in bicarbonate reabsorption)

ETIOLOGY AND PATHOPHYSIOLOGY

- Type I RTA
  - Genetic: autosomal dominant, autosomal recessive associated with sensorineural deafness
  - Sporadic
  - Other familial disorders: Ehlers-Danlos syndrome, glycogenosis type III, Fabry disease, Wilson disease
  - Autoimmune diseases: Sjögren syndrome, rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), thyroiditis (1)
  - Hematologic diseases: sickle cell disease (hyperkalemic), hereditary elliptocytosis
  - Medications: amphotericin B, lithium, ifosfamide, foscarnet, amiloride, triamterene, trimethoprim, pentamidine
  - Toxins: toluene, glue
  - Hypercalciuria, diseases causing nephrocalcinosis
  - Vitamin D intoxication
  - Medullary cystic disease
  - Obstructive uropathy (hyperkalemic)
  - Hypergammaglobulinemic syndrome
  - Chronic pyelonephritis
  - Chronic renal transplant rejection
  - Leprosy
  - Chronic active hepatitis, primary biliary cirrhosis
  - Malnutrition
- Type II RTA
  - Familial (cystinosis, tyrosinemia, hereditary fructose intolerance, galactosemia, glycogen storage disease type I, Wilson disease, Lowe syndrome, inherited carbonic anhydrase deficiency)
  - Sporadic
  - Multiple myeloma, other dysproteinemic states
  - Amyloidosis
  - Heavy metal poisoning (e.g., cadmium, lead, mercury, copper)
  - Medications: acetazolamide, ifosfamide, tenofovir, sulfanilamide, outdated tetracycline, topiramate (2), aminoglycosides

  - Interstitial renal disease
  - Paroxysmal nocturnal hemoglobinuria
  - Defects in calcium metabolism (hyperparathyroidism)
- Type IV RTA
  - Medications: NSAIDs, ACE inhibitors, ARBs, heparin/low-molecular-weight heparin, ketoconazole, calcineurin inhibitors (tacrolimus, cyclosporine—by decreasing expression of mineralocorticoid receptor [3])
  - Diabetic nephropathy
  - Tubulointerstitial nephropathies
  - Primary adrenal insufficiency
  - Markedly decreased distal Na^+ delivery
  - Pseudohypoaldosteronism (PHA) (end-organ resistance to aldosterone)
    - PHA type 1
    - PHA type 2 (Gordon syndrome)

Genetics

- Type I RTA: Hereditary forms due to mutations affecting intercalated cells in collecting tubules (4). May occur in association with other genetic diseases (e.g., Ehlers-Danlos syndrome, hereditary elliptocytosis, or sickle cell nephropathy). The autosomal recessive form is associated with sensorineural deafness.
- Type II RTA: Autosomal dominant form is rare. Autosomal recessive form is associated with ophthalmologic abnormalities and mental retardation. Occurs in Fanconi syndrome, which is associated with several genetic diseases (e.g., cystinosis, Wilson disease, tyrosinemia, hereditary fructose intolerance, Lowe syndrome, galactosemia, glycogen storage disease, metachromatic leukodystrophy)
- Type IV RTA: Some cases are familial, such as PHA type I (autosomal dominant).

GENERAL PREVENTION

Careful use/avoidance of causative agents

COMMONLY ASSOCIATED CONDITIONS

- Type I RTA in children: hypercalciuria leading to rickets, nephrocalcinosis

- Type I RTA in adults: autoimmune diseases (Sjögren syndrome, RA, SLE), hypercalciuria
- Type II RTA: Fanconi syndrome (generalized proximal tubular dysfunction resulting in glycosuria, aminoaciduria, hyperuricosuria, phosphaturia, bicarbonaturia)
- Type II RTA in adults: multiple myeloma, carbonic anhydrase inhibitors (acetazolamide) (5)
- Type IV RTA: diabetic nephropathy

DIAGNOSIS

HISTORY

- Often asymptomatic (particularly type IV)
- In children: failure to thrive, rickets
- Anorexia, nausea/vomiting, constipation
- Weakness or polyuria (due to hypokalemia)
- Polydipsia
- Osteomalacia in adults

DIFFERENTIAL DIAGNOSIS

- Plasma anion gap should be normal. If not, evaluate for causes of anion-gap metabolic acidosis. (MUDPILES: **m**ethanol, **u**remia, **d**iabetic ketoacidosis, **p**ropylene glycol/paraldehyde, **i**ron/isoniazid ingestion, **l**actic acidosis, **e**thylene glycol, **s**alicylates)
- Extrarenal HCO_3 losses
  - Diarrhea
  - Small bowel, pancreatic, or biliary fistulas
  - Urinary diversion (e.g., ureterosigmoidostomy, ileal conduit)
- Acidosis of chronic renal failure (develops when GFR ≤20 to 30 mL/min)
- Excessive administration of acid load via chloride salts (NaCl, HCl, NH_4Cl, lysine HCl, $CaCl_2$, $MgCl_2$)

DIAGNOSTIC TESTS & INTERPRETATION

- Electrolytes reveal hyperchloremic metabolic acidosis.

- Plasma anion gap normal (anion gap = Na − [Cl + HCO_3]). Normal values (in mEq/L) depend on analyzer used: infants/children 5 to 15; adolescents/adults 4 to 12) (6). Must increase calculated anion gap by 2.5 mEq/L for each 1 g/dL decrease in **albumin** below 4 g/dL
- Plasma K+: Low in type I (if due to impaired distal H^+ secretion/increased H^+ back leak), type II; high in type IV, type I (if due to impaired distal Na^+ reabsorption)
- Plasma HCO_3 (in untreated RTA): type I: <10 to 20 mEq/L; type II: 12 to 18 mEq/L (1); type IV: >17 mEq/L
- BUN/Cr normal or near normal (rules out renal failure as cause of acidosis)
- Urinalysis: Urine pH inappropriately alkaline (>5.5) despite metabolic acidosis in type I; also in type II if HCO_3 above reabsorptive threshold (12 to 18 mEq/L)
- Urine culture: Rule out UTI with urea-splitting organism (may elevate pH) and chronic infection.
- Urine anion gap (UAG; urine [Na^+ + K^+] − Cl^- on a random specimen): reflects unmeasured urine anions, so inversely related to urine NH_4^+ (or acid) excretion. Positive UAG in an acidemic patient indicates impaired renal acid excretion. Urine Na^+ >25 mEq/L required for accurate interpretation of UAG. Results tend to be
  - Negative in HCO_3 losses due to diarrhea, UTI caused by urea-splitting organisms, and other extrarenal causes of nonanion gap metabolic acidosis
  - Variable in type II RTA
  - Positive in type I RTA (7), type IV RTA
  - Positive in impaired acid excretion due to renal failure
- Urine calcium
  - High in type I
  - Typically normal in type II
- Drugs that may alter lab results
  - Diuretics
  - Sodium bicarbonate (and other alkali)
  - Cholestyramine

Initial Tests (lab, imaging)

Serum electrolytes; consider urinalysis, urine culture.

Diagnostic Procedures/Other

- Helpful to measure urine pH on fresh sample with pH meter for increased accuracy instead of dipstick. Pour film of oil over urine to avoid loss of CO_2 if pH cannot be measured quickly.
- Urine NH_4^+ excretion (anion gap only provides a qualitative estimate)
- Urinary acidification (impaired in type I RTA) can be assessed by oral administration of furosemide and fludrocortisone; patients with type I RTA unable to reduce urine pH to <5.3 (8)
- Fractional excretion of HCO_3 >15% during HCO_3 infusion (type II RTA) (1)

Test Interpretation

- Nephrocalcinosis
- Nephrolithiasis
- Rickets
- Osteomalacia, osteopenia
- Findings of an underlying disease causing RTA

TREATMENT

MEDICATION

First Line

- Provide oral alkali to raise serum HCO_3 to normal. Start at a low dose and increase until HCO_3 is normal. Give as sodium bicarbonate (7.7 mEq $NaHCO_3$/650 mg tab), sodium citrate (oral solution, 1 mEq HCO_3 equivalent/mL), sodium/potassium citrate (oral solution), or potassium citrate (tablet, powder, or oral solution: 2 mEq K/mL, 2 mEq HCO_3/mL), depending on need for potassium.
- Type I RTA: Typical doses 1 to 2 mEq/kg/day (in adults), 3 to 4 mEq/kg/day (in children) PO alkali divided 3 to 4 times per day (require much higher doses if HCO_3 wasting is present). May require K^+ supplementation
- Type II RTA: Typical doses 10 to 15 mEq/kg/day alkali, divided 4 to 6 times

per day. Very difficult to restore plasma HCO_3 to normal, as renal HCO_3 losses increase once plasma HCO_3 is corrected above resorptive threshold. Exogenous HCO_3 increases K^+ losses, requiring supplemental K^+. Often need supplemental PO_4 and vitamin D due to proximal PO_4 losses. May add thiazide diuretic to induce mild hypovolemia, which increases proximal Na^+/HCO_3^- reabsorption

- Type IV RTA: Avoid inciting medications; restrict dietary K^+. May augment K^+ excretion with loop diuretic, thiazide diuretic, or Kayexalate. Correcting hyperkalemia increases activity of the urea cycle, augmenting renal ammoniagenesis and adding substrate for renal acid excretion. If necessary, 1 to 5 mEq/kg/day alkali divided 2 to 3 times per day. If mineralocorticoid deficiency, fludrocortisone: 0.1 to 0.3 mg/day
- Precautions
  - Sodium-containing compounds will increase urinary calcium excretion, potentially increasing the risk of nephrolithiasis.
  - Mineralocorticoids and sodium-based alkali may lead to hypertension and/or edema.
  - Aluminum-containing medications (antacids, sucralfate) should be avoided if solutions containing citric acid are prescribed because citric acid increases aluminum absorption.
  - Sodium bicarbonate may cause flatulence because CO_2 is formed, whereas citrate is metabolized to HCO_3 in the liver, avoiding gas production.

Second Line

Thiazide diuretics may be used as adjunctive therapy in type II RTA (after maximal alkali replacement) but are likely to further increase urinary K^+ losses.

SURGERY/OTHER PROCEDURES

If distal RTA is due to obstructive uropathy, surgical intervention may be required.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Generally managed as outpatient; inpatient if acidosis severe, patient unreliable,

emesis persistent, or infant with severe failure to thrive

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Electrolytes 1 to 2 weeks following initiation of therapy, monthly until serum HCO_3 corrected to desired range, then as clinically indicated
- Monitor underlying disease as indicated.
- Poor compliance common due to 3 to 6 times per day alkali dosing schedule

DIET

Varies based on serum K^+ level and volume status

PATIENT EDUCATION

- National Kidney & Urologic Diseases Information Clearinghouse, Box NKUDIC, Bethesda, MD 20893, 301-468-6345: http://www.kidney.niddk.nih.gov/
- National Kidney Foundation: https://www.kidney.org/

PROGNOSIS

- Depends on associated disease; otherwise, good with therapy
- Transient forms of all types of RTA may occur.

COMPLICATIONS

- Nephrocalcinosis, nephrolithiasis (type I)
- Hypercalciuria (type I)
- Hypokalemia (type I, type II if given bicarbonate)
- Hyperkalemia (type IV, some causes of type I)
- Osteomalacia (type II due to phosphate wasting), osteopenia (due to buffering of acid in bone)

CODES

ICD10

N25.89 Oth disorders resulting from impaired renal tubular function

CLINICAL PEARLS

- Consider RTA in cases of normal anion gap metabolic acidosis with normal/near-normal renal function.
- Type I RTA: urine pH >5.5 in setting of acidemia; positive urine anion gap; acidemia can be severe.
- Type II RTA: urine pH <5.5 unless HCO3 raised above reabsorptive threshold (12 to 18 mEq/L)
- Type IV RTA: most common subtype; hyperkalemia; urine pH < 5.5; acidemia usually mild

- Treatment includes avoidance of inciting causes, provision of oral alkali (HCO_3 or citrate), and measures to supplement (type II, many type I) or restrict (type IV) potassium.

RESPIRATORY DISTRESS SYNDROME, ACUTE (ARDS)

Muhammad Imran Khan, MD • Najm Hasan Siddiqui, MD

BASICS

DESCRIPTION

- ARDS is an acute, diffuse, inflammatory lung injury that leads to increased pulmonary vascular permeability, increased lung weight, and a loss of aerated tissue (1) with clinical hallmarks of severe hypoxemia and bilateral pulmonary infiltrates.
  - Absence of left atrial hypertension (HTN)
  - By consensus, PaO_2/FiO_2 <200
  - Most severe form of acute lung injury
- System(s) affected: pulmonary; cardiovascular
- Synonym(s): shock lung; wet lung; noncardiac pulmonary edema

EPIDEMIOLOGY

Incidence

ARDS: 10.1 to 86.2 cases/100,000 annually (2)

ETIOLOGY AND PATHOPHYSIOLOGY

Three phases

- Acute exudative phase: characterized by profound hypoxia and associated with inflammation with infiltration of inflammatory and proinflammatory mediators and diffuse alveolar damage
- Fibrosing alveolitis phase: coincides with recovery or after ~1 to 2 weeks; patients continue to be hypoxic and have increased dead space and decreased compliance.
- Resolution may require 6 to 12 months.
- Several mediators are involved in the initiation and perpetuation of ARDS.
  - Cytokines

  - Complement activation
  - Coagulation activation
  - Platelet-activating factor
  - Oxygen free radicals
  - Lipoxygenase pathways
  - Neutrophil proteases
  - Nitric oxide
  - Endotoxin
  - Cyclooxygenase pathway products
- Systemic inflammatory response with activation of the previous mediators can occur with direct or indirect injury to the lung.
  - Direct
    - Aspiration
    - Pulmonary infections
    - Air, fat, or amniotic fluid emboli
    - Near-drowning
    - Pulmonary contusion
    - Inhalation of toxic gases and dusts
  - Indirect
    - Sepsis
    - Shock
    - Transfusion
    - Trauma
    - Overdose
    - Pancreatitis, severe
    - Eclampsia

RISK FACTORS

- Severe infection (localized or systemic) most common
- Aspiration of gastric contents
- Shock
- Infection
- Trauma with or without lung contusion
- Pneumonia
- Toxic inhalation

- Pancreatitis
- Fat embolism
- Near-drowning
- Multiple blood transfusions

GENERAL PREVENTION

No effective measures have been identified.

COMMONLY ASSOCIATED CONDITIONS

- Severe sepsis
- Trauma
- Shock

DIAGNOSIS

HISTORY

- No history of heart disease
- Precipitating event (see "Commonly Associated Conditions"): abrupt onset of respiratory distress

PHYSICAL EXAM

- Tachypnea and tachycardia during the first 12 to 24 hours; respiratory distress
- Lethargy, obtundation
- Flat neck veins
- Hyperdynamic pulses
- Physiologic gallop
- Absence of edema
- Moist, cyanotic skin
- Manifestations of underlying disease

DIFFERENTIAL DIAGNOSIS

- Left ventricular failure
- Interstitial and airway diseases
- Hypersensitivity pneumonitis
- Veno-occlusive disease
- Mitral stenosis: intravascular volume overload

- Toxic shock syndrome

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Arterial blood gases (ABGs) show evidence of severe hypoxemia.
- PaO_2/FiO_2 <200
- ECG: sinus tachycardia; nonspecific ST-T–wave changes
- Pulmonary artery wedge pressure (PAWP) <15 mm Hg
- Cardiac index >3.5 L/min/m^2
- Chest x-ray (CXR): normal heart size; fluffy, bilateral infiltrates; air bronchograms common
- Chest CT scan: diffuse interstitial opacities and bullae

Follow-Up Tests & Special Considerations

- Serial blood gases
- Monitor for and treat multisystem organ failure when it occurs.
- Serial CXRs

Diagnostic Procedures/Other

Invasive monitoring of vital signs, cardiac output, and PAWP has been questioned by large clinical trials.

Test Interpretation

- Lungs show exudative, early proliferative or late proliferative phases.
- Interstitial and alveolar edema is present.
- Inflammatory cells and erythrocytes spill into the interstitium and the alveolus.
- Type 1 cells are destroyed, leaving a denuded basement membrane.
- Protein-rich fluid fills the alveoli.
- Type 2 alveolar cells initially appear unaltered.
- Type 2 cells begin to proliferate within 72 hours of initial insult and cover the denuded basement membrane.
- Aggregates of plasma proteins, cellular debris, fibrin, and surfactant remnants form hyaline membranes.
- Over the next 3 to 10 days, alveolar septum thickens by proliferating fibroblasts, leukocytes, and plasma cells.

- Capillary injury begins to occur.
- Hyaline membranes begin to reorganize.
- Fibrosis becomes apparent in respiratory ducts and bronchioles.

TREATMENT

GENERAL MEASURES

- Ensure adequate oxygenation.
- Ventilatory support generally requires endotracheal intubation and use of positive end-expiratory pressure (PEEP) (3)[A].
- Provide appropriate cardiorespiratory monitoring.
- Fluid management

MEDICATION

- No single drug or combination of drugs prevents or treats full-blown ARDS. Treatment is supportive while addressing the underlying cause.
- Supplemental oxygen
- Ventilatory support
  - Most often requires endotracheal intubation with emphasis on lower tidal volumes per weight and optimization of PEEP
  - High-frequency oscillation ventilation seems not to increase the risk of barotrauma or hypotension and reduces the risk of oxygenation failure, it does not improve survival in adult ARDS patients (4)[A].

ISSUES FOR REFERRAL

- All patients with ARDS should be cared for in an ICU with appropriately trained staff.
- Pregnant patients with ARDS also should be followed by a high-risk perinatologist or obstetrician.

ADDITIONAL THERAPIES

- Inotropic agents: dobutamine to maintain adequate cardiac output after appropriate fluid resuscitation fails to restore perfusion
- Corticosteroids: Short-term use during the acute phase has not been shown to be effective. However, prolonged methylprednisolone treatment accelerates

the resolution of ARDS, improving a broad spectrum of interrelated clinical outcomes and decreasing hospital mortality and healthcare utilization (5)[A].

- Vasodilators: Inhaled nitric oxide (INO) is not recommended for patients with ARDS. INO results in a transient improvement in oxygenation but does not reduce mortality and may be harmful (6)[A].
- Pulmonary surfactant: successful in neonatal respiratory distress syndrome; investigational outside this age group
- Inhaled β_2-agonists may be helpful during the resolution phase.
- There is no current evidence to support or refute the routine use of aerosolized prostacyclin for patients with ARDS (7)[A].
- There is no effect on mortality with granulocyte-macrophage colony–stimulating factor, neutrophil elastase inhibitors, intravenous salbutamol, surfactant, or *N*-acetylcysteine (8)[A].
- Inhaled granulocyte-monocyte colony–stimulating factor demonstrated significant improvement in oxygenation, lung compliance and severity of illness score in patients with pneumonia associated ARDS (9)[B].
- Early use of neuromuscular-blocking agent treatment of patients with severe sepsis and severe ARDS cannot only improve the severity but also reduce 21-day mortality (10)A].
- Antioxidants (e.g., Procysteine) have produced conflicting results.
- Exogenously administered mesenchymal stem cells may help to attenuate lung injury and promote repair (11)[B].
- Activated protein-C may be helpful in patients with sepsis.
- Deep vein thrombosis (DVT) prophylaxis
- Ulcer prophylaxis

Pregnancy Considerations

Supportive care while identifying the underlying cause of ARDS continues to be important in the management of pregnant women with ARDS. However, fetal well-being, possible need for delivery, and physiologic changes associated with pregnancy must be considered.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

All patients with ARDS should be managed in an ICU setting.

- Consider prone positioning.
- Identify and treat underlying condition.
- Circulatory support, adequate fluid volume, and nutritional support
- Supplemental oxygen
- Monitoring blood gases, pulse oximetry, bedside pulmonary function test
- Support ventilation using lung-protective strategies and PEEP.
- Monitor for systemic hypotension and hypovolemia without fluid overload.
- BP support, if necessary
- Vasopressor agents
- Fluid management with IV crystalloid solutions while monitoring pulmonary status
- Pulmonary catheter pressure monitoring
- Treat underlying disease process.
- Prevent complications.
- Maintain the intravascular volume at the lowest level consistent with adequate perfusion (assessed by metabolic acid–base balance and renal function).
- If perfusion is inadequate after restoration of intravascular volume (e.g., septic shock), vasopressor therapy is indicated.
- Increase oxygen content with packed erythrocyte transfusions as necessary.
- Provide appropriate nutritional support with enteral or parenteral nutrition.
- Steroid therapy
- Nursing may include any or all of the following:
  - Skin, eye, and mouth care
  - DVT prophylaxis
  - GI prophylaxis
  - Suctioning
  - Ensure adequate level of sedation and/or paralysis while on mechanical ventilation.
  - Oxygen supplementation
  - Nebulizer therapy
  - Chest physiotherapy
  - Tracheostomy care
  - Explain all procedures to patient and family; reduce anxiety.
- Discharge criteria

- Supplemental oxygen
- Nutrition counseling
- Family monitoring of signs and symptoms of respiratory distress

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Vital capacity and static lung compliance are important measures of lung mechanics.
- Daily labs are needed until the patient is no longer critical.
- CXRs to assess endotracheal tube placement, the presence of progressing infiltrates, catheter placement, and complications of mechanical ventilation (e.g., air leaks)
- A Swan-Ganz catheter to assess oxygen delivery, oxygen consumption, and cardiac output may be helpful but has not been shown to improve survival.

DIET

- Nutritional support
- Conservative fluid management shortens ventilator and ICU time but does not affect survival.

PATIENT EDUCATION

ARDS support center and brochure titled “Learn About ARDS”: www.ards.org

PROGNOSIS

- Mortality rate is 43% (12).
- Survivors may have pulmonary sequelae with mild abnormalities in oxygenation, diffusion, and lung mechanics as well as some pulmonary symptoms of cough and dyspnea.
- The prognosis worsens with elevated cardiac troponin-T levels in ARDS patients (13).

COMPLICATIONS

- Permanent lung disease

- Oxygen toxicity
- Barotrauma
- Superinfection
- Multiple organ dysfunction syndrome
- Death

CODES

ICD10

J80 Acute respiratory distress syndrome

CLINICAL PEARLS

- ARDS is an acute, diffuse, inflammatory lung injury that leads to increased pulmonary vascular permeability, increased lung weight, and a loss of aerated tissue (1) with clinical hallmarks of severe hypoxemia and bilateral pulmonary infiltrates. Treatment of ARDS requires aggressive supportive care in an ICU setting while also addressing the underlying cause.
- The benefit of invasive monitoring of vital signs, cardiac output, and PAWP

has been questioned by large clinical trials.

RESPIRATORY DISTRESS SYNDROME, NEONATAL

Mary Cataletto, MD, FAAP, FCCP • Margaret J. McCormick, MS, RN, CNE

BASICS

DESCRIPTION

- Neonatal respiratory distress syndrome (NRDS) is a serious disorder of prematurity with a clinical manifestation of respiratory distress.
- System(s) affected: pulmonary
- Synonym(s): hyaline membrane disease; surfactant deficiency

ALERT

A disorder of the neonatal period

EPIDEMIOLOGY

Incidence

- Predominant age: 93% incidence in infants born at or before 28 weeks' gestational age
- Inversely proportional to gestational age and birth weight
- Predominant sex: slight male predominance
- Eighth leading cause of infant death in United States in 2013: 13.3 infant deaths per 100,000 live births (1)
- Despite advances, survival of infants born before 25 weeks' gestation is rare (2).

Prevalence

Common disorder in premature infants, especially those born <28 weeks' gestation

ETIOLOGY AND PATHOPHYSIOLOGY

- Impaired surfactant synthesis and secretion
- High oxygen exposure and barotrauma can cause further damage to alveolar

epithelium.

Genetics

No known genetic pattern

RISK FACTORS

- Premature birth
- Infants of diabetic mothers
- Perinatal asphyxia
- History of RDS in a sibling

GENERAL PREVENTION

- Prevention of premature birth with education, regular prenatal care, and management of maternal medical conditions
- Promote healthy behaviors during pregnancy including diet; exercise; and avoidance of exposure to tobacco smoke, alcohol, and illegal drugs.
- Antenatal corticosteroids (3),(4)[A]

DIAGNOSIS

HISTORY

Preterm neonates with worsening respiratory distress beginning at or shortly after birth and progressing over first few hours of life.

PHYSICAL EXAM

- Tachypnea
- Grunting
- Nasal flaring
- Subcostal and intercostal retractions
- Decreased breath sounds
- Cyanosis

DIFFERENTIAL DIAGNOSIS

- Early-onset group B streptococcal pneumonia and/or sepsis
- Transient tachypnea of newborn
- Meconium aspiration pneumonia

DIAGNOSTIC TESTS & INTERPRETATION

- Arterial blood gases (ABGs)
  - Evaluate for evidence of acid-base abnormalities, hypoxemia, and hypercarbia.
- Chest x-ray (CXR):
  - Diffuse reticulogranular pattern (ground-glass appearance)
  - Air bronchograms
  - Low lung volumes

Diagnostic Procedures/Other

- Echocardiogram: Consider if murmur is present to evaluate for patent ductus arteriosus (PDA) and contribution to lung disease due to L → R shunting.
- Lung pathology (autopsy findings)
  - Macroscopically: uniformly ruddy, airless appearance of lungs
  - Microscopically: diffuse atelectasis and hyaline membranes (eosinophilic and fibrinous membrane lining air spaces)

TREATMENT

GENERAL MEASURES

- Supportive care:
  - Thermoneutral environment
  - Optimize metabolic status
  - Provide for nutritional needs
- Support ventilation and ensure adequate oxygenation.
- In preterm infants with RDS (without respiratory failure), → CPAP and consider selective surfactant administration (5,6)[A].
- For preterms who fail nCPAP or who are in respiratory failure, → positive-pressure ventilation by ETT via conventional mechanical ventilator and administration of surfactant (5,6)[A].
- Respiratory monitoring options
  - Noninvasive respiratory monitoring
    - Transcutaneous monitor or end tidal CO_2 monitor
    - Pulse oximetry

- Invasive respiratory monitoring
  - Umbilical artery catheter placement for monitoring and sampling ABGs.
  - Direct sampling of ABGs

MEDICATION

- Pulmonary surfactant (6)[A]
- Side effects: bradycardia, hypotension, airway obstruction/endotracheal tube blockage with administration; rapid changes in tidal volume due to increased compliance can cause a pneumothorax and small risk of pulmonary hemorrhage.
- Precautions: Transient adverse effects seen with the administration of surfactant may require stopping administration and alleviating situation; may proceed with dosing when stable
- Contraindications: presence of congenital anomalies incompatible with life beyond neonatal period; infant with laboratory evidence of lung maturity

ISSUES FOR REFERRAL

Comorbid conditions associated with prematurity may require consultation during the course of the infant's NICU admission, including PDA (cardiology consult), necrotizing enterocolitis (NEC) (gastroenterology), retinopathy of prematurity (ROP) (ophthalmology), and so forth.

ADDITIONAL THERAPIES

Treat associated problems of prematurity.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

All neonates with respiratory distress require immediate evaluation, monitoring, and treatment in the delivery room with transfer to an NICU.

- IV Fluids
  - To maintain blood pressure and perfusion, when necessary
  - To provide optimal fluid balance, provide nutritional support
- Nursing
  - Supportive care
  - Thermoneutral environment
  - Respiratory monitoring

  - Establish relationship with family to provide education and emotional support.
- Discharge Criteria
  - Should have stable vital signs and pulse oximetry before discharge
  - Medical home and support services should be in place.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Following discharge, infants should be followed closely by their physicians to monitor growth and respiratory symptomatology.

DIET

As clinically indicated

PATIENT EDUCATION

- Educate parents regarding the risks in subsequent pregnancies.
- Advise parents regarding potential issues with chronic lung disease.
- For patient education materials favorably reviewed on this topic, go to Boston Children's Hospital Web site (www.childrenshospital.org) and search for respiratory distress syndrome in the "My Child Has" window.

PROGNOSIS

Prognosis and outcome are highly dependent on gestational age and birth weight. Almost half of the infants in Jarjour study who were born at or <25 weeks' gestation had significant neurodevelopmental disabilities on short- and long-term follow-up.

COMPLICATIONS

- Complications specific to NRDS
  - Pneumothorax
  - Chronic lung disease, bronchopulmonary dysplasia (BPD)
  - Pulmonary interstitial edema (PIE)
- Additional complications may occur related to therapeutic interventions and comorbid conditions.

CODES

ICD10

P22.0 Respiratory distress syndrome of newborn

CLINICAL PEARLS

- Early treatment with CPAP or pulmonary surfactant can modify clinical course.
- Prognosis and outcome are highly dependent on gestational age and birth weight.

RESPIRATORY SYNCYTIAL VIRUS (RSV) INFECTION

Elizabeth C. McKeen, MD

BASICS

Respiratory syncytial virus (RSV) is a medium-sized, membrane-bound ribonucleic acid (RNA) virus that causes acute respiratory tract illness in all ages. The most clinically significant disease occurs in infants and young children.

DESCRIPTION

A major cause of respiratory illness, either of the upper respiratory tract (URT) or of the lower respiratory tract (LRT/bronchiolitis)

- In adults, RSV causes URT infections (URTIs).
- In infants and children, RSV causes URTIs and LRT infections (bronchiolitis and pneumonia).

Pediatric Considerations

- 90–95% of children are infected at least once by the age of 24 months; reinfection is common.
- Leading cause of pediatric bronchiolitis (50–90%)
- Premature infants are at increased risk for severe acute RSV infection.

EPIDEMIOLOGY

- Seasonality: Highest incidence of RSV in the United States occurs between December and March.
- Morbidity: RSV infection leads to over 100,000 annual hospitalizations.
- Mortality: Deaths associated with RSV are uncommon. Children with complex chronic conditions account for the majority of deaths, and the relative contribution of RSV infection to their deaths is unclear (1)[B].

ETIOLOGY AND PATHOPHYSIOLOGY

- RSV-induced bronchiolitis causes acute inflammation, edema, and necrosis of small airway epithelium, air trapping, bronchospasm, and increased mucus

production.

- RSV develops in the cytoplasm of infected cells and matures by budding from the plasma membrane.
- Infection spreads through droplets, either airborne or personal contact, that inoculate the nose of a susceptible individual.

Genetics

- A genetic predisposition to severe RSV infections may be associated with polymorphisms in cytokine- and chemokine-related genes, including *CCR5*; *IL4*; and affiliated receptors, *IL8*, *IL10*, and *IL13*.
- Infants with transplacentally acquired antibody against RSV are not protected against infection but may have milder symptoms.

RISK FACTORS

- Risk factors for severe disease
  - Prematurity
  - Age <12 weeks
  - Underlying cardiopulmonary disease
  - Immunodeficiency
- Other risk factors
  - Low socioeconomic status
  - Exposure to environmental air pollutants
  - Child care attendance
  - Severe neuromuscular disease
  - Adults: occupational exposure to young children, hospital staff, teachers, and daycare workers

GENERAL PREVENTION

- Hand hygiene is the most important step to prevent the spread of RSV.
  - Alcohol-based rubs are preferred; an alternative is hand washing with soap and water (2)[B].
- Avoid exposure to passive tobacco smoke, especially in infants and children (3)[A].
- Isolate patients with proven or suspected RSV.
- Palivizumab (Synagis), a monoclonal antibody directed against the fusion (F)

protein of RSV, is indicated as prophylaxis for:

- Infants and children <24 months of age with
  - Chronic lung disease of prematurity requiring medical therapy within 6 months of the start of RSV season
  - Hemodynamically significant congenital heart disease
  - Congenital abnormalities of the airway or neuromuscular disease that compromises handling airway secretions
- Infants born at ≤28 weeks' gestation if they are <12 months of age at the start of the RSV season; prophylaxis should be maintained through the end of the RSV season.
- Infants born at 29 to 32 weeks' gestation if they are <6 months of age at the start of the RSV season; prophylaxis should be maintained through the end of the RSV season.
- Infants born at 32 to 35 weeks' gestation who are <3 months of age at the start of the RSV season or who are born during the RSV season if they have one of the following two risk factors:
  - Infant attends child care
  - ≥1 more siblings or other children <5 years of age living permanently in the child's household

- Dosage: maximum of 5 monthly doses beginning in November or December at 15 mg/kg per dose IM
- Current palivizumab guidelines in the *Red Book*

COMMONLY ASSOCIATED CONDITIONS

- Asthma
- Otitis media
- Serious bacterial infection (SBI) in infants and children with concurrent RSV infection is rare.

DIAGNOSIS

ALERT

In most cases, diagnosis is clinical. Laboratory and radiologic studies are not routinely necessary (2)[B].

HISTORY

- Rhinorrhea and upper respiratory congestion
- Difficulty feeding in infants (due to respiratory effort)
- Increased respiratory rate or signs of increased work of breathing (grunting, flaring, retracting)
- Cough; fever; wheezing
- History of prematurity, secondhand tobacco exposure, daycare, number and age of siblings
- Immunization history
- Family history of respiratory disease

PHYSICAL EXAM

- Vital signs: fever, signs of increased work of breathing (tachypnea, grunting, flaring, retracting), pulse rate; pulse oximetry ("fifth vital sign") to assess oxygenation
- Ear, nose, throat: rhinorrhea, dry mucous membranes (dehydration)
- Serous otitis or acute otitis; pulmonary: wheezing, crackles
- Skin turgor
- Serial examinations to assess status

Pediatric Considerations

Young infants with bronchiolitis may develop apnea with increased risk of prolonged hospitalization, ICU admission, and mechanical ventilation.

DIFFERENTIAL DIAGNOSIS

- Mild illness/URTI
  - Other respiratory viral infections: rhinovirus, human metapneumovirus, influenza virus, human bocavirus
  - Allergic rhinitis
  - Sinusitis
- Severe illness/LRTI
  - Bronchiolitis
  - Asthma
  - Pneumonia
  - Foreign body aspiration

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Routine laboratory testing is not necessary.
  - If obtained, WBC count normal or elevated
  - Virologic tests for RSV, despite high predictive value, rarely change management decisions or outcomes for patients with clinical bronchiolitis.
- Given the low risk of systemic bacterial infection (SBI), full septic workups are not necessary unless child appears toxic.
- Chest x-ray (CXR) does not predict disease severity or change patient outcomes but may be helpful if a patient does not improve as expected, if the severity of the disease requires further investigation, or if another diagnosis is suspected.
- When obtained, typical CXR findings include:
  - Hyperinflation and peribronchiolar thickening
  - Atelectasis
  - Interstitial infiltrates
  - Segmental or lobar consolidation

TREATMENT

GENERAL MEASURES

- Assess hydration status and ability to take fluids orally. Treat dehydration adequately with an oral or IV fluid, particularly in infants.
- Supplemental oxygen is indicated if pulse oximetry falls persistently <90% in previously healthy patients.

MEDICATION

First Line

No first-line medication for RSV infections; treatment is usually supportive; oxygen as needed

Second Line

- Bronchodilators do not improve oxygen saturation, reduce hospital admission after outpatient treatment, shorten the duration of hospitalization, or reduce

the time to resolution of illness at home. Routine use not recommended (2)[B]
- Nebulized epinephrine is superior to placebo for short-term outcomes in the outpatient setting, particularly in the first 24 hours (4)[A].
- Glucocorticoids do not alter admissions or length of hospitalization (5)[A].
  - Some data suggest that the combination of dexamethasone and epinephrine may reduce outpatient admissions.
- A recent study found that montelukast (Singulair) has no effect on the clinical course of acute bronchiolitis.
- Ribavirin, a nucleoside analogue and antiviral agent, has not been shown to be efficacious, particularly in immunocompromised patients.
- There is no current evidence that nebulized rhDNase changes clinical outcomes in children <24 months of age hospitalized with acute RSV bronchiolitis.
- Reserve use of antibacterial agents for patients who have specific findings that suggest a coexisting SBI.
- Nebulized 3% saline may reduce the length of stay and improve the clinical severity score in infants hospitalized with acute viral bronchiolitis.
- Heliox therapy may significantly reduce a clinical score evaluating respiratory distress in the first hour after starting treatment for infants with acute bronchiolitis, but there does not seem to be a reduction in the rate of intubation, in the rate of emergency department discharge, or in the length of treatment for respiratory distress (5)[A].

ADDITIONAL THERAPIES

- Bulb suctioning of the nares may provide some comfort to infants and allow for easier feeding.
- Efforts are underway to develop an RSV vaccine (6)[C].

Pediatric Considerations

Over-the-counter (OTC) cough and cold medications should not be used in children <6 years due to lack of efficacy and the risk of life-threatening side effects.

COMPLEMENTARY & ALTERNATIVE MEDICINE

No complementary, alternative, or integrative therapies are of proven benefit in

the prevention or treatment of RSV bronchiolitis.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Clinical judgment of the patient's degree of respiratory distress is the most important consideration. Ill-appearing infants should be hospitalized.
- Significant respiratory distress, an oxygen requirement to keep SpO_2 >90%, and the inability to hydrate orally are indications for admission.
- Mechanical ventilation is required in about 5% of infants hospitalized with RSV and 20% of children with underlying congenital heart disease, chronic lung disease, or immunosuppression.
- IV fluids: See "Treatment."
- No set criteria for discharge; patients should be recovering and demonstrate:
  - Stable respiratory status with no oxygen requirement
  - Ability to maintain oral intake and sustain hydration
  - Home resources adequate to support necessary home therapies, including caretaker ability to clear the infant's airway with bulb suctioning if needed
  - Adequate follow-up and patient education

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Primary care follow-up to ensure resolution

PATIENT EDUCATION

Bronchiolitis and Your Child, available at http://familydoctor.org/familydoctor/en/diseases-conditions/bronchiolitis.html

PROGNOSIS

Most patients with RSV infection recover fully within 7 to 10 days. Reinfection is common.

COMPLICATIONS

- Infants hospitalized for RSV may be at increased risk for recurrent wheezing and reduced pulmonary function, particularly during the 1st decade of life.

- Overall mortality for infants and children <24 months of age is <1%.
- Although the relationship between RSV and asthma is unclear, RSV bronchiolitis in infancy has been linked to subsequent asthma.

CODES

ICD10

- B97.4 Respiratory syncytial virus causing diseases classd elswhr
- J06.9 Acute upper respiratory infection, unspecified
- J21.0 Acute bronchiolitis due to respiratory syncytial virus

CLINICAL PEARLS

- RSV causes 50–90% of pediatric bronchiolitis.
- Hand sanitation is the primary step for preventing RSV in the general population.
- The diagnosis of RSV is clinical in most cases. Routine lab testing or radiology studies are not necessary.
- Treatment of RSV is usually supportive.
- Palivizumab should be used to prevent RSV in high-risk patients.

RESTLESS LEGS SYNDROME

Donald E. Watenpaugh, PhD • John R. Burk, MD

BASICS

DESCRIPTION

- Sensorimotor disorder consisting of a strong urge to move the legs, usually with paresthesia (1)[A]
- Symptoms emerge during inactivity.
- Movement relieves symptoms, but they soon recur with inactivity.
- Symptoms occur preferentially in the evening/night.
- Symptoms may involve the arms or be more generalized.
- Patient may also report involuntary leg jerks (1)[A].
- Associated with insomnia and/or functional impairment(s)
- Not solely accounted for by another disorder
- System(s) affected: musculoskeletal; nervous
- Synonym(s): Willis-Ekbom disease

EPIDEMIOLOGY

Incidence

- Onset at any age; increases with age
- Predominant sex: male = female (nulliparous); female (parous) two times > male
- May increase in summer (warm) months

Prevalence

- 4–15% of Caucasian adults; underdiagnosed
- 1–3% in children and adolescents
- Increases with age
- Lower in non-Caucasians (2)[B]

Pregnancy Considerations

10–30% prevalence; exacerbates existing restless legs syndrome (RLS)

ETIOLOGY AND PATHOPHYSIOLOGY

- Primary (early-onset) RLS: subcortical dopamine deficiency/dysmetabolism
- Late-onset (often secondary) RLS:
  - Iron deficiency and associated conditions
  - Chronic extremity tissue pathology/inflammation
  - Medications
- Most antidepressants (exceptions: bupropion and desipramine)
- Dopamine-blocking antiemetics (e.g., metoclopramide, prochlorperazine)
- Some antiepileptic agents (e.g., phenytoin)
- Phenothiazine antipsychotics; donepezil
- Theophylline and other xanthines
- Antihistamines/over-the-counter (OTC) cold preparations (e.g., pseudoephedrine)
- Adrenergics, stimulants

Genetics

- Early-onset RLS heritability: ~50%
- Genetically heterogenous
  - Susceptibility loci: 2p14, 2q, 6p21.2, 9p, 12q, 14q, 15q23, and 20p
  - Genes: *MEIS1*, *MAP2K5*/LBXCOR1, and *BTBD9*

RISK FACTORS

- Family history
- Aging
- Chronic inactivity
- Inadequate sleep
- Associated conditions (see "Commonly Associated Conditions")
- Certain medications (see "Etiology and Pathophysiology")

GENERAL PREVENTION

- Regular physical activity/exercise
- Adequate sleep
- Avoid evening caffeine, alcohol, tobacco.
- Avoid late-day use of medications that cause RLS.

COMMONLY ASSOCIATED CONDITIONS

- Periodic limb movements of sleep, insomnia, sleep walking, other

parasomnias, delayed sleep phase
- Iron deficiency, renal disease/uremia/dialysis, gastric surgery, liver disease
- Parkinson disease, multiple sclerosis, peripheral neuropathy, Machado-Joseph disease, migraine
- Orthopedic problems, arthritis, fibromyalgia
- Venous insufficiency/peripheral vascular disease, erectile dysfunction
- Pulmonary hypertension, lung transplantation, chronic obstructive pulmonary disease (COPD)
- ADHD, anxiety/depression, “sundowning”
- Pregnancy (especially if Fe- or folate-deficient) (3)[A]

DIAGNOSIS

- Depends on history, yet often “difficult to describe”
- May go undiagnosed for years by multiple doctors

HISTORY

- Signs/symptoms (see also “Description”) (1)[A]
  - Limited to evening, night
  - Example descriptions: burning, achy, itching, antsy, “can’t get comfortable”
  - Painful in ~35% of patients
  - Discomfort associated with overwhelming urge to move and relieved by movement
  - Urge to move may be the only “discomfort.”
  - Movement frequency every 10 to 90 seconds (mean ~25 seconds)
  - Some patients must get up and walk.
  - May involve arms or, rarely, whole body
  - Periodic movements in sleep in ~80% of patients.
  - Insomnia, fatigue, anxiety
- Severity range: from rare, minor problem to daily severe impact on quality of life
- Early-onset RLS (before age 45 years) progresses slowly.
- Late-onset RLS (1)[A]
  - Sometimes secondary to other factors

  - Tends to progress more rapidly
  - May resolve to extent that cause(s) resolve

Pediatric Considerations

Consider child's own words in describing symptoms and these additional supportive findings (1)[A]:

- Insomnia or sleep disturbance
- RLS in immediate biologic relative
- Periodic limb movements during sleep

Geriatric Considerations

For diagnosis in the cognitively impaired

- Rubbing or kneading the legs in evening
- Evening hyperactivity (foot tapping, pacing, fidgeting, tossing/turning in bed)

DIFFERENTIAL DIAGNOSIS

- Claudication: Movement does not relieve pain and may worsen it.
- Motor neuron disease fasciculation/tremor: no discomfort or circadian pattern
- Peripheral neuropathy: usually no circadian pattern; unresponsive to dopamine agonists
- Dermatitis/pruritus: movement only to scratch; no circadian pattern
- Sleep-related leg cramps: isolated and very painful muscle contracture
- Periodic limb movement disorder: no wakeful movements
- Sleep starts: isolated involuntary events
- Rhythmic movement sleep disorder: movement periodicity faster than RLS
- Growing pains: no urge to move or relief by movement; circadian pattern opposite RLS
- ADHD: no sleep disorders or complaints in diagnostic criteria

DIAGNOSTIC TESTS & INTERPRETATION

Serum ferritin to assess for iron deficiency

Diagnostic Procedures/Other

- Sleep study helpful but not required
  - Frequent, periodic movements during wake
- Suggested immobilization test

  - Conducted before nocturnal polysomnography
  - Patient attempts to sit still in bed for 1 hour.
  - >40 movements per hour suggest RLS.
- Ankle actigraphy for in-home use
- Electromyography, nerve conduction studies for peripheral neuropathy, radiculopathy

Test Interpretation

- Serum ferritin should be >75 ng/mL.
- Transferrin saturation should be >16%.

TREATMENT

First-line treatments

- Prescribed daily exercise (3,4,5,6,7,8)[A]; adequate sleep
- Correct iron deficiency.
- Dopaminergic medications
- For secondary RLS, treat cause(s).
- Multiple possible causes are *not* mutually exclusive.

GENERAL MEASURES

- If iron deficient, supplement:
  - 325 mg $FeSO_4$ TID
  - Repletion requires months.
- Daily exercise. However, avoid unusual activity that may exacerbate symptoms.
- Regular and replete sleep
- Hot bath and leg massage
- Warm the legs (long heavy socks, electric blanket).
- Intense mental activity (games, puzzles, etc.)
- Avoid exacerbating factors.

MEDICATION

- Titrate to minimum dose necessary to fully control symptoms.
- Preferentially use longer acting/extended-release options.

- Daytime sleepiness unusual with doses and timing for RLS
- Severe/refractory RLS may require combination therapy (4,5,6)[A].

First Line

- Dopamine agonists (4,5,6)[A]:
  - Pramipexole (Mirapex): 0.125 to 0.5 mg 1 hour before symptoms; titrate by 0.125 mg.
  - Ropinirole (Requip): 0.25 to 4 mg 1 hour before symptoms; titrate by 0.25 mg.
  - Divide dose for evening and bedtime symptoms.
  - Transdermal rotigotine (Neupro): 1 to 3 mg/24 hour patch; initiate with 1 mg/day; titrate by 1 mg weekly
  - Avoid dopamine agonists in psychotic patients, particularly if taking dopamine antagonists.
  - Add a different class of medication before exceeding dopamine agonist recommended dose.
- $\alpha 2\delta$ ligands (4,5,6)[A]:
  - Gabapentin enacarbil (Horizant): 600 mg every day ~5:00 PM (4,5)[A]
  - Pregabalin (Lyrica): 50 to 300 mg/day (off-label)

Second Line

Off-label (4,5,6)[B]

- Other anticonvulsants (for comorbid neuropathy).
  - Carbamazepine: 200 to 800 mg/day
- Opioids (low risk of tolerance/addiction at bedtime)
  - Hydrocodone: 5 to 20 mg/day
  - Tramadol: 50 mg/day
  - Oxycodone: 2.5 to 20 mg/day
- Benzodiazepines and agonists (for associated insomnia or anxiety)
  - Clonazepam (Klonopin): 0.5 to 3 mg/day
  - Temazepam, triazolam, alprazolam, zaleplon, zolpidem, and diazepam
- Short-acting dopamine agonists
  - Carbidopa-levodopa (Sinemet or Sinemet CR): 10/100 to 25/250; PRN for sporadic symptoms

Pregnancy Considerations

- Initial approach: nonpharmacologic therapies, assess/correct iron deficiency
- Avoid medications class C or D.
- In 3rd trimester, may consider low-dose clonazepam, clonidine, or opioids (3) [B]

Pediatric Considerations

- First-line treatment: nonpharmacologic therapies, assess/correct iron deficiency
- Low-dose clonidine or clonazepam may be considered.

Geriatric Considerations

- Avoid medications that cause dizziness or unsteadiness.
- Many medications given to elderly cause/exacerbate RLS.

ISSUES FOR REFERRAL

- Severe, intractable symptoms
- Augmentation response to dopaminergic therapy
- Peripheral neuropathy; orthopedic problems
- Peripheral vascular disease; intransigent iron deficiency

ADDITIONAL THERAPIES

- Vitamin, mineral supplements: Ca, Mg, vitamin B_{12}, folate
- Clonidine: 0.05 to 0.1 mg/day
- Baclofen: 20 to 80 mg/day
- Methadone: 5 to 10 mg/day
- Oxycodone PR-Naloxone PR: 10 or 5 mg/day
- Prescription or OTC hypnotics

SURGERY/OTHER PROCEDURES

For orthopedic, neuropathic, or leg vascular disease (laser ablation, sclerotherapy, etc.)

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Relaxis leg vibration device (FDA approved; see http://myrelaxis.com)
- Sequential pneumatic leg compression
- Enhanced external counterpulsation

- Compression stockings
- Acupuncture
- MicroVas therapy
- Near-infrared light (7)[B]

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Can prolong hospitalization and/or compromise outcomes (8)
- Addition/withdrawal of medications exacerbating/treating RLS
- Control RLS especially after orthopedic procedures.
- Changes in medical status may require medication changes (e.g., Mirapex contraindicated in renal failure, Requip contraindicated in liver disease).
- Iron infusion when oral Fe fails or contraindicated.
- When NPO, consider IV opiates.
- Evening walks, hot baths, leg massage, and warming
- Sleep interruption risks prolonged wakefulness.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- At 2-week intervals until stable, then annually
- If taking iron, remeasure ferritin.
- If status changes, assess for associated conditions and medications.

DIET

Avoid evening caffeine and alcohol.

PATIENT EDUCATION

- Restless Legs Syndrome Foundation: www.rls.org
- National Sleep Foundation: sleepfoundation.org
- American Academy of Sleep Medicine: http://sleepeducation.com/

PROGNOSIS

- Early-onset: lifelong condition with no current cure

- Late-onset/secondary: may subside with resolution of precipitating factors
- Current therapies usually control symptoms

COMPLICATIONS

- Vicious cycle between sleep loss from RLS and exacerbation of RLS by sleep loss
- Augmentation of symptoms from prolonged dopaminergic therapy
  - Symptoms increase in severity, occur earlier, and/or spread.
  - Higher doses increase risk.
  - Highest risk from daily levodopa or Sinemet
  - Iron deficiency increases risk.
  - Add alternative medication and then slowly down-titrate dopamine agonist.
- Obsessive-compulsive or impulse-control disorders from dopamine agonists
- Iatrogenic RLS (from antidepressants, etc.)

SEE ALSO

- Periodic Limb Movement Disorder
- Algorithm: Restless Legs Syndrome

CODES

ICD10

G25.81 Restless legs syndrome

CLINICAL PEARLS

- Insomnia with frequent tossing/turning and difficulty “getting comfortable” is often RLS.
- Many antidepressants, antipsychotics, antiemetics, and antihistamines cause or exacerbate RLS.
- Titrate medication for RLS, especially dopaminergics, only up to the minimum dose necessary to control symptoms.

- RLS may interfere with use of positive airway pressure to treat obstructive sleep apnea.
- RLS and other sleep disorders may cause ADHD.

RETINAL DETACHMENT

Richard W. Allinson, MD

BASICS

DESCRIPTION

- Separation of the sensory retina from the underlying retinal pigment epithelium
- Rhegmatogenous retinal detachment (RRD): most common type; occurs when the fluid vitreous gains access to the subretinal space through a break in the retina (Greek *rhegma*, "rent")
- Exudative or serous detachment: occurs in the absence of a retinal break, usually in association with inflammation or a tumor
- Traction detachment: Vitreoretinal adhesions mechanically pull the retina from the retinal pigment epithelium. The most common cause is proliferative diabetic retinopathy.
- System(s) affected: nervous

EPIDEMIOLOGY

Incidence

- Predominant age: Incidence increases with age.
- Predominant sex: male > female (3:2)
- Per year: 1/10,000 in patients who have not had cataract surgery

Prevalence

After cataract surgery, 1–3% of patients will develop a retinal detachment.

ETIOLOGY AND PATHOPHYSIOLOGY

- Traction from a posterior vitreous detachment (PVD) causes most retinal tears. With aging, vitreous gel liquefies, leading to separation of the vitreous from the retina. The vitreous gel remains attached at the vitreous base, in the retinal periphery, resulting in vitreous traction that produces tears in the retinal periphery. There is an ~15% chance of developing a retinal tear from a PVD.
- PVD associated with vitreous hemorrhage has a high incidence of retinal

tears.
- Exudative detachment
  - Tumors
  - Inflammatory diseases (Vogt-Koyanagi-Harada disease, posterior scleritis)
  - Miscellaneous (central serous retinopathy, uveal effusion syndrome, malignant hypertension, drugs—ipilimumab)
- Traction detachment
  - Proliferative diabetic retinopathy
  - Cicatricial retinopathy of prematurity
  - Proliferative sickle-cell retinopathy
- Penetrating trauma

Genetics

- Most cases are sporadic.
- There is an increased risk of RRD if a sibling has been affected by this condition. The risk increases with higher levels of myopia in the family history.

RISK FACTORS

- Myopia (>5 diopters)
- Aphakia or pseudophakia
  - In patients undergoing small-incision coaxial phacoemulsification with high myopia (axial length ≥26 mm), the incidence of retinal detachment is 2.7%.
- PVD and associated conditions (e.g., aphakia, inflammatory disease, and trauma)
- Trauma
- Retinal detachment in fellow eye
- Lattice degeneration: a vitreoretinal abnormality found in 6–10% of the general population
- Glaucoma: 4–7% of patients with retinal detachment have chronic open-angle glaucoma.
- Vitreoretinal tufts: Peripheral retinal tufts are caused by focal areas of vitreous traction.
- Meridional folds: Redundant retina usually is found in the supranasal quadrant.

GENERAL PREVENTION

Patients at risk for retinal detachment should have regular ophthalmologic exams.

Geriatric Considerations

- PVD
- Cataract surgery

Pediatric Considerations

Usually associated with underlying vitreoretinal disorders and/or retinopathy of prematurity

COMMONLY ASSOCIATED CONDITIONS

- Lattice degeneration
- High myopia
- Cataract surgery
- Glaucoma
- History of retinal detachment in the fellow eye
- Trauma

Pregnancy Considerations

Preeclampsia/eclampsia may be associated with exudative retinal detachment. No intervention is indicated, provided hypertension is controlled. Prognosis is usually good.

DIAGNOSIS

HISTORY

- Sudden flashes (photopsia)
- Shower of floaters
- Visual field loss: “curtain coming across vision”
- Central vision will be preserved if the macula is not detached.
- Poor visual acuity (20/200 or worse), with loss of central vision when macula is detached

PHYSICAL EXAM

- Slit-lamp exam
- Dilated fundus exam with binocular indirect ophthalmoscopy

DIFFERENTIAL DIAGNOSIS

Retinoschisis (splitting of the retina)

- Vitreous cells and vitreous hemorrhage are found rarely in the vitreous with retinoschisis, whereas they are seen commonly in RRD.
- Retinoschisis usually has a smooth surface and is dome-shaped, whereas RRD often has a corrugated, irregular surface.

DIAGNOSTIC TESTS & INTERPRETATION

Visual field testing: differentiates RRD from retinoschisis. An absolute scotoma is seen in retinoschisis, whereas RRD causes a relative scotoma.

Initial Tests (lab, imaging)

- Ultrasound (US) can demonstrate a detached retina and may be helpful when the retina cannot be visualized directly (e.g., with cataracts or vitreous hemorrhage).
- Fluorescein dye leakage can be seen in exudative retinal detachment; caused by central serous retinopathy and other inflammatory conditions

Test Interpretation

- Elevation of the neurosensory retina from the underlying retinal pigment epithelium
- Elevation of retina associated with ≥1 retinal tears in RRD or elevation of the retina without tears in exudative detachment
- In 3–10% of patients with presumed RRD, no definite retinal break is found.
- Tenting of the retina without retinal tears in traction detachment
- Pigmented cells within the vitreous (“tobacco dust”)

TREATMENT

GENERAL MEASURES

- Not all retinal tears or breaks need to be treated:
  - Flap or horseshoe tears in symptomatic patients (e.g., patients with flashes or floaters) are treated frequently.

  - Operculated holes in symptomatic patients are treated sometimes.
  - Atrophic holes in symptomatic patients are treated rarely.
- Lattice degeneration with or without holes within the lattice in an asymptomatic patient with prior retinal detachment in the fellow eye may be treated prophylactically.
- Flap retinal tears in asymptomatic patients frequently are treated prophylactically.
- Exudative detachments usually are managed by treating underlying disorder.
- Traction detachments usually are managed by observation. If the fovea is involved, a vitrectomy is needed.

MEDICATION

First Line

- Intraocular gases
  - Air
  - Perfluoropropane (C_3F_8)
  - Sulfur hexafluoride (SF_6)
- Perfluorocarbon liquids
- Silicone oil
- Contraindications to intraocular gas: patients with poorly controlled glaucoma
- Precautions with intraocular gas: Expanding intraocular gas bubble increases intraocular pressure; therefore, avoid higher altitudes.
- Significant possible interactions with intraocular gas: Nitrous oxide used in general anesthesia can expand an intraocular gas bubble.

Second Line

Steroids may cause worsening of central serous retinopathy.

SURGERY/OTHER PROCEDURES

- Timing of repairs
  - Macula attached: within 24 hours if possible. If the detachment is peripheral and does not have features suggestive of rapid progression (e.g., large and/or superior tears), repair can be performed within a few days.
- Macula recently detached: within 10 days of development of a macula-off retinal detachment (1)[B]

  - Old macular detachment: elective repair within 2 weeks
- If a retinal break has led to the development of a retinal detachment, surgery is needed. Surgical options (and combinations) include the following:
  - Demarcation laser treatment
  - Pneumatic retinopexy: Head positioning is required postoperatively.
  - Scleral buckle
  - Vitrectomy
  - Perfluorocarbon liquids for giant tears (circumferential tears ≥90 degrees)
  - Silicone oil for complex repairs
- Anesthesia: local or general
- RRD may have >1 break. If any retinal break is not closed at the time of surgery, the surgery will fail.
- Additional surgery may be required if the retina redetaches secondary to a new retinal break or because of proliferative vitreoretinopathy (PVR).
- Adjuvant combination therapy using 5-fluorouracil (5-FU) and low-molecular-weight heparin (LMWH) may reduce the incidence of PVR in patients undergoing vitrectomy for RRD who are at a greater risk of developing PVR, such as patients with uveitis, but does not seem to be of benefit in cases of established PVR.
- If a vitreous hemorrhage is present, presumably from a retinal tear and the fundus cannot be well visualized, consideration can be given for early vitrectomy (2)[C].
  - Patients who underwent pars plana vitrectomy (PPV) within the first week of presentation had a significantly lower risk of having a macula-off RD.
  - Both phakic and pseudophakic patients had a similar chance of developing a retinal detachment. Phakic patients who underwent PPV had a higher chance of requiring subsequent cataract surgery.
- There is a trend toward primary vitrectomy in the management of RRD. Eyes undergoing PPV for primary RRD repair may not need the addition of a scleral buckle (3)[B].
- There is no statistical difference in the primary reattachment rate between eyes treated with PPV and scleral buckle for RRD in both phakic and pseudophakic/aphakic eyes (4)[A].
- Patients with RRD who are at high risk for PVR (retinal detachment in two or

more quadrants, retinal tears >1 clock hour, preoperative PVR, or vitreous hemorrhage). PPV-scleral buckle was associated with higher rates of anatomical success compared to PPV alone (5)[B].

- There is a reduced incidence of intraoperative retinal tear formation using a transconjunctival cannulated PPV system compared to the standard 20-gauge system requiring suture closure.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Recognition of condition is key (see "Diagnosis").
- Refer to an ophthalmologist for exam and treatment, if indicated.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Bed rest prior to surgery
- Postoperatively, if intraocular gas has been used, the patient may need specific head positioning and should not travel to high altitudes.

Patient Monitoring

- Alert ophthalmologist if there is new onset of floaters or flashes, increase in floaters or flashes, sudden shower of floaters, curtain or shadow in the peripheral visual field, or reduced vision.
- Patients with acute symptomatic PVD should be reexamined by the ophthalmologist in 3 to 4 weeks. The development of a retinal detachment is unlikely if no retinal tears are present on reexamination in 3 to 4 weeks.
- If acute symptomatic PVD is associated with gross vitreous hemorrhage that interferes with complete visualization of the retinal periphery by indirect ophthalmoscopy, the patient should be reexamined at short intervals with indirect ophthalmoscopy until the entire retinal periphery can be observed. Early PPV can be considered.
- If the examiner is not certain whether the retina is detached in the presence of opaque medium, US should be performed.

DIET

NPO if surgery is imminent

PATIENT EDUCATION

American Academy of Ophthalmology, 655 E. Beach Street, San Francisco, CA 94109-1336

PROGNOSIS

- RRD
  - 90% of retinal detachments can be reattached successfully after ≥1 surgical procedure. Postoperative visual acuity depends primarily on the status of the macula preoperatively. Also important is the length of time between the detachment and the repair (75% of eyes with macular detachments of <1 week will obtain a final visual acuity of 20/70 or better).
  - 87% of eyes with a retinal detachment not involving the macula attain a visual acuity of 20/50 or better postoperatively. 37% of eyes with a detached macula preoperatively attain 20/50 or better vision postoperatively.
  - In 10–15% of successfully repaired retinal detachments not involving the macula preoperatively, visual acuity does not return to the preoperative level. This decrease is secondary to complications such as macular edema and macular pucker.
  - Failed primary pneumatic retinopexy selects for RDs that are inherently more difficult to reattach.
- Risk factors associated with primary RRD repair failure include choroidal detachment, significant hypotony, grade C-1 PVR, four detached quadrants, and large or giant retinal breaks (6)[B]. Additional risk factors associated with primary RRD repair failure include increased number of breaks and inferior location of retinal breaks (7)[B].
- Tractional retinal detachment
  - When not involving the fovea, the patient usually can be observed because it is uncommon for these to extend into the fovea.
- Exudative retinal detachment
  - Management is usually nonsurgical.
  - The presence of shifting fluid is highly suggestive of an exudative retinal detachment. Fixed retinal folds, which are indicative of PVR, are seen

rarely in exudative retinal detachment. If the underlying condition is treated, the prognosis generally is good.

COMPLICATIONS

- PVR is the most common cause of failed retinal detachment repair; 10–15% of retinas that reattach initially after retinal surgery will redetach subsequently, usually within 6 weeks, as a result of cellular proliferation and contraction on the retinal surface.
- Partial or total loss of vision due to macular detachment and/or PVR
- Moderate to severe forms of PVR usually are treated with PPV and fluid–gas exchange. If a segmental scleral buckle was placed at the initial procedure, it may need to be revised.
- Primary retinectomy can be used in cases of PVR without a scleral buckle (8) [C].
- Scleral buckles may erode the overlying conjunctiva and lead to an infection.
- Optic neuropathy after PPV for macula-sparing primary RRD

Retinopathy, Diabetic

CODES

ICD10

- H33.001 Unspecified retinal detachment with retinal break, right eye
- H33.019 Retinal detachment with single break, unspecified eye
- H33.20 Serous retinal detachment, unspecified eye

CLINICAL PEARLS

- If a patient complains of the new onset of floaters or flashes of light, the patient should undergo a dilated eye exam to rule out a retinal tear or retinal detachment.
- There is an increased risk of retinal detachment after cataract surgery.
- PVR can result in redetachment of the retina after an initially successful repair.

RETINOPATHY, DIABETIC

Richard W. Allinson, MD

BASICS

DESCRIPTION

- Noninflammatory retinal disorder characterized by retinal capillary closure and microaneurysms. Retinal ischemia leads to release of a vasoproliferative factor, stimulating neovascularization on retina, optic nerve, or iris.
- Most patients with diabetes mellitus (DM) will develop diabetic retinopathy (DR). It is the leading cause of new cases of legal blindness among residents in the United States between the ages of 20 and 64 years.
- DR can be divided into three stages.
  - Nonproliferative (background)
  - Severe nonproliferative (preproliferative)
  - Proliferative
- System(s) affected: nervous

Geriatric Considerations

Prevalence will increase, as population generally ages and patients with diabetes live longer.

Pregnancy Considerations

- Pregnancy can exacerbate condition.
- Pregnant diabetic women should be examined in 1st trimester and then every 3 months until delivery.

EPIDEMIOLOGY

Incidence

- Peak incidence of type 1, juvenile-onset DM is between the ages of 12 and 15 years.
- Peak incidence of type 2, adult-onset DM is between the ages of 50 and 70 years.
- Incidence of DR is directly related to the duration of diabetes.

- <10 years of age, it is unusual to see DR, regardless of DM duration.

Prevalence

- 6.6% of the U.S. population between ages of 20 and 74 years has DM.
- ~25% of the diabetic population has some form of DR.
- Predominant age
  - Risk increases after puberty.
  - 2/3 of juvenile-onset diabetics who have had DM for at least 35 years will develop proliferative DR (PDR), and 1/3 will develop macular edema. Proportions are reversed for adult-onset diabetes.
- Predominant sex: male = female (type 1, juvenile-onset DM); female > male (type 2)

ETIOLOGY AND PATHOPHYSIOLOGY

- Related to development of diabetic microaneurysms and microvascular abnormalities
- Reduction in perifoveal capillary blood flow velocity, perifoveal capillary occlusion, and increased retinal thickness at the central fovea in diabetic patients are associated with visual impairment in patients with diabetic macular edema (DME).

RISK FACTORS

- Duration of DM (usually >10 years)
- Poor glycemic control
- Pregnancy
- Renal disease
- Systemic hypertension (HTN)
- Smoking
- Elevated lipid levels associated with increased risk of retinal lipid deposits (hard exudates)
- Myopic eyes (eyes with longer axial length) have a lower risk of DR.

GENERAL PREVENTION

- See "General Measures."
- Monitor and control of blood glucose.
- Schedule yearly ophthalmologic eye exams.

COMMONLY ASSOCIATED CONDITIONS

- Glaucoma
- Cataracts
- Retinal detachment
- Vitreous hemorrhage (VH)
- Disc edema (diabetic papillopathy); may occur in type 1 and type 2 DM

DIAGNOSIS

HISTORY

Diabetic patients should be encouraged to have an annual ophthalmologic exam because early eye changes may be asymptomatic.

PHYSICAL EXAM

- Eye exam: measurement of visual acuity and documentation of the status of the iris, lens, vitreous, and fundus
- Nonproliferative (background) DR
  - Microaneurysms
  - Intraretinal hemorrhage
  - Macular edema causing decrease in central vision
  - Lipid deposits
- Severe nonproliferative (preproliferative) DR
  - Nerve fiber layer infarctions (“cotton wool spots”)
  - Venous beading
  - Venous dilatation
  - Intraretinal microvascular abnormalities (IRMA)
  - Extensive retinal hemorrhage
  - The Early Treatment Diabetic Retinopathy Study (ETDRS) developed the 4:2:1 rule for severe nonproliferative diabetic retinopathy (NPDR). Severe NPDR was defined as having any one of the following features:
    - Severe intraretinal hemorrhages and microaneurysms in 4 quadrants
    - Venous beading in 2 or more quadrants
    - IRMAs in 1 or more quadrants
- PDR

  - New blood vessel proliferation (neovascularization) on the retinal surface, optic nerve, and iris
  - Visual loss caused by VH, traction retinal detachment. Neovascularization can result in contracting fibrovascular tissue on a vitreous scaffold which can lead to VH and traction retinal detachment.

GENERAL MEASURES

- The Diabetes Control and Complications Trial (DCCT) recommended that for most patients with insulin-dependent DM, blood glucose levels should be as close to the nondiabetic range as is safe to reduce the risk and rate of progression of DR.
  - In the DCCT, insulin-dependent DM patients were randomly assigned into either conventional or intensive insulin treatment. Conventional treatment consisted of one to two daily insulin injections, with daily self-monitoring of urine/blood glucose. Intensive treatment consisted of insulin administered ≥3 times daily by injection/an external pump, with self-monitored blood glucose levels measured at least 4 times per day.
  - The DCCT demonstrated that intensive insulin therapy reduced the risk of DME and retinal neovascularization. The benefit of intensive insulin therapy with the reduced risk of DR-associated microvascular complications persist for at least 10 years.
- In the DCCT, intensive insulin therapy was more effective in reducing the risk of progression of DR in the less advanced stages. However, advanced DR also benefited from the intensive insulin therapy.
- Intensive therapy in patients with type 1 diabetes is associated with a substantial reduction in the long-term risk of ocular surgery (1)[A].
- The ETDRS demonstrated that aspirin therapy did not prevent the development of PDR or reduce the risk of visual loss associated with DR.
- Microvascular complications, including PDR, are increased when blood sugar levels are ≥200 mg/dL.
- Cataracts are more common among those with DM. Try to delay cataract surgery in DM patients with retinopathy until the symptoms are severe. Cataract surgery can cause retinopathy to worsen and increase the risk for development of DME.

- HTN has a detrimental effect on DR and must be controlled.

DIFFERENTIAL DIAGNOSIS

Other causes of retinopathy (e.g., radiation, retinal venous obstruction, HTN)

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other

- Fluorescein angiography demonstrates retinal nonperfusion, retinal leakage, and PDR.
- Optical coherence tomography (OCT) can be used to help detect DME by measuring retinal thickness.

Test Interpretation

- Increased capillary permeability
- Microaneurysms
- Hemorrhages in retina
- Exudates in retina
- Capillary nonperfusion

TREATMENT

MEDICATION

- Treatment with the angiotensin-receptor blocker candesartan has been shown to result in regression of DR in some patients.
- Nutritional antioxidant intake of vitamins C and E and of β-carotene has no protective effect on DR.
- Atorvastatin may reduce the severity of lipid deposits with clinically significant diabetic macular edema (CSDME) in type 2 DM and dyslipidemia.
- Aspirin
  - Does not alter progression of DR
  - Does not increase the risk of VH

SURGERY/OTHER PROCEDURES

- Intravitreal anti-vascular endothelial growth factor (VEGF) is first-line treatment for DME:

- Ranibizumab, an antibody fragment that binds vascular VEGF, can be used to treat DME when injected intravitreally. Ranibizumab 0.3 mg given monthly to treat DME resulted in improved vision and reduced central foveal thickness (2)[A]. It is indicated for DME and for DR in patients with DME.
  - Anti-VEGF therapy is the preferred method of treatment for visual impairment resulting from DME. Anti-VEGF treatment results in superior clinical outcomes compared to laser photocoagulation for DME (3)[A].
  - Intravitreal ranibizumab treatment for DME may also improve DR severity and reduce the risk of DR progression (4)[A].
- Bevacizumab, a full-length antibody that binds VEGF, can be used to treat DME when injected intravitreally. This is an off-label use.
- Aflibercept, a decoy receptor for VEGF that inhibits all isoforms of VEGF-A and placental growth factor. Aflibercept 2 mg (0.05 mL) injected intravitreally every 4 weeks for the first 5 injections followed by 2 mg (0.05 mL) intravitreally once every 8 weeks. It is indicated for patients with DME and for DR in patients with DME.
  - Intravitreal aflibercept injection (IAI) has demonstrated significant superiority in functional and anatomic end points over macular laser photocoagulation (5)[A].
  - At worse levels of initial visual acuity (20/50 or worse) in patients with DME, IAI was more effective in improving vision than ranibizumab or bevacizumab with 1-year follow-up. When the initial vision loss was mild (20/32 to 20/40) in patients with DME, there was no significant difference between aflibercept, ranibizumab, and bevacizumab (6)[A].
- Vitrectomy may benefit some with diffuse macular edema. This may apply especially to eyes with vitreomacular traction found on OCT and with persistent CSDME.
- Intravitreal triamcinolone may be used for DM-related macular edema that fails laser treatment. No long-term benefit of intravitreal triamcinolone relative to focal/grid photocoagulation in patients with CSDME. This is an off-label use.
- Intraocular steroid implants for DME. A dexamethasone implant and a

fluocinolone acetonide implant. Complications of these implants include cataract and glaucoma.

- Treatment for PDR:
  - Thermal laser photocoagulation in a panretinal pattern is the primary form of treatment for PDR. The goal of panretinal photocoagulation (PRP) is regression or involution of neovascularization. PRP destroys ischemic retina and decreases the neovascular stimulus.
  - The Diabetic Retinopathy Study demonstrated that when PRP was used to treat PDR or severe NPDR, eyes treated with PRP had a reduction of 50% or more in the rates of severe vision loss compared with untreated control eyes. In certain subgroups, the incidence of severe visual loss in untreated eyes was as high as 36.9% at 2 years.
  - Patients with CSDME and high-risk proliferative disease can have simultaneous focal and PRP without adversely affecting the visual outcome.
  - Pars Plana Vitrectomy (PPV): recommended for patients with severe PDR, traction retinal detachment involving the macula, and nonclearing VH
    - The Diabetic Retinopathy Vitrectomy Study (DRVS) demonstrated the benefits of early PPV (1 to 6 months after onset of VH) in type 1 diabetes and for eyes with very severe PDR.
    - Immediate PPV with endolaser may be considered for PDR-associated VH (<30 days) (7)[C].
    - Preoperative bevacizumab can be used as an adjuvant to vitrectomy for complications of proliferative DR. This is an off-label use.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Scheduled ophthalmologic eye exams

- Yearly follow-up if no retinopathy
- Every 6 months with background DR
- At least every 3 to 4 months with pre-PDR
- Every 2 to 3 months with active PDR
- Patients with DME should be followed every 4 to 6 weeks.

DIET

Follow prescribed diet for patients with diabetes.

PATIENT EDUCATION

- Patient education should include regular ophthalmic exams.
- Stress importance of strict blood glucose control through diet, exercise, drugs/insulin, and monitoring of blood glucose.

PROGNOSIS

If the condition is diagnosed and treated early in development, outlook is good. If treatment is delayed, blindness may result.

COMPLICATIONS

- Repeated intravitreal injection of anti-VEGF therapy may increase the risk of sustained intraocular pressure elevation and the possible need for ocular hypotensive treatment (8)[A].
- Blindness

CODES

ICD10

- E11.319 Type 2 diabetes mellitus with unspecified diabetic retinopathy without macular edema
- E10.319 Type 1 diabetes mellitus with unspecified diabetic retinopathy without macular edema
- E10.329 Type 1 diab w mild nonprlf diabetic rtnop w/o macular edema

CLINICAL PEARLS

- Options for the treatment of diffuse macular edema include focal laser treatment, intravitreal triamcinolone, intravitreal ranibizumab, intravitreal bevacizumab, intravitreal aflibercept, intraocular steroid implants, and vitrectomy.
- High BP should be controlled to reduce the risk of diabetic eye complications.
- Blood glucose levels should be well controlled to help reduce the risk and rate of DR progression.
- Schedule yearly ophthalmologic eye exams.

RH INCOMPATIBILITY

Kirsten A. Winnie, MD • Jennifer G. Chang, MD

BASICS

DESCRIPTION

- Antibody-mediated destruction of red blood cells (RBCs) that bear Rh surface antigens in individuals who lack the antigens and have become isoimmunized (sensitized) to them
- System(s) affected: hematologic/lymphatic/immunologic
- Synonym(s): Rh isoimmunization; Rh alloimmunization; Rh sensitization

EPIDEMIOLOGY

Incidence

Predominant age and sex: affects fetuses/neonates of isoimmunized, childbearing females

ETIOLOGY AND PATHOPHYSIOLOGY

- Circulating antibodies to Rh antigens (transplacentally transferred antibodies in the case of a fetus/newborn) attach to Rh antigens on RBCs.
- Immune-mediated destruction of RBCs leads to hemolysis, anemia, and increased bilirubin production.
- Transfusion of Rh-positive blood to Rh-negative recipient
- Maternal exposure to fetal Rh antigens, either antepartum or intrapartum
- Most commonly seen in the Rh-positive fetus or infant of an Rh-negative mother

Genetics

- Complex autosomal inheritance of polypeptide Rh antigens; three genetic loci with closely related genes carry an assortment of alleles: Dd, Cc, and Ee.
- Individuals who express the D antigen (also called *Rho* or *Rho[D]*) are considered Rh-positive. Individuals lacking the D antigen are Rh-negative.
- Variant D alleles (weak D and partial D) are heterogenous, altered forms of the D antigen. Some D variants are at risk of formation of anti-D antibodies,

whereas others are not. With current blood typing procedures, certain D variants likely to produce alloimmunization are typed as D-negative, although this does not include all genetic subtypes at risk of isoimmunization (1).

- Another variant D antigen, DEL, has been identified in some individuals (predominantly Asians) who are classified as Rh-negative by the usual assays. Although testing Rh-negative, these individuals are not likely to be sensitized by exposure to Rh-D antigens through pregnancy or transfusion and should be considered clinically Rh-positive (2).
- Antibodies may be produced to C, c, D, E, or e in individuals lacking the specific antigen; only D is strongly immunogenic (3).
- Isoimmunization to Rh antigens in susceptible individuals is acquired, not inherited.

RISK FACTORS

- ~15% of the white population and smaller fractions of other races are Rh-negative and susceptible to sensitization (4).
- Any Rh-positive pregnancy in an Rh-negative woman can result in sensitization.
- Weak D and partial D women are a heterogenous group. Although previously reported to be Rh positive and treated as such, alloimmunization has been reported and can result in HDFN or fatal hydrops fetalis (5).
- Native risk of isoimmunization after Rh-positive pregnancy had been estimated at ≤15% but seems to be decreasing.
- The risk of isoimmunization antepartum is only 1–2%.
- The risk of isoimmunization is 1–2% after spontaneous abortion and 4–5% after induced abortion (6).
- Use of Rho(D) immunoglobulin prophylaxis has reduced incidence of isoimmunization to <1% of susceptible pregnancies (7)[A].

GENERAL PREVENTION

- Blood typing (ABO and Rh) on all pregnant women and prior to blood transfusions
- Antibody screening early in pregnancy
- Rh immunoglobulin prevents only sensitization to the D antigen.
- For prophylaxis, Rho(D) immunoglobulin (RhIG, RhoGAM, HyperRHO,

Rhophylac) given to unsensitized, Rh-negative women after the following:
  - Spontaneous abortion
  - Induced abortion
  - Ectopic pregnancy
  - Antepartum hemorrhage
  - Trauma to abdomen
  - Amniocentesis
  - Chorionic villus sampling
  - Within 72 hours of delivery of an Rh-positive infant
  - Given routinely at 28 weeks' gestation
- Prophylaxis is to prevent sensitization affecting a subsequent pregnancy and has little effect on the current pregnancy.
- Dose for prophylaxis
  - 50-μg dose for events up to 12 weeks' gestation
  - 300-μg dose for events after 12 weeks' gestation
  - Higher doses may be required in the event of a large fetal–maternal hemorrhage (>30 mL of whole blood).

COMMONLY ASSOCIATED CONDITIONS

- Hemolytic disease of newborn
- Hydrops fetalis
- Neonatal jaundice
- Kernicterus
- See "Erythroblastosis Fetalis" topic.

DIAGNOSIS

PHYSICAL EXAM

- Jaundice of newborn
- Kernicterus
- Fetal hydrops or fetal death in utero if severe (see "Erythroblastosis Fetalis" topic)

DIFFERENTIAL DIAGNOSIS

- ABO incompatibility

- Other blood group (non-Rh) isoimmunization
- Nonimmune fetal hydrops
- Hereditary spherocytosis
- RBC enzyme defects

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Positive indirect Coombs test (antibody screen) during pregnancy
- Paternal blood type
- Kleihauer-Betke (fetal hemoglobin acid elution, Hb F slide elution) test to quantify an acute fetal–maternal bleed
- Flow cytometry using antibody to hemoglobin F is emerging as an alternative to the Kleihauer-Betke test to detect or quantify fetal–maternal bleed (8).
- Congenital or fetal anemia
- Blood type, direct Coombs test in newborn
- Cell-free fetal DNA (Cff DNA) test (see "Clinical Pearls")

Follow-Up Tests & Special Considerations

Prior administration of Rho(D) may lead to weakly (false-) positive indirect Coombs test in mother and direct Coombs test in infant.

TREATMENT

GENERAL MEASURES

- Depending on severity of involvement, treatment of fetus may include the following:
  - Intrauterine transfusion (9)[C]
  - Early delivery
- Treatment of newborn may include the following:
  - Exchange transfusion
  - Transfusion after delivery
  - Phototherapy
- Inconclusive evidence on efficacy of IVIG to reduce need for exchange transfusion (10)[A]

ISSUES FOR REFERRAL

Because of the specialized, somewhat hazardous treatment measures involved, pregnancies in Rh-sensitized women are usually managed at tertiary-care facilities with maternal fetal medicine specialists.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Initial monitoring of the newborn is inpatient or in special care nursery if treatment interventions are needed.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- In most cases, outpatient ambulatory management is appropriate during the antepartum period.
- Antibody titer measured at 20 weeks and every 4 weeks thereafter during pregnancy; a titer of ≥1:16 indicates the need for further testing (5).
- If the patient had a previously affected infant, an Rh-positive fetus in the current pregnancy should be considered at risk regardless of antibody titers (11).
  - Fetal heart rate testing/US to assess fetal status
  - Doppler US measurement of cerebral blood flow is now a suitable alternative to invasive tests (amniocentesis, cordocentesis) for diagnosing fetal anemia (11).
  - Umbilical blood sampling (cordocentesis) for fetal blood type, hematocrit, reticulocyte count, and presence of erythroblasts (5)
  - Amniocentesis for amniotic fluid bilirubin levels (5)
  - Amniocentesis for fetal lung maturity if early delivery is a treatment option (5).

PROGNOSIS

- With appropriate monitoring and treatment, infants born of severely affected pregnancies have a survival rate of >80% (11).

- Even with severe disease, the neurologic outcome of survivors is generally good (8)[C].
- Fetuses with hydrops have a higher mortality rate and higher risk of neurologic impairment (8)[C].
- Disease is likely to be more severe in affected subsequent pregnancies.

COMPLICATIONS

- Pregnancy loss from umbilical blood sampling
- Pregnancy loss from intrauterine transfusion
- Fetal distress requiring emergent delivery (12)

CODES

ICD10

- P55.0 Rh isoimmunization of newborn
- O36.0990 Maternal care for other rhesus isoimmunization, unspecified

trimester, not applicable or unspecified
- T80.40XA Rh incompat react due to tranfs of bld/bld prod, unsp, init

CLINICAL PEARLS

- If paternity is certain, determining that the father does not carry the Rh(D) blood group antigen eliminates the need to give RhIG prophylaxis during pregnancy or the need for special fetal surveillance if the mother is already sensitized.
- Cell-free fetal DNA (Cff DNA) testing has evolved as the standard practice in many European countries; it is available in the United States but is not a widely covered benefit. It allows detection of fetal Rh genotype with accuracy of 97.1%, sensitivity of 97.2%, and specificity of 96.8% (11).
- Cff DNA testing with selective administration of Rh immunoglobulin when the fetus tests Rh positive has been shown to be as effective at preventing new Rh sensitization when compared to routine administration of Rh-immunoglobulin to all Rh-negative women. Such an approach avoids unnecessary use of Rh immunoglobulin (13). Currently, routine administration of Rh immune globulin is more cost effective than use of Cff DNA testing in the United States (14).
- The dose of RhIG for prophylaxis is affected by gestational age. The fetal blood volume is only a few milliliters at 12 weeks' gestation. Therefore, a 50-μg dose of RhIG may be used for threatened, spontaneous, or induced abortions up to 12 weeks' gestation, instead of the standard 300-μg dose.

RHABDOMYOLYSIS

Caroline Tschibelu, MD • Chirag N. Shah, MD, FACEP

BASICS

DESCRIPTION

- Breakdown of skeletal muscle cells and release of intracellular contents into the circulation
- Rhabdomyolysis typically manifests with muscle aches, pains and weakness, and reddish brown (tea-colored) urine, but up to 50% of patients are asymptomatic.

EPIDEMIOLOGY

Incidence

Annually in the United States: 26,000 hospitalized cases

ETIOLOGY AND PATHOPHYSIOLOGY

- Direct muscle trauma (most common cause)
  - Crush injuries
  - Extended periods of muscle pressure (during surgery, unconscious from alcohol ingestion)
  - Burns, electrocution, lightning strike
- Muscle exertion
  - Intense and/or prolonged physical exercise (marathon runners, athletes, contact sports)
  - Seizures
  - Delirium tremens
- Drugs and toxins
  - Alcohol
  - Cocaine (most common recreational drug), methamphetamine, phencyclidine
  - Antipsychotics (due to neuroleptic malignant syndrome, malignant hyperthermia, and severe dystonia)
  - Zidovudine

  - Antimalarials
  - Heroin
  - HMG-CoA reductase inhibitors (statins) (risk <0.01%), higher with high dose and in combination with fibrates
  - Fibrates
  - Colchicine
  - Corticosteroids
  - Carbon monoxide
  - Snake envenomation
  - Bath salts (1)[B]
  - Synthetic cannabinoid: Abuse of synthetic marijuana has been associated with severe rhabdomyolysis (2)[C].
- Muscle ischemia
  - Thrombosis, embolism, sickle cell disease
  - Compartment syndrome
  - Tourniquets
- Infections
  - Viral: influenza A and B, coxsackievirus, HIV, varicella
  - Bacterial: *Streptococcus* or *Staphylococcus* sepsis, gas gangrene, necrotizing fasciitis, *Salmonella*, *Legionella*
  - Malaria
- Hypothermia
- Hyperthermia
- Autoimmune and genetic disorders
  - Polymyositis, dermatomyositis
  - Muscular dystrophies
  - Disorders of lipid metabolism (e.g., carnitine palmitoyltransferase deficiency)
  - Disorders of carbohydrate metabolism (i.e., phosphofructokinase deficiency, phosphoglycerate mutase, myophosphorylase deficiency, aka McArdle disease/deficiency)
  - Glycogen storage diseases (e.g., phosphorylase B kinase deficiency) and others (e.g., lactate dehydrogenase A deficiency)
- Metabolic and endocrinologic:

- Hypothyroidism or thyrotoxicosis
- Electrolyte imbalances (e.g., hyponatremia, hypernatremia, hypokalemia, hypocalcemia, hypophosphatemia)
- Diabetic ketoacidosis
- Hyperosmolar state

Genetics

- Hereditary causes of rhabdomyolysis are rare but should be suspected for children, patients with recurrent attacks, or patients who have attacks after minimal exertion, mild illness, or starvation.
- The main inherited disorders are described earlier in "Etiology and Pathophysiology."

RISK FACTORS

See "Etiology and Pathophysiology."

GENERAL PREVENTION

- Avoid excessive exertional muscle injury. Preventing hypovolemia is important to prevent renal hypoperfusion, acidemia, and subsequent renal failure.
- Avoid precipitating drugs, metabolic and electrolyte abnormalities.

DIAGNOSIS

HISTORY

- Crush injury: direct trauma, prolonged compression/immobility. Causes include motor vehicle accidents (MVA) and entrapment in collapsed buildings. The elderly are more susceptible to crush injury due to immobility and falls. Rhabdomyolysis usually occurs after 1 hour of immobilization, but cases reported with compression lasting <20 minutes.
- Possible history of overexertion or use of drug/toxin (e.g., cocaine, amphetamine, statins)
- Patient may complain of muscle aches, cramps, or fatigue.
- Agitation while patients are in restraints

PHYSICAL EXAM

- May have obvious muscle tenderness/injury and swelling on exam, or muscle exam may be completely normal
- Tea-colored urine is indicative of myoglobinuria.
- Decreased urine output may indicate renal failure.

DIFFERENTIAL DIAGNOSIS

- For acute renal failure with rhabdomyolysis: Any disease that causes acute tubular necrosis may be confused with rhabdomyolysis.
- Renal pigment injury from hemoglobin resembles pigment injury from myoglobin.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Creatine kinase (CK) is the most important diagnostic enzyme: Elevated >5 times the upper limit of normal or >1,000 U/L. CK levels >5,000 U/L are causally related to acute renal failure (ARF) (3)[A] and should prompt aggressive fluid resuscitation.
- CK levels peak at ~24 hours and return to normal after 3 to 5 days, making it a more sensitive marker than myoglobin. CK is also a cheaper and an easier surrogate than myoglobin. Myoglobin is the enzyme responsible for kidney failure (3)[A].
- Serum myoglobin levels peak within a few hours and return to normal after ~24 hours, as it is cleared quickly from the circulation. Urine/serum myoglobin levels may be useful markers early on, but normal levels do not rule out rhabdomyolysis because of its rapid clearance.
- Urinalysis: Dipstick test positive for blood without erythrocytes in sediment is suggestive of injury from either hemoglobin or myoglobin. However, rhabdomyolysis often presents with hematuria, which is a limitation to using dipstick due to false-positive results.
- Marked elevations of potassium from the muscle injury sometimes are compounded by ARF.
- Initial hypocalcemia: Calcium enters the injured muscle cells and precipitates as calcium phosphate, leading to calcification of ischemic muscle cells. Only correct initial hypocalcemia if patient is symptomatic or has ECG changes; it will self-resolve during the renal recovery phase.

- Hypercalcemia during renal recovery phase: Unique to rhabdomyolysis-induced ARF for 20–30% of patients (3)[A]. As renal function improves, there is mobilization of the precipitated calcium, increase in calcitriol, and hyperphosphatemia resolves.
- Extreme hyperuricemia may be present and can cause acute uric acid nephropathy in the setting of rhabdomyolysis.
- Elevations in BUN and creatinine are indicative of acute renal failure.
- Reversible hepatic dysfunction can occur. However, elevations in alanine aminotransferase (ALT), aspartate aminotransferase (AST), and lactic dehydrogenase may be due to muscle injury and may not indicate any hepatic injury.
- Disseminated intravascular coagulation (DIC) can occur, with increase in coagulation times, fibrin degradation products, and D-dimer; decreases in platelets and fibrinogen.
- Place patient on a 12-lead ECG if rhabdomyolysis is suspected because hyperkalemia can induce fatal arrhythmias.

Follow-Up Tests & Special Considerations

- Delayed renal failure/electrolyte abnormalities despite normal initial levels
- Ongoing muscle injury is manifested by rising creatine phosphokinase (CPK).
- Any renal imaging is similar to other evaluations of acute renal failure.

Diagnostic Procedures/Other

Muscle compartment pressures if compartment syndrome is suspected

Test Interpretation

- Muscle necrosis
- Myoglobin-related renal injury may resemble acute tubular necrosis from other causes.

TREATMENT

GENERAL MEASURES

- Aggressive hydration is often necessary. With severe muscle trauma (crush injuries), up to 12 L of fluid may be sequestered in the muscles, leading to

intravascular volume depletion and explaining the low urine output despite fluid resuscitation, which increase the risk for renal failure.
- Monitor CK levels to ensure that rhabdomyolysis has ended.
- Monitor renal function and electrolytes.
- Continuous monitoring of potassium levels to prevent hyperkalemic arrhythmias and potential hypokalemia and arrhythmias.
- If DIC/hepatic dysfunction occurs, patients will need treatment and monitoring appropriate to these conditions.

MEDICATION

First Line

- When rhabdomyolysis is identified, appropriate intervention may prevent renal failure.
- Aggressive fluid resuscitation is the most important intervention: normal saline (NS) and 5% glucose solution with a target urine output of 200 mL/hr. Alternating NS and 5% glucose is recommended to prevent volume overload. Infusion rate should be 500 mL/hr (4)[C].
- Alkalinization of the urine is thought to decrease myoglobin-induced nephrotoxicity in the tubules (sodium bicarbonate to increase urine pH >6.5):
  - Use is controversial without strong evidence of efficacy.
  - Side effects include worsening hypocalcemia.
  - Sodium bicarbonate may be of use in patients with very high CK levels, an acidotic state, or coexisting hyperkalemia.
  - Place 150 mEq (3 ampules) NaHCO3 in 1 L of D5W and infuse at 200 mL/hr.

Second Line

- IV mannitol as a bolus if urine output remains low, 1 to 2 g/kg, not to exceed 200 g in 24 hours and cumulative dose up to 800 g. It is used to prevent ARF (5)[C]. Plasma osmolality should be closely monitored and stopped if diuresis is not adequate (>20 mL/hr).
  - Increases prostaglandins production leading to renal vasodilation and diuresis, making the kidneys less susceptible to myoglobin injury. Also an osmotic agent, filtered but not reabsorbed by the tubules, it increases sodium delivery and diuresis. This may remove necrotic cell debris and

fluids trapped in damaged muscle cells preventing rise in compartment pressure and compartment syndrome.
  - Use of mannitol is controversial in this setting because no good evidence indicates that it improves outcomes more than aggressive IV hydration. It is a free-radical scavenger and has renal protective effects when used early, before tubular occlusion.
  - Consider adding furosemide to force diuresis if necessary (40 to 120 mg/day).
  - Diuresis should not be used in anuric renal failure. Customize the regimen for elderly and patients with heart disease.
- Hyperkalemia can result from massive release of intracellular potassium stores or ARF. Severe hyperkalemia may be life-threatening. Treatment is warranted when ECG changes are present (tall, thin T waves; PR prolongation; QRS widening; P wave flattening).
- Treatments aiming at resolving hyperkalemia:
  - Calcium gluconate: to stabilize the cardiac membrane. IV 1 to 2 ampules (0.5 mL 10% Calcium gluconate = 4 mg elemental calcium; give 4 mg/kg/hr for 4 hours)
  - If acidosis is present: 1 to 2 ampules (2 to 3 mL/kg) sodium bicarbonate IV. Remember that sodium bicarbonate administration worsens hypocalcemia.
  - If tolerated: Oral sodium polystyrene sulfonate (Kayexalate) as much as 20 g (1 g/kg) can be given via enema.
  - Insulin and albuterol will transiently drive potassium into the cells. Administration of glucose can prevent the hypoglycemic effects of insulin.
  - Precautions: See “Etiology and Pathophysiology,” especially drug combinations. Continuous monitoring of potassium levels to prevent overcorrecting with potential hypokalemia and arrhythmias.
  - Indications for dialysis include resistant and symptomatic hyperkalemia (ECG), oliguria (<0.5 mL/kg over 12-hour period), anuria, volume overload, or persistent acidosis (pH <7.1).

ISSUES FOR REFERRAL

- Usually managed as an inpatient
- Diagnosis of muscle entrapment/compartment syndromes may require surgical intervention (fasciotomy) to stop rhabdomyolysis.

- Early escharotomy for compartment syndrome related to burn
- Renal dialysis may be indicated in ARF.

ADDITIONAL THERAPIES

During the oliguric phase, symptomatic hypocalcemia is possible but rare and may benefit from IV calcium gluconate.

SURGERY/OTHER PROCEDURES

For muscle entrapment/compartment syndrome

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Patients with significant elevations of CK should be admitted for IV hydration and serial laboratory monitoring.
- Usually required for symptomatic patients or other complications
- Volume expansion with normal saline to increase urine output to at least 150 mL/hr
- Monitoring of vital signs and urine output
- CK usually peaks 24 to 36 hours after muscle injury, so monitoring should confirm that the CK is trending down. Renal function should be stable/improving. Electrolytes should be normal. Patients with mild CK elevation, trending down, and normal renal function may be discharged after observation phase.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Outpatient assessment within a few days to recheck CPK, electrolytes, and renal function

Patient Monitoring

- Contingent on disease: essential for metabolic myopathies
- Myotoxic drugs should be discontinued/monitored closely.

DIET

- With renal failure, restrict protein intake to lower BUN level.

- Limit potassium intake.
- With anuria, essential to restrict volume intake

PROGNOSIS

Contingent on primary cause of rhabdomyolysis and on recovery from ARF without complications

COMPLICATIONS

- Death, especially from hyperkalemia/renal failure
- With dialysis and supportive care, the prognosis is very good.

SEE ALSO

Algorithm: Acute Kidney Injury (Acute Renal Failure)

CODES

ICD10

- M62.82 Rhabdomyolysis
- T79.6XXA Traumatic ischemia of muscle, initial encounter
- T79.6XXD Traumatic ischemia of muscle, subsequent encounter

CLINICAL PEARLS

- Acute CPK elevation into the thousands (often tens of thousands) is necessary before one sees myoglobinuric renal failure.
- The cornerstone of treatment of rhabdomyolysis is aggressive fluid administration.
- Frequent monitoring of potassium, calcium, and creatinine is necessary in the acute period.

RHABDOMYOSARCOMA

Olusola Fasusi, MD • E. James Kruse, DO

BASICS

DESCRIPTION

- Rhabdomyosarcoma (RMS) is the most common soft tissue sarcoma in children <20 years of age. (It is exceedingly rare in adults, representing 3% of all soft tissue sarcomas.)
  - 50% occur in the 1st decade of life.
- Overall, it is an uncommon malignancy that arises from myoblasts.
- Common anatomic sites
  - Head and neck (most common primary site in children)
  - Genitourinary
  - Musculoskeletal (Extremities are the most common primary sites in adults.)
- Subtypes
  - Alveolar (ARMS): 23% of cases
    - More common in the trunk and extremities; clinically more aggressive
  - Embryonal (ERMS): early onset; 57% of cases (most common subtype in children)
    - More likely to occur in the head, neck, and genitourinary areas
      - Classic: comprises 50% of cases
      - Botryoid: Sarcoma botryoids is typically seen in girls <4 years of age, 6% of cases.
      - Spindle cell: 3% of cases pleomorphic: usually occurs in adults, 1% of cases
- Sarcoma (not otherwise specified): comprises 11% of all cases of RMS (most common subtype in adults, reflects inability for pathologists to characterize tumor)
- Undifferentiated: comprises 8% of all cases of RMS
- Associated term(s): soft tissue sarcoma

EPIDEMIOLOGY

Incidence

- 4.5 cases of RMS per 1 million patients <20 years old per year
  - 50% occur within 1st decade of life.
- In adults, RMS represents 3% of all soft tissue sarcomas in adults.

Prevalence

- RMS comprises 3% of all childhood cancers.
- Predominant sex: male > female (1.37:1)

Genetics

- Alveolar: *PAX3-FOXO1* or *PAX7-FOXO1* fusion genes as a result of t(2;13) and t(1;13), respectively; found in 75% of ARMS
- Embryonal: Loss of alleles on chromosome 11 may be seen.

RISK FACTORS

Smoking, advanced maternal age, in utero x-ray exposure, maternal recreational drug use, and history of stillbirths

COMMONLY ASSOCIATED CONDITIONS

- Neurofibromatosis (NF1) 1: 20-fold increased risk of RMS in patients with NF1
- Li-Fraumeni syndrome: p53 mutations predispose to multiple tumors, including RMS.

DIAGNOSIS

HISTORY

- Presents as a progressive painless mass of the head and neck, genitourinary tissue, trunk, or extremities
- RMS of genitourinary tissue may present as vaginal bleeding in females.
- Other symptoms may be noted due to mass effect of the primary or metastatic lesions.
- Family history of genetic syndromes (i.e., NF1, Li-Fraumeni syndrome)

PHYSICAL EXAM

- Painless, enlarging mass

- Polypoid mass protruding from vagina (botryoid)
- Exophthalmos and chemosis (orbital involvement)
- Abdominal pain
- Compression symptoms (i.e., seizures, visual field defects, nerve palsy, headaches)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Ultrasound: used for differentiation of cystic versus solid mass
- MRI/CT: used to evaluate tumor
- Staging tests: chest x-ray, CT thorax, fluorodeoxyglucose (FDG)-PET
  - Most common site of metastasis is lung; evaluated by CT
  - FDG-PET scans may be useful to detect lymph node or distant metastases; not readily evident on CT or MRI scans

Diagnostic Procedures/Other

- Core needle biopsy, incisional biopsy, or excisional biopsy (based on size of mass)
  - The presence of rhabdomyoblast indicates the diagnosis.
- Immunohistochemical markers
  - Myogenin: commonly expressed in ARMS
  - Desmin: associated with multiple subtypes of RMS
- Pathology
  - Alveolar: rhabdomyoblasts arranged in what grossly appears to mimic pulmonary alveoli
  - Embryonal
  - Classic: rhabdomyoblasts configured in sheets without alveolar pattern
  - Botryoid: “grape-like” appearance of rhabdomyoblasts with notable clustering in the subepithelium forming the cambium layer
  - Spindle cell: rhabdomyoblasts with a spindle-like appearance
- Undifferentiated: rhabdomyoblast arrangement that cannot be classified as any other subtype
- Staging
  - Based on site, size, regional nodal involvement, and distance spread
  - See table.

Stage	Site	T	Tumor diameter	N	M
1	Orbit; head and neck (excluding parameningeal); genitourinary—nonbladder and nonprostate; biliary tract	T1 or T2	a or b	N0 or N1 or NX	M0
2	Bladder or prostate; extremity; cranial parameningeal; other (includes trunk, retroperitoneum, etc.)	T1 or T2	a	N0 or NX	M0
3	Bladder or prostate; extremity; cranial parameningeal; other (includes trunk, retroperitoneum, etc.)	T1 or T2	a	N1	M0
			0 or N1 or NX	M0	
4	All sites	T1 or T2	a or b	N0 or N1	M1

Note: a, ≤5 cm in diameter; b, >5 cm in diameter; M0, no distant metastasis present; M1, metastasis present; N0, regional nodes not clinically involved; N1, regional nodes clinically involved by neoplasm; Nx, clinical status of regional nodes unknown; M0 T1, confined to site of origin; T2, extension and/or fixation to surrounding tissue.

TREATMENT

The three tenets of treatment for adults and children are composed of surgical resection, radiation therapy, and chemotherapy. Patients should be referred to a multidisciplinary treatment team with expertise in oncology for definitive treatment.

SURGERY/OTHER PROCEDURES

- Wide local resection of tumor. If possible, resect metastasis as well.
- However, wide resection may not be feasible in cases where grossly impaired functionality results.
  - All children receive chemotherapy (1)[B].
  - In North America, the three-drug combination of vincristine, dactinomycin, and cyclophosphamide (VAC) is the standard regimen:
    - Vincristine
      - Adverse reactions: alopecia, constipation, peripheral neuropathy
    - Actinomycin-D
      - Adverse reactions: pancytopenia, hepatotoxicity
    - Cyclophosphamide
      - Adverse reactions: hemorrhagic cystitis (mesna for prophylaxis), sterility, transitional cell carcinoma
- In addition, ifosfamide, topotecan, doxorubicin, etoposide, and irinotecan may also be used.
- Duration of chemotherapy depends on risk stratification and ranges from 6 to

12 months.
- Chemotherapy has been less commonly used in adults, who generally undergo treatment with resection and radiation therapy.
- Radiotherapy is currently used for those whose tumor cannot be completely resected.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patients should follow up with their multidisciplinary treatment team. Long-term follow-up is necessary for detection of recurrence, metastatic disease, and development of secondary malignancies. Follow-up is composed of physical exam, chest x-ray, and imaging of the primary tumor site every 3 to 6 months for the first 3 years.

PROGNOSIS

- RMS (all cases): 62% 5-year survival
- ARMS: 48% 5-year survival
- ERMS: 73% 5-year survival
- Prognosis in adults is worse; it is unclear whether this is related to subtype of tumor or lack of clear guidelines for adults; this is a rare presentation in adults.

COMPLICATIONS

- Recurrence
- Secondary neoplasm
- Growth abnormalities
- Treatment side effects

CODES

ICD10

- C49.9 Malignant neoplasm of connective and soft tissue, unsp
- C49.0 Malignant neoplasm of connective and soft tissue of head, face and neck
- C49.5 Malignant neoplasm of connective and soft tissue of pelvis

CLINICAL PEARLS

- RMS is the most common soft tissue sarcoma in children.

- They can arise at any site and in any tissue except bone.
- All persistent soft tissue masses should be evaluated with imaging (ultrasound to rule out cystic vs. solid, then MRI/CT).
- Fine-needle aspiration may be helpful but core needle versus incisional/excisional biopsy for confirmation.

RHEUMATIC FEVER

Jonathan Schimmel, MD • Achyut B. Kamat, MD

BASICS

DESCRIPTION

- Acute rheumatic fever (ARF) is a delayed inflammatory sequela of group A *Streptococcus* (GAS) tonsillopharyngitis that affects multiple organ systems.
- Can lead to rheumatic heart disease (RHD)
- Recurrence in adults and children is common if antibiotic prophylaxis is withheld.
- Systems affected: cardiovascular, nervous, hematologic/lymphatic/immunologic, skin/exocrine, musculoskeletal

Pediatric Considerations

Can affect any age but most common ages 5 to 15 years

EPIDEMIOLOGY

- ARF and RHD are now largely restricted to developing countries and some poor populations of wealthy countries.
- Male = female, but females more likely to develop chorea.
- Can occur as an epidemic

Incidence

- Worldwide, incidence (new cases) has been declining for decades, attributed to increasing antibiotic use and improved living conditions. Most new cases are in developing countries.
- In early studies, ARF developed in 3% of children with untreated GAS pharyngitis.
- Incidence of ARF in the United States in the 1960s was 13.3/100,000 and is currently <1/100,000.
- 95% of cases currently occur in developing countries.

Prevalence

Worldwide, more than 15 million people have RHD, and prevalence has been

rising due to improved medical care and longer survival (despite decreasing incidence of ARF).

ETIOLOGY AND PATHOPHYSIOLOGY

- Preceded by tonsillopharyngitis of GAS, also known as *Streptococcus pyogenes*, a gram–positive organism
- Molecular mimicry: Antibodies against M protein on GAS cross-reacts with cardiac and vessel endothelial proteins, leading to an inflammatory cascade.

Genetics

- Susceptibility is associated with certain genetic polymorphisms, including toll-like receptors, cytokines, and human leukocyte antigen genes. Not fully understood
- Increased susceptibility in certain populations, including Australian aborigines, New Zealand Maori, and Pacific Islanders

RISK FACTORS

Genetic susceptibility and possible increased risk with iron deficiency or low serum albumin.

GENERAL PREVENTION

- Primary prevention: Antibiotics are effective at reducing incidence of ARF after known or suspected GAS pharyngitis. Number needed to treat is 100 (1).
- Secondary prevention: long-term antibiotic prophylaxis to prevent recurrence

DIAGNOSIS

- Requires laboratory evidence of preceding GAS infection (See "Initial Tests (lab, imaging).")
- Revised Jones criteria
- Initial ARF: 2 major OR 1 major + 2 minor
- Recurrent ARF: 2 major OR 1 major + 2 minor OR 3 minor

Major Criteria	Minor Criteria
• Carditis/valvulitis	• Low-risk: fever ≥38.5°C • Mod-high risk: fever ≥38°C

- Low-risk: polyarthritis
- Mod-high risk: mono/polyarthritis
- Sydenham chorea
- Erythema marginatum
- Subcutaneous nodules

- Low-risk: polyarthralgia
- Mod-high risk: monoarthralgia
- ↑PR interval
- CRP ≥3 mg/dL, and/or
- Low-risk: ESR ≥60 mm/hr
- Mod-high risk: ESR ≥30 mm/hr

- The revised criteria distinguish between patients with low-risk versus moderate-high risk of having ARF. Patients can be considered low-risk if they are from and among a low-incidence group (2)[C].

HISTORY

- ARF presents 1 to 4 weeks following GAS tonsillopharyngitis.
- Polyarthritis is often first, affecting the knees, ankles, elbows, and wrists. Each resolves in days, thus seems to "migrate." Usually self-limited <1 month. Mod-high risk patients may develop monoarthritis. Use of NSAID or aspirin may mask the arthritis.
- Fever
- Erythema marginatum rash
- Pancarditis or valvulitis (50–70%) can be subclinical (asymptomatic without auscultatory findings) or clinically apparent (symptomatic or auscultatory findings).
- Sydenham chorea (clinical diagnosis, in 10–30%)
  - 1 to 6 months after infection, so lab evidence of preceding infection may be absent.
  - More common in 5 to 15 years old, more common in females
  - Improves or ceases during sleep
  - Psychiatric symptoms may have onset prior to chorea, with emotional lability and obsessive-compulsive symptoms.
  - Usually self-resolves over several months and can relapse

PHYSICAL EXAM

- Neuro: Sydenham chorea: Involuntary movements may be general or unilateral and may involve the face. "Milkmaid grip" is intermittent hypotonia

appreciated on test of grip strength.

- Cardiac: pericardial friction rub, blowing holosystolic murmur, rarely diastolic, or new or changing murmur; rarely evidence of heart failure
- Skin
  - Subcutaneous nodules (<10%): firm, painless, up to 2 cm, over bony surfaces or tendons, usually extensor surfaces. More common in severe ARF, persists up to several weeks
  - Erythema marginatum (5–13%): nonpruritic, blanching, evanescent, pale pink macular transitions to central clearing, found on trunk and occasionally limbs, accentuated by warming the skin

DIFFERENTIAL DIAGNOSIS

- Systemic lupus erythematosus
- Poststreptococcal reactive arthritis
- Juvenile rheumatoid arthritis
- Infectious arthritis
- Viral myocarditis
- Innocent cardiac murmur
- Tourette syndrome
- Kawasaki syndrome
- Pediatric autoimmune neuropsychiatric disorders associated with streptococcal infections (PANDAS)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Bacteriologic/serologic evidence of GAS infection (2)[B]:
  - Rapid streptococcal antigen test with high pre-test probability
  - Throat culture (sensitivity 25% by time of ARF)
  - Elevated or rising antistreptolysin O (ASO) titer; peaks ~1 month postinfection.
- If ASO negative, check anti-DNAse B (peaks ~2.5 months, remains elevated up to 9 months), streptokinase, and antihyaluronidase (3).
- Bacteriologic/serologic evidence may be negative in chorea or chronic indolent rheumatic carditis.
- ESR and CRP are acute-phase reactants that almost always increase in ARF.

- CBC with differential: leukocytosis, possible normocytic anemia
- Complement levels normal (do not need to check)
- ECG: PR prolongation, AV block, signs of pericarditis
- Arthrocentesis of affected joints shows sterile inflammatory fluid with 10 to 100,000 WBC/mm^3.
- Chest x-ray: may have cardiomegaly from myocarditis
- Echocardiogram: Assess chamber size and function, pericardial effusion, and valve disease.
- All cases of confirmed or suspected ARF should have an echocardiogram (2) [B], due to the 18% prevalence of subclinical carditis.
- Antimyosin scintigraphy can detect carditis (nonspecific).

Follow-Up Tests & Special Considerations

- ESR and CRP are useful to monitor rebound inflammation.
- Repeat echocardiograms to monitor evolution of carditis, even if not initially present (2)[C].
- Household contacts should be screened with throat culture even if asymptomatic and treated with antibiotics if positive.

Test Interpretation

Prior treatment with aspirin or steroids may lead to falsely normal lab results.

TREATMENT

GENERAL MEASURES

- Antibiotic
- Anti-inflammatory agent (aspirin or naproxen)
- Manage cardiac manifestations as needed in addition to standard ARF treatment (e.g., dysrhythmia, pericarditis, myocarditis, valvular disease, or heart failure).

MEDICATION

First Line

- Eradication: Treat initially as if active GAS infection, then begin prophylaxis.
- If no penicillin allergy

  - Penicillin VK PO BID for 10 days, or benzathine penicillin G IM for 1, or amoxicillin PO for 10 days (preferred in children) (4)[A]
- If penicillin allergy
  - Cephalosporin 1st generation PO for 10 days (4)[A], azithromycin PO for 5 days, or clindamycin PO for 10 days, or clarithromycin PO for 10 days (4)[B]
- If there is heart failure, AV block third degree, or other severe manifestations of carditis, appropriate traditional management should be initiated.
- Aspirin high-dose is effective for treatment of arthritis and fever (5)[B], but has not been shown to reduce or improve cardiac manifestations (6)[B]. High-dose aspirin for prolonged periods risks salicylate toxicity and if used, consider following salicylate levels.
- If severe carditis is present, consider prednisone, although not shown to prevent or reduce cardiac manifestations (6)[B].
- Chorea generally self-resolves and does not require treatment, but if symptoms are severe, can use valproic acid, carbamazepine, or an antipsychotic if still resistant (3)[B]. If symptoms persist, consider prednisone, which unlike cardiac disease, has been shown effective for Sydenham chorea (3)[B].

Second Line

- If penicillin allergy is present, erythromycin is preferred by the New Zealand guidelines, but not by the Infectious Diseases Society of America.
- Naproxen is a reasonable alternative to aspirin (see "Pediatric Considerations").

ISSUES FOR REFERRAL

A cardiologist should be involved in management of ARF.

SURGERY/OTHER PROCEDURES

Valve stenosis is a late sequela that can result from fibrosis and calcification; it may require surgical correction (valve repair preferred over replacement) (7).

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Initial hospitalization may be helpful for diagnosis and to ensure stability.

- Heart failure requires prompt hospitalization.

IV Fluids

Only if signs of dehydration or to augment preload; use caution if heart failure present.

Nursing

Consider bedrest if severe symptoms, with gradual return to ambulation as tolerated (8)[C].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- ARF patients should be on a prophylactic antibiotic throughout childhood until age 21 years and possibly indefinitely depending on cardiac damage because recurrence can worsen prognosis (9)[C].
  - First-line prophylaxis is **long-acting** benzathine penicillin G monthly IM injections (9)[A].
  - Penicillin V PO 250 mg BID is an alternative but has risk of nonadherence (9)[B].
  - If penicillin allergy, treat with sulfadiazine (9)[B].
  - If penicillin and sulfa drug allergy, treat with azithromycin (9)[C].
- If diagnostic uncertainty exists, consider 1 year of secondary antibiotic prophylaxis followed by reassessment and echocardiogram (2)[C].
- Routine antibiotic prophylaxis for dental procedures is no longer recommended by the American Heart Association for patients with RHD (7).
- Have low threshold to test and treat episodes of acute tonsillopharyngitis.

Patient Monitoring

Initially weekly, then every 6 months

Pediatric Considerations

- Use aspirin with caution in children given the risk of Reye syndrome.
- Naproxen (10 to 20 mg/kg/day) has been found noninferior to aspirin with fewer risks in ARF, in a small study (5)[B].

Pregnancy Considerations

May exacerbate valve disease, particularly mitral stenosis. Refer pregnant patients to a cardiologist.

DIET

Regular diet or low-sodium if heart failure present.

PATIENT EDUCATION

American Heart Association: http://www.heart.org

PROGNOSIS

Sequelae are generally limited to the heart and depend on the severity of carditis during an acute attack.

COMPLICATIONS

- Recurrence of ARF due to GAS reinfection
- RHD can occur 10 to 20 years after ARF, with mitral more common than aortic regurgitation, can lead to stenosis. Heart failure is worst complication.
- Jaccoud arthropathy is chronic and involves painless deformities of hands/feet.

CODES

ICD10

- I00 Rheumatic fever without heart involvement
- I01.9 Acute rheumatic heart disease, unspecified
- I01.0 Acute rheumatic pericarditis

CLINICAL PEARLS

- ARF is an inflammatory disease that affects multiple organ systems including the heart.
- Modified Jones criteria for diagnosis include 2 major or 1 major + 2 minor manifestation in the context of a preceding documented GAS infection.
- Treatment involves aspirin and antibiotic eradication followed immediately by

long-term antibiotic prophylaxis.

RHINITIS, ALLERGIC

Naureen Rafiq, MD

BASICS

Allergic rhinitis is the collection of symptoms involving mucous membranes of nose, eyes, ears, and throat after an exposure to allergens such as pollen, dust, or dander.

DESCRIPTION

- IgE-mediated inflammation of the nasal mucosa following exposure to an extrinsic protein; an immediate symptomatic response is characterized by sneezing, congestion, and rhinorrhea followed by a persistent late phase dominated by congestion and mucosal hyperreactivity.
- Allergic rhinitis can be classified into seasonal or perennial and can be intermittent or persistent.
- Seasonal responses are usually due to outdoor allergens such as tree pollen, flowering shrubs in spring, grasses and flowering plants in summer, and ragweed and mold in fall.
- Perennial responses, or year-round symptoms, are usually associated with indoor allergens like dust mites, mold, and animal dander.
- Occupational allergic rhinitis is caused by allergens at the workplace and can be sporadic or year-round.
- Nonallergic rhinitis (e.g., vasomotor, rhinitis of pregnancy, and rhinitis medicamentosa) can occur.

Pediatric Considerations

Chronic nasal obstruction can result in facial deformities, dental malocclusions, and sleep disorders.

Pregnancy Considerations

Physiologic changes during pregnancy may aggravate all types of rhinitis, frequently in the 2nd trimester.

EPIDEMIOLOGY

- Onset usually in first 2 decades, rarely before 6 months of age, with tendency declining with advancing age
- The mean age of onset is 8 to 11 years, and about 80% of cases have established allergic rhinitis by age 20 years.

Prevalence

- ~10–25% of the U.S. adult population and 9–42% of the U.S. pediatric population are affected.
- 44–87% of patients with allergic rhinitis have mixed allergic and nonallergic rhinitis, which is more common than either pure form (1).
- Scandinavian studies have demonstrated cumulative prevalence rate of 14% in men and 15% in women.

ETIOLOGY AND PATHOPHYSIOLOGY

- Aeroallergen-driven mucosal inflammation due to resident and infiltrating inflammatory cells as well as vasoactive and proinflammatory mediators (e.g., cytokines)
- Inhalant allergens:
  - Perennial: house dust mites, indoor molds, animal dander, cockroach/insect detritus
  - Seasonal: tree, grass, and weed pollens; outdoor molds
  - Occupational: latex, plant products (e.g., baking flour), sensitizing chemicals, and certain animals for people working in farms and vet clinics

Genetics

Complex but strong genetic predilection present (80% have family history of allergic disorders)

RISK FACTORS

- Family history of atopy, with a greater risk if both parents have atopy
- Higher socioeconomic status
- Tobacco smoke can exacerbate symptoms and increase risk of developing asthma in patients with allergic rhinitis.
- Having other allergies such as asthma
- Unclear evidence regarding risk due to early, repeated exposure to offending allergen and early introduction of solid food

- Pets in house and houses infested with cockroaches can cause perennial allergic rhinitis.

GENERAL PREVENTION

- Primary prevention of atopic disease has not been proven effective by maternal diet or maternal allergen avoidance (2).
- Exclusive breastfeeding to 6 months of age lowers risk of some atopic disorders.
- Symptomatic control by environmental avoidance is the “first-line treatment.”
- No evidence to support use of acaricides with mite-proof mattress and pillow covers, carpet and drape removal, removal of plants in the home, and pet control (2,3)[B].
- Air conditioning and limited outside exposure during allergy season (1)[B]
- HEPA air cleaners and vacuum bags of unclear efficacy
- Close doors and windows during allergy season.
- Use a dehumidifier to reduce indoor humidity.

COMMONLY ASSOCIATED CONDITIONS

Other IgE-mediated conditions: asthma, atopic dermatitis, allergic conjunctivitis, food allergy

DIAGNOSIS

Diagnosis is made primarily by history and physical exam.

HISTORY

- Evaluation of nature, duration, and time course of symptoms
- History of atopic dermatitis and/or food allergies
- History of nasal congestion; rhinorrhea; pruritus of nose, eyes, ears, and/or palate; sneezing; itching; and watering eyes
- Family history of allergic diseases
- History of environmental and occupational exposure and various nasal stimuli can help differentiate between allergic and vasomotor rhinitis.

PHYSICAL EXAM

Many findings are suggestive of but not specific for allergic rhinitis:

- Dark circles under eyes, “allergic shiners” (infraorbital venous congestion)
- Transverse nasal crease from rubbing nose upward; typically seen in children
- Rhinorrhea, usually with clear discharge
- Pale, boggy, blue-gray nasal mucosa
- Postnasal mucus discharge
- Oropharyngeal lymphoid tissue hypertrophy

DIFFERENTIAL DIAGNOSIS

- Infectious rhinitis: usually viral, commonly with secondary bacterial infection
  - Usually associated with sinusitis and is known as rhinosinusitis
  - Viral rhinitis averages 6 episodes/year from ages 2 to 6 years.
  - IgA deficiency with recurrent sinusitis
  - Rhinitis medicamentosa:
    - Rebound effect associated with continued use of topical decongestant drops and sprays
    - ACE inhibitors, reserpine, β-blockers, oral contraceptive pills (OCPs), guanethidine, methyldopa
    - Aspirin, NSAIDs
  - Vasomotor (idiopathic) rhinitis caused by numerous nasal stimuli such as warm or cold air, scents and odors, light or particulate matter
  - Hormonal: pregnancy, thyroid, OCPs
  - Nonallergic rhinitis with eosinophilia syndrome (NARES)
  - Gustatory: watery rhinorrhea in response to alcohol or food
  - “Skier’s nose”: watery rhinorrhea in response to cold air
- Conditions associated with rhinitis:
  - Nasal polyps, tumor
  - Septal/anatomic obstruction
    - Adenoidal hypertrophy, particularly in children
    - Septal abnormality or deflected nasal septum (DNS) in adults

DIAGNOSTIC TESTS & INTERPRETATION

- Lab tests rarely needed
- Skin testing is done to identify the allergen for immunotherapy.

Initial Tests (lab, imaging)

- Testing is rarely indicated.
- If diagnosis implies other causes, consider the following:
  - CBC with differential may show elevated eosinophils.
  - Increased total serum IgE level
  - Nasal probe smear may show elevated eosinophils.
- Medications that may alter lab results
  - Corticosteroids may decrease eosinophilia.
  - Antihistamines suppress reactivity to skin tests; stop antihistamines 7 days before testing.
- CT scan of sinuses is not routinely done but can be used to check for complete opacity, fluid level, and mucosal thickening.

Diagnostic Procedures/Other

- Consider testing in only those cases where allergic symptoms do not respond to treatment and/or considering immunotherapy.
- Specific allergen sensitivity with allergen skin testing or radioallergosorbent testing (RAST); clinical correlation based on history is essential in interpreting results.
- Diagnostic allergen prick tests are used to select agent to determine appropriate environmental control measures as well as to direct immunotherapy:
  - Prick or puncture: superficial injury to epidermis with application of test antigen
  - Intradermal
- RAST: more expensive and less sensitive than skin testing; typically used in patients in whom skin testing is not practical or a severe reaction is possible
- Rhinoscopy: useful to visualize intranasal anatomy and posterior pharyngeal structures, including adenoids, polyps, and larynx

Test Interpretation

- Nasal washing/scraping: Eosinophils predominate but may see basophils, mast cells.
- Nasal mucosa: submucosal edema but without destruction; eosinophilic infiltration; congested mucous glands and goblet cells

TREATMENT

There are three mainstays of treatment of allergic rhinitis:

- Allergen avoidance
- Medication
- Allergy immunotherapy

GENERAL MEASURES

- Establish specific cause(s) by history and appropriate testing.
- Limit exposure to offending allergen.
- Allergen immunotherapy (desensitization)
  - Reserved when symptoms are uncontrollable with medical therapy or have a comorbidity (e.g., asthma)
  - Specific allergen extract is injected SC in increasing doses to induce patient tolerance.

MEDICATION

Oral medication and intranasal sprays are commonly used.

First Line

- Mild symptoms: 2nd-generation nonsedating antihistamines are the first-line therapy for mild to moderate allergic rhinitis (1,4).
- Adverse effects: mild sedation, mild anticholinergic effects
- Generic (cetirizine, fexofenadine, loratadine; most to least effective)
  - Levocetirizine is a 2nd-generation nonsedating antihistamine that is effective but costly.
- Intranasal corticosteroids are first-line therapy for moderate to severe allergic rhinitis (1,4)[A]:
  - Most effective drug class for symptoms of allergic rhinitis
  - Use nasal sprays after showering and direct spray away from septum to improve deposition on mucosal surface.
  - May be used as needed; however, more effective with daily use (1)
  - Adverse effects: nosebleed, nasal septal perforation, and systemic corticosteroid effects
- Systemic steroids should be considered only in urgent cases and only for

short-term use.

Second Line

1st-generation antihistamines, such as the following:

- Brompheniramine: 12 to 24 mg PO BID
- Chlorpheniramine: 4 mg PO q4–6h PRN
- Clemastine: 1 to 2 mg PO BID PRN
- Diphenhydramine: 25 to 50 mg PO q4–6h PRN:
  - May precipitate urinary retention in men with prostatism and/or hypertrophy
  - Adverse effects: sedation, prolonged QT interval, performance impairment, and anticholinergic effect
- Nasal antihistamines effective but may be systemically absorbed and thus cause sedation: azelastine, olopatadine
- Decongestants
  - Phenylephrine: 10 mg PO q4h PRN
  - Pseudoephedrine: 60 mg PO q4–6h PRN
  - Oxymetazoline nasal spray (Afrin): 2 to 3 sprays per nostril q10–12h PRN (max 3 days). Intranasal agents should not be used for >3 days due to rebound rhinitis. Discourage use in patients with hypertension (HTN) or cardiac arrhythmia.
- Intranasal anticholinergics such as ipratropium nasal spray 2 sprays per nostril BID to TID
  - Intranasal anticholinergics can increase efficacy in combination with steroid use.
- Leukotriene antagonists such as montelukast 10 mg/day PO
  - Should generally be used as an adjunct, not monotherapy
  - May be first line in those with concomitant asthma
- Mast cell stabilizers such as cromolyn nasal spray 1 spray per nostril TID to QID
  - May take 2 to 4 weeks of therapy for optimal efficacy
  - May be ineffective in patients with nonallergic rhinitis and nasal polyps

ISSUES FOR REFERRAL

Refer to allergist for consideration of immunotherapy.

ADDITIONAL THERAPIES

- Immunotherapy, either by injection (5)[A] or sublingually, which may be better tolerated by children (6)[A]
- Nasal saline use has evidence of efficacy as sole agent or as adjunctive treatment (1,7)[A].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

No specific restrictions on activity; emphasize avoiding activity where exposure to the allergen is likely.

Patient Monitoring

Initiation of patient education is critical.

DIET

- No special diet unless concomitant food reactions are suspected and evaluated
- Some patients with severe sensitivity to seasonal pollens may have oral allergy syndrome, which is associated with itching in the mouth with the ingestion of fresh fruits that may cross-react with the allergens.

PATIENT EDUCATION

- Asthma & Allergy Foundation of America, 1717 Massachusetts Ave., Suite 305, Washington, DC 20036; (800) 7-ASTHMA: http://www.aafa.org/
- Other helpful information available at http://www.acaai.org/ and http://www.aaaai.org/home.aspx

PROGNOSIS

- Acceptable control of symptoms is the goal.
- Treatment is helpful to reduce the risk of comorbidities, such as sinusitis and asthma.

COMPLICATIONS

- Secondary infection such as otitis media or sinusitis
- Epistaxis
- Nasopharyngeal lymphoid hyperplasia

- Airway hyperreactivity with allergen exposure
- Asthma
- Facial changes, especially in children who are mouth breathers
- Sleep disturbance

SEE ALSO

Conjunctivitis, Acute

CODES

ICD10

- J30.9 Allergic rhinitis, unspecified
- J30.1 Allergic rhinitis due to pollen
- J30.2 Other seasonal allergic rhinitis

CLINICAL PEARLS

- Nasal saline irrigation (flushing 6 to 8 oz) may be very helpful in clearing upper airway of secretions and may precede the use of nasal corticosteroids.
- 2nd-generation antihistamines and intranasal corticosteroids are first-line therapies for allergic rhinitis.
- Referral to allergist is appropriate for identification of offending allergens and consideration of immunotherapy for inadequate symptom control.

ROCKY MOUNTAIN SPOTTED FEVER

Ginny H. Lee, MD • Alison Southern, MD, MS, FACEP

BASICS

DESCRIPTION

- Rocky Mountain spotted fever (RMSF) is a potentially fatal tick-borne systemic small vessel vasculitis caused by the bacterium *Rickettsia rickettsii*.
- RMSF is the most common and lethal rickettsial disease in the United States.
- Typically characterized by fever, headache, and myalgias followed by a centripetal (moving inward from the extremities toward the trunk) rash
- System(s) affected: cardiovascular, musculoskeletal, skin, CNS, renal, hepatic, and pulmonary

EPIDEMIOLOGY

Incidence

- In the United States, the incidence of RMSF increased from <2 cases per million persons in 2000 to >8 per million in 2008 (1).
- Reported in all states except Hawaii, Alaska, and Maine
- North Carolina, Tennessee, Oklahoma, Arkansas, and Missouri account for ~60% of cases. RMSF also found in areas of Canada and in Central and South America (2).
- Predominant age: All ages are susceptible; highest prevalence in children 5 to 9 years of age (2,3).
- Predominant sex: male > female, likely due to increased outdoor exposures (3,4).
- Peak incidence occurs with tick exposure, typically in late spring and summer (3).

Prevalence

In the United States, about 2,000 cases are reported annually (2).

- <0.1% of ticks carry virulent Rickettsial species.

ETIOLOGY AND PATHOPHYSIOLOGY

- Infected ticks include the American dog tick, *Dermacentor variabilis* in the eastern United States; the Rocky Mountain wood tick, *Dermacentor andersoni* in the western United States; and the Brown dog tick, *Rhipicephalus sanguineus* in the southwest (1,2).
- An adult tick releases *Rickettsia rickettsii* from its salivary glands after 6 to 10 hours of feeding (1).
- Rickettsiae proliferate inside endothelial cells by binary fission and invade contiguous vascular endothelial cells, causing a small-vessel vasculitis and the characteristic rash.
- Increased vascular permeability leads to edema, hypovolemia, and hypoalbuminemia, with subsequent end-organ injury.
- Platelets are consumed locally due to vascular injury, but coagulopathy or disseminated intravascular coagulation (DIC) is rare (4).
- Incubation time: 2 to 14 days; median 4 to 7 days
- Transplacental transmission of infection has not been demonstrated.
- RMSF can rarely be caused by direct inoculation of tick blood into open wounds or conjunctivae.

RISK FACTORS

- Known tick bite, engorged tick, or presence of tick for >20 hours; *likelihood of infection increases with duration of tick attachment*
- Crushed tick during its removal
- Accumulated outdoor exposure or residence in a wooded area
- Contact with outdoor pets or wild animals

GENERAL PREVENTION

In known tick-prone areas (2,4,5)

- Limit time spent in tall grasses, open areas of low bushy vegetation, and wooded areas.
- Cover exposed skin; wear a hat, long sleeves, pants and closed-toed shoes.
- Use DEET-containing insect repellents on exposed skin. Permethrin can be used on clothing.
- “Tick checks”: Carefully inspect the entire body after possible exposure, especially the scalp, neck, and axillae. Ticks are commonly hidden by hair. Closely inspect legs, groin, external genitalia, and waistlines.

- Remove attached ticks in their entirety with fine-tipped tweezers. Grasp the tick close to the skin and gently pull upward. If mouth-parts separate, try to remove gently. Nail polish, petrolatum jelly, and heating do not aid in tick removal. Wear gloves if possible.
- Wash hands and site of bite thoroughly after tick removal to avoid potential mucosal inoculation.
- Prophylactic antibiotic treatment is not recommended.

DIAGNOSIS

Delay in presentation and initiation of therapy increases risk of long-term sequelae and mortality.

HISTORY

Consider RMSF in acute febrile illness, especially with history of potential tick exposure within previous 14 days, travels to an endemic area, and presentation in the late spring or summer. *The painless tick bite goes unnoticed 30–50% of the time. Many patients do not report a bite* (2,4).

- Early disease (days 1 to 3) presents like a viral illness with frontal headache, fever, malaise, body aches, nausea, and vomiting. RMSF is easily mistaken for gastroenteritis, pharyngitis, or mononucleosis.
- Signs and symptoms associated with RMSF with frequency of occurrence
  - Fever, usually >102°F (99–100%)
  - Rash, macular/maculopapular/petechial, blanching (88–90%)
  - Headache (79–91%)
  - “Classic triad” of headache, fever, and rash (50–60%)
  - Myalgias (72–83%)
  - Nausea/vomiting (56–60%)
  - Abdominal pain, particularly in children (35–52%)
  - Cough, nonproductive (33%)
  - CNS dysfunction, stupor/confusion/coma/focal abnormalities (10–30%)
  - Patients may also have malaise, restlessness, arthralgia, conjunctivitis, and peripheral or periorbital edema.

PHYSICAL EXAM

On days 3 to 4, a centripetal rash usually forms (80% of adults), involving the palms and soles, spreading centrally to arms, legs, and trunk. The rash typically starts as an erythematous, macular, or maculopapular exanthem; 50% become petechial or purpuric; blanchable.

- 20% never develop the “classic” rash, delaying diagnosis and resulting in a more severe outcome. Rash can be difficult to visualize on dark-skinned patients.
- Rash may be variable in appearance. *Do not rely solely on the presence or absence of the typical rash for diagnosis*.
- In severe cases, the rash can involve the entire body and mucosal membranes and may progress to necrotic or gangrenous lesions.
- The rash is not associated with pruritus or urticaria; when present, this makes RMSF less likely.
- Hepatosplenomegaly (12–16%)
- Lymphadenopathy (27%)

DIFFERENTIAL DIAGNOSIS

- Viral exanthems (e.g., measles, rubella, roseola)
- Meningoencephalitis (viral meningitis or encephalitis, bacterial meningitis)
- Meningococcemia
- Typhus
- Ehrlichiosis
- Lyme disease
- Leptospirosis
- Toxic shock syndrome
- Adenovirus infection
- Drug reaction or serum sickness
- Mononucleosis
- Kawasaki disease

DIAGNOSTIC TESTS & INTERPRETATION

Diagnosis is often clinical in patients with exposure history in an endemic area. Retrospective confirmation by serology. Do not delay treatment awaiting serology.

Initial Tests (lab, imaging)

- Specific laboratory diagnosis
  - Serum indirect fluorescent antibody (IFA): Titer of >1:64 is diagnostic. A 4-fold increase of acute and convalescent titers confirms an active case of RMSF (1).
  - Antibodies usually develop 7 to 10 days after onset of symptoms; optimal time for testing, therefore, is 14 to 21 days after symptom onset. *Do not delay treatment*.
  - Early treatment may limit antibody formation.
  - Seropositivity increases with age in endemic states. Positive spotted fever group *Rickettsia* antibody does not necessarily signify an acute infection.
- Nonspecific laboratory changes (incidence) (4)
  - WBC count: variable and frequently normal
  - Thrombocytopenia (32–52%)
  - Hyponatremia, mild (19–56%)
  - Anemia, mild (5–24%)
  - Azotemia (12–14%)
  - Elevated AST (36–62%)
  - Coagulation derangements are uncommon, despite vascular damage.
  - CSF is usually normal; some patients may have mononuclear pleocytosis, elevated protein, and normal glucose.
- Other than occasional nonspecific pneumonic infiltrates on chest radiograph, imaging procedures are rarely helpful.

Diagnostic Procedures/Other

Skin biopsy can offer definitive diagnosis. A 3-mm punch biopsy is sufficient to perform a rapid direct fluorescent antibody (DFA) test (sensitivity 70%, specificity 100%). Electron microscopy (EM) can also identify rickettsiae within endothelial cells. Western immunoblotting confirms the specific spotted fever group species (1,2,4).

Test Interpretation

- Rickettsiae can be demonstrated within endothelial cells by DFA or EM.
- Petechiae due to the vasculitis may be seen on various organ surfaces (e.g., liver, brain, or epicardium).

- Secondary thromboses and tissue necrosis may be seen.

TREATMENT

MEDICATION

First Line

Doxycycline is the treatment of choice in both adults and children (1–4).

- Untreated rickettsial infections have a high rate of morbidity and mortality. Other antibiotics are considerably less effective.
- The ONLY contraindication to doxycycline is severe allergy.
- For adults: 100 mg PO or IV q12h for 7 to 10 days, treat for at least 3 days after the fever resolves.
- For children weighing <45 kg (100 lbs): 2.2 mg/kg/dose (max 200 mg) q12h for 7 to 10 days, treating for at least 3 days after fever resolves; those ≥45 kg, refer to adult dosing (4)
- Fever should subside within 24 to 72 hours with early treatment; may take longer if patient is severely ill.
- If patient has no response to doxycycline, consider an alternate diagnosis. Rickettsial resistance to doxycycline has NOT been documented.
- Side effects of doxycycline
  - Dyspepsia. Take medication with food and water. Avoid dairy products, iron preparations, or antacids, as they may inhibit drug absorption.
  - Photosensitivity may occur. Minimize sun exposure and use sunscreen.
  - Risk of dental staining in children <8 years old is minimal if short courses are administered.

Second Line

- Chloramphenicol: 50 mg/kg/day IV divided q6h (4 g/day max); same dose in renal failure
  - Associated with aplastic anemia and an increased case mortality
- Fluoroquinolones have not been evaluated clinically in RMSF, but they have shown in vitro activity against *R. rickettsii*.
- Sulfa-containing drugs may worsen tick-borne infections and are contraindicated.

Pregnancy Considerations

- Doxycycline is appropriate for this life-threatening infection in pregnancy if suspicion is high, despite the potential risk to fetal bones/teeth.
- Chloramphenicol may be considered during the first 2 trimesters but should be avoided in the 3rd trimester due to potential for gray baby syndrome.

ISSUES FOR REFERRAL

- Consider infectious disease consult.
- Report cases of RMSF to public health authorities.

ADDITIONAL THERAPIES

Patients with neurologic injury or loss of limbs caused by gangrene may require prolonged physical and cognitive therapy.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Admission criteria/initial stabilization
  - CNS dysfunction
  - Nausea/vomiting preventing oral antibiotic therapy
  - Immunocompromised patients
  - Specific acute organ failure
  - Failure of oral pain management
  - ICU placement for acutely ill patients with shock
- Aggressive fluid resuscitation and electrolyte management may be required in critically ill patients.
- Discharge criteria
  - Resolution of fever
  - Ability to take oral therapy and nutrition

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Hospitalize patients with moderate to severe disease
- Patients with mild disease may be treated as outpatients. Close follow-up is important to identify complications.

- Infection does not confer lifelong immunity.

Patient Monitoring

- Outpatients should be seen every 2 to 3 days until symptoms resolve.
- Follow up CBC, electrolytes, LFTs if clinically indicated.

DIET

Consider nutritional supplementation if intake is poor.

PROGNOSIS

- Prognosis is closely related to timely administration of appropriate antibiotics. Treatment before day 5 of illness can prevent morbidity and mortality (6).
- When treated promptly, prognosis is usually excellent with resolution of symptoms over several days and no sequelae.
- If complications develop, course may be more severe and long-term sequelae (especially neurologic sequelae) more likely (6).
- Children aged 5 to 9 years and elderly >70 years are at higher risk of morbidity and/or mortality (4,6).
  - Black males with G6PD deficiency are at highest risk for fulminant RMSF, in which death can occur within 5 days (4).

COMPLICATIONS

- Encephalopathy (30–40%); most commonly transient impaired level of consciousness or meningismus
- Seizures, focal neurologic deficit (10%)
- Renal injury (10%)
- Hepatitis (10%)
- Congestive heart failure (CHF) (5%)
- Respiratory failure (5%)
- Proximal muscle weakness, changes in personality, paresthesias, distal necrosis, and deafness

A77.0 Spotted fever due to Rickettsia rickettsii

CLINICAL PEARLS

- Diagnosis of RMSF requires a high index of clinical suspicion. Painless tick bites often go unnoticed, and some patients may never develop a rash.
- Treatment should begin immediately in suspected cases. Doxycycline is indicated for treatment of RMSF in both adults AND children. The only absolute contraindication is severe allergy to the drug.
- Lab testing is nonspecific and frequently normal.
- Although prevalence is highest in central and southeastern United States, cases have been reported in almost all states.

ROSEOLA

Jeffrey D. Quinlan, MD, FAAFP

BASICS

Omnipresent infection occurring in infancy and childhood. Majority of cases are caused by human herpesvirus 6 (HHV-6). May be associated with other diseases including encephalitis

DESCRIPTION

- Acute infection of infants or very young children (1)
- Causes a high fever followed by a skin eruption as the fever resolves (1)
- Transmission via contact with salivary secretions or respiratory droplet (1)
- Incubation period of 9 to 10 days (2)
- System(s) affected: skin/exocrine, metabolic, gastrointestinal, respiratory, neurologic
- Synonym(s): roseola infantum, exanthem subitum; pseudorubella; sixth disease; 3-day fever (3)

Pediatric Considerations

A disease of infants and very young children (4)

EPIDEMIOLOGY

- Predominant age
  - HHV-6
    - Infants and very young children (<2 years old) (5)
    - Peak age infection 6 to 9 months, rarely congenital or perinatal infection (1)
    - 95% of children have been infected with HHV-6 by 2 years of life.
  - HHV-7
    - Later childhood
    - Mean age of infection 26 months
    - >90% population with HHV-7 by 10 years (1)
- Predominant sex: male = female (1)
- No seasonal variance

Incidence

Common—accounts for 20% ED visits for febrile illness among children 6 to 8 months (6)

Prevalence

- Peak prevalence is between 9 and 21 months (5).
- Nearly 100% population carrying HHV-6 by 3 years (1)
- Approximately 20% patients with primary HHV-6 have roseola (6).

ETIOLOGY AND PATHOPHYSIOLOGY

- HHV-6 and HHV-7 (4)
- Majority of cases (60–74%) due to HHV-6
  - HHV-6B > HHV-6A (4)
  - HHV-6A seen in children in Africa
  - HHV-6 binds to CD46 receptors on all nucleated cells (4).
- Primary infection typically through respiratory droplets or saliva
- Congenital infection/vertical transmission occurs in 1% of cases (1).
  - Transplacental transmission
  - Chromosomal integration (clinical significance unknown)
- Lifelong latent or persistent asymptomatic infection occurs after primary infection (1).
  - 80–90% population intermittently sheds HHV-6/HHV-7 in saliva (4).
  - Patients are viremic from 2 days prior to fever until defervescence and onset of rash.
  - HHV-6 latency is also implicated in CSF (6).

Genetics

HHV-6 is integrated into the chromosomes of 0.2–3.0% of the population. This leads to vertical transmission of the virus. Clinical significance of this is unknown (1).

RISK FACTORS

- Female gender (5)
- Having older siblings (5)
- At-risk adults: immunocompromised (7)
  - Renal, liver, other solid organ, and bone marrow transplant (BMT) (5)

- HHV-6 reactivation can occur in 1st week posttransplant (7). HHV-6 viremia occurs in 30–45% of BMT within the first several weeks after transplantation (6).
  - Usually asymptomatic (6)
  - Up to 82% of HHV-6 reactivation/reinfection in solid organ transplant (7)
- Nonrisk factors (5)
  - Child care attendance
  - Method of delivery
  - Breastfeeding (HHV does not appear to pass through breast milk)
  - Maternal age
  - Season

DIAGNOSIS

HISTORY

- 3 to 5 days abrupt fever 102.2–104.0°F (39–40°C) not associated with a rash (1)
- The child may be fussy during this prodrome (1,6).
- Sudden drop of fever associated with appearance of rash (1)
  - Rash on trunk then spreads centrifugally mainly to neck, possibly also to peripheral extremities, and face.
- Diarrhea (5)
- Mild upper respiratory symptoms (5)
- Rhinorrhea (5)
- Febrile seizure occurs in 13% of cases (1).

PHYSICAL EXAM

- Rash (exanthem subitum) (1)
  - Rose-pink macules and/or papules that blanch
  - First appears on the trunk then peripherally
  - May occur up to 3 days after fever resolves (1)
  - Fades within 2 days
  - Occurs in approximately 20% of patients in the United States (1)
- Mild inflammation of tympanic membrane, pharynx, and/or conjunctiva (1,6)

- Ulcers on soft palate and uvula (Nagayama spots) (1)
- Cervical lymphadenopathy (1)
- Periorbital edema (4)

DIFFERENTIAL DIAGNOSIS

- Enterovirus infection (8)
- Adenovirus infection (1)
- Epstein-Barr virus
- Fifth disease—parvovirus B19 (8)
- Rubella (8)
- Scarlet fever (8)
- Drug eruption (1)
- Measles (1)

DIAGNOSTIC TESTS & INTERPRETATION

- Primarily a clinical diagnosis not requiring laboratory or radiologic testing (1)
- Tests often cannot differentiate latent or active disease (9).
- Specific diagnosis only necessary in severe cases, unclear diagnosis where more serious disease needs to be ruled out, or if considering antiviral therapy (1).

Initial Tests (lab, imaging)

- HHV-6 and HHV-7 by PCR (1,7)
  - Serum, whole blood, CSF, or saliva
  - Becoming more widely available
- HHV-6 IgM immunofluorescence (1)
  - Diagnostic for acute infection
  - Spike seen in 1st week of illness
- HHV-6 IgG immunofluorescence (1)
  - Check at diagnosis and then 2 weeks later.
  - Use with IgM to show primary infection.
  - Negative initial test and rise on follow-up suggests primary infection.
- Viral culture (7)
  - Rarely done
  - No clinical use (very time consuming)

- Other laboratory findings (1)
  - Decreased total leukocytes, lymphocytes, and neutrophils
  - Elevated transaminases
  - Thrombocytopenia

Diagnostic Procedures/Other

- Urine culture: to rule out UTI as source of fever (2)
- Chest x-ray (CXR): if a child has respiratory symptoms

TREATMENT

No treatment necessary, resolves without sequelae (1)[C].

GENERAL MEASURES

- Symptomatic relief including antipyretics (1)[C]
- Hydration (1)[C]

MEDICATION

First Line

- No specific first-line treatment in immunocompetent hosts beyond supportive measures (4)[C]
  - Antivirals are not recommended in immunocompetent.
- No approved antiviral treatment in immunocompromised (4).
- Second-line IV ganciclovir, cidofovir, foscarnet tested in vitro studies in stem cell transplant patients
  - HHV-6B susceptible: ganciclovir and foscarnet (7)[C]
  - HHV-6A and HHV-7 are more resistant to ganciclovir (7).
- Antivirals suggested in individual cases of encephalitis (associated with reactivation of HHV-6) (7)
- In bone marrow and stem cell transplant recipients receiving immunosuppression, ganciclovir prophylaxis is effective in preventing reactivation of HHV-6 (10)[B].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- During febrile prodrome, monitor for dehydration.
- None after typical rash appears and fever resolves
- Mean duration of illness is 6 days (6).
- If febrile seizures occur, they will cease after fever subsides and will not likely recur (6).
- Symptomatic reactivation in immunocompromised (1)

DIET

Encourage fluids.

PATIENT EDUCATION

- Parental reassurance that this is usually a benign, self-limited disease (1).
- There is no specific recommended period of exclusion from out-of-home care for affected children.
- Patient is viremic a few days prior to fever until time of defervescence and rash onset.

PROGNOSIS

- Course: acute, complete recovery without sequelae (1)
- Reactivation in immunocompromised patients is common (6).

COMPLICATIONS

- Febrile seizures
  - 13% patients with roseola (1,6)
  - Accounts for 1/3 of primary seizures in children <2 years old (1)
- Medication hypersensitivity syndromes (drug reaction with eosinophilia and systemic symptoms) (4)
- Reactivation can occur in transplant patients, HIV-1 infection, and other immunocompromised individuals (6).
- Meningoencephalitis occurs in immunocompetent and in immunosuppressed patients (6). Poor association with multiple sclerosis (6)
- Pityriasis rosea (1)
- Possible association with progressive multifocal leukoencephalopathy (6)

CODES

ICD10

- B08.20 Exanthema subitum [sixth disease], unspecified
- B08.21 Exanthema subitum [sixth disease] due to human herpesvirus 6
- B08.22 Exanthema subitum [sixth disease] due to human herpesvirus 7

CLINICAL PEARLS

- Roseola infection should be suspected if an infant or young child presents with a high temperature without other clinical findings.
- As the fever abates, a macular rash will be seen on the trunk, with eventual spread to the face and extremities in 20% of patients.
- Roseola is a clinical diagnosis, and laboratory testing is not necessary for most children with classic presentation.
- For atypical presentations, complications, and immunocompromised hosts, several laboratory tools are available, including serologic testing for antibody, viral PCR testing, and viral culture.

- Infection is typically self-limiting and without sequelae.
- Usually only symptomatic treatment is needed.
- Consider prophylaxis in patients undergoing bone marrow or stem cell transplant and receiving immunosuppressive therapy.

ROTATOR CUFF IMPINGEMENT SYNDROME

Faren H. Williams, MD, MS • Minjin Fromm, MD

BASICS

DESCRIPTION

- Compression of rotator cuff tendons and subacromial bursa between the humeral head and the structures comprising the coracoacromial arch and proximal humerus
- Most common cause of atraumatic shoulder pain in patients >25 years of age
- Primary symptom is pain that is most severe when the arm is abducted between 60 and 120 degrees (the “painful arc”).
- Classically divided into three stages
  - Stage I: acute inflammation, edema, or hemorrhage of the underlying tendons due to overuse (typically in those age <25 years)
  - Stage II: progressive tendinosis that leads to partial rotator cuff tear along with underlying thickening or fibrosis of surrounding structures (commonly, ages 25 to 40 years)
  - Stage III: full-thickness tear (typically in patients age >40 years)

EPIDEMIOLOGY

Incidence

- Shoulder pain accounts for 1% of all primary care visits.
- Peak incidence of 25/1,000 patients/year occurs in patients aged 42 to 46 years.
- Impingement responsible for 18–74% of shoulder pain diagnoses.

Prevalence

Prevalence of shoulder pain in general population ranges from ~7% to 30%.

RISK FACTORS

- Repetitive overhead motions (throwing, swimming)
- Glenohumeral joint instability or muscle imbalance
- Acromioclavicular arthritis or osteophytes

- Thickened coracoacromial ligament
- Shoulder trauma
- Increasing age
- Smoking

GENERAL PREVENTION

- Proper throwing and lifting techniques
- Proper strengthening to balance rotator cuff and scapula stabilizer muscles

DIAGNOSIS

HISTORY

- Gradual increase in shoulder pain with overhead activities (sudden onset of sharp pain suggests a tear)
- Night pain is common, exacerbated by lying on the affected shoulder or sleeping with the affected arm above the head.
- Anterolateral shoulder pain with overhead activities
- May progress to weakness and decreased range of motion if shoulder is not used through full range of motion

PHYSICAL EXAM

- Examine patient for atrophy/asymmetry. Observe how the patient takes off his or her shirt during exam.
- Neer impingement test: Examiner stabilizes the scapula and moves the affected upper extremity through a flexion arc. Positive is pain with flexion of the shoulder. Sensitivity: 78%. Specificity: 58% (1)[A]
- Hawkins-Kennedy impingement test: Examiner places the arm in 90 degrees of forward flexion and then gently internally rotates the arm. End point for internal rotation is when the patient feels pain or when the rotation of the scapula is felt or observed by the examiner. Test is positive when patient experiences pain during the maneuver. Sensitivity: 74%. Specificity: 57% (1) [A]
- Empty can test (supraspinatus): Examiner asks the patient to elevate and internally rotate the arm with thumbs pointing downward in the scapular plane. Elbow should be fully extended. Examiner applies downward pressure

on upper surface of the arm. Test is positive when patient complains of pain with resistance. Sensitivity: 69%. Specificity: 62% (1)[A]

- Lift-off test (subscapularis): Patient internally rotates the shoulder, placing the hand on ipsilateral buttock, then lifts hand off buttock against resistance. A tear in the subscapularis muscle produces weakness of this action. Sensitivity: 42%. Specificity: 97% (1)[A]
- Drop-arm test: Patient fully elevates arm and then slowly reverses the motion. If the arm is dropped suddenly or the patient has extreme pain, the test is positive for a possible rotator cuff tear. Sensitivity: 21%. Specificity: 92% (1)[A]
- Resisted external rotation: weakness suggestive of infraspinatus and/or teres minor tendon involvement
- Examine cervical spine to rule out cervical pathology as source of shoulder pain.
- Neurovascular exam of the upper extremity

DIFFERENTIAL DIAGNOSIS

- Labral injury
- Acromioclavicular arthritis (more common in older patients; positive cross-arm test—pain when affected arm is fully adducted across the chest in the horizontal plane)
- Adhesive capsulitis (rotator cuff tendonitis leads to decreased use and atrophy of rotator cuff muscles, followed by contracture; linked to diabetes and potentially prior trauma)
- Anterior shoulder instability (prior trauma; more common in patients <25 years old)
- Multidirectional instability
- Biceps tendonitis or rupture (perform Speed and Yergason tests and look for visible or palpable defect of biceps—“Popeye sign”)
- Calcific tendonitis
- Cervical radiculopathy (spinal or foraminal stenosis, can test with Spurling maneuver)
- Glenohumeral arthritis (evaluate with plain films)
- Suprascapular nerve entrapment (look for focal muscle atrophy of supra- or infraspinatus)

- Traumatic rotator cuff tear

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Plain-film radiographs of the shoulder (three views): anteroposterior, axillary, scapular Y views
- Plain films may reveal:
  - Osteoarthritis of the acromioclavicular and glenohumeral joints
  - Superior migration of the humeral head (indicative of a large rotator cuff tear)
  - Cystic change of the humeral head and sclerosis of the inferior acromion (indicative of chronic rotator cuff disease)
  - Calcific tendonitis
- MRI is used to definitively assess rotator cuff tendinopathy, partial tears, and complete tears.
- MR arthrogram is preferred for labral pathology.
- Ultrasound is sensitive and specific for rotator cuff tears but is highly operator-dependent.
- CT scan is preferred for bony pathology or for those unable to undergo MRI.

Diagnostic Procedures/Other

- Lidocaine injection test
  - Inject lidocaine into the subacromial space:
    - Repeat impingement tests; if pain is completely relieved and range of motion is improved, likely impingement syndrome (rather than cuff tear).
  - Allows for more accurate strength testing on physical examination:
    - If strength is intact, rule out rotator cuff tear.
    - If range of motion does not improve in any plane, more likely adhesive capsulitis
  - Some pain relief and improved range of motion occurs after lidocaine injection with
    - Glenoid labral tear
    - Capsular strain
    - Glenohumeral osteoarthritis
    - Glenohumeral instability

- A lack of any pain relief suggests other sources or inappropriate placement of injection.

Test Interpretation

May have tendinosis, tendonitis, or muscle/tendon tear

TREATMENT

Pain control in combination with aggressive rehabilitation improves and fully resolves rotator cuff tendonitis in most patients.

GENERAL MEASURES

- Rest
- Ice or heat for symptom relief
- Activity modification, with avoidance of aggravating activities, particularly overhead motions
- Range-of-motion exercises
- Rotator-cuff and adjacent muscle strengthening to enhance stability and prevent further injuries

MEDICATION

First Line

NSAIDs or other analgesic, often for 6 to 12 weeks

ISSUES FOR REFERRAL

Failure of conservative treatment, persistent pain, weakness, or complete tear of rotator cuff

ADDITIONAL THERAPIES

- Supervised- or home-exercise regimens provide significant pain reduction and improve function (2)[A].
- Physical therapy is effective for short-term and long-term recovery of function (3)[A]:
  - Initial goal is to restore range of motion.
  - After pain resolves, gradually strengthen rotator cuff muscles in internal rotation, external rotation, and abduction.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Acupuncture is potentially beneficial for reducing pain and improving function, particularly when used with physical therapy (4)[A].

SURGERY/OTHER PROCEDURES

- Steroid injections may have a significant benefit on pain and function in the short term but do not appear to have a significant long-term effect (5)[A]:
- No evidence that surgery is superior to conservative management or that one surgical technique is superior to another for impingement syndrome (6)[A]
- Platelet-rich therapies for musculoskeletal soft tissue injuries are increasingly common.
  - No apparent effect of platelet-rich plasma injection during arthroscopic rotator cuff repair on overall retear rates or shoulder-specific outcomes
- Extracorporeal shock wave therapy is currently under study as an emerging treatment for calcific tendonitis.

ONGOING CARE

PATIENT EDUCATION

- Physical rehabilitation is necessary, both in conservative course of treatment (i.e., NSAIDs, physical therapy, home exercises) and in surgical intervention. An aggressive trial of rehabilitation should be encouraged prior to extensive testing or surgical intervention. Providing pain relief prior to beginning a program of physical therapy improves adherence and outcomes.
- Symptoms often recur if not fully addressed.

PROGNOSIS

- Variable, depends on underlying pathology
- Most patients improve with conservative management. Recovery can be slow.
- Patients with more severe symptoms—those with symptoms for >1 year—are less likely to respond well with conservative therapies.

COMPLICATIONS

- Progression of injury
- Tendon retraction in complete rotator cuff tear

CODES

ICD10

- M75.40 Impingement syndrome of unspecified shoulder
- M75.110 Incmpl rotatr-cuff tear/ruptr of unsp shoulder, not trauma
- M75.120 Complete rotatr-cuff tear/ruptr of unsp shoulder, not trauma

CLINICAL PEARLS

- Consider impingement syndrome in patients who engage in activities with repetitive overhead motions (e.g., swimming, throwing) who present with shoulder pain.
- Atraumatic shoulder pain in middle age often represents rotator cuff tendonitis.
- The supraspinatus tendon is most commonly affected in impingement syndrome.
- Neer and Hawkins tests specifically check for shoulder impingement.
- The empty can maneuver tests for weakness of supraspinatus muscle.
- The drop-arm test is specific for rotator cuff tear.
- Physical therapy over 6 to 12 weeks promotes return to function
- Most patients with shoulder impingement respond well to conservative management.

SALIVARY GLAND CALCULI/SIALADENITIS

Jason E. Cohn, DO, MS • Mark Weitzel, DO • Seth Zwillenberg, MD

BASICS

DESCRIPTION

- Inflammation and/or infection involving one or more salivary gland
- Sialolithiasis is the cause of ~90% of all obstructive salivary gland diseases.
- Salivary obstruction is usually characterized by a painful swelling of the affected gland when eating, known as “mealtime syndrome.”
- The submandibular gland is more commonly affected (80–90% of cases) by sialolithiasis and infection than the parotid gland. Submandibular stones occur more commonly due to higher mucinous content of saliva, longer course of Wharton duct, slow salivary flow, and saliva flow against gravity.
- Can be acute or chronic
  - Types: infectious, obstructive (sialolithiasis), and autoimmune

EPIDEMIOLOGY

Incidence

- Predominant age: Peak incidence is 30 to 60 years.
- Most common in debilitated and dehydrated patients
- 49% men and 51% women, average age 47.5 years; 82% submandibular stones and 18% parotid stones, 44% had a positive smoking history, and 20% of patients were taking diuretics.

Prevalence

- Salivary calculi can be found in 1.2% of the adult population.
- Only 5% of all cases occur in the pediatric population.
- In those with sialographic evidence of benign intraductal obstruction, the obstruction is caused by salivary calculi in >73% of cases.

ETIOLOGY AND PATHOPHYSIOLOGY

- Decreased salivary outflow from anticholinergics, dehydration, or radiation is

thought to allow bacterial infection of salivary glands.

- Salivary calculi form by deposition of calcium phosphate. Predisposing factors include salivary stasis, retrograde bacterial contamination from the oral cavity, increased alkalinity of saliva, and physical trauma to salivary duct or gland.
- Gout is a well-known systemic disease known to be associated with salivary stone development. In gout, sialoliths are composed of uric acid.
- Sialadenitis occurs by recurrent inflammatory reactions that result in progressive acinar destruction with fibrous replacement and sialectasis.
- Bacterial sialadenitis: *Staphylococcus aureus*, *Streptococcus viridans*, *Streptococcus pyogenes*, *Haemophilus influenzae*, *Escherichia coli*, *Pseudomonas aeruginosa*, and group B streptococci (neonates and prepubescent children)
- Viral sialadenitis: mumps, cytomegalovirus (CMV), Epstein-Barr virus (EBV), HIV, and enteroviruses

Pediatric Considerations

The two most common causes of sialadenitis in children are mumps and idiopathic juvenile recurrent parotitis.

Genetics

Polygenic cause, with several loci under investigation

RISK FACTORS

- Dehydration
- Anticholinergic use
- Antihistamine use
- Diuretic use
- Poor oral hygiene
- Malnutrition
- Head/neck radiation
- Tuberculosis (TB)
- HIV
- Failure to immunize (mumps)
- Gout

- Diabetes mellitus
- Hypothyroidism
- Renal failure
- Duct strictures
- Previous intraoral procedures

GENERAL PREVENTION

- Adequate hydration
- Maintain proper oral care and hygiene.
- Avoid antihistamines, anticholinergics, and other causes of xerostomia, especially if other risk factors are present.

COMMONLY ASSOCIATED CONDITIONS

- Postoperative dehydration
- Radiation-induced xerostomia
- Drug-induced xerostomia
- Sjögren syndrome
- Hypercalcemia

DIAGNOSIS

HISTORY

- Acute onset of pain and swelling over the affected salivary gland, especially postprandial
- Dental pain, discharge, foul breath (halitosis), and pain with chewing
- Fever, unintentional weight loss
- Xerostomia
- Recent dental work, surgery
- Immunization history
- Radiation, TB, and HIV exposure
- History of alcoholism, bulimia, and malnutrition (suggest sialadenosis)

PHYSICAL EXAM

- Palpate all salivary glands, floor of mouth, tongue, and neck to assess symmetry, tenderness, induration, edema, presence of stones, and

lymphadenopathy.
- Examine duct openings for purulent discharge and saliva.
- Palpate gland gently to express purulent material.
- Examine eyes for interstitial keratitis.
- Note lingual papillary atrophy and/or loss of tooth enamel.

Pediatric Considerations

Stones in children are traditionally smaller in size, within the duct distally, and present with a shorter symptom duration.

DIFFERENTIAL DIAGNOSIS

- Acute bacterial parotitis
- Chronic bacterial parotitis
- Idiopathic juvenile recurrent parotitis
- Dental abscess
- Mumps
- TB
- HIV (in pediatric populations)
- EBV, CMV, enteroviruses
- Tularemia
- Cystic fibrosis
- Lupus
- Sjögren syndrome
- Alcoholism
- Bulimia
- Hypothyroidism
- Pleomorphic adenoma
- Lymphoma
- Sarcoidosis
- Collagen vascular disease
- Metal poisoning

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Consider CBC, rarely electrolytes

- Culture and sensitivity of any expressed pus
- CT scan with IV contrast is the preferred imaging modality if needed.
- Ultrasound can localize abscesses as well as stones. Stones appear hyperechoic with posterior shadowing.
- Sonopalpation (concurrent ultrasound with transoral palpation) proved to have a sensitivity and specificity of 96.6% and 90% in finding a calculus.
- Minor salivary gland biopsy

Follow-Up Tests & Special Considerations

- If autoimmune process is suspected, consider ordering appropriate labs, such as autoantibody titers: Sjögren syndrome A (SS-A) and Sjögren syndrome B (SS-B), rheumatoid factor (RF), and antinuclear antibodies (ANAs). Erythrocyte sedimentation rate (ESR) may also be conducted.
- Consider serial CT scans with contrast to evaluate disease resolution.
- Ultrasound can identify indicators of persistent obstruction in patients undergoing sialolithotomy.

Diagnostic Procedures/Other

- Sialography to evaluate sialolithiasis and other obstructive lesions
- Sialendoscopy to find and remove sialoliths. In one study, sialendoscopy confirmed 221 (79%) parotid and 812 (93%) submandibular stones.
- One study revealed that sonography, cone beam CT, and sialendoscopy all had excellent specificity and positive predictive value in diagnosing stones. However, sialendoscopy was superior in sensitivity and negative predictive value (1)[B].
- When sialendoscopy fails, a novel ultrasound-guided needle localization approach has been proposed.
- Technetium-99m pertechnetate scintigraphy showed decreased gland excretion and decreased uptake in patients with sialolithiasis.

Test Interpretation

In chronic sialadenitis, loss of acini, fibrosis, and periductal lymphocytosis are evident; degree indicates chronicity.

TREATMENT

GENERAL MEASURES

- Maintain hydration.
- Apply warm compresses with massage.
- Maintain good oral hygiene.
- Antibiotics if indicated by diagnosis

MEDICATION

First Line

- Antistaphylococcal penicillins (nafcillin, dicloxacillin) are indicated in areas where methicillin-resistant *Staphylococcus aureus* (MRSA) is not predominant.
- Penicillin-allergic: Use clindamycin 300 mg PO q8h.
- Gram negative: 3rd-generation cephalosporin or fluoroquinolone
- Anaerobic: metronidazole or clindamycin
- Antibiotic coverage should be narrowed once culture and sensitivity are available.
- Continue antibiotic therapy for 10 to 14 days.

Second Line

- 1st-generation cephalosporin (cephalexin or cefazolin) or clindamycin is also indicated for empiric coverage.
- If MRSA than Vancomycin

ISSUES FOR REFERRAL

In the case of poor dentition and dental abscess, refer patient to a dentist.

ADDITIONAL THERAPIES

In the case of chronic sialadenitis with strictures, consider sialostent placement.

SURGERY/OTHER PROCEDURES

- Submandibular stones found in the anterior floor of the mouth can be excised intraorally (sialodochoplasty), whereas those in the hilum require gland excision. Parotid stones usually require parotidectomy (2)[A].
- Good results in patient symptom relief, quality of life, and safety have been

reported in sialadenitis and sialolithiasis using sialendoscopy (2,3,4)[A]. However, one study revealed a complication rate of 3.23%. Complications include strictures, ranulas, and lingual nerve injury.

- A combined approach using limited intraoral incision with sialendoscopy has shown a 87% success rate.
- Incision and drainage of parotid abscess is indicated after failing 3 to 5 days of medical management.
- Sialoliths and stenoses can be successfully treated by radiologically or fluoroscopically controlled or sialendoscopically based methods in ~80% of cases. Extracorporeal shock wave lithotripsy (ESWL) is successful in up to 50% of cases.
- Transoral duct slitting is an important method for extraparenchymal submandibular stones, with a success rate of 90%.
- Sialolithotomy with sialendoscopy can now be successfully performed robotically (5)[B].
- Recent evidence shows that larger stones can be successfully and safely treated with holmium: YAG laser lithotripsy.

Pediatric Considerations

The most effective diagnostic and therapeutic modality for children with sialadenitis is sialendoscopy with stone retrieval (6)[B].

COMPLEMENTARY & ALTERNATIVE MEDICINE

Consider lemon drops or other sialogogues to promote salivation. In one study, postoperative use of sialogogues nearly halved rates of sialadenitis.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Parotid abscess
- Sepsis
- Inability to tolerate PO intake
- Airway, breathing, circulation
- Check vital signs, with particular attention to blood pressure, as patient may be septic secondary to abscess formation.
- Evaluate airway patency.

- Nursing responsibilities may include ensuring excellent oral hygiene and avoiding administration of drugs that cause decreased production or flow of saliva.
- Discharge criteria
  - Exclude abscess or sepsis.
  - Ensure ability to tolerate PO intake.
  - Stable vital signs

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Provide regular follow-up visits for patients with chronic sialadenitis.
- Avoid prescribing medications that cause xerostomia.

Patient Monitoring

Continue to monitor patients with chronic sialadenitis, as decreased salivary gland function due to fibrosis and loss of acini can lead to acute exacerbations.

DIET

- Avoid sialogogues during acute attacks.
- Maintain adequate hydration on an outpatient basis.

PATIENT EDUCATION

- Educate patients on maintaining excellent oral hygiene.
- Educate patients on maintaining good hydration.

PROGNOSIS

- Generally excellent, with acute symptoms resolving in about a week with appropriate treatment
- Patients with autoimmune etiology may have prolonged course due to systemic involvement.

COMPLICATIONS

Abscess, dental caries, recurrent sialadenitis, facial nerve impingement, Ludwig angina

CODES

ICD10

- K11.5 Sialolithiasis
- K11.20 Sialoadenitis, unspecified
- K11.21 Acute sialoadenitis

CLINICAL PEARLS

- Sialadenitis occurs mainly in debilitated patients who lack ability to control hydration.

- Sialadenitis is associated with conditions that predispose patient to xerostomia.
- Mainstay of treatment is hydration, good oral hygiene, sialogogues, and possible surgical excision.
- Many cases are now being successfully and safely treated with sialendoscopy.

SALMONELLA INFECTION

Justin Thomas Ertle, BS, MD • Marie L. Borum, MD, EdD, MPH

BASICS

DESCRIPTION

- Infection caused by any serotype of the bacterial genus *Salmonella*, a gram-negative anaerobic bacillus
- Nontyphoidal *Salmonella* typically causes gastroenteritis via foodborne infection and sporadic outbreaks. Less commonly causes infection outside the gastrointestinal tract

Clinical syndromes

- Enteric fever (see "Typhoid Fever")
- Nontyphoidal gastroenteritis
  - Chronic carrier state (>1 year)
- Nontyphoidal invasive disease
  - Bacteremia
    - Endovascular complications
    - Localized infection outside GI tract

Geriatric Considerations

Patients >65 years old have increased risk of developing invasive disease with bacteremia and endovascular complications due to comorbidities (atherosclerotic endovascular lesions, prostheses, etc.) that increase risk of seeding (1).

Pediatric Considerations

Neonates (<3 months) are more susceptible to invasive disease and complications (1).

EPIDEMIOLOGY

Incidence

- Global incidence of nontyphoidal *Salmonella* enteritidis estimated to be 93.8 million per year in 2009 (2).

  - Wide variation by region from 40 to 3,980 estimated cases per 100,000 in 2009 (2)
- Global incidence of invasive nontyphoidal *Salmonella* infection estimated to be 2.1 to 6.5 million in 2010 (2).
  - Wide variation by region from 0.8 to 227 estimated cases per 100,000 in 2010 (2)
- Most commonly identified foodborne illness in the United States and a common cause of traveler's diarrhea (3)
- Second most common bacteria isolated from stool cultures in diarrheal illness (following *Campylobacter*) in the United States (3)
- Highest incidence in children <5 years old
- Hospitalization rates higher in patients >50 years old
- Peak frequency: July to November

ETIOLOGY AND PATHOPHYSIOLOGY

- *Salmonella enterica*
  - Most pathogenic species in humans
  - 2,500 different serotypes

Etiology

- ~95% of cases are foodborne (3).
- Majority of the other 5% of cases are due to direct or indirect fecal–oral contact with animals or human carriers.
- Iatrogenic contamination (e.g., blood transfusion, endoscopy) is possible, although rare.

Pathophysiology

- Typical infectious dose in immunocompetent patients is ingestion of one million bacteria (3).
- Bacteria ingested invade the distal ileal and proximal colonic mucosa to produce an inflammatory and cytotoxic response.
- Bacteria can enter the mesenteric lymphatic system and then into systemic circulation to cause disseminated/invasive disease.

RISK FACTORS

- Recent travel
- Consumption of undercooked meat, egg, or unpasteurized dairy products.

Nonanimal products have also been implicated in outbreaks.
- Contact with live reptiles or poultry.
- Contact with human carrier who has *Salmonella* fecal shedding.
- Impaired gastric acidity: H_2 receptor blockers, antacids, proton pump inhibitors (PPIs), gastrectomy, achlorhydria, pernicious anemia, infants
- Recent antibiotic use
- Reticuloendothelial blockade: sickle cell disease, malaria, bartonellosis
- Immunosuppression: HIV, diabetes, corticosteroid or other immunosuppressant use, chemotherapy
- Iron overload, chronic granulomatous disease
- Age <5 years or >50 years

GENERAL PREVENTION

- Proper hygiene in production, transport, and storage of food (e.g., refrigeration during food storage and thoroughly cooking food prior to consumption)
- Control of animal reservoirs: Avoid contact with high-risk animals, animal feces, and polluted waters.
- Hand hygiene
- CDC Web site (http://www.cdc.gov/salmonella/) tracks outbreaks

COMMONLY ASSOCIATED CONDITIONS

- Gastroenteritis
- Bacteremia: immunocompromised patients or those with underlying medical conditions (e.g., cholelithiasis, prostheses)
- Osteomyelitis: higher incidence in sickle cell disease
- Abscesses: higher incidence with malignant tumors
- Reactive arthritis

DIAGNOSIS

HISTORY

- *Salmonella* infections are typically asymptomatic or result in mild, self-limited gastroenteritis (1)[C].
- Exposure history: travel; contact with infected human, reptile, or poultry;

improper food preparation
- Host factors: age, immune status, other risk factors
- Symptoms typically begin 12 to 72 hours after ingestion and resolve within 4 to 10 days (4)[A].
- Acute uncomplicated illness
  - Sudden onset of nausea, vomiting, diarrhea (1)[C]
  - Abdominal cramping (1)[C]
  - Headache (1)[C]
  - Myalgias (1)[C]
  - Fever (1)[C]

PHYSICAL EXAM

- Fever (1)[A]
- Evidence of hypovolemia (1)[C]
- Abdominal tenderness (1)[C]
- Heme-positive stool in some patients (1)[C]
- Hepatosplenomegaly in some patients (3)[C]

DIFFERENTIAL DIAGNOSIS

- Viral gastroenteritis
- Bacterial enteritis due to other organisms
- Pseudomembranous colitis
- Inflammatory bowel disease

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Gastroenteritis
  - Stool culture for *Salmonella*, *Escherichia coli*, *Shigella*, and *Campylobacter* (1)[C]
  - Indications for stool culture include:
    - Severe diarrhea (≥6 loose stools daily) (1)[C]
    - Diarrhea >1 week in duration (1)[C]
    - Fever (1)[C]
    - Diarrhea containing blood or mucous (1)[C]
    - Multiple cases suggesting an outbreak (1)[C]

  - Fecal leukocytes: positive
- Bacteremia
  - Blood cultures (1)[C]
  - Stool cultures: may also be positive (1)[C]
- Endovascular infection
  - Consider angiography in patients >50 years of age with bacteremia if aortic or vascular source is suspected (4)[A].
- Local infections
  - Wound culture
  - Consider CT or MRI for soft tissue or bone infections (3)[C].
- Chronic carrier state
  - Stool culture positive for >1 year (3)[C]
  - Urine culture may be positive in chronic carriers.

Follow-Up Tests & Special Considerations

- Diarrhea lasting >10 days should prompt investigation for other causes.
- Asymptomatic excretion of *Salmonella* may occur for weeks after infection; follow-up fecal cultures are generally not indicated for patients with uncomplicated gastroenteritis (3,4)[C].
- Follow-up blood cultures are suggested for patients with bacteremia (3)[C].

Test Interpretation

Intestinal biopsies (if taken) may show mucosal ulceration, hemorrhage, and necrosis seen on along with reticuloendothelial hypertrophy/hyperplasia.

TREATMENT

- Treatment for nonsevere nontyphoidal *Salmonella* gastroenteritis in immunocompetent patients is supportive. The illness is typically self-limited. There is no proven benefit to treatment of mild disease. Treatment can suppress the host immunologic, and higher rates of relapse have been reported (1)[C],(5)[A].
- Consider antibiotics in immunocompetent hosts with severe diarrhea, high fever, or in those requiring hospitalization (1)[C].
- Some patients are at increased risk of bacteremia and benefit from antibiotics:

- Infants <3 months of age (1)[C]
- Persons >50 years old especially >65 years old (1,3)[C]
- Patients with hemoglobinopathies, atherosclerotic lesions, and prosthetic valves, grafts, or joints or any immunosuppressed state (1,3)[C],(4)[A]

- Chronic carriage of nontyphoidal *Salmonella*
  - 4 to 6 weeks of antimicrobial therapy
  - Prophylactic therapy in immunocompromised patients (4)[A]

GENERAL MEASURES

- Hydration and electrolyte replacement
- Hand washing and barrier precautions for inpatients
- Avoid antimotility drugs in patients with fever or dysentery. Antimotility drugs may increase contact time of the enteropathogen in the gut mucosa (1)[C].

MEDICATION

First Line

- Gastroenteritis, uncomplicated: No specific medications are necessary. Supportive care (1)[A]

- Gastroenteritis, complicated (due to illness severity or host risk factors such as immunocompromise)
  - Adults (treat for 14 days if immunocompromised)
    - Levofloxacin (or other fluoroquinolone) 500 mg/day PO for 7 to 10 days (1)[C]; or
    - Trimethoprim-sulfamethoxazole: 160/800 mg PO BID for 7 to 10 days *or*
    - Amoxicillin: 500 mg PO TID for 7 to 10 days *or*
    - Ceftriaxone: 1 to 2 g/day IV for 7 to 10 days *or*
    - Azithromycin: 500 mg/day PO for 7 days (1)[C]
  - Children
    - Ceftriaxone: 100 mg/kg/day IV or IM in 2 equally divided doses for 7 to 10 days (1)[C]; *or*
    - Azithromycin: 20 mg/kg/day PO daily for 7 days (1)[C]
  - HIV patients
    - Increased duration of antimicrobial therapy and/or zidovudine may decrease relapse (4)[C].

- Bacteremia: Due to resistance trends, treat life-threatening infections in adults with a fluoroquinolone *and* a 3rd-generation cephalosporin until susceptibilities are determined (4)[A].
  - Adults
    - Ciprofloxacin (or other fluoroquinolone): 400 mg IV BID for 10 to 14 days; *plus*
    - Ceftriaxone: 1 to 2 g/day IV for 10 to 14 days; *or*
    - Cefotaxime: 2 g IV q8h for 10 to 14 days
  - Children
    - Ampicillin: 200 mg/kg/day in 4 divided doses for 10 to 14 days; *or*
    - Trimethoprim-sulfamethoxazole: 8 to 12 mg/kg/day of trimethoprim component in 2 divided doses for 10 to 14 days; *or*
    - Ceftriaxone: 50 to 75 mg/kg/day (max 1 g) once per day for 10 to 14 days
- Localized infection (e.g., septic arthritis, osteomyelitis, cholangitis, and pneumonia)
  - Same treatment as for bacteremia
  - In sustained bacteremia, prolonged local infection, or immunocompromised patients, give antibiotics PO for 4 to 6 weeks (4)[A].
- Chronic carrier state (shedding >1 year duration)
  - Amoxicillin: 1 g PO TID for 12 weeks; *or*
  - Trimethoprim-sulfamethoxazole 160 mg/800 mg PO BID for 12 weeks; *or*
  - Ciprofloxacin: 500 mg PO BID for 4 weeks, *or*
  - Levofloxacin 500 mg/day for 4 weeks; *or*
  - Norfloxacin 400 mg PO BID for 4 weeks if gallstones are present.

ALERT

Antimicrobial resistance

- Strains resistant to ampicillin, chloramphenicol, and trimethoprim-sulfamethoxazole have been reported (6)[B].
- Fluoroquinolone resistance is increasing, perhaps due to increasing use in livestock (6)[B].
- Extended-spectrum cephalosporin resistance has been reported with increasing frequency (6)[B].

Second Line

- Aztreonam is an alternative agent that may be useful in patients with multiple allergies or organisms with unusual resistance patterns (4)[A].
- Fluoroquinolones are now routinely given to children for 5 to 7 days in areas of the world where multidrug-resistant *Salmonella typhi* is common (4)[A].

SURGERY/OTHER PROCEDURES

- Surgical excision and drainage for infected tissue sites, followed by a minimum of 2 weeks of antibiotic therapy (4)[A]
- If biliary tract disease is present, a preoperative 10- to 14-day course of parenteral antibiotics is recommended prior to cholecystectomy.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Asymptomatic shedding of *Salmonella* may occur for weeks after infection. Follow-up fecal cultures are generally not indicated for patients with uncomplicated gastroenteritis. Requirements may differ during a *Salmonella* outbreak (4)[A].
- Criteria may vary by state and local regulations. Some public health departments require negative stool cultures for health workers and food handlers prior to returning to work. Shedding may last 4 to 8 weeks (4)[A].
- Serotyping of isolates can be performed at public health laboratories.

DIET

Easily digestible foods (1)[C]

PATIENT EDUCATION

- Meticulous hand hygiene; caution handling raw meat, poultry, and eggs
- Fruits and vegetables should be thoroughly washed prior to consumption.
- Thoroughly cooking meats eliminates *Salmonella*.
- Caution when handling animals with high fecal carriage rates
- www.cdc.gov/salmonella/general/prevention.html

PROGNOSIS

- Most cases of *Salmonella* gastroenteritis are self-limited and have an excellent prognosis.
- Increased mortality is seen in the young (<3 months), elderly (>65 years), and immunocompromised (1–3).
- Increased mortality is seen with bacteremia and other invasive infections (2,5).
- Mortality is increased in multidrug-resistant strains (5).

COMPLICATIONS

Toxic megacolon, hypovolemic shock, metastatic abscess formation, endocarditis, infectious endarteritis, meningitis, septic arthritis, reactive arthritis, osteomyelitis, pneumonia, appendicitis, cholecystitis (1,3,4)

SEE ALSO

Gastroenteritis; Typhoid Fever

CODES

ICD10

- A02.9 Salmonella infection, unspecified
- A02.0 Salmonella enteritis
- A02.1 Salmonella sepsis

CLINICAL PEARLS

- Nontyphoidal *Salmonella* infection is typically a foodborne infection associated with a self-limited gastroenteritis.
- Clinical syndromes include gastroenteritis, bacteremia, endovascular infection, localized infection outside the GI tract, and a chronic carrier state.
- Those at greatest risk of complications from *Salmonella* infection include the young, the elderly, and immunocompromised patients.
- Uncomplicated gastroenteritis in healthy patients can be treated with supportive care.
- Antibiotics should be used in infants, the elderly, immunocompromised

patients, and for invasive infections such as bacteremia outside the GI tract.

SARCOIDOSIS

Donnah Mathews, MD, FACP

BASICS

DESCRIPTION

- Sarcoidosis is a noninfectious, multisystem, granulomatous disease of unknown cause, commonly affecting young and middle-aged adults.
  - Frequently presents with hilar adenopathy, pulmonary infiltrates, ocular or skin lesions
  - In ~50% of cases, it is diagnosed in asymptomatic patients with abnormal chest x-rays (CXRs).
  - Almost any organ may be involved.
- System(s) affected: primarily pulmonary but also cardiovascular, gastrointestinal, hematologic/lymphatic, endocrine, renal, neurologic, dermatologic, ophthalmologic, musculoskeletal
- Synonym(s): Löfgren syndrome (erythema nodosum [EN], hilar adenopathy, fever, arthralgias); Heerfordt syndrome (uveitis, parotid enlargement, facial palsy, fever); Besnier-Boeck disease; Boeck sarcoid; Schaumann disease (1,2,3,4)[C]

EPIDEMIOLOGY

Incidence

Estimated 6/100 person-years (4,5)[C]

Prevalence

- Estimated 10 to 20/100,000 persons
- Usually occurs in younger persons, peak age 20 to 39 years
- Rare in children (3,4)[C],(5)[B]

ETIOLOGY AND PATHOPHYSIOLOGY

- Despite extensive research, mostly unknown
- Thought to be due to exaggerated cell-mediated immune response to unknown antigen(s)

- In the lungs, the initial lesion is CD4+ T-cell alveolitis, causing noncaseating granulomata, which may resolve or may undergo fibrosis.
- "Immune paradox" with affected organs showing an intense immune response and yet anergy exists elsewhere (1,6)[C]

Genetics

- Reports of familial clustering, with genetic linkage to a section within MHC on short arm of chromosome 6
- 3 to 4 times more common in African Americans
- Although worldwide in distribution, increased prevalence in Scandinavians, Japanese, African Americans, and women (5)[B]
- In Northern Europe, 5 to 40 cases/100,000 persons. In Black Americans, 35 cases/100,000 persons. In Caucasian Americans, 11 cases/100,000 persons (4) [C]

RISK FACTORS

Exact etiology and pathogenesis remain unknown.

GENERAL PREVENTION

None

COMMONLY ASSOCIATED CONDITIONS

None

DIAGNOSIS

HISTORY

- Patients may be asymptomatic.
- Patients may have nonspecific complaints, such as the following:
  - Nonproductive cough
  - Shortness of breath
  - Fever
  - Night sweats
  - Weight loss
  - General fatigue
  - Eye pain

- Chest pain/palpitations
- Skin lesions
- Polyarthritis
- Renal calculi
- Facial droop due to Bell palsy
- Encephalopathy, seizures, hydrocephalus (rare)
- Patients >70 years old more likely to have systemic symptoms (6)[C]

PHYSICAL EXAM

- Many patients have a normal physical exam.
- Lungs may reveal wheezing/fine interstitial crackles in advanced disease.
- ~30% of patients have extrapulmonary manifestations (2)[C], which may include the following:
  - Uveitis
  - Other eye findings: conjunctival nodules, lacrimal gland enlargement, cataracts, glaucoma, papilledema
  - Cranial nerve palsies
  - Salivary gland swelling
  - Lymphadenopathy
  - Arrhythmias
  - Hepatosplenomegaly
  - Polyarthritis
  - Rashes (7)[B]
    - Maculopapular of nares, eyelids, forehead, base of neck at hairline, and previous trauma sites
    - Waxy nodular of face, trunk, and extensor surfaces of extremities
    - Plaques (lupus pernio) of nose, cheeks, chin, and ears
    - EN (component of Löfgren syndrome)
    - Atypical lesions

DIFFERENTIAL DIAGNOSIS

- Sarcoidosis is a diagnosis of exclusion.
- Infectious granulomatous disease, such as tuberculosis and fungal infections
- Hypersensitivity pneumonitis
- Lymphoma

- Other malignancies associated with lymphadenopathy
- Berylliosis (1)[B]

DIAGNOSTIC TESTS & INTERPRETATION

No definitive test for diagnosis, but diagnosis is suggested by the following:

- Clinical and radiographic manifestations
- Exclusion of other diagnoses
- Histopathologic detection of noncaseating granulomas

Initial Tests (lab, imaging)

- CBC: Anemia/leukopenia ± eosinophilia can be seen.
- Hypergammaglobulinemia can exist.
- LFTs: Abnormal liver function and increased alkaline phosphatase can be encountered with hepatic involvement.
- Calcium: Hypercalciuria occurs in up to 10% of patients, with hypercalcemia less frequent.
- Serum ACE inhibitors elevated in >75% of patients but is not diagnostic or exclusionary
  - Drugs may alter lab results: Prednisone will lower serum ACE and normalize gallium scan. ACE inhibitors will lower serum ACE level.
  - Disorders may alter lab results: Hyperthyroidism and diabetes will increase serum ACE level.
- CXR or CT scan may reveal granulomas/hilar adenopathy. Routine CXRs are staged using Scadding classification.
  - Stage 0 = normal
  - Stage 1 = bilateral hilar adenopathy alone
  - Stage 2 = bilateral hilar adenopathy + parenchymal infiltrates
  - Stage 3 = parenchymal infiltrates alone (primarily upper lobes)
  - Stage 4 = pulmonary fibrosis (8)[C]
- Chest CT scan may enhance appreciation of lymph nodes.
- High-resolution chest CT scan may reveal peribronchial disease.
- Gallium scan will be positive in areas of acute disease/inflammation but is not specific.
- Positron emission tomography (PET) scan can indicate areas of disease activity in lungs, lymph nodes, and other areas of the body but does not

differentiate between malignancy and sarcoidosis.
- Cardiac PET scan may detect cardiac sarcoidosis (3,4,8)[C]

Diagnostic Procedures/Other

- Pulmonary function tests (PFTs) may reveal restrictive pattern with decreased carbon monoxide diffusing capacity (DLCO).
- Characteristically in active disease, bronchioalveolar lavage fluid has an increased CD4-to-CD8 ratio.
- Ophthalmologic examination may reveal uveitis, retinal vasculitis, or conjunctivitis.
- ECG
- Tuberculin skin test
- Biopsy of lesions should reveal noncaseating granulomas.
- If lungs are affected, bronchoscopy with biopsy of central and peripheral airways is helpful. Endobronchial US (EBUS)–guided transbronchial needle aspiration may potentially have a better diagnostic yield (8)[A].
- Kveim test (ongoing research): Suspension of sterilized splenic cells from a patient with sarcoidosis is injected in an intradermal skin test to evoke a sarcoid granulomatous response over 3 weeks, similar to a tuberculin skin test.

ALERT

If signs indicate Löfgren syndrome (acute sarcoid with bilateral hilar lymphadenopathy, EN, and diffuse arthritis/arthralgias), it is not necessary to perform a biopsy because prognosis is good with observation alone, and biopsy would not change management.

Test Interpretation

Noncaseating epithelioid granulomas without evidence of fungal/mycobacterial infection

TREATMENT

- Many patients undergo spontaneous remission. It is difficult to assess disease activity and severity, however, making it challenging to develop guidelines.
- No treatment may be necessary in asymptomatic individuals, but treatment

may be needed for specific indications, such as cardiac, CNS, renal, or ocular involvement.

- No treatment is indicated for asymptomatic patients with stage I to III radiographic changes with normal/mildly abnormal lung function, although close follow-up is recommended.
- Treatment of pulmonary and skin manifestations is done on the basis of impairment. The symptoms that necessitate systemic therapy remain controversial.
  - Worsening pulmonary symptoms
  - Deteriorating lung function
  - Worsening radiographic findings (9)[B]

MEDICATION

Systemic therapy is clearly indicated for hypercalcemia, cardiac disease, neurologic disease, and eye disease not responding to topical therapy. Most patients with pulmonary sarcoidosis do not require treatment with medications, as many are asymptomatic or have a spontaneous remission.

First Line

- There is no FDA-approved treatment specifically for sarcoidosis.
- Systemic corticosteroids in the symptomatic individual (dyspnea, cough, hemoptysis) or in the individual with worsening lung function or radiographic findings
  - The optimal dose of glucocorticoids is not known.
  - Usually prednisone initially, 0.3 to 0.6 mg/kg ideal body weight (20 to 40 mg/day) for 4 to 6 weeks
  - If stable, taper by 5 mg/week to 10 to 20 mg/day over the next 6 weeks.
  - If no relapse, 10 to 20 mg/day for 8 to 12 months
  - Relapse is common.
  - Higher doses (80 to 100 mg/day) may be warranted in patients with acute respiratory failure, cardiac, neurologic, or ocular disease.
- In patients with skin disease, topical steroids may be effective.
- Inhaled steroids (budesonide 800 to 1,600 μg BID) may be of some clinical benefit in early disease with mild pulmonary symptoms.
  - Contraindications: patients with known problems with corticosteroids

- Precautions: careful monitoring in patients with diabetes mellitus and/or hypertension
- Significant possible interactions: Refer to the manufacturer's profile of each drug (1,4,9)[C].

Second Line

- All alternative agents to glucocorticoids carry substantial risk for toxicity, including myelosuppression, hepatotoxicity, and opportunistic infection.
- Methotrexate: initially 7.5 mg/week, increasing gradually to 10 to 15 mg/week
- Azathioprine: generally a supplement to prednisone in an attempt to lower steroid doses
- Leflunomide: 20 mg/day
- Use of immunosuppressants, such as methotrexate or azathioprine, will require regular monitoring of CBC and LFTs.
- Antimalarial agents, such as chloroquine or hydroxychloroquine
- Tumor necrosis factor antagonists, such as infliximab, have been useful in refractory cases (4,9)[C].

ISSUES FOR REFERRAL

May be followed by a pulmonologist, with referrals to other specialists as dictated by involvement of other organ systems. If requiring a second-line therapy, should be followed by a specialist.

SURGERY/OTHER PROCEDURES

Lung transplantation in severe, refractory cases; long-term outcomes are unknown.

COMPLEMENTARY & ALTERNATIVE MEDICINE

None known to be effective

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

There is limited data on indications for the specific tests and optimal frequency of monitoring of disease activity. Suggestions follow.

Patient Monitoring

- Patients on prednisone for symptoms should be seen q1–2mo while on therapy.
- Patients not requiring therapy should be seen regularly (q3mo) for at least the first 2 years after diagnosis, obtaining a thorough history and physical exam, laboratory testing tailored to sites of disease activity, PFTs, and ambulatory pulse oximetry.
- If active disease
  - Every 6 to 12 months, obtain ophthalmologic exam if on hydroxychloroquine.
  - Annually, CBC, creatinine, calcium, LFTs, ECG, 25-hydroxy vitamin D and 1,25 dihydroxy vitamin D, CXR, ophthalmologic examination
- Other testing per individual patient's symptoms, including HRCT, echocardiogram, Holter monitoring, urinalysis (UA), thyroid-stimulating hormone (TSH), bone density, MRI of brain
- The serum ACE level is used by some physicians to follow the disease activity. In patients with an initially elevated ACE level, it should fall toward normal while on the therapy or when the disease resolves.
- If inactive disease, follow annually with history and physical exam, PFTs, ambulatory pulse oximetry, CBC, creatinine, calcium, liver enzymes, 1,25 dihydroxy vitamin D, ECG, ophthalmologic exam.

DIET

No special diet

PATIENT EDUCATION

- The American Lung Association: www.lungusa.org/lung-disease/sarcoidosis/?gclid=CPX6zuipm6MCFQxW2godISFepQ
- Sarcoidosis by Medline Plus: www.nlm.nih.gov/medlineplus/sarcoidosis.html

PROGNOSIS

- 50% of patients will have spontaneous resolution within 2 years.
- 25% of patients will have significant fibrosis, but no further worsening of the disease after 2 years.
- 25% of patients (higher in some populations, including African Americans)

will have chronic disease.
- Patients on corticosteroids for >6 months have a greater chance of having chronic disease.
- Overall death rate: <5%

COMPLICATIONS

- Patients may develop significant respiratory involvement, including cor pulmonale.
- Pulmonary hemorrhage from infection with aspergillosis in the damaged lung is possible.
- Other organs, especially the heart (congestive heart failure, arrhythmias), eyes (rarely blindness), and CNS, can be involved with serious consequences. Cardiac, ocular, and CNS involvement usually manifests early on in patients with these complications of the disease.

CODES

ICD10

- D86.9 Sarcoidosis, unspecified
- D86.0 Sarcoidosis of lung
- D86.86 Sarcoid arthropathy

CLINICAL PEARLS

- Sarcoidosis is a noninfectious, multisystem, granulomatous disease of unknown cause, typically affecting young and middle-aged adults.
- Any organ can be affected.
- Diagnosis is based on clinical findings, exclusion of other disorders, and pathologic detection of noncaseating granulomas.
- Most patients do not need systemic treatment, and the disease resolves spontaneously; a few will have life-threatening progressive organ dysfunction.

SCABIES

Kaelen C. Dunican, PharmD • Brandi Hoag, DO

BASICS

DESCRIPTION

- A contagious parasitic infection of the skin caused by the mite *Sarcoptes scabiei*, var. *hominis*
- System(s) affected: skin/exocrine
- Synonym(s): sarcoptic mange

EPIDEMIOLOGY

Incidence

Predominant age: children and young adults

Prevalence

- Global prevalence is estimated at 300 million cases per year.
- May be more prevalent in urban areas and areas of overcrowding

ETIOLOGY AND PATHOPHYSIOLOGY

Itching is a delayed hypersensitivity reaction to the mite saliva, eggs, or excrement.

S. scabiei, var. *hominis*

- An obligate human parasite
- Female mite lays eggs in burrows in the stratum corneum and epidermis.
- Primarily transmitted by prolonged human-to-human direct skin contact
- Infrequently transmitted via fomites (e.g., bedding, clothing, or furnishings)

RISK FACTORS

- Personal skin-to-skin contact (e.g., sexual promiscuity, crowding, nosocomial infection)
- Poor nutritional status, poverty, and homelessness
- Hot, tropical climates
- Seasonal variation: Incidence may be higher in the winter than in the summer (may be due to overcrowding).

- Immunocompromised patients, including those with HIV/AIDS, are at increased risk of developing severe (crusted/Norwegian) scabies.

GENERAL PREVENTION

Prevent outbreaks by prompt treatment and cleansing of fomites (see "Additional Therapies").

DIAGNOSIS

HISTORY

- Generalized itching is often severe and worse at night.
- Determine any contact with infected individuals.
- Initial infection may be asymptomatic.
- Symptoms may develop after 3 to 6 weeks.

PHYSICAL EXAM

- Lesions (inflammatory, erythematous, pruritic papules) most commonly located in the finger webs, flexor surfaces of the wrists, elbows, axillae, buttocks, genitalia, feet, and ankles
- Burrows (thin, curvy, elevated lines in the upper epidermis that measure 1 to 10 mm in length) may be seen in involved areas—a pathognomic sign of scabies.
- Secondary erosions or excoriations from scratching
- Pustules (if secondarily infected)
- Pruritic nodules in covered areas (buttocks, groin, axillae) resulting from an exaggerated hypersensitivity reaction
- Crusted scabies (Norwegian scabies) is a psoriasiform dermatosis occurring with hyperinfestation with thousands of mites (more common in immunosuppressed patients).

Geriatric Considerations

The elderly often itch more severely despite fewer cutaneous lesions and are at risk for extensive infestations, perhaps related to a decline in cell-mediated immunity. There may be back involvement in those who are bedridden.

Pediatric Considerations

Infants and very young children often present with vesicles, papules, and pustules and have more widespread involvement, including the hands, palms, feet, soles, body folds, and head (rare for adults).

DIFFERENTIAL DIAGNOSIS

- Atopic dermatitis
- Contact dermatitis
- Folliculitis/impetigo
- Tinea corporis
- Dermatitis herpetiformis
- Eczema
- Insect bites
- Papular urticaria
- Pediculosis corporis
- Pityriasis rosea
- Prurigo
- Psoriasis (crusted scabies)
- Pyoderma
- Seborrheic dermatitis
- Syphilis

DIAGNOSTIC TESTS & INTERPRETATION

- Definitive diagnosis is based on microscopic identification of mites, eggs, or fecal pellets (scybala) but diagnosis may be based on history and physical exam(1–4)[C].
- A failure to find mites does not rule out scabies.

Initial Tests (lab, imaging)

CBC is rarely needed but may show eosinophilia.

Diagnostic Procedures/Other

- Examination of skin with magnifying lens
  - Look for typical burrows in finger webs and on flexor aspect of the wrists and on the penis.
  - Look for a dark point at the end of the burrow (the mite).
  - Presumptive diagnosis based on clinical presentation, skin lesions, and

identification of burrow (1–3).

- Skin scraping
  - Place a drop of mineral oil over a nonexcoriated lesion or burrow.
  - Scrape the lesion with a surgical blade.
  - Examine under a microscope for mites, eggs, egg casings, or feces (1,2)[C].
  - Scraping from under fingernails often may be positive.
  - When mite is not found with scraping, biopsy may reveal mite, eggs, or feces (1,3).
- Potassium hydroxide (KOH) wet mount not recommended because it can dissolve mite pellets.
- Burrow ink test
  - If burrows are not obvious, apply gentian violet or India ink to an area of rash. Wash off the ink with alcohol. A burrow should remain stained and become more evident.
  - Then apply mineral oil, scrape, and observe microscopically, as noted previously (1,3)[C].

Test Interpretation

Skin biopsy of a nodule (although performed rarely) will reveal portions of the mite in the corneal layer.

TREATMENT

GENERAL MEASURES

- Treat all intimate contacts and close household and family members.
- Wash all clothing, bed linens, and towels in hot (60°C) water and dry in hot dryer.
- Personal items that cannot be washed should be sealed in a plastic bag for at least 3 to 5 days.
- Some itching and dermatitis may persist for up to 6 weeks and can be treated with oral antihistamines and/or topical or oral corticosteroids.

MEDICATION

First Line

Permethrin 5% cream (Elimite) is generally accepted as first-line therapy (1–3,5) [A].

- After bathing or showering, apply cream from the neck to the soles of the feet paying particular attention to areas that are most involved; then wash off after 8 to 14 hours and repeat in 1 week.
- The adult dose is usually 30 g per treatment.
- Side effects include itching and stinging (minimal absorption).
- Crusted scabies may require more frequent application (q2–3d for 1 to 2 weeks) in combination with repeated doses of PO ivermectin on days 1, 2, 8, 9, and 15 (2,3,5)[C].

Pediatric Considerations

Permethrin may be used on infants >2 months of age. In children <5 years of age, the cream should be applied to the head and neck as well as to the entire body.

Second Line

- Ivermectin (Stromectol)
  - Not FDA approved for scabies
  - 200 to 250 μg/kg PO as single dose; repeated in 1 week
  - Take with food to improve bioavailability and enhance penetration into the epidermis.
  - May need higher doses or may need to use in combination with topical scabicide for HIV-positive patients
- Crotamiton (Eurax) 10% cream
  - Apply from the neck down for 24 hours, rinse off, then reapply for an additional 24 hours, and then thoroughly wash off.
  - Nodular scabies: Apply to nodules for 24 hours, rinse off, reapply for an additional 24 hours, then thoroughly wash off.
- Precipitated sulfur 2–10% in petrolatum
  - Not FDA approved for scabies
  - Apply to the entire body from the neck down for 24 hours, rinse by bathing, then repeat for 2 more days (3 days total). It is malodorous and messy but is thought to be safer than lindane, especially in infants <6 months of age, and safer than permethrin in infants <2 months of age.

- Lindane (γ-benzene hexachloride, Kwell) 1% lotion
  - Apply to all skin surfaces from the neck down and wash off 6 to 8 hours later.
  - Two applications 1 week apart are recommended but may increase the risk of toxicity.
  - 2 oz is usually adequate for an adult.
    - Side effects: neurotoxicity (seizures, muscle spasms), aplastic anemia
    - Contraindications: uncontrolled seizure disorder, premature infants
    - Precautions: Do not use on excoriated skin, on immunocompromised patients, in conditions that may increase risk of seizures, or with medications that decrease seizure threshold.
    - Possible interactions: concomitant use with medications that lower the seizure threshold

ALERT

Lindane: FDA black box warning of severe neurologic toxicity; use only when all other agents have failed.

Pediatric Considerations

- The FDA recommends caution when using lindane in patients who weigh <50 kg. It is not recommended for infants and is contraindicated in premature infants.
- PO ivermectin should be avoided in children <5 years and in those weighing <15 kg.

Pregnancy Considerations

- Permethrin is pregnancy Category B, and lindane, ivermectin, and crotamiton are Category C.
- Permethrin is considered compatible with lactation, but if permethrin is used while breastfeeding, the infant should be bottlefed until the cream has been thoroughly washed off.

ADDITIONAL THERAPIES

- Crusted scabies may require use of keratolytics to improve penetration of permethrin.
- Benzyl benzoate lotion (not available in the United States but used widely in

developing countries)
  - Not FDA approved for scabies.
  - Dose for adults is 25–28%; dilute to 12.5% for children and 6.25% for infants
  - After bathing, apply lotion from the neck to soles of feet for 24 hours.
- Topical ivermectin 1% lotion (investigational, not available for use in the United States) (4)
  - Not FDA approved for scabies.
  - Apply to affected sites and wash off 8 hours later.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Herbal products such as tea tree oil, clove oil, neem oil, and aloe vera require additional evidence to establish efficacy (4).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Recheck patient at weekly intervals only if rash or itching persists. Scrape new lesions and retreat if mites or products are found.

PATIENT EDUCATION

- Patients should be instructed on proper application and cautioned not to overuse the medication when applying it to the skin.
- A patient fact sheet is available from the CDC: http://www.cdc.gov/parasites/scabies/

PROGNOSIS

- Lesions begin to regress in 1 to 2 days, along with the worst itching, but eczema and itching may persist for up to 6 weeks after treatment.
- Nodular lesions may persist for several weeks, perhaps necessitating intralesional or systemic steroids.
- Some instances of lindane-resistant scabies have now been reported. These cases do respond to permethrin.

COMPLICATIONS

- Poor sleep due to pruritus
- Social stigma
- Secondary bacterial infection (group A streptococci and *Staphylococcus aureus*)
- Sepsis
- Glomerulonephritis
- Eczema
- Pyoderma
- Postscabetic pruritus
- Nodules (nodular scabies) may persist for weeks to months after treatment.

SEE ALSO

Arthropod Bites and Stings; Pediculosis (Lice)

CODES

ICD10

B86 Scabies

CLINICAL PEARLS

- Prior to diagnosis, use of a topical steroid to treat pruritic symptoms may

mask symptoms and is termed *scabies incognito*.

- Environmental control is recommended. All linens, towels, and clothing used in the previous 4 days should be washed in hot water or dry-cleaned. Personal items that cannot be washed or dry-cleaned should be sealed in a plastic bag for 3 to 5 days.
- All members of the affected household may require treatment, especially close contacts (those sharing the same bed or who have intimate contact).
- Eczema and itching may persist for up to 6 weeks after treatment, causing many patients to falsely believe that they have failed treatment or are being reinfected.
- In patients with actual reinfection, either the patient has not applied the medication properly or, more likely, the index patient has not been identified and treated.

SCARLET FEVER

John C. Huscher, MD

BASICS

DESCRIPTION

- A disease (typically in childhood) characterized by fever, pharyngitis, and rash caused by group A β-hemolytic *Streptococcus pyogenes* (GAS) that produces erythrogenic toxin
- Incubation period: 1 to 7 days
- Duration of illness: 4 to 10 days
- Rash usually appears on the second day of illness.
- Rash first appears on the upper chest and flexural creases and then spreads rapidly all over the body.
- Rash clears at the end of the 1st week and is followed by several weeks of desquamation.
- System(s) affected: head, eyes, ears, nose, throat, skin/exocrine
- Synonym(s): scarlatina

EPIDEMIOLOGY

Incidence

- Rare in infancy because of maternal antitoxin antibodies
- Predominant age: 6 to 12 years
- Peak age: 4 to 8 years
- Predominant sex: male = female
- Rare in the United States in persons >12 years because of high rates (>80%) of lifelong protective antibodies to erythrogenic toxins
- Increased rates are noted in United Kingdom in 2013.

Prevalence

- 5–30% of cases of pharyngitis in children are due to GAS.
- <10% of children with streptococcal pharyngitis develop scarlet fever.

ETIOLOGY AND PATHOPHYSIOLOGY

- Erythrogenic toxin production is necessary to develop scarlet fever.
- Three toxin types: A, B, C
- Toxins damage capillaries (producing rash) and act as superantigens, stimulating cytokine release.
- Antibodies to toxins prevent development of rash but do not protect against underlying infection.
- Primary site of streptococcal infection is usually within the tonsils, but scarlet fever may also occur with infection of skin, surgical wounds, or uterus (puerperal scarlet fever).

RISK FACTORS

- Winter/spring seasonal increase
- More common in school-aged children
- Contact with infected individual(s)
- Crowded living conditions (e.g., lower socioeconomic status, barracks, child care, schools)

GENERAL PREVENTION

- Spread by contact with airborne respiratory droplets
- Asymptomatic contacts do not require cultures/prophylaxis.
- Symptomatic contacts may be treated with or without culture.
- Children should not return to school/daycare until they have received 24 hours of antibiotic therapy.

COMMONLY ASSOCIATED CONDITIONS

- Pharyngitis
- Impetigo
- Rheumatic fever
- Glomerulonephritis

DIAGNOSIS

HISTORY

Prodrome 1 to 2 days

- Sore throat

- Headache
- Myalgias
- Malaise
- Fever (>38°C [100.4°F])
- Vomiting
- Abdominal pain (may mimic acute abdomen)
- Rash—scarlatiniform erythematous punctate eruption
- Cough, conjunctivitis, hoarseness, and rhinorrhea are more commonly associated with viral infections.

PHYSICAL EXAM

- Oral exam
  - Beefy red tonsils and pharynx with/without exudate
  - Petechiae on palate
  - White coating on tongue: White strawberry tongue appears on days 1 to 2. This sheds by days 4 to 5, leaving a red strawberry tongue, which is shiny and erythematous with prominent papillae.
- Exanthem (appears within 1 to 5 days)
  - Scarlet macules with generalized erythema; blanches when pressed
  - Orange-red punctate skin eruption with sandpaper-like texture, “sunburn with goose pimples”
  - Coarse “sandpaper” rash—helpful in dark-skinned individuals
  - Initially, rash appears on chest and axillae. It then spreads to abdomen and extremities; prominent in skin folds, flexural surfaces (e.g., axillae, groin, buttocks), with sparing of palms and soles.
  - Flushed face with circumoral pallor, red lips
  - Pastia lines: transverse red streaks in skin folds of abdomen, antecubital space, and axillae
  - Desquamation begins on face after 7 to 10 days and proceeds over trunk to hands and feet; may persist for 6 weeks.
  - In severe cases, small vesicular lesions (miliary sudamina) may appear on abdomen, hands, and feet.

DIFFERENTIAL DIAGNOSIS

- Viral exanthem: measles; rubella; roseola

- Infectious mononucleosis
- *Mycoplasma* pneumonia
- Secondary syphilis
- Toxic shock syndrome
- Staphylococcal scalded-skin syndrome
- Kawasaki disease
- Drug hypersensitivity
- Severe sunburn

DIAGNOSTIC TESTS & INTERPRETATION

- Test for GAS pharyngitis by rapid antigen detection test (RADT) and/or culture with pharyngeal swab because clinical features alone do not reliably discriminate between GAS and viral pharyngitis.
- Testing for GAS pharyngitis is *not recommended* for patients with symptoms suggesting a viral etiology (e.g., cough, rhinorrhea, hoarseness, oral ulcers).

Initial Tests (lab, imaging)

- RADT: diagnostic if positive, 95% specific; sensitivity approaches that of culture. Negative RADT should be confirmed by throat culture. Positive RADTs do not require backup culture (1)[C].
- Throat culture: β-hemolytic colonies that are catalase negative and sensitive to bacitracin; culture is the gold standard for confirming streptococcal infection (99% specific, 90–97% sensitive; 5–10% of healthy individuals are carriers) (1).
- Serologic tests (antistreptolysin O titer and streptozyme tests, antihyaluronidase): Confirm recent GAS infection; not helpful or recommended for diagnosis of acute disease.
- Gram stain: gram-positive cocci in chains
- CBC may show elevated WBC count (12,000 to 16,000/mm^3); eosinophilia later (second week).
- Follow-up (posttreatment) throat cultures or RADT not routinely recommended
- Diagnostic testing and empiric treatment of asymptomatic household contacts of patients with acute streptococcal pharyngitis is not routinely recommended (2)[B].

- Appropriately symptomatic patients >3 years old with a family member recently diagnosed with laboratory-confirmed GAS pharyngitis may be treated without screening or confirmatory testing (3)[C].

Follow-Up Tests & Special Considerations

- Recent antibiotic therapy may impact culture results.
- Within 5 days of symptoms, antibiotics can delay/abolish antistreptolysin O response.

Test Interpretation

Skin lesions reveal characteristic inflammatory reaction, specifically hyperemia, edema, and polymorphonuclear cell infiltration.

TREATMENT

GENERAL MEASURES

Supportive care; analgesic/antipyretic such as acetaminophen or an NSAID, for treatment of moderate to severe symptoms or control of fever

MEDICATION

First Line

The main reason for treating GAS is to decrease the risk of acute rheumatic fever. Early treatment decreases duration of symptoms by 1 to 2 days and decreases the period of contagiousness (3)[B].

- Penicillin (PO; penicillin V and others) for 10 days
  - 250 mg PO BID or TID for ≥27 kg (60 lb); 500 mg BID or TID for >27 kg (60 lb) adolescents and adults(1,4,5)[A]
  - If compliance is questionable, use penicillin G, benzathine: single IM dose 600,000 U for ≥27 kg (60 lb); 1.2 mU for those >27 kg.
- Amoxicillin (PO) 50 mg/kg once daily or 25 mg/kg twice daily for 10 days (use only for definitive GAS because it can induce rash with some viral infections) (6)[A]
  - Contraindications: penicillin allergy
- Acetaminophen for fever and pain
- Precautions: Avoid in patients with penicillin allergy (anaphylaxis).

Second Line

- For patients allergic to penicillin
  - Azithromycin (Zithromax, Z pack): 12 mg/kg/day (max 500 mg) for 5 days (4)[A]
  - Clarithromycin (Biaxin): children >6 months: 7.5 mg/kg BID for 10 days; adults: 250 mg BID for 10 days
- Oral cephalosporins: Many are effective, but first-generation cephalosporins are less expensive:
  - Cephalexin 25 to 50 mg/kg/day divided every 12 hours for 10 days; max 500 mg every 12 hours (1)[A]
  - Cefadroxil 30 mg/kg/day divided BID; max 500 mg BID for 10 days (1)
- Clindamycin 20 mg/kg/day divided TID for 10 days (4)[B]
- Tetracyclines and sulfonamides should not be used.

ALERT
Avoid aspirin in children due to risk of Reye syndrome.

ISSUES FOR REFERRAL

Peritonsillar abscess; shock symptoms: hypotension, disseminated intravascular coagulation (DIC), cardiac, liver, renal dysfunction

SURGERY/OTHER PROCEDURES

- Tonsillectomy is recommended with recurrent bouts of pharyngitis (≥6 positive strep cultures in 1 year).
- While children still may get streptococcal pharyngitis (“strep throat”) after a tonsillectomy, the procedure reduces the frequency and severity of infections.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Follow-up throat culture is not needed unless the patient is symptomatic.

Patient Monitoring

GAS is uniformly susceptible to penicillin, treatment failures are typically due to:

- Poor adherence to recommended antibiotic therapy
- β-Lactamase oral flora hydrolyzing penicillin
- GAS carrier state and concurrent viral rash (requires no treatment)
- Repeat exposure to carriers in family: Streptococci persist on nonrinsed toothbrushes and orthodontic appliances for up to 15 days.
- Recurrent GAS pharyngitis after a recent oral antibiotic course can be retreated with the same agent, an alternative oral agent, or IM penicillin G.

DIET

No special diet

PATIENT EDUCATION

- A brief delay in initiating treatment awaiting culture results does not increase the risk of rheumatic fever.
- Complete the entire course of antibiotics.
- Children should not return to school/daycare until they have received >24 hours of antibiotic therapy.
- Can spread person to person: attend to personal hygiene (wash hands, don‘t share utensils)
- “Recurring strep throat: When is tonsillectomy useful?” (http://www.mayoclinic.org/diseases-conditions/strep-throat/expert-answers/recurring-strep-throat/faq-20058360)

PROGNOSIS

- Symptoms are shortened by 12 to 24 hours with penicillin.
- Recurrent attacks are possible (different erythrogenic toxins).

COMPLICATIONS

- Suppurative
  - Sinusitis
  - Otitis media/mastoiditis
  - Cervical adenitis
  - Peritonsillar abscess/retropharyngeal abscess
  - Pneumonia
  - Bacteremia with metastatic infectious foci: meningitis, brain abscess, osteomyelitis, septic arthritis, endocarditis, intracranial venous sinus

thrombosis, necrotizing fasciitis

- Nonsuppurative
  - Rheumatic fever: Therapy prevents rheumatic fever when started as long as 10 days after onset of acute GAS infection.
  - Glomerulonephritis: due to nephritogenic strain of *Streptococcus*; prevention even after adequate treatment of GAS is less certain
  - Streptococcal toxic shock syndrome: fever; hypotension; DIC; and cardiac, liver, and/or kidney dysfunction related to other toxin-mediated sequelae
  - Cellulitis
  - Weeks to months later, may develop transverse grooves in nail plates and hair loss (telogen effluvium)

SEE ALSO

- Pharyngitis
- Algorithm: Pharyngitis

CODES

ICD10

- A38.9 Scarlet fever, uncomplicated
- J02.0 Streptococcal pharyngitis
- A38.0 Scarlet fever with otitis media

CLINICAL PEARLS

- Consider scarlet fever in the differential diagnosis of children with fever and an exanthematous rash.
- Key clinical findings include strawberry tongue, circumoral pallor, and a coarse sandpaper rash.
- Desquamation (7 to 10 days after symptom onset) may last for several weeks following acute illness in scarlet fever.
- Throat culture remains the diagnostic test of choice to document streptococcal illness.
- Penicillin is the drug of choice for treatment.

SCHIZOPHRENIA

Margarita Abi Zeid Daou, MD • Jeffrey Stovall, MD

BASICS

Schizophrenia is a persistent and severe psychiatric condition characterized by neurocognitive decline and impairment in reality testing.

DESCRIPTION

- Major psychiatric disorder characterized by prodrome, active, and residual psychotic symptoms involving disturbances in appearance, speech, behavior, perception, and thought that last for at least 6 months.
- *DSM-5* eliminated subcategories of schizophrenia (1).
- System(s) affected: central nervous system (CNS)

EPIDEMIOLOGY

Incidence

- 7.7 to 43/100,000
- Predominant sex: male-to-female ratio = 1.4:1.0
- Age of onset: typically <30 years, earlier in males (early to mid-20s) than females (late 20s), with a smaller peak that occurs in women >45 years

Prevalence

- Lifetime (1%): highest prevalence in lower socioeconomic classes and urban settings (2-fold higher risk)
- 1.1% of the population >18 years old; similar rates in all countries

ETIOLOGY AND PATHOPHYSIOLOGY

- Stems from a complex interaction between genetic and environmental factors; higher incidence if prenatal infection or hypoxia, winter births, first-generation immigrants, advanced paternal age, drug use, and genetic (velocardiofacial) syndromes
- Overstimulation of mesolimbic dopamine D_2 receptors, deficient prefrontal dopamine, and aberrant prefrontal glutamate (NMDA) activity results in perceptual disturbances, disordered thought process, and cognitive

impairments.

Genetics

If first-degree biologic relative has schizophrenia, risk is 8–10%; a 10-fold increase

GENERAL PREVENTION

- Currently, no known preventive measures decrease the incidence of schizophrenia.
- Interventions to improve long-term outcome and associated comorbid conditions are employed during management.

COMMONLY ASSOCIATED CONDITIONS

- Nicotine dependence (>50%) (1) and substance use disorders are common and lead to significant long-term medical and social complications (2).
- Metabolic syndrome, diabetes mellitus, obesity, and certain infectious diseases, including HIV, hepatitis B, and hepatitis C all occur in higher-than-expected rates in individuals with schizophrenia.

DIAGNOSIS

Focus on identifying an insidious social and functional decline per history with the onset of ≥2 of the following characteristic symptoms on mental status exam:

- Delusions (fixed, false beliefs)
- Hallucinations (auditory > visual disturbances)
- Disorganized thought (derailed or incoherent speech)
- Grossly disorganized/catatonic behavior (hyper- or hypoactive movements that are often repetitive)
- Negative symptoms (affective flattening, avolition, asociality, alogia, anhedonia) (1)

PHYSICAL EXAM

No physical findings characterize the illness; however, chronic treatment with neuroleptic agents may result in parkinsonism, tardive dyskinesia, and other extrapyramidal symptoms.

DIFFERENTIAL DIAGNOSIS

- Psychotic disorder due to another medical condition
  - Disorientation, in particular, indicates delirium
  - Possible medical illnesses include porphyria, TBI, infection, tumor, metabolic, endocrine, and intoxication, including withdrawal states and disorders that affect the CNS (i.e., epilepsy, Huntington disease, Wilson disease, lupus cerebritis, anti-NMDA limbic encephalitis, metachromatic leukodystrophy).
- Substance-induced psychosis: secondary to substance use/abuse, such as cocaine, hallucinogens (amphetamines, LSD, phencyclidine), cannabis (including synthetic), bath salts, alcohol, or prescribed medications including steroids, anticholinergics, and opiates
- Personality disorders (paranoid, schizotypal, schizoid, borderline personality disorder)
- Mood disorders: bipolar disorder, major depressive disorders with psychotic features or catatonia
- Other thought disorders: delusional disorder, schizoaffective disorder
- Posttraumatic stress disorder
- Cultural belief system
- Autism spectrum disorder or neurodevelopmental disorders

DIAGNOSTIC TESTS & INTERPRETATION

- No tests are available to indicate schizophrenia.
- Imaging (MRI), EEG, LP, and laboratory tests may be needed to rule out other causes and may be used as clinical presentation warrants.

Initial Tests (lab, imaging)

These are needed to rule out a medical etiology of psychotic symptoms and when starting antipsychotic medications; these may include the following:

- CBC, blood chemistries
- Thyroid-stimulating hormone (TSH)
- Blood glucose level, preferably fasting
- Hemoglobin A1C, fasting lipid panel
- Vitamin levels (thiamine, vitamin D, vitamin B_{12})
- Drug/alcohol screen of blood and urine

- Urinalysis, urine pregnancy test
- Rapid plasma reagin (RPR), HIV
- Heavy-metal exposure: lead, mercury
- Ceruloplasmin, urine porphobilinogen as indicated
- ECG, for baseline QTc

Follow-Up Tests & Special Considerations

Clinical and laboratory tests for routine monitoring, at least yearly, if using antipsychotic medications (3)[A]

- Blood pressure, weight, and waist circumference
- CBC, blood chemistries
- Fasting blood glucose level, hemoglobin A1C
- Lipid panel, TSH
- Pregnancy test and prolactin level, if indicated
- ECG, monitoring for QTc prolongation

Diagnostic Procedures/Other

Neuropsychologic testing: not a routine part of assessment but can help assess cognitive level to predict functioning and need for assistance

Test Interpretation

No diagnostic pathologic findings; however, ventriculomegaly is frequently seen on MRI with whole brain grey matter loss and white matter loss in medial temporal lobe structures preferentially (4)[A].

TREATMENT

MEDICATION

First Line

- Two classes of antipsychotic medications: typical and atypical. First-line treatment is with an atypical antipsychotic given lower potential for extrapyramidal side effects.
  - Atypical (2nd generation)
    - Risperidone, olanzapine, ziprasidone, aripiprazole, quetiapine, paliperidone, iloperidone, asenapine, lurasidone, clozapine,

brexpiprazole, cariprazine
  - Typical (1st generation)
    - Haloperidol, chlorpromazine, fluphenazine, trifluoperazine, perphenazine, thioridazine, thiothixene, loxapine
- Medication choice is based on clinical and subjective response and side effect profile (3)[A].
- Sensitivity to extrapyramidal adverse effects: atypicals
- For least risk of tardive dyskinesia: quetiapine, clozapine
- For least risk of metabolic syndrome: aripiprazole, ziprasidone, lurasidone
- For poor compliance/high risk of relapse: injectable form of long-acting antipsychotic such as haloperidol, fluphenazine, risperidone, olanzapine, aripiprazole, or paliperidone
- Usual oral daily dose (initial dose may be lower)
  - Chlorpromazine: 200 mg BID
  - Aripiprazole: 10 to 30 mg/day
  - Asenapine: 5 mg BID (sublingual)
  - Fluphenazine: 5 mg BID
  - Haloperidol: 5 mg BID
  - Lurasidone: 40 to 80 mg/day (with meal)
  - Olanzapine: 15 to 30 mg/day
  - Paliperidone: 3 to 12 mg/day
  - Perphenazine: 24 mg/day divided BID or TID
  - Quetiapine: 200 to 300 mg BID
  - Risperidone: 3 mg/day
  - Ziprasidone: 60 to 80 mg BID (with meal)
  - Cariprazine: 1.5 to 6 mg/day
  - Brexpiprazole: 2 to 4 mg/day
  - Clozapine: 200 mg BID
    - Start 12.5 mg/day and increase daily by 25 mg until dose of 300 mg/day split into BID dosing; do not exceed 900 mg/day.
    - Effective in treatment of refractory or suicidal patients (3)[A]
    - Serious risk of agranulocytosis mandates registration with National Clozapine Registry and monitoring regular periodic CBC with differential (weekly to once monthly).

- Significant risk of seizure at higher doses
- Side effects can include myocarditis, DVT, sialorrhea, tachycardia, and weight gain.

ALERT

All antipsychotics are associated with weight gain and carry the risk of metabolic SE and tardive dyskinesia.

- Managing adverse effects of antipsychotics
  - Dystonic reaction (especially of head and neck): Give diphenhydramine 25 to 50 mg IM or benztropine 1 to 2 mg IM.
  - Akathisia (restlessness): propranolol 20 to 30 mg BID or lorazepam 0.5 to 1 mg BID
  - Parkinsonism: trihexyphenidyl 2 mg BID (may be increased to 15 mg/day if needed) or benztropine 0.5 BID (1 to 4 mg/day); amantadine 100 mg daily (up to 300 mg daily)
  - Neuroleptic malignant syndrome: hyperthermia, autonomic dysfunction, and extrapyramidal symptoms; requires hospitalization and supportive management (IVF and cessation of offending neuroleptic)
- Geriatric considerations: All antipsychotics carry a black box warning for increased mortality risk in elderly patients with dementia.
- Adjunctive treatments
  - Benzodiazepines
    - May be effective adjuncts to antipsychotics during acute phase of illness
    - Useful for the treatment of catatonia
    - Withdrawal reactions with psychosis or seizures; risk for dependence and cognitive impairment
  - Mood stabilizers (valproic acid, lithium, lamotrigine, carbamazepine): may be effective adjuncts for those with agitated/violent behavior (3,5)[A]
  - Antidepressants: if prominent symptoms of depression are present
  - Metformin: helps minimize risk of metabolic SE with use of AP (6)[A]

ISSUES FOR REFERRAL

- Consider in cases of suicidality, coexistence of an addiction, difficulty in engagement, or poor self-care.

- Patients with schizophrenia should receive multidisciplinary care from both a primary care physician and a psychiatrist.
- Family members often benefit from referral to family advocacy organizations such as NAMI (7)[A].

ADDITIONAL THERAPIES

- Family patient education and psychotherapy: These include specific treatments to reduce the impact of psychotic symptoms and to enhance social functioning. Cognitive-behavioral therapy has been shown to be effective for specific symptoms of schizophrenia (8)[C].
- Cognitive remediation is a new approach for cognitive retraining and psychosocial recovery.
- Vocational support programs have shown success in returning individuals to work.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Omega-3 fatty acids may improve cognitive symptoms, but evidence remains inconclusive (9).

SURGERY/OTHER PROCEDURES

- Electroconvulsive therapy (ECT) should be considered early for patients presenting with catatonic features when response to benzodiazepines is insufficient (3)[B].
- Surgical interventions are not available.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Initial stabilization focuses on maintaining a safe environment and reducing acute psychotic symptoms and agitation through the initiation of pharmacologic treatment.
- The decision to admit is usually based on the patient’s risk of self-harm or harm to others and the inability to care for self as governed by local legal statute.
- Monitor for safety concerns and establish a safe and supportive environment.
- Discharge criteria based on the patient’s ability to remain safe in the community. It reflects a combination of suicide risk, level of psychotic

symptoms, support systems, and the availability of appropriate outpatient services.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Long-term symptom management and rehabilitation depend on engagement in ongoing pharmacologic and psychosocial treatment.
- Monitoring is based on evaluation of symptoms (including safety and psychotic symptoms), looking for the emergence of comorbidities, medication side effects, and prevention of complications.

DIET

- Newer atypical antipsychotics confer a higher risk of metabolic side effects such as diabetes, hypercholesterolemia, and weight gain.
- Although there are no specific dietary requirements, attention should be paid to the high risk of development of obesity and metabolic syndrome in individuals with schizophrenia.

PATIENT EDUCATION

- National Institute of Mental Health: *Schizophrenia*, at www.nimh.nih.gov/health/topics/schizophrenia/index.shtml
- *Helping a Family Member with Schizophrenia*: www.aafp.org/afp/20070615/1830ph.html
- National Alliance on Mental Illness (NAMI): www.NAMI.org

PROGNOSIS

- Typical course is one of remissions and exacerbations. Although uncommon, there are known cases of complete remission and of refractory illness.
- Negative symptoms are often most difficult to treat.
- About 20% attempt suicide. 5–6% die of suicide (1).
- Decreased life span related to comorbidities (coronary artery disease, pulmonary disease, or substance use disorders) and suboptimal care; guarded prognosis

COMPLICATIONS

- Side effects from antipsychotic medications including tardive dyskinesia, orthostatic hypotension, QTc prolongation, and metabolic syndrome
- Self-inflicted trauma and suicide
- Combative behavior toward others (only 5% of crimes are caused by mental illness including psychosis) (10)
- Comorbid addictions, including nicotine (11)[A]

Algorithm: Delirium

CODES

ICD10

- F20.9 Schizophrenia, unspecified
- F20.0 Paranoid schizophrenia
- F20.1 Disorganized schizophrenia

CLINICAL PEARLS

- A debilitating chronic mental illness that affects all cultures
- Schizophrenia is characterized by positive symptoms, including hallucinations such as voices that converse with/about the patient, delusions that are often paranoid and negative symptoms, including flattened affect, loss of a sense of pleasure, loss of will/drive, and social withdrawal.
- Requires a multidisciplinary team approach to assist with coping and treatment and promote recovery

SCLERITIS

Matthew J. Schear, DO, MS • Anne S. Steiner, MD

BASICS

DESCRIPTION

- Scleritis is a painful, inflammatory process of the sclera, part of the eye's outer coat.
  - Categorized into anterior or posterior and diffuse, nodular, or necrotizing
  - Commonly associated with systemic disorders
  - Frequently requires systemic anti-inflammatory therapy
  - Potentially vision-threatening
- In contrast, episcleritis is a self-limited inflammation of the superficial episclera with only mild discomfort.
- System(s) affected: ocular

EPIDEMIOLOGY

- Mean age is 54 years (range 12 to 96).
- Predominant sex: female > male (1.6:1)

Incidence

Estimated to be 6 cases/100,000 people in the general population

Prevalence

- Anterior scleritis, about 94% of cases (1)[B]
  - Diffuse anterior scleritis, about 75% (most common)
- Remaining 6% have posterior scleritis.

ETIOLOGY AND PATHOPHYSIOLOGY

- Frequently associated with a systemic illness (1)[B]
  - Most commonly associated with rheumatoid arthritis
  - In about 38% of cases, scleritis is the presenting manifestation of an underlying systemic disorder.
  - Necrotizing scleritis has the highest association with systemic disease.
- Other etiologies

- Proposed pathogenesis is dependent on type of scleritis. In necrotizing scleritis, the predominant mechanism is likely due to the activity of matrix metalloproteinases.
- Drug-induced scleritis has been reported in patients on bisphosphonate therapy.
- Surgically induced necrotizing scleritis is exceedingly rare and occurs after multiple surgeries.
- Infectious scleritis occurs most commonly after surgical trauma, and *Pseudomonas aeruginosa* in poorly controlled diabetic patients is the most common causative organism (2)[B].

RISK FACTORS

Individuals with autoimmune disorders are most at risk.

COMMONLY ASSOCIATED CONDITIONS

- Rheumatoid arthritis (most common)
- Sjögren syndrome
- Granulomatosis with polyangiitis
- HLA-B27-associated ankylosing spondylitis
- Systemic lupus erythematosus
- Reactive arthritis
- Behçet disease
- Juvenile idiopathic arthritis
- Cogan disease
- Relapsing polychondritis
- Polyarteritis nodosa
- Sarcoidosis
- Inflammatory bowel disease
- Herpes zoster
- Herpes simplex
- HIV
- Syphilis
- Lyme disease
- Tuberculosis

DIAGNOSIS

HISTORY

- Redness and inflammation of the sclera
  - Can be bilateral in about 40% of cases (1)[B]
- Photophobia and tearing
- Pain ranging from mild discomfort to extreme localized tenderness
  - May be described as constant, deep, boring, or pulsating
  - Pain may be referred to the eyebrow, temple, or jaw.
  - Pain may awaken patient from sleep in early hours of morning.
  - Severe pain is most commonly associated with necrotizing scleritis (1)[B].

PHYSICAL EXAM

- Examine sclera in all directions of gaze by gross inspection.
  - A bluish hue may suggest thinning of sclera.
  - Inspect for breadth and degree of injection.
- Check visual acuity.
  - Decrease in visual acuity of two or more Snellen lines occurs in about 16% of patients (1)[B].
- Slit-lamp exam using red-free light
  - Episcleritis: conjunctival and superficial vascular plexuses displaced anteriorly. Blanches with phenylephrine.
  - Scleritis: Deep episcleral plexus is the maximum site of vascular congestion, displaced anteriorly d/t edema of underlying sclera. Characteristic blue or violet color, absent in patients with episcleritis.
- Ocular tenderness
- Dilated fundus exam to rule out posterior involvement
- A complete physical exam, particularly of the skin, joints, heart, and lungs, should be done to evaluate for associated conditions.

DIFFERENTIAL DIAGNOSIS

- Conjunctivitis
- Episcleritis
- Iritis (anterior uveitis)
- Blepharitis

- Ocular rosacea

DIAGNOSTIC TESTS & INTERPRETATION

- Consider further tests if warranted by history and physical.
- Routine tests to exclude systemic disease
  - CBC, serum chemistry, urinalysis, ESR, and/or C-reactive protein
- Specific tests for underlying systemic illness
  - Rheumatoid factor, anticyclic citrullinated peptide antibodies, ACE level, antineutrophil cytoplasmic antibodies, QuantiFERON-TB level, fluorescent treponemal antibody absorption (FTA-ABS), rapid plasma regain (RPR), lyme titers and antinuclear antibody may aid in the diagnosis.
- Further imaging studies, such as a chest x-ray and sacroiliac joint films, may be useful if a specific systemic illness is suspected.
- B-scan US to detect posterior scleritis. Look at thickness of sclera and for T-sign, fluid in Tenon's space at interface between the optic nerve and sclera.
- MRI/CT scan may provide additional diagnostic benefit and detect orbital disease.

Diagnostic Procedures/Other

Biopsy is not routinely required unless diagnosis remains uncertain after above investigations.

Test Interpretation

Different subtypes of scleritis are associated with varying presentations and distinct findings.

- Diffuse anterior scleritis: widespread inflammation
- Nodular anterior scleritis: immovable, inflamed nodule
- Necrotizing anterior scleritis
  - "With inflammation": Sclera becomes transparent.
  - Scleromalacia perforans without inflammation: painless and often associated with rheumatoid arthritis
- Posterior scleritis: associated with retinal and choroidal complications, adjacent swelling of orbital tissues may occur

TREATMENT

GENERAL MEASURES

If scleral thinning, glasses/eye shield should be worn to prevent perforation.

MEDICATION

- First-line therapies for noninfectious scleritis (3)[C]
  - Oral NSAID therapy, choice based on availability, example is ibuprofen 600 to 800 mg PO TID–QID provided no contraindications exists. About 37% successful (4)[B].
  - Systemic steroids (initial if necrotizing scleritis and preferentially IV if vision threatening, otherwise use if failure of NSAIDs), prednisone 40 to 60 mg PO QD, taper over 4 to 6 weeks
  - Antimetabolites including methotrexate, azathioprine, mycophenolate mofetil, cyclophosphamide, and cyclosporine may be used as steroid-sparing agents. They are generally recommended if steroids cannot be tapered below 10 mg PO QD (4)[C].
- Second-line therapies (4)[C],(5)[A]
  - Immunomodulatory agents, infliximab, rituximab and adalimumab can be used if patient has failed or is not a candidate for antimetabolites or calcineurin inhibitors. These agents are preferred over etanercept due to higher treatment success.
- Adjunct therapy considerations
  - Topical steroids: prednisolone acetate 1% under ophthalmologist care
  - Subconjunctival triamcinolone acetonide injection only for nonnecrotizing, 40 mg/mL, 97% improvement after one injection. Increased risk of ocular HTN, cataract, and globe perforation.
- Necrotizing anterior scleritis and posterior scleritis
  - May require immunosuppressive therapy in addition to systemic steroids
  - Treat aggressively due to possible complications if left untreated; may need patch grafting to maintain globe integrity
- Infectious
  - Antibiotic therapy resolves about 18% of cases, whereas the remaining often requires surgical intervention such as débridement (2)[B].

ISSUES FOR REFERRAL

- All patients with scleritis should be managed by an ophthalmologist familiar with this condition.
- Rheumatology referral for coexistent systemic disease is helpful for long-term success.

ADDITIONAL THERAPIES

Immunosuppressants used for autoimmune and collagen vascular disorders may be of help in active scleritis.

SURGERY/OTHER PROCEDURES

- In rare cases, scleral biopsy may be indicated to confirm infection or malignancy.
- Ocular perforation requires scleral grafting.
- Infectious scleritis may require operative care.

ONGOING CARE

Follow-Up Tests & Special Considerations

- Avoid contact lenses—wear only if there is corneal involvement, which is rare.

Patient Monitoring

- Patient in the active stage of inflammation should be followed very closely by an ophthalmologist to assess the effectiveness of therapy.
- Medication use mandates close surveillance for adverse effects.

DIET

No special diet

PATIENT EDUCATION

Scleritis at PubMed Health:
http://www.ncbi.nlm.nih.gov/pubmedhealth/PMHT0024411/

PROGNOSIS

Scleritis is indolent, chronic, and often progressive.

- Diffuse anterior scleritis (best prognosis)
- Necrotizing anterior scleritis (worst prognosis)
- Recurrent bouts of inflammation may occur.
- Scleromalacia perforans has the highest risk of perforation of the globe.

COMPLICATIONS

- Decrease in vision, anterior uveitis, ocular HTN, and peripheral keratitis
- Cataract and glaucoma can result from disease or treatment with steroids.
- Ocular perforation can occur in severe stages.

CODES

ICD10

- H15.009 Unspecified scleritis, unspecified eye
- H15.019 Anterior scleritis, unspecified eye
- H15.039 Posterior scleritis, unspecified eye

CLINICAL PEARLS

- Episcleritis is a self-limited inflammation of the eye with mild discomfort. Scleritis is a painful, severe, and potentially vision-threatening condition. Both conditions can be associated with underlying inflammatory diseases.
- About 35% of all cases of scleritis are associated with a systemic disease such as rheumatoid arthritis. Necrotizing scleritis has the highest association.

SCLERODERMA

Ann M. Lynch, PharmD, RPh, AE-C • Deborah M. DeMarco, MD, FACP

BASICS

DESCRIPTION

- Scleroderma (systemic sclerosis [SSc]) is a chronic disease of unknown cause characterized by diffuse fibrosis of skin and visceral organs and vascular abnormalities.
- Most manifestations have vascular features (e.g., Raynaud phenomenon), but frank vasculitis is rarely seen.
- Can range from a mild disease, affecting the skin, to a systemic disease that can cause death in a few months
- The disease is categorized into two major clinical variants (1).
  - Diffuse: distal and proximal extremity and truncal skin thickening
  - Limited
    - Restricted to the fingers, hands, and face
    - CREST syndrome (calcinosis, Raynaud phenomenon, esophageal dysmotility, sclerodactyly, telangiectasia)
- System(s) affected: include, but not limited to skin; renal; cardiovascular; pulmonary; musculoskeletal; gastrointestinal

Geriatric Considerations

Uncommon >75 years of age

Pediatric Considerations

Rare in this age group

Pregnancy Considerations

- Safe and healthy pregnancies are common and possible despite higher frequency of premature births.
- High-risk management must be standard care to avoid complications, specifically renal crisis.

- Diffuse scleroderma causes greater risk for developing serious cardiopulmonary and renal problems. Pregnancy should be delayed until disease stabilizes.

EPIDEMIOLOGY

Incidence

- In the United States: 1 to 2/100,000/year
- Predominant age
  - Young adult (16 to 40 years); middle-aged (40 to 75 years), peak onset 30 to 50 years
  - Symptoms usually appear in the 3rd to 5th decades.
- Predominant sex: female > male (4:1)

Prevalence

In the United States: 1 to 25/100,000

ETIOLOGY AND PATHOPHYSIOLOGY

Pathophysiology involves both a vascular component and a fibrotic component. Both occur simultaneously. The inciting event is unknown, but there is an increase in certain cytokines after endothelial cell activation that are profibrotic (TGF-β and PDGF).

- Unknown
- Possible alterations in immune response
- Possibly some association with exposure to quartz mining, quarrying, vinyl chloride, hydrocarbons, toxin exposure
- Treatment with bleomycin has caused a scleroderma-like syndrome, as has exposure to rapeseed oil.

Genetics

Familial clustering is rare, but has been seen.

RISK FACTORS

Unknown

DIAGNOSIS

HISTORY

- Raynaud phenomenon is generally the presenting complaint (differentiated from Raynaud disease, generally affecting younger individuals and without digital ulcers).
- Skin thickening, “puffy hands,” pruritus, and gastroesophageal reflux disease (GERD) are often noted early in the disease process.

PHYSICAL EXAM

- Skin
  - Digital ulcerations
  - Digital pitting
  - Tightness, swelling, thickening of digits
  - Hyperpigmentation/hypopigmentation
  - Narrowed oral aperture
  - SC calcinosis
- Peripheral vascular system
  - Telangiectasia
- Joints, tendons, and bones
  - Flexion contractures
  - Friction rub on tendon movement
  - Hand swelling
  - Joint stiffness
  - Polyarthralgia
  - Sclerodactyly
- Muscle
  - Proximal muscle weakness
- GI tract
  - Dysphagia
  - Esophageal reflux due to dysmotility (most common systemic sign in diffuse disease)
  - Malabsorptive diarrhea
  - Nausea and vomiting
  - Weight loss
  - Xerostomia

- Kidney
  - Hypertension
  - May develop scleroderma renal crisis: acute renal failure (ARF)
- Pulmonary
  - Dry crackles at lung bases
  - Dyspnea
- Nervous system
  - Peripheral neuropathy
  - Trigeminal neuropathy
- Cardiac (progressive disease)
  - Conduction abnormalities
  - Cardiomyopathy
  - Pericarditis
  - Secondary cor pulmonale

DIFFERENTIAL DIAGNOSIS

- Mixed connective tissue disease/overlap syndromes
- Scleredema
- Nephrogenic systemic fibrosis
- Toxic oil syndrome (Madrid, 1981, affecting 20,000 people)
- Eosinophilia–myalgia syndrome
- Diffuse fasciitis with eosinophilia
- Scleredema of Buschke

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Nail fold capillary microscopy—drop out is most significant finding
- CBC
- Creatinine
- Urinalysis (albuminuria, microscopic hematuria)
- Antinuclear antibodies (ANA): positive in >90% of patients
- Anti–Scl-70 (anti-topoisomerase [ATA]) antibody is highly specific for systemic disease and confers a higher risk of interstitial lung disease (ILD).
- Anticentromere antibody usually associated with CREST variant
- Chest radiograph

  - Diffuse reticular pattern
  - Bilateral basilar pulmonary fibrosis
- Hand radiograph
  - Soft tissue atrophy and acro-osteolysis
  - Can see overlap syndromes such as rheumatoid arthritis
  - SC calcinosis

Follow-Up Tests & Special Considerations

- Pulmonary function tests (PFTs)
  - Decreased maximum breathing capacity
  - Increased residual volume
  - Diffusion defect
- Antibodies to U3-RNP—higher risk for scleroderma-associated pulmonary hypertension
- Anti–PM-Scl antibodies (for myositis) (2)[B]
- Anti-RNA polymerase III—higher risk for diffuse cutaneous involvement and renal crisis (3)[A]
- ECG (low voltage): possible nonspecific abnormalities, arrhythmia, and conduction defects
- Echocardiography: pulmonary hypertension or cardiomyopathy
- Nail fold capillary loop abnormalities
- Upper GI
  - Distal esophageal dilatation
  - Atonic esophagus
  - Esophageal dysmotility
  - Duodenal diverticula
- Barium enema
  - Colonic diverticula
  - Megacolon
- High-resolution CT scan for detecting alveolitis, which has a ground-glass appearance or fibrosis predominant in bilateral lower lobes

Diagnostic Procedures/Other

- Skin biopsy
  - Compact collagen fibers in the reticular dermis and hyalinization and

fibrosis of arterioles
  - Thinning of epidermis, with loss of rete pegs, and atrophy of dermal appendages
  - Accumulation of mononuclear cells is also seen.
- Right-sided heart catheterization: Pulmonary hypertension is an ominous prognostic feature.

Test Interpretation

- Skin
  - Edema, fibrosis, or atrophy (late stage)
  - Lymphocytic infiltrate around sweat glands
  - Loss of capillaries
  - Endothelial proliferation
  - Hair follicle atrophy
- Synovium
  - Pannus formation
  - Fibrin deposits in tendons
- Kidney
  - Small kidneys
  - Intimal proliferation in interlobular arteries
- Heart
  - Endocardial thickening
  - Myocardial interstitial fibrosis
  - Ischemic band necrosis
  - Enlarged heart
  - Cardiac hypertrophy
  - Pulmonary hypertension
- Lung
  - Interstitial pneumonitis
  - Cyst formation
  - Interstitial fibrosis
  - Bronchiectasis
- Esophagus
  - Esophageal atrophy
  - Fibrosis

TREATMENT

GENERAL MEASURES

- Treatment is symptomatic and supportive.
- Esophageal dilation may be used for strictures.
- Avoid cold; dress appropriately in layers for the weather; be wary of air conditioning.
- Avoid smoking (crucial).
- Avoid finger sticks (e.g., blood tests).
- Elevate the head of the bed during sleep to help relieve GI symptoms.
- Use softening lotions, ointments, and bath oils to help prevent dryness and cracking of skin.
- Dialysis may be necessary in renal crisis.

MEDICATION

First Line

- ACE inhibitors (ACEIs): for preservation of renal blood flow and for treatment of hypertensive renal crisis
- Corticosteroids: for disabling myositis, pulmonary alveolitis, or mixed connective tissue disease (not recommended in high doses due to increased incidence of renal failure)
- NSAIDs: for joint or tendon symptoms. Caution with long-term concurrent use with ACEIs (potential renal complications)
- Antibiotics: for secondary infections in bowel and active skin infections
- Antacids, proton pump inhibitors: for gastric reflux
- Metoclopramide: for intestinal dysfunction
- Hydrophilic skin ointments: for skin therapy
- Topical clindamycin, erythromycin, or silver sulfadiazine: for prevention of recurrent infectious cutaneous ulcers
- Consider immunosuppressives for treatment of life-threatening or potentially crippling scleroderma or interstitial pneumonitis such as cyclophosphamide for ILD (4)[B].
- Nitrates and dihydropyridine calcium-channel blockers for Raynaud phenomenon

- Avoidance of caffeine, nicotine, and sympathomimetics may ease Raynaud symptoms.
- PDE-5 antagonists (e.g., sildenafil), prostanoids, and endothelin-1 antagonists are changing the management of pulmonary hypertension (5).
- Alveolitis: immunosuppressants and alkylating agents (e.g., cyclophosphamide)

ADDITIONAL THERAPIES

- Anti–TNF-α therapy: Preliminary suggestion is that these may reduce joint symptoms and disability in inflammatory arthritis, but small sample sizes and observational biases lend to the need for further well-designed, adequately powered, longitudinal clinical trials.
- Physical therapy to maintain function and promote strength
- Heat therapy to relieve joint stiffness

SURGERY/OTHER PROCEDURES

- Some success with gastroplasty for correction of GERD
- Limited role for sympathectomy for Raynaud phenomenon
- Lung transplantation for pulmonary hypertension and ILD

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Monitor every 3 to 6 months for end-organ and skin involvement and medications. Provide encouragement.
- Echocardiology and PFTs yearly

DIET

Drink plenty of fluids with meals.

PATIENT EDUCATION

- Stay as active as possible, but avoid fatigue.
- Printed patient information available from the Scleroderma Federation, 1725 York Avenue, No. 29F, New York, NY 10128; (212) 427-7040

- Advise the patient to report any abnormal bruising or nonhealing abrasions.
- Assist the patient about smoking cessation, if needed.

PROGNOSIS

- Possible improvement but incurable
- Prognosis is poor if cardiac, pulmonary, or renal manifestations present early.

COMPLICATIONS

- Renal failure
- Respiratory failure
- Flexion contractures
- Disability
- Esophageal dysmotility
- Reflux esophagitis
- Arrhythmia
- Megacolon
- Pneumatosis intestinalis
- Obstructive bowel
- Cardiomyopathy
- Pulmonary hypertension
- Possible association with lung and other cancers
- Death

SEE ALSO

Morphea

CODES

ICD10

- M34.9 Systemic sclerosis, unspecified
- M34.1 CR(E)ST syndrome
- L94.0 Localized scleroderma [morphea]

CLINICAL PEARLS

- Raynaud phenomenon is frequently the initial complaint.
- Skin thickening, “puffy hands,” and GERD are often noted early in disease.
- Patients must be followed proactively for development of pulmonary hypertension or ILD.

SEASONAL AFFECTIVE DISORDER

Christopher White, MD, JD, MHA

BASICS

DESCRIPTION

- Seasonal affective disorder (SAD) is a heterogeneous mood disorder with depressive episodes usually occurring in winter months, with full remissions in the spring and summer.
- Ranges from a milder form (winter blues) to a seriously disabling illness
- Must separate out patients with other mood disorders (such as major depressive disorder and bipolar affective disorder) whose symptoms persist during spring and summer months

EPIDEMIOLOGY

Incidence

- Affects up to 500,000 people every winter
- Up to 30% of patients visiting a primary care physician (PCP) during winter may report winter depressive symptoms.
- Predominant age: occurs at any age; peaks in 20s and 30s
- Predominant sex: female > male (3:1)

Prevalence

- 1–9% of the general population
- 10–20% of patients identified as having mood symptoms will have a seasonal component.

ETIOLOGY AND PATHOPHYSIOLOGY

The major theories currently involve the interplay of phase-shifted circadian rhythms, genetic vulnerability, and serotonin dysregulation.

- Melatonin produced by the pineal gland at increased levels in the dark has been linked to depressive symptoms; light therapy on the retina acts to inhibit melatonin secretion.
- Serotonin dysregulation because it is secreted less during winter months, must

be present for light therapy to work, and treatment with SSRIs appears to reverse SAD symptoms
- Decreased levels of vitamin D, often occurring during low-light winter months, may be associated with depressive episodes in some individuals experiencing SAD symptoms.

Genetics

- Some twin studies and a preliminary study on GPR50 melatonin receptor variants have suggested a genetic component.
- Recent studies indicate an association with the melanopsin gene (OPN4).
- Increased incidence of depression, ADHD, and alcoholism in close relatives

RISK FACTORS

- Most common during months of January and February: Patients frequently visit PCP during winter months complaining of recurrent flu, chronic fatigue, and unexplained weight gain.
- Working in a building without windows or other environment without exposure to sunlight

GENERAL PREVENTION

- Consider use of light therapy at start of winter (if prior episodes begin in October), increase time outside during daylight, or move to a more southern location.
- Bupropion (Wellbutrin) is an FDA-approved antidepressant for the prevention of SAD.

COMMONLY ASSOCIATED CONDITIONS

Some individuals with SAD have a weakened immune system and may be more vulnerable to infections.

DIAGNOSIS

- Carefully document the presence or absence of prior manic episodes.
- Screen for the existence of any suicidal ideation and safety risk factors.
- Remission of symptoms during spring and summer
- Symptoms have occurred for the past 2 years.

- Seasonal episodes associated with winter months substantially outnumber any nonseasonal depressive episodes.
- Under *DSM-5*, SAD is denoted by adding the "with seasonal pattern" specifier to a diagnosis of major depressive disorder, recurrent.

HISTORY

- Symptoms of depression meeting the criteria for major depressive disorder are the following:
  - Sleep disturbance: either too much or too little
  - Lack of interest in life and absence of pleasure from hobbies/activities
  - Guilt: feelings of guilt or worthlessness
  - Energy: fatigue or constantly feeling tired
  - Concentration: difficulty with concentration and memory
  - Appetite: changes in appetite and weight
  - Psychomotor retardation: Patients feel slowed down with decreased activity.
  - Suicidal thoughts: Patients report thoughts of suicide.
- In SAD, hypersomnia, hyperphagia (craving for carbohydrates and sweets), and weight gain usually predominate. Despite sleeping more, patients report daytime sleepiness and fatigue. Cravings may lead to binge eating and weight gains >20 lb.
- Obtain collateral history if patient is unable to provide insight into the seasonal component.

PHYSICAL EXAM

Use exam to exclude other organic causes for symptoms. Focal neurologic deficits, signs of endocrine dysfunction, or stigmata of substance abuse should prompt further testing.

DIFFERENTIAL DIAGNOSIS

- Similar to that of major depression, meaning that organic causes of low energy and fatigue, such as hypothyroidism, anemia, and mononucleosis (or other viral syndromes), need to be considered.
- Other mood disorders without a seasonal component such as major depression, bipolar disorder, adjustment disorder, or dysthymia
- Symptoms should not be better accounted for by seasonal psychosocial

stressors, which often accompany the winter holiday seasons.
- Substance abuse

DIAGNOSTIC TESTS & INTERPRETATION

- Thyroid-stimulating hormone to rule out hypothyroidism
- CBC to rule out anemia
- Rule out electrolyte and glucose dysregulation.
- 25-OH vitamin D level
- Pregnancy test for women of childbearing potential
- Urine toxicology screen if substance abuse is a concern
- Imaging is not useful unless focal neurologic finding or looking to exclude an organic cause.

TREATMENT

MEDICATION

Lack of evidence to determine whether light therapy or medication should be the first-line agent. Both supported by the literature and in some studies have equal efficacy. Medications have more side effects. Adherence to both remains a critical issue. The ultimate choice depends on the acuity of the patient and the comfort level of the prescribing clinician with each treatment modality (1)[B].

- SSRIs such as sertraline (Zoloft), paroxetine (Paxil), fluoxetine (Prozac), citalopram (Celexa), and escitalopram (Lexapro) in their traditional antidepressant doses (2)[B]
- Bupropion (Wellbutrin) is the only antidepressant currently approved by the FDA for the prevention of SAD (3)[B].

ISSUES FOR REFERRAL

- Patients with a history of ocular disease should be referred for an ophthalmologic exam before phototherapy and for serial monitoring.
- Patients who fail to respond or who develop manic symptoms or suicidal ideation once treatment is initiated should be considered for psychiatric referral.

ADDITIONAL THERAPIES

- Phototherapy using special light sources has been shown to be effective in 60–90% of patients, often providing relief with a few sessions (2,4)[B].
- Variables that can regulate effect are the following:
  - Light intensity: Although the minimum light source intensity is under investigation, at least 2,500 lux is suggested (domestic lights emit, on average, 200 to 500 lux). There is good evidence for 10,000 lux as the recommended source (2)[B].
  - Treatment duration: Exposure time varies based on intensity of light source, with daily sessions of 30 minutes to a few hours.
  - Time of treatment: Most patients respond better by using the light therapy early in the morning.
  - Color of light source: Emerging data suggest that shorter sessions of lower intensity light-emitting diodes enriched in the blue spectrum have equal efficacy to the traditional white light treatment and possibly capable of being delivered in a transcranial manner (5)[B].
- Light box is placed on table several feet away, and the light is allowed to shine onto the patient's eyes (sunglasses should be avoided). Ensure that the light box has an ultraviolet filter.
- Most common side effects are eye strain and headache. Insomnia can result if the light box is used too late in the day. Light boxes also can precipitate mania in some patients.
- Dawn simulation machines gradually increase illumination while the patient sleeps, simulating sunrise while using a significantly less intense light source.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Work to reduce stress levels through meditation, progressive relaxation exercises, and/or lifestyle modification.
- The potential role of vitamin D supplementation is under investigation. Currently, there is a lack of consistent research to satisfactorily demonstrate that treatment improves SAD symptoms. Reported doses vary widely but typically are between 400 and 800 IU/day (6)[B].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

If the patient develops suicidal ideation as part of his or her depression or mania

after treatment is initiated

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Regular monitoring by PCP or psychiatrist for response to treatment; patients may become manic when treated with SSRIs or light therapy.

Patient Monitoring

Patients should be seen in the outpatient clinic weekly to biweekly when initiating light or pharmacotherapy to monitor treatment results, side effects, and any increased suicidal thoughts if using SSRIs.

DIET

No specific diet modification needed

PATIENT EDUCATION

- Increase time outdoors during daylight.
- Rearrange home or work environment to get more direct sunlight through windows.

PROGNOSIS

Symptoms, if untreated, generally remit within 5 months with exposure to spring light, only to return in subsequent winters. If treated, patients usually respond within 3 to 6 weeks.

COMPLICATIONS

Development of suicidal ideation and mania are two outcomes the clinician needs to monitor.

SEE ALSO

- Bipolar I Disorder; Bipolar II Disorder; Depression
- Algorithm: Depressive Episode, Major

CODES

ICD10

- F33.9 Major depressive disorder, recurrent, unspecified
- F33.0 Major depressive disorder, recurrent, mild
- F33.1 Major depressive disorder, recurrent, moderate

CLINICAL PEARLS

- SAD is a subtype of major depressive disorder. Once the patient has a diagnosed mood disorder, such as depression or bipolar, ask whether the symptoms vary in a seasonal pattern to qualify for the diagnosis of SAD. Generally, these patients will report sleeping too much, eating too much (especially carbs and sweets), and gaining weight during winter months.
- As with all psychiatric diagnoses, ensure that the symptoms are not due to an organic process or better explained by substance abuse.
- Lack of good evidence to decide whether light therapy or SSRIs should be the first-line agent. Guidelines suggest using SSRIs first if the patient is more acute or has contraindications to light therapy or the clinician is not comfortable with light therapy.
- Light therapy boxes are available from numerous online suppliers but are not extensively regulated; practitioners should take care to ensure that patients are using devices from reputable suppliers.
- If using SSRIs, recent studies indicate that some patients may begin to experience increased suicidal thoughts on therapy; these patients need to be monitored closely as outpatients every 1 to 2 weeks. Patients on light therapy also should be monitored closely initially in order to adjust treatment. Once stabilized, both groups of patients can be seen every 4 to 8 weeks during the winter months.
- All patients who demonstrate suicidal ideation or symptoms of mania should be referred for consideration of hospitalization.

SEIZURE DISORDER, ABSENCE

Felicia Chu, MD

BASICS

DESCRIPTION

An absence seizure is a generalized epileptic seizure characterized by a brief lapse of awareness.

Absence Seizure Types

Absence seizure types according to the International League Again Epilepsy (ILAE) 2010 classification include (1):

- Typical absence
  - Formerly called *petit mal seizures*
  - Abrupt-onset behavioral arrest, loss of awareness, and blank staring, sometimes with mild upward eye deviation, repetitive blinking
  - May include automatisms, tonic or atonic features, eyelid or facial clonus, autonomic features
  - Lasts 5 to 30 seconds
  - Immediate return to normal consciousness
  - Associated with genetic generalized epilepsies, namely, childhood absence epilepsy, juvenile absence epilepsy, and juvenile myoclonic epilepsy
- Atypical absence
  - Onset and offset less abrupt than typical absence seizures
  - Lasts 10 to 45 seconds
  - Impairment of consciousness often incomplete with continued purposeful activity.
  - Postictal confusion sometimes occur.
  - Associated clinical features more pronounced and frequent than in typical absence; atonia is most common.
  - Associated with syndromic epilepsies, such as Lennox-Gastaut and nonsyndromic epilepsies in patients with developmental delay
- Absence with special features
  - Myoclonic absence:

    - Rhythmic clonic jerking at 2 to 4 Hz which lasts 5 to 10 seconds.
    - Unlike myoclonic seizures with no impairment of consciousness, brief lapses of awareness are characteristic of myoclonic absence.
  - Eyelid myoclonia:
    - Rhythmic clonic jerking of the eyelids at 5 to 6 Hz which lasts 3 to 5 seconds
    - Eyelid myoclonia with absence associated with an impairment of consciousness

Epilepsy Diagnoses

Specific diagnoses according to ILAE (2010):

- Childhood absence epilepsy (CAE)
  - Also known as *pyknolepsy*
  - Typical absence seizures are the only seizure type in 90% of children.
  - 10% develop additional generalized tonic–clonic seizures.
  - Seizures last ~10 seconds and often occur hundreds of times per day.
  - Normal neurologic state and development
  - Spontaneous remission occurs in 65–70% of patients during adolescence.
- Juvenile absence epilepsy (JAE)
  - Typical absence seizures are the main seizure type.
  - Seizures last longer than in CAE and occur usually less than once a day.
  - Generalized tonic–clonic seizures occur in most patients, often in the first 1 to 2 hours after awakening.
  - Seizures often persist into adulthood.

EPIDEMIOLOGY

- Predominant age
  - CAE: onset ages 4 to 10 years, with peak at ages 5 to 8 years
  - JAE: onset ages 9 to 16 years, with peak at ages 10 to 12 years
- Predominant gender
  - Female > male (3:2 to 2:1)
  - Absence epilepsy with myoclonus has male predominance.

Incidence

6 to 8/100,000 per year

Prevalence

5 to 50/100,000

ETIOLOGY AND PATHOPHYSIOLOGY

- Corticoreticular theory implicates abnormal activity in thalamocortical circuits.
- Thalamic reticular nucleus is responsible for both normal sleep spindles and pathologic slow-wave discharges; contains inhibitory gamma-aminobutyric acid-ergic (GABAergic) neurons
- These neurons affect low-threshold calcium currents.
- These circuits can fire in oscillatory/rhythmic fashion:
  - Normally, activation of $GABA_A$ receptors causes 10-Hz oscillations in sleep spindle frequency.
  - If $GABA_B$ receptors are strongly activated, oscillation frequency will be 3 to 4 Hz, similar to spike-and-wave typical absence seizure frequency.

Genetics

- 70–85% concordance occurs in monozygotic twins; 82% share EEG features.
- 33% concordance among first-degree relatives
- 15–45% have a family history of epilepsy.
- Complex multifactorial inheritance
- For childhood absence, genes/loci implicated include 6q, 8q24, and 5q14.
- Mutations of $GABA_A$ receptor and voltage-gated Ca^{2+} channel are implicated.

COMMONLY ASSOCIATED CONDITIONS

- 3–8% of CAE cases evolve into juvenile myoclonic epilepsy.
- Associated with difficulties in visual attention and visuospatial skills, verbal learning and memory, and reduced language abilities.
- Children with CAE have elevated rates of behavioral and psychiatric comorbidities including attentional deficits, anxiety, depression, isolation, and low self-esteem.
- A large study in 2010 detected overall normal cognition, but 35% of subjects had pretreatment attentional deficits that did not resolve with seizure control.

DIAGNOSIS

Seizures are often so brief that untrained observers are not aware of the occurrence.

HISTORY

- Frequently diagnosed in children being evaluated for poor school performance
- Teachers report that child seems to daydream or zone out frequently.
- Child will forget portions of conversations.
- Child with normal IQ underperforms in school.

PHYSICAL EXAM

- Unless a child has another genetic or acquired abnormality, a neurologic exam usually is normal.
- Seizures may be frequent enough to be observed during physical exam:
  - Manifest by behavioral arrest: Child will stop speaking in midsentence, stare blankly, and so forth.
  - Automatisms (repetitive stereotyped behaviors) may be present.
  - Child resumes previous activity.
  - Absence seizures can have a variable effect on respiratory rate, but bradypnea is common.
- Seizures may be induced by hyperventilation:
  - Have the child blow on a pinwheel or similar exercise to provoke seizure.
  - Alternatively, ask the patient to perform hyperventilation with eyes closed and count. Patient will open eyes at onset of seizure and stop counting.
- Patient manifests unresponsiveness but retains postural tone in a typical absence seizure.

DIFFERENTIAL DIAGNOSIS

- Complex partial seizures
- Psychogenic nonepileptic seizures
- Attention deficit hyperactivity disorder (ADHD)
- Confusional states and acute memory disorders
- Migraine variants
- Panic/anxiety attacks

- Breath-holding spells
- Nonepileptic staring spells: suggestive features include:
  - Events do not interrupt play.
  - Events are first noticed by professional such as school teacher, speech therapist, occupational therapist, or physician (rather than parent).
  - During a staring spell, child is responsive to touch or other external stimuli.

DIAGNOSTIC TESTS & INTERPRETATION

- No specific hematologic workup
- Follow blood chemistry, hepatic function, and blood counts specific to drug regimen.
- Drug levels are useful in evaluating symptoms of toxicity or for breakthrough seizures.

Initial Tests (lab, imaging)

- EEG is standard for diagnosis.
  - Typical absence features: 3-Hz spike-and-wave activity on normal EEG background
  - Seizures feature bursts of 34-Hz spike-and-wave activity, which may slow to 2.5- to 3-Hz during seizure.
  - Seizure usually is evident clinically if bursts last >3 seconds, subtle changes of transient cognitive impairment may be evident with briefer seizures.
  - Hyperventilation and occasionally photic stimulation may induce seizure, thus confirming diagnosis of typical absence epilepsy. In contrast, atypical absence seizures are not susceptible to induction by hyperventilation or photic stimulation.
- Imaging is not routinely indicated in children with typical absence and normal neurologic exam and IQ.
  - Brain MRI is indicated in atypical absence and in children with mixed seizure types when combined with abnormal neurologic exam or low IQ.
  - If imaging is performed, MRI is preferable to CT scan due to higher sensitivity for anatomic abnormalities.
  - A review of the brain MRIs of 134 patients with idiopathic generalized epilepsy in 2006 showed 24% with structural abnormalities, 88% of which were nonspecific (2)[B].

TREATMENT

GENERAL MEASURES

- Review seizure precautions with every patient diagnosed with or suspected to have epilepsy.
- Seizure precautions include bathroom, kitchen, home, driving, outdoors, and sports safety topics as well as special considerations for parents.

MEDICATION

Concern regarding generic medications allowing more breakthrough seizures has not been supported in evidence-based studies (3)[A].

ALERT

Certain common anticonvulsants may exacerbate absence including carbamazepine, oxcarbazepine, phenytoin, phenobarbital, tiagabine, vigabatrin, pregabalin, and gabapentin.

First Line

- Ethosuximide blocks T-type calcium channels:
  - First line, except in absence patients with tonic–clonic seizures (lacks efficacy)
  - High efficacy (4)[A], fastest onset of efficacy (5)[B], and fewer adverse attentional effects compared to valproic acid (4)[A]
  - Side effects: vomiting, diarrhea, abdominal discomfort, hiccups, headache, sedation
  - Adverse effects: rare blood dyscrasias (monitor CBC)
- Valproic acid has multiple mechanisms:
  - First choice in absence patients with tonic–clonic, myoclonic, mixed seizure types
  - Very effective but has highest rate of adverse events leading to treatment discontinuation, including negative attentional effects (4)[A]
  - Side effects: tremor, drowsiness, dizziness, weight gain, alopecia, sedation, vomiting
  - Adverse effects: teratogenicity, pancreatitis, thrombocytopenia, rare fulminant hepatic failure (especially in children <2 years)

Second Line

- Lamotrigine affects sodium channels:
  - Controls seizures but may be less efficacious than ethosuximide or valproic acid (4)[A]
  - May be equally as efficacious for new-onset CAE (5)[B]
  - Side effects: rash, diplopia, headache, insomnia, dizziness, nausea, vomiting, diarrhea
  - Adverse effects: rare Stevens-Johnson rash, more often when coadministered with valproic acid
- Topiramate affects GABA and excitatory neurotransmission:
  - FDA-approved for Lennox-Gastaut syndrome
  - Side effects: psychomotor slowing
  - Adverse effects: weight loss, renal stones, myopia, glaucoma (rare), anhidrosis
- Levetiracetam is used off-label:
  - Has been used as both monotherapy and adjunct therapy for absence seizures
  - A small multicenter randomized controlled trial (RCT) showed modest efficacy but not statistically significant versus placebo (6)[C].
- Zonisamide is also used off-label.
- Clonazepam, nitrazepam, and clobazam may be effective in the short-term but are not recommended for long-term management due to development of tolerance (few months to a year) and side effects.

Pregnancy Considerations

Anticonvulsants, especially valproic acid, are associated with an increase in fetal malformations. Use of valproic acid in women who are or are likely to become pregnant generally is contraindicated. Obtain specialty consultation.

ADDITIONAL THERAPIES

- Most absence seizure patients respond to a single medication.
- Male sex and an early age at diagnosis are associated with the need for two medications to control the disease (7)[B].
- Vagal nerve stimulator (VNS) may be considered as an option for medically refractory absence epilepsy (8)[C].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Absence epilepsy rarely requires admission.
- Status epilepticus requires inpatient management.

Discharge Criteria

Resolution of status epilepticus

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Patients with associated tonic–clonic seizures should avoid high places and swimming alone.
- Absence rarely persists into adulthood, but affected adults may be restricted from driving, working over open flames, and so forth, as with other generalized and partial epilepsy subtypes.
- Patients should be monitored periodically by a neurologist for evolution of absence epilepsy into tonic–clonic or other seizure types.

PROGNOSIS

- Patients whose shortest pretreatment EEG seizures are >20 seconds in duration are more likely to achieve seizure freedom, regardless of treatment (9)[A].
- Of those with CAE without tonic–clonic seizures, 90% remit by adulthood.
- 35% of patients with tonic–clonic seizures experience complete remission of absence seizures.
- 15% of patients develop juvenile myoclonic epilepsy.

COMPLICATIONS

Reported frequencies of typical absence status epilepticus range from 5.8% to 9.4% of patients with CAE.

CODES

ICD10

- G40.409 Other generalized epilepsy and epileptic syndromes, not intractable, without status epilepticus
- G40.419 Oth generalized epilepsy, intractable, w/o stat epi
- G40.401 Oth generalized epilepsy, not intractable, w stat epi

CLINICAL PEARLS

- If parents are unable to determine the cause of a staring spell, try suggesting that parents mention something exciting or unexpected like “ice cream” during a spell to get the child’s attention rather than calling his or her name.
- To help aid with diagnosis during an exam, try having the child blow repetitively on a pinwheel (causing hyperventilation) to attempt to trigger absence seizure.
- Ethosuximide and valproic acid are first-line agents in treatment of absence seizures. Valproic acid and lamotrigine are recommended for absence patients with tonic–clonic and mixed seizure types.

SEIZURE DISORDER, PARTIAL

Noel Dunn, MD • David Haight, MD

BASICS

DESCRIPTION

- Seizures occur when abnormal synchronous neuronal discharges in the brain cause transient cortical dysfunction.
- Generalized seizures involve bilateral cerebral cortex from the seizure's onset.
- Partial seizures originate from a discrete focus in the cerebral cortex.
- Partial seizures are further divided into simple and complex subtypes:
  - If consciousness is impaired during a partial seizure, it is classified as complex.
  - If consciousness is preserved, it is a simple partial seizure.

EPIDEMIOLOGY

Prevalence

Partial seizures occur in 20/100,000 persons in the United States.

ETIOLOGY AND PATHOPHYSIOLOGY

- Partial seizures begin when a localized seizure focus produces an abnormal, synchronized depolarization that spreads to a discrete portion of the surrounding cortex.
- The area of cortex involved in the seizure determines the symptoms; for example, an epileptogenic focus in motor cortex produces contralateral motor symptoms.
- In some cases, etiology is related to structural abnormalities that are susceptible to epileptogenesis. Most common etiologies vary by life stage:
  - Early childhood: developmental/congenital malformation, trauma
  - Young adults: developmental, infection, trauma
  - Adults 40 to 60 years of age: cerebrovascular insult, infection, trauma
  - Adults >60 years of age: cerebrovascular insult, trauma, neoplasm
- Complex partial seizures: A common cause is mesial temporal sclerosis.

Genetics

Benign rolandic epilepsy, a form of partial seizure disorder, has an autosomal dominant inheritance pattern with penetrance depending on multiple factors.

RISK FACTORS

- History of traumatic brain injury (TBI)
- Children exposed to a thiamine-deficient formula.

COMMONLY ASSOCIATED CONDITIONS

Epilepsy patients have a higher incidence of depression than the general population.

DIAGNOSIS

- Seizure activity usually stereotyped.
- Duration: seconds to minutes, unless status epilepticus develops; status epilepticus may present as focal/generalized convulsions/altered mental status without convulsions.
- Simple partial seizures
  - Simple partial seizures are characterized by localized symptoms. The patient is conscious. Symptoms may involve motor, sensory, or psychic systems.
  - Motor: Seizure activity in motor strip causes contraction (tonic) or rhythmic jerking (clonic) movements that may involve one entire side of body or may be more localized (i.e., hands, feet, or face).
    - Jacksonian march: As discharge spreads through motor cortex, tonic–clonic activity spreads in predictable fashion (i.e., beginning in hand and progressing up arm and to the face).
  - Sensory/psychic
    - Todd paralysis: after motor seizure, residual, temporary weakness in the affected area
    - Parietal lobe: sensory loss/paresthesias, dizziness
    - Temporal lobe: déjà vu, rising sensation in epigastrium, auditory hallucinations/forced memories, unpleasant smell/taste
  - Occipital: visual hallucinations

- Complex partial seizures
  - Impaired consciousness by definition
  - May have aura; this is start of seizure.
- Amnesia for the event, postictal confusion
  - Most often, focus in complex partial seizures is temporal/frontal.
  - Motor manifestations may include dystonic posturing/automatisms (i.e., simple, repetitive movements of face and hands such as lip smacking, picking, or more complex actions such as purposeless walking).
  - Frontal lobe seizure is characterized by brief, bilateral complex movements, vocalizations, often with onset during sleep.

HISTORY

- A detailed description of the seizure should be obtained from an observer.
- Review medication list for drugs that lower seizure threshold (e.g., tramadol, bupropion, theophylline).
- Obtain history of drugs of abuse (e.g., cocaine), as they may lower seizure threshold.
- Review history of any prior TBI.

PHYSICAL EXAM

Include neurologic exam, with attention to lateralizing signs suggestive of structural lesion.

DIFFERENTIAL DIAGNOSIS

- Nonepileptic seizure
- Syncope/postanoxic myoclonus
- Hypoglycemia
- For hemiparesis following event
  - Transient ischemic attack
  - Hemiplegic migraine

DIAGNOSTIC TESTS & INTERPRETATION

EEG: spikes/sharp waves over seizure focus

- Yield of EEG is increased by being obtained in the first 24 hours following seizure and by sleep deprivation.
- Frontal lobe seizure focus may be difficult to detect by routine EEG.

- If difficulty with diagnosis, continuous video–EEG monitoring may be appropriate.
- Serum electrolytes, including calcium, magnesium, phosphorus; hepatic function panel; CBC; drugs of abuse urine drug screen
- Elevated prolactin, if measured within 10 to 20 minutes of suspected seizure, or elevated creatine phosphokinase; if measured within 6 to 24 hours, may help to differentiate generalized/complex partial seizure from psychogenic seizure (1)[B].
- CSF exam if infection is suspected.
- Urinalysis, chest x-ray, levels of antiepileptic drugs (AEDs) for breakthrough seizure
- Technologic advances in neuroimaging are usually directed at the diagnosis and prognosis for seizure control (2)[C].
- Emergency evaluation of new seizure: CT scan to screen for hemorrhage and stroke
- After emergency evaluation, MRI with thin cuts through area of interest
- If planning epilepsy surgery, positron emission tomography (PET) scan and/or interictal single-photon emission computed tomography (SPECT) may be of value.
- Magnetoencephalography (MEG) is an evolving technology for localizing seizure focus.

TREATMENT

GENERAL MEASURES

- Ask the patient to maintain a seizure diary.
- Note potential triggers, such as stress, sleep deprivation, drug use, discontinuation of alcohol/benzodiazepines, menses.

MEDICATION

- Current guidelines do not recommend for or against starting an AED after a single unprovoked seizure. Patients should be counseled that AEDs will reduce risk of repeat seizure over 2 years but have no effect on long-term remission (3)[C].

- AEDs act on voltage-gated ion channels, affect neuronal inhibition via enhancement of γ-aminobutyric acid (GABA, an inhibitory neurotransmitter), or decrease neuronal excitation. End result is to decrease the abnormal synchronized firing and to prevent seizure propagation.
- 50% of those with newly diagnosed partial seizures respond to, and tolerate, first AED trial. Up to 50% of those who fail the first AED trial will also fail a second AED trial (4)[B].
- Choose AED based on seizure type, side effect profile, and patient characteristics. Increase dose until seizure control is obtained/side effects become unacceptable.
- Attempt monotherapy, but many patients will require adjunctive agents.
- *Refractory to medications* is defined as failure of at least three anticonvulsants to achieve adequate control.
- AEDs may prevent seizures after a TBI in the short-term, although they provide no efficacy in long-term prevention (5)[B].
- Several AEDs induce/inhibit cytochrome P450 enzymes (watch for drug interactions).

First Line

- Carbamazepine: affects sodium channels; side effects include GI distress, hyponatremia, diplopia, dizziness, rare pancytopenia/marrow suppression, and exfoliative rash.
- Oxcarbazepine: affects sodium channels; side effects include dizziness, diplopia, hyponatremia, and headache.
- Lamotrigine: affects sodium channels
  - Side effects include insomnia, dizziness, and ataxia.
  - Risk of Stevens-Johnson reaction (potentially fatal exfoliative rash), especially when given with valproate, requires slow titration
- Levetiracetam: multiple mechanisms; side effects include sedation, ataxia, and irritability.

Second Line

- Phenytoin: affects sodium channels; side effects include ataxia, dizziness, diplopia, tremor, GI upset, gingival hyperplasia, and fever.
- Phenobarbital: multiple mechanisms; side effects include sedation and

withdrawal seizures.

- Valproate: multiple mechanisms; side effects include GI upset, weight gain, alopecia, and tremor; less common, thrombocytopenia, hepatitis, pancreatitis
- Topiramate: multiple mechanisms; side effects include anorexia, cognitive slowing, sedation, nephrolithiasis, and anhidrosis.
- Gabapentin: multiple mechanisms; side effects include sedation, dizziness, and ataxia.
- Pregabalin: affects calcium channels; side effects include sedation, dizziness, and weight gain.
- Zonisamide: affects sodium channels
  - Side effects include sedation, anorexia, nausea, dizziness, ataxia, anhidrosis, and nephrolithiasis.
  - Cross-reaction with sulfa allergy

Pregnancy Considerations

- Folate should be prescribed for all women of childbearing age who are taking AEDs. AED therapy during the 1st trimester is associated with doubled risk for major fetal malformations (6% vs. 3%).
- Phenytoin in pregnancy may result in fetal hydantoin syndrome.
- Valproate is associated with neural tube defects.
- Fetal insult from seizures following withdrawal of therapy also may be severe. Risk-to-benefit balance should be evaluated with high-risk pregnancy and neurology consultations. Most patients remain on anticonvulsants.
- Consider vagal nerve stimulator during pregnancy (6)[B].

ISSUES FOR REFERRAL

For refractory seizures, consider referral to an epilepsy specialist.

ADDITIONAL THERAPIES

- Vagal nerve stimulator provides periodic stimulation to vagus nerve; may induce hoarseness, cough, and dysphagia. High-frequency stimulation in adults provides greater reduction in seizure frequency than low-frequency stimulation but also has greater rates of side effects (7)[B].
- Deep brain stimulation may decrease seizure frequency in medically refractive epilepsy, but its efficacy varies by seizure source location (8)[B].

- Repetitive magnetic transcranial stimulation may reduce the frequency of seizures in individuals with refractory focal seizures (9)[B].

SURGERY/OTHER PROCEDURES

- For refractory partial complex seizures with identifiable focus
- Preoperative testing, such as Wada test, should be done to decrease likelihood of inducing aphasia and memory loss.
- 34–74% will be seizure-free after temporal lobe surgery. Prognosis varies for surgical resection of extratemporal foci (10)[B].
- Goal of surgical intervention is to reduce reliance on medications; most patients remain on anticonvulsants postoperatively.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Admit for unremitting seizure (partial/secondary generalized status epilepticus).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Most states have restrictions on driving for those with seizure disorders.
- Depending on seizure manifestation, may also recommend against activities such as swimming, climbing to heights, or operating heavy machinery

Patient Monitoring

AED levels if concern over toxicity, noncompliance, or for breakthrough seizures

DIET

Ketogenic or low-glycemic index diet may improve seizure control in some patients but is not well-tolerated (11)[B].

PATIENT EDUCATION

Avoid potential triggers such as alcohol or drug use and sleep deprivation.

PROGNOSIS

- Risk of seizure recurrence: ~30% after first seizure; of these, 50% will occur

in the first 6 months; 90% in the first 2 years.

- Depends on seizure type; rolandic epilepsy has a good prognosis; temporal lobe epilepsy is more likely to be persistent.
- ~25–30% of all seizures are refractory to current medications.
- AEDs initiated after an initial seizure have been shown to decrease the risk of seizure over the first 5 years but are not demonstrated to reduce long-term risk of recurrence or mortality.
- The potential for AEDs to confer neuroprotection is under investigation.
- The risk of developing seizure after mild TBI remains high for a long period (>10 years).

COMPLICATIONS

- Risk of accidental injury
- Up to 50–60% of individuals with epilepsy will also have a mood disorder, the most common being depression and anxiety.
- 20–30% of individuals with epilepsy will have memory impairment.

CODES

ICD10

- G40.109 Local-rel symptc epi w simp prt seiz, not ntrct, w/o stat epi
- G40.209 Local-rel symptc epi w cmplx prt seiz, not ntrct, w/o stat epi
- G40.119 Local-rel symptc epi w simple part seiz, ntrct, w/o stat epi

CLINICAL PEARLS

- It is controversial whether AED treatment is indicated after a first seizure. Treatment should be strongly considered when a clear structural cause is identified/risk of injury from seizure is high (e.g., osteoporosis, anticoagulation).
- Consider vagus nerve stimulation in pregnancy and in patients with medically refractory seizures.
- Postictal elevation in prolactin and CPK levels can help distinguish

physiologic from psychogenic seizures.

SEIZURES, FEBRILE

Swati Avashia, MD, FAAP, FACP, ABIHM

BASICS

DESCRIPTION

Febrile seizures occur in children aged 6 months to 5 years with fever ≥100.4°F (38°C) and absence of underlying neurologic abnormality, metabolic condition, or intracranial infection.

- Defined as simple or complex (1):
  - Simple (65–90%; must meet all criteria)
    - Generalized clonic or tonic–clonic seizure activity without focal features
    - Duration <15 minutes
    - Does not recur within 24 hours
    - Resolves spontaneously
    - No history of previous afebrile seizure or seizure disorder
  - Complex (20–30%; only one criterion must be met)
    - Partial seizure, focal activity
    - Duration >15 minutes
    - Recurrence within 24 hours
    - Postictal neurologic abnormalities (e.g., Todd paresis) (2)

EPIDEMIOLOGY

Incidence

- Approximately 500,000 febrile seizures occur in the United States annually.
- Most occur in children 6 months to 3 years old; only 6–15% occur in patients ≥4 years
- Peak incidence is 18 months of age (2).
- Bimodal seasonal pattern that mirrors peaks of febrile respiratory (November to January) and gastrointestinal infections (June to August) (2).
- Febrile status epilepticus (duration > 30 minutes) represents 5% of febrile seizures (2).

Prevalence

- 2–5% of children in United States and Western Europe have at least one febrile seizure.
- Cumulative incidence varies in other populations (0.5–14%), with higher prevalence in Asia (3).

ETIOLOGY AND PATHOPHYSIOLOGY

A variety of mechanisms have been proposed:

- A lower baseline seizure threshold in the age group affected by febrile seizures
- Familial genotypes may influence seizure thresholds.
- Fever may alter ion channel activity, resulting in increased circuit excitability.
- Cytokines released secondary to infection, specifically interleukin (IL)-1β, increase neuronal activity.

Genetics

- Evidence for genetic association:
  - Greater concordance in monozygotic than dizygotic twins
  - Risk of febrile seizure with a previously affected sibling is increased.
  - Having two affected parents doubles a child's risk of febrile seizure.
  - 25–40% of cases have a positive family history (4).
  - Autosomal dominant inheritance reported (2)
- Several rare familial epileptic syndromes present with febrile seizure.

RISK FACTORS

- Family history of febrile seizures; risk increases with the number of affected first-degree relatives.
- Any condition causing fever
- Recent vaccination
  - As febrile seizures are a benign entity, the benefits of vaccination outweigh the risk.
  - Risk increases after the administration of all measles-containing vaccines; peak incidence occurs 7 to 10 days after vaccination.
  - Risk increased with DTaP-IPV-Hib combination vaccine administration; fever rate increases by 70% compared to giving them separately.
  - Absolute vaccination-associated risk is very low.

- Prenatal exposure to alcohol and tobacco, daycare attendance, premature birth, developmental delay, and prolonged NICU stay
- Children with iron deficiency anemia may have increased risk for febrile seizures. Consider checking for anemia if the history suggests a risk for iron deficiency (5)[C].

GENERAL PREVENTION

Prevention is not usually indicated given the benign nature of this condition, lack of effective interventions, and side effects of prophylactic medications.

COMMONLY ASSOCIATED CONDITIONS

- Viral infections: Common pathogens include human herpesvirus 6, influenza, parainfluenza, adenovirus, and respiratory syncytial virus (RSV).
- Bacterial infections: Frequently associated infections include otitis media, pharyngitis, urinary tract infection (UTI), pneumonia, and gastroenteritis.

DIAGNOSIS

HISTORY

- History of present illness:
  - Description of seizure:
    - Febrile seizures are generalized with clonic or tonic–clonic activity.
    - Absence, myoclonic, atonic, and focal seizures are atypical of febrile seizures and warrant further evaluation.
  - Seizure duration
  - Presence of postictal state (consistent with febrile seizure)
  - Number of seizures in previous 24 hours
  - Lethargy, irritability, or decreased level of consciousness as reported by the caretaker
  - Symptoms of underlying infection
  - Symptoms concerning for neurologic deficits
- Past medical history:
  - Existing conditions, including developmental delay, cerebral palsy, and metabolic disorders
  - Recent antibiotic course

  - History of febrile seizures
  - History of afebrile seizures or seizure disorder
  - History of head injury
  - Vaccination status, recent immunization
- Family history: febrile seizures, afebrile seizures, epilepsy, metabolic disorders, and other neurologic conditions
- Social history: factors concerning for child abuse

PHYSICAL EXAM

- Vital signs should be stable and consistent with intercurrent febrile illness; unstable vital signs or toxic appearance warrant further evaluation.
- Identify the presence or absence of focal deficits on a complete neurologic exam.
- Assess for signs of meningitis, including decreased level of consciousness, irritability, meningeal signs, bulging fontanelle, papilledema, and petechiae.
- Identify cause of fever.
- Assess thoroughly for manifestations of child abuse with a careful skin exam, inspection and palpation for occult trauma, and retinal exam if possible.

DIFFERENTIAL DIAGNOSIS

- Seizures due to an etiology other than febrile seizure:
  - Meningitis, encephalitis
  - Primary epilepsy
  - Neonatal seizure
  - Dravet syndrome
  - Intracranial mass
  - Nonaccidental trauma
  - Electrolyte abnormality
  - Hypoglycemia
  - Metabolic disorder
- Conditions presenting similarly to seizure:
  - Rigors
  - Crying
  - Benign myoclonus of infancy
  - Breath-holding spell

- Choking episode
- Tic disorder
- Parasomnia
- Arrhythmia
- Metabolic disorder
- Dystonic reaction

DIAGNOSTIC TESTS & INTERPRETATION

- Routine laboratory tests are not recommended to identify an underlying cause of a simple febrile seizure (1)[C].
- Rates of UTI in children with simple febrile seizures and in febrile children without seizure are comparable; decisions regarding urinalysis should be based on current UTI screening guidelines (2)[B].
- Blood glucose is no longer routinely recommended (2)[B].
- Lumbar puncture
  - In studies of patients with simple febrile seizures conducted since the initiation of routine infant vaccination against *Haemophilus influenzae*, rates of acute bacterial meningitis were very low (0–0.8%).
  - Seizure is unlikely to be the only presenting symptom of meningitis. Symptoms indicating increased likelihood of meningitis include toxic appearance, altered level of consciousness, meningeal signs, focal neurologic deficits, bulging fontanelle, and petechiae.
  - Cases of bacterial meningitis in children with febrile seizures who return to baseline or in the absence of other signs or symptoms are rare (2).
  - Recommendations:
    - Lumbar puncture should be performed in a child with fever and seizure if meningeal signs are present or if there is concern for meningitis or other intracranial pathology based on history and exam (6)[B].
    - In infants aged 6 to 12 months, consider lumbar puncture if the child has not been vaccinated against *H. influenzae* or *Streptococcus pneumoniae* according to schedule (6)[C].
    - Consider lumbar puncture for children with fever and seizure who have recently been treated with antibiotics, as antibiotics may mask meningeal signs and symptoms (6)[C].

- The yield of lumbar puncture in children with complex febrile seizure is very low and the rate of acute bacterial meningitis in U.S. patients with complex febrile seizures is too low to routinely recommend lumbar puncture.
- Neuroimaging is not routinely recommended for the purposes of identifying the cause of a simple febrile seizure (6)[B].

- Studies have demonstrated limited utility of emergent imaging in patients who meet criteria for complex febrile seizure based on multiple episodes in 24 hours; however, imaging may be indicated for focal findings or concerning history or exam. There are no current guidelines regarding imaging with complex febrile seizures (7)[B].

Diagnostic Procedures/Other

- EEG is not recommended in neurologically normal children presenting with simple febrile seizure (6)[B].
- There is mixed evidence for use of EEG after complex febrile seizures; some recommend outpatient EEG on follow-up because EEGs can show generalized slowing for 24 hours after initial presentation and up to 7 days after febrile status epilepticus (2).

TREATMENT

GENERAL MEASURES

- Acute seizure management
  - Airway: Position the patient laterally, suction secretions, and place a nasopharyngeal airway if necessary.
  - Breathing: Administer oxygen for cyanosis; consider bag-mask ventilation or intubation for inadequate ventilation.
  - Circulation: Establish IV access if first-line buccal or nasal midazolam is not effective.
- Antipyretics are helpful for patient comfort but do not prevent seizure recurrence during the initial febrile episode (1)[A].
- Provide supportive care and treat underlying infection if necessary.

MEDICATION

First Line

Treat seizures of ≥5 minutes duration with anticonvulsants (2):

- Out of hospital: Buccal midazolam 0.4 mg/kg, nasal midazolam 0.2 mg/kg
- In hospital: IV or IM lorazepam 0.1 mg/kg or IV diazepam 0.2 mg/kg

Second Line

Rectal diazepam is less effective and more commonly associated with respiratory depression (1)[B].

ISSUES FOR REFERRAL

Simple febrile seizures do not require referral to a pediatric neurologist.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Unstable vital signs
- Concerning findings on history or physical exam
- Prolonged seizure requiring anticonvulsants
- Persistent change in mental status
- Inpatient management of underlying condition is required.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Anticonvulsant prophylaxis during subsequent febrile episodes:
  - The American Academy of Pediatrics recommends against prophylaxis with anticonvulsants due to an unacceptable risk–benefit ratio (8)[B].
  - Phenobarbital is effective but can have serious side effects, including lowering IQ (8)[B].
  - Primidone 15 to 20 mg/kg/day also reduces recurrence but adverse effects include behavioral disturbances, irritability, and sleep disturbance (8)[B].
  - Prophylaxis with valproic acid is as effective as phenobarbital but can cause fatal hepatotoxicity and/or hyperammonemia, thrombocytopenia, gastrointestinal disturbances, pancreatitis, weight gain or weight loss (8)[B].

  - Prophylaxis with phenytoin and carbamazepine is ineffective (8)[B].
  - Intermittent oral and rectal diazepam are effective in reducing recurrence of simple and complex febrile seizures but are not recommended due to the benign nature of febrile seizures and because so many febrile seizures precede the development of the fever (2)[B].
- Antipyretic prophylaxis during subsequent febrile episodes (1)[A]:
  - No study has demonstrated that fever management will prevent recurrence.
  - Ibuprofen and acetaminophen are no more effective than placebo in preventing recurrence.

PATIENT EDUCATION

There is frequently a high degree of parental anxiety associated with febrile seizures. Suggested anticipatory guidance:

- Febrile seizures do not cause brain damage and are associated with a low risk for sequelae.
- Parents should be reassured after a simple febrile seizure that there is no negative impact on intellect, behavior, or risk of death (1)[B].
- Parents should be prepared for a high probability of recurrence.
- If seizure recurs, position the child safely and do not intervene inappropriately.
- Time the seizure; call rescue if the child turns blue, has difficulty breathing, or the seizure lasts >5 minutes.
- If the seizure spontaneously resolves in <5 minutes and the child is well but sleepy, seek immediate attention, but calling rescue is not necessary.

PROGNOSIS

- Recurrence:
  - Estimates of recurrence rates vary (30–50%).
  - 10% will experience 3 or more febrile seizures (2).
  - Factors associated with seizure recurrence include age <18 months at time of first episode, first-degree relative with history of febrile seizure, history of complex febrile seizures, history of complex febrile seizures, lower peak temperatures, and shorter duration of fever prior to seizure occurrence (2).
- Intellectual and behavioral outcomes (8)
  - Febrile seizures do not impact IQ, behavioral abnormalities, academic performance, or neurocognitive inattention.

  - Outcomes in children with single and multiple febrile seizures are similar.
- Subsequent development of epilepsy (2)
  - Risk of epilepsy after a simple partial seizure is close to the overall rate in the general population.
  - Risk is up to 7% in those with multiple simple febrile seizures under age <12 months and a short duration of fever prior to seizure onset.
  - Factors associated with increased risk include presenting with complex febrile seizure, family history of epilepsy or febrile seizures, cerebral palsy, developmental delay, low birth weight, and prematurity.
- Mortality:
  - Theoretical increased risk of mortality as a result of injury, aspiration, or arrhythmia, but this has not been reported (8)
  - There is not an increased risk for SIDS in siblings of children who have febrile seizures.

COMPLICATIONS

Seizure-related injury, aspiration pneumonia, side effects of prescribed medications or diagnostic procedures, and subsequent parental perception of the child as being vulnerable, especially during subsequent fevers

CODES

ICD10

- R56.00 Simple febrile convulsions
- R56.01 Complex febrile convulsions
- G40.901 Epilepsy, unsp, not intractable, with status epilepticus

CLINICAL PEARLS

- Febrile seizures are generally benign, and families can be reassured that children are at low risk of death, subsequent development of epilepsy, and learning or behavioral abnormalities.
- History and physical exam are important tools in identifying children presenting with febrile seizure who may be at greater risk for meningitis or other intracranial pathology.
- For simple febrile seizures, routine labs, lumbar puncture, neuroimaging studies, and EEG are not recommended in the absence of clinical suspicion of serious underlying pathology.
- Prophylaxis with anticonvulsants or antipyretics during subsequent febrile episodes is not recommended due to their lack of effectiveness and the risk of medication-associated side effects.

SEROTONIN SYNDROME

Robert A. Baldor, MD, FAAFP

BASICS

DESCRIPTION

- A potentially life-threatening adverse drug reaction that results from excessive stimulation of peripheral and CNS serotonergic receptors
- It is a concentration-dependent toxicity that can develop in any individual who has ingested drug combinations that synergistically increase synaptic 5-HT.
- Serotonin toxicity occurs in three main settings: (i) therapeutic drug use, which often results in mild to moderate symptoms; (ii) intentional overdose of a single serotonergic agent, which typically leads to moderate symptoms; and (iii) as the result of a drug interaction between numerous serotonergic agents (most commonly, selective serotonin reuptake inhibitors [SSRIs] and monoamine oxidase inhibitors [MAOIs]), most often associated with severe serotonin toxicity.
- Classically characterized by a triad of symptoms that include mental status change, neuromuscular abnormalities, and autonomic hyperactivity
- Onset is usually within 24 hours with 60% of cases occurring within 6 hours of exposure to, or change in, dosing of a serotonergic agent. Rarely, cases have been reported weeks after discontinuation of serotonergic agents.

Geriatric Considerations

Elderly are at increased risk given use of multiple meds.

Pediatric Considerations

- Serotonin syndrome has similar manifestations in children and adults.
- General management is unchanged in children, other than medication dosing.

Pregnancy Considerations

- 3rd-trimester exposure to SSRIs has been associated with transient neonatal complications that may reflect either acute drug withdrawal or serotonergic toxicity.

- Symptoms in neonates may include tremors, increased muscle tone, jitteriness, shivering, feeding/digestive disturbances, irritability, agitation, sleep disturbances, increased reflexes, excessive crying, and respiratory disturbances.

EPIDEMIOLOGY

Seen in about 14–16% of SSRI overdose patients

Incidence

- About 100,000 adverse events reported with antidepressant use including some deaths, annually. Most associated with SSRIs, either alone or in combination with other drugs. In a 2008 study, SSRIs alone were responsible for adverse events in 18.8% of cases, with 55.7% due to intentional causes, 39.5% unintentional, and remainder of causes unknown. Of patients reporting adverse effects with SSRIs, 46.6% had symptoms requiring hospitalization, and significant toxic effects occurred in 90 patients with 2 resultant deaths (1) [A].
- The incidence of serotonin syndrome is rising because serotonergic agents are increasingly used in clinical practice and in combination with other serotonergic agents.
- Predominant age: affects all age groups
- Predominant sex: male = female

ETIOLOGY AND PATHOPHYSIOLOGY

- The result of excessive stimulation in peripheral and CNS serotonergic receptors
- Risk is mediated in a dose-related manner to the action of 5-HT/5-HT agonists on 5HT-1a and/or 5HT-2a receptors. The development mechanism of the syndrome is unknown.
- It is hypothesized that the degree of serotonin elevation in blood plasma has to be 10–15% times above baseline levels to result in serotonin toxicity (2)[A].
- A number of drugs are associated with the serotonin syndrome, which usually involves combination with an SSRI. These include SSRIs (e.g., citalopram, escitalopram, fluoxetine, fluvoxamine, paroxetine, sertraline); MAOIs; SNRIs (duloxetine, venlafaxine, desvenlafaxine); tricyclic antidepressants (e.g.,

amitriptyline); other antidepressants (buspirone, nefazodone, trazodone); lithium; triptans; anticonvulsants (Depakote); analgesics (fentanyl, meperidine, pentazocine, tramadol); antibiotics (linezolid [weak MAOI], ritonavir); over-the-counter (OTC) cough medications (dextromethorphan); some antipsychotics (risperidone, olanzapine); antiemetics (ondansetron, granisetron); other medications, such as metoclopramide, cyclobenzaprine, L-dopa; dietary supplements (tryptophan); herbal supplements (St. John's wort, nutmeg); methylene blue; and drugs of abuse (e.g., methylenedioxymethamphetamine [MDMA], cocaine, D-lysergic acid diethylamide [LSD], and amphetamine).

- Initially, patients can develop a peripheral tremor, confusion, and ataxia; systemic signs are next (e.g., agitation, diaphoresis, hyperreflexia, and shivering). If it worsens, the severe signs of fever, jerking, and diarrhea may develop. Serotonin syndrome can last from hours to days after the offending agents are stopped and supportive care is initiated.
- Drug interactions are most often the cause of severe cases of serotonin syndrome. Many of the same classes of medications listed earlier are involved, especially MAOIs (including linezolid) with SSRIs.

Genetics

Unknown

RISK FACTORS

- Serotonergic agents
- Reported following ingestion of a single agent. However, the greatest number of adverse events has been shown to be associated with SSRIs in combination with other substances, and the combination of SSRIs and MAOIs carries the greatest risk of developing serotonin toxicity.

GENERAL PREVENTION

- Consider drug–drug interactions when a multidrug regimen is required and avoid if possible.
- Caution patients about taking SSRIs with OTC medications (e.g., dextromethorphan) or herbal supplements (e.g., St. John's wort) prior to consulting a physician.

- Clinician education
- Continual improvement in use of health information technology

DIAGNOSIS

- Serotonin syndrome is a clinical diagnosis.
- Epidemiologic data suggest that up to 85% of practitioners are unaware of serotonin syndrome.
- *Hunter Toxicity Criteria Decision Rules* aid in the diagnosis of clinically significant serotonin toxicity (sensitivity, 84%; specificity, 97%).
- To fulfill Hunter criteria, a patient must have taken a serotonergic agent and have one of the following:
  - Spontaneous clonus
  - Inducible clonus plus agitation/diaphoresis
  - Ocular clonus plus agitation/diaphoresis
  - Tremor and hyperreflexia
  - Hypertonia
  - Temperature >38°C plus ocular clonus/inducible clonus (3)[A]

HISTORY

- Obtain a thorough drug history, including prescription medications, OTC remedies, dietary supplements, herbal supplements, and illicit drugs. Ask about dose, formulation, and recent changes.
- Address possibility of drug overdose and obtain collateral information if intentional overdose is suspected.
- Elicit description of symptoms, including their onset and progression.

PHYSICAL EXAM

- Vital signs: tachycardia, hypertension, and hyperthermia (severe cases)
- Neuromuscular findings (seen in over half of patients with serotonin syndrome)
  - Hyperreflexia (greater in lower extremities)
  - Clonus (involuntary muscle contractions, most commonly tested by flexing foot upward rapidly; includes ocular)
  - Myoclonus (greater in lower extremities)

- Tremor (greater in lower extremities)
- Hypertonia
- Bilateral Babinski sign
- Akathisia
- Tonic–clonic seizures (severe cases)
- Autonomic signs
  - Diaphoresis
  - Mydriasis
  - Flushing
  - Dry mucous membranes
  - Vomiting, diarrhea, increased bowel sounds
  - Mental status changes: anxiety, disorientation, delirium (4)[A]
  - Severe cases have led to altered level of consciousness, rhabdomyolysis, metabolic acidosis, and disseminated intravascular coagulation (DIC).

DIFFERENTIAL DIAGNOSIS

- Neuroleptic malignant syndrome (NMS)
- Anticholinergic fever (e.g., benztropine, diphenhydramine, oxybutynin, nifedipine, famotidine, atropine, scopolamine; plant poisoning from belladonna/“deadly nightshade,” datura, henbane, mandrake, brugmansia)
- Malignant hyperthermia
- Heat stroke
- CNS infection (meningitis, encephalitis)
- Sympathomimetic toxicity
- Nonconvulsive seizures
- Hyperthyroidism
- Tetanus
- Acute baclofen withdrawal

DIAGNOSTIC TESTS & INTERPRETATION

- Serum serotonin levels do not correlate with clinical findings.
- Nonspecific lab findings that may develop include the following:
  - Elevated WBC count
  - Elevated creatine phosphokinase (CK or CPK)
  - Decreased serum bicarbonate

  - Elevated hepatic transaminases
- In severe cases, the following complications may develop:
  - DIC
  - Metabolic acidosis
  - Rhabdomyolysis
  - Renal failure
  - Myoglobinuria
  - Acute respiratory distress syndrome (ARDS) (4)[A]

TREATMENT

- Discontinue all serotonergic agents.
- Supportive care is the mainstay of therapy. This includes administration of oxygen and aggressive IV fluids, continuous cardiac monitoring, and correction of vital signs.
  - Benzodiazepines may be effective for the management of agitation in patients with serotonin syndrome.
  - Administration of serotonin antagonists: Cyproheptadine (histamine and serotonin antagonist) may be useful if supportive measures and sedation (benzodiazepines) are unable to control agitation and correct vital signs.
- Mild cases (afebrile, tachycardia, shivering, diaphoresis, mydriasis, hyperreflexia, intermittent tremor or myoclonus)
  - Discontinue precipitating agent(s).
  - Supportive care
  - Sedation
- Moderate cases (temperature >38°C, autonomic instability, mydriasis, hyperactive bowel sounds, diarrhea, diaphoresis, ocular clonus, hyperreflexia, tremor, mild agitation, or hypervigilance)
  - Discontinue precipitating agent(s).
  - Supportive care
  - Sedation
  - Aggressive treatment of autonomic instability
  - Treatment with cyproheptadine should be initiated if agitation and vital sign abnormalities are unimproved with benzodiazepines and supportive care.

- Hypotension from MAOI interactions should be treated with low doses of direct-acting sympathomimetics (e.g., norepinephrine, phenylephrine, epinephrine); indirect serotonin agonists, such as dopamine, should be avoided.
- Severe hypertension and tachycardia should be treated with short-acting agents, such as nitroprusside or esmolol.
- Avoid use of longer acting agents, such as propranolol.

- Severe cases (temperature >41.1°C, autonomic instability, delirium, muscular rigidity, and hypertonicity)
  - Discontinue precipitating agent(s).
  - Immediate sedation
  - Endotracheal intubation as clinically indicated
  - Paralysis as clinically indicated (maintained with nondepolarizing continuous paralytic agents such as vecuronium, cisatracurium, rocuronium)
  - Antipyretic medications are not effective (4)[A]; the increased body temperature is due to muscle activity, not an alteration in the hypothalamic set point.

MEDICATION

- Activated charcoal: may be used in patients who intentionally overdose on serotonergic agents (3)[A]
- Benzodiazepines: may be used to manage agitation in serotonin syndrome and also may correct mild increases in BP and heart rate. Use with caution in patients with delirium, given the known paradoxical effect of exacerbating delirium.
- Cyproheptadine (Periactin): Consider use if benzodiazepines and supportive measures are unable to control agitation and correct vital signs:
  - Adults: initial dose 12 mg PO (can also be crushed and given via nasogastric [NG] tube) followed by 2 mg q2h until clinical response observed; 12 to 32 mg of drug may be required in a 24-hour period.
  - Children
    - <2 years: 0.06 mg/kg q6h
    - 2 to 6 years: 2 mg q6h

    - 7 to 14 years: 4 mg q6h
  - Unlikely to be effective in patients who have received activated charcoal.
- Use of antipsychotics with 5-HT_{2A} antagonist activity, such as olanzapine and chlorpromazine, is not recommended (4)[A].

ISSUES FOR REFERRAL

- Psychiatry: for assistance with medication management and follow-up care (inpatient psychiatric care vs. outpatient psychiatric follow-up)
- Toxicology/clinical pharmacology service
- Poison control center

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Patients with known/suspected serotonin syndrome should be admitted to a medical inpatient unit for observation.
- Discharge criteria
  - Mental status has returned to baseline.
  - Stable vital signs
  - No increase in clonus
  - Close patient follow-up is ensured.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- In mild cases of serotonin toxicity, address risks and benefits of restarting offending agents. Serotonergic medications need to be titrated slowly, and patients must have close outpatient follow-up with physician.
- If patient developed severe serotonin syndrome, the offending agent should likely not be resumed unless precipitant for serotonin syndrome is found (e.g., combination with another serotonin agonist); the patient can be carefully monitored, or there is clear benefit versus risk of restarting the medication.

PROGNOSIS

- Generally favorable with early recognition of the syndrome and prompt initiation of treatment

- Most cases resolve within 24 hours of discontinuation of serotonergic agents; this can be longer depending on the drug's half-life:
  - MAOIs can result in toxicity for several days.
  - SSRIs can result in toxicity for up to several weeks after discontinuation.
- ICU admission is often indicated in severe cases.

COMPLICATIONS

- Adverse outcomes, including death, are usually the consequence of poorly treated hyperthermia.
- Nonhyperthermic patients who survive typically do not have long-term sequelae.

CODES

ICD10

G25.79 Other drug induced movement disorders

CLINICAL PEARLS

Consider serotonin syndrome in patients with recent use of a serotonergic agent (particularly if multiple proserotonergic agents are involved) presenting with unexplained tachycardia, hypertension, hyperthermia, clonus, hyperreflexia, and change in mental status.

SEXUAL DYSFUNCTION IN WOMEN

Amanda M. Carnes, MD • Lisa M. Harris, DO

BASICS

- Very common: ~40% of women surveyed in the United States have sexual concerns.
- May present as a lack of sexual desire, impaired arousal, pain with sexual activity, or inability to achieve orgasm and may be lifelong or acquired

DESCRIPTION

- Female sexual interest or arousal disorder—lack of or significantly reduced sexual interest or arousal as manifested by three of the following:
  - Absent or reduced interest in sexual activity
  - Absent or reduced sexual or erotic thoughts or fantasies
  - No or reduced initiation of sexual activity and unreceptive to partner's attempts to initiate
  - Absent or reduced sexual excitement or pleasure during sexual activity in almost all (75–100%) of sexual encounters
  - Absent or reduced sexual interest or arousal in response to any internal or external sexual or erotic cues
  - Absent or reduced genital or nongenital sensation during sexual activity in almost all (75–100%) of sexual encounters
- Female orgasmic disorder—presence of either of the following in almost all (75–100%) occasions of sexual activity:
  - Marked delay in, marked infrequency of, or absence of orgasm
  - Markedly reduced intensity of orgasmic sensations
- Genito-pelvic pain or penetration disorder—persistent or recurrent difficulties with one or more of the following:
  - Vaginal penetration during intercourse
  - Marked vulvovaginal or pelvic pain during intercourse or penetration attempts
  - Marked fear or anxiety about vulvovaginal or pelvic pain in anticipation of, during, or because of vaginal penetration

- Marked tensing or tightening of pelvic floor muscles during attempted vaginal penetration

ALERT

- Symptoms must be present for ≥6 months; cause clinically significant distress or impairment; and not be caused by another condition (psychiatric or medical), substance/medication, relationship distress, or other stressor.
- System(s) affected: nervous; reproductive; genitourinary; psychiatric
- Synonym(s): hypoactive sexual desire disorder; sexual aversion disorder; female sexual arousal disorder; inhibited female orgasm

EPIDEMIOLOGY

In two large studies, approximately 40% of women reported sexual problems.

Incidence

Sexual problems are highest in women aged 45 to 64 years and then declines secondary to changes in sexual-related personal distress.

Prevalence

Low sexual desire is the most common manifestation, followed by difficulty with orgasm, difficulty with arousal, and sexual pain.

ETIOLOGY AND PATHOPHYSIOLOGY

The pathophysiology of sexual dysfunction is complex and multifactorial because it can be the result of any etiology that interferes with the nonlinear model of female sexual response cycle (emotional intimacy, sexual stimuli, psychological factors, and relationship satisfaction).

- Physiologic
  - Prescription medications
    - SSRIs, MAOIs, and TCAs
    - β-Blockers, ACE inhibitors, and calcium channel blockers
    - GNRH agonists
    - Injectable progestins
    - Antiepileptics
    - Gabapentin
- Endocrine

  - Disorders of the hypothalamic-pituitary-adrenal system, hormonal imbalance/disorders of ovarian function, menopause (surgical or natural)
  - Thyroid disease
  - Diabetes
- Neurologic
  - Spinal cord damage
- Psychological
  - Maladaptive thoughts/behaviors
  - Interrelational difficulties
  - Body image issues
  - Drug and alcohol abuse
  - Sexual abuse

RISK FACTORS

- Advancing age/menopause
- Previous sexual trauma
- Lack of knowledge about sexual stimulation and response
- Chronic medical problems
  - Depression, anxiety, chronic pain syndromes, and other psychiatric disorders
  - Cardiovascular disease
  - Endocrine disorders
  - Dermatologic disorders
  - Neurologic disorders
  - Cancer
- Gynecologic issues
  - Childbirth
  - Pelvic floor or bladder dysfunction
  - Endometriosis
  - Uterine fibroids
  - Chronic vulvovaginal candidiasis/vaginal infections
  - Female genital mutilation
- Relationship factors such as couple discrepancies in expectations and/or cultural backgrounds and attitudes toward sexuality in family of origin
- Medications or substance abuse

COMMONLY ASSOCIATED CONDITIONS

- Marital/relationship discord
- Depression

DIAGNOSIS

- Female sexual dysfunction is diagnosed by utilizing a validated sexual function screening instrument and a structured interview, including detailed medical and sexual history, to confirm diagnosis.
  - Female Sexual Function Index
  - Brief Index of Sexual Functioning for Women
  - Brief Sexual Symptom Checklist
  - Decreased Sexual Desire Screener
- The diagnosis requires that the sexual problem be recurrent or persistent and cause personal distress rather than be due solely to partner or relationship issues.

HISTORY

- Detailed sexual history (1)[C]
  - Degree of personal distress
  - Lifelong versus acquired problem
  - Situational versus generalized problem
  - Cultural/societal beliefs regarding sexuality
  - History of sexual trauma
  - Concerns about safety, pregnancy, or STIs
  - Concerns regarding privacy
- Interpersonal relationship factors
  - Current relationship status
  - Family dysfunction
- Physiologic/biologic history
  - Urinary/anal incontinence
  - Medications (including herbal and OTC)
  - Pregnancy/childbirth history
  - Infertility

  - Menopausal status (natural, surgical, or postchemotherapy)
  - STIs and vaginitis
  - Pelvic surgery, injury, or cancer
  - Chronic pelvic pain
  - Abnormal genital tract bleeding
- Psychological history
  - Low self-image
  - Anxiety
  - Depression
  - Negative past sexual experiences
  - Substance misuse/abuse

PHYSICAL EXAM

- Most commonly, patients have a normal physical exam (1)[C].
  - Assess for anatomic abnormalities.
  - Assess for scars or evidence of trauma.
  - Assess for vaginal atrophy, adequate estrogenization.
  - Assess for infection.
  - Recognize signs of anxiety, apprehension, and pain during the speculum and pelvic exam.
- General physical exam, signs of chronic disease

DIFFERENTIAL DIAGNOSIS

- Medication side effects
- Vaginitis
- Decreased vaginal lubrication secondary to hormonal imbalance
- Decreased sensation secondary to nerve injury
- Multiple sclerosis
- Anatomic abnormalities
- Abdominal surgery (which can interfere with pelvic innervation)
- Depression
- Marital dysfunction, including domestic violence
- Pregnancy
- Pseudodyspareunia (use of complaint of pain to distance self from partner)

DIAGNOSTIC TESTS & INTERPRETATION

Laboratory studies are rarely helpful. There are no reliable correlations between serum hormone levels and sexual dysfunction.

Initial Tests (lab, imaging)

As needed to identify infections and other medical causes (1)[C]

TREATMENT

- Set realistic goals and expectations (2)[C].
- Address underlying medical and psychiatric conditions (3)[C].
- Review basic sex education, sexual response, heterogeneity of normal response, and sexual activity other than intercourse (2,4)[C].
- Education on communication (4)[C]
- Educate on healthy lifestyle, including diet, exercise, sleep, avoidance of tobacco, and reduced alcohol use (2,4)[C].
- Vaginal moisturizers and lubricants (4)[C]
- Cognitive-behavioral therapy (CBT) (individual or couples) to target maladaptive thoughts and behaviors and to disrupt the dysfunctional cycle (3,4)[C]
- Mindfulness-based CBT (2,4)[C]
- Sex therapy: sensate focus, systematic desensitization exercises, homework exchanging physical touch with partner, or directed masturbation alone (3,4)[C]
- Physical therapy/biofeedback (4)[C]

MEDICATION

Sexual dysfunction is often a multifactorial psychosocial condition. Using medications does not usually address the cause of the problem and can, in some cases, make the condition worse.

- Bupropion (2,4)[C]: adjunct for SSRI-induced sexual dysfunction. Improves sexual arousal and orgasm but not desire. Dose: bupropion SR 150 mg orally once or twice daily.
- Flibanserin (3)[C],(5)[A]: possible improvement in sexual desire. Clinical improvement versus placebo is minimal, and side effects are common.

Mechanism of action: 5-HT_{1A} agonist and 5-HT_{2A} antagonist. Dose: 100 mg at bedtime.

- Estrogen replacement with or without progestins (2)[C],(6)[A]: may improve sexual desire, vaginal atrophy, and clitoral sensitivity. Vaginal estrogen therapy is available in cream, vaginal tablet, or ring form.
- Ospemifene (2)[C]: selective estrogen receptor modulator FDA-approved for dyspareunia due to vulvo- or vaginal atrophy in postmenopausal women. Dose: ospemifene 60 mg orally once daily.
- Testosterone (2,3,4)[C]
  - Use in premenopausal women not supported by data.
  - In naturally or surgically postmenopausal women, adding short-term testosterone to hormone replacement may increase desire.
  - Use >6 months contingent on clear improvement and no adverse effects.
  - Side effects: hirsutism, androgenic alopecia, acne, decreased HDL, liver dysfunction; not FDA-approved for sexual dysfunction in women
  - Contraindicated in breast or endometrial cancer, thromboembolic disease, or coronary artery disease
  - Dose: oral methyltestosterone 1.25 to 2.5 mg/day (1/10 of men's dose) or topical (patch, gel)
- Dehydroepiandrosterone (DHEA) and tissue-selective estrogen complexes (TSECs) (3,4)[C]: may improve vaginal atrophy, dryness, and dyspareunia. Not FDA approved. Additional studies needed.
- Phosphodiesterase type 5 (PDE-5) inhibitors (4)[C]: not recommended

ISSUES FOR REFERRAL

Consider referral for CBT, marriage/couples counseling, or sex therapy.

ADDITIONAL THERAPIES

- Smoking cessation and reduction of alcohol intake
- For childhood trauma: scripting, psychotherapy, cognitive restructuring
- For prescription-drug causes: reduced dosages or change to different medication

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Zestra for Women botanical feminine massage oil: Small trial showed

increased arousal, desire, genital sensation, ability to have orgasm, and sexual pleasure.
- Yohimbine: not recommended, potentially dangerous
- Ginseng and St. John's wort: no evidence to support treatment of sexual dysfunction

ONGOING CARE

DIET

Weight reduction if overweight or obese

PATIENT EDUCATION

- American Association of Sex Educators, Counselors, and Therapists: www.aasect.org
- National Women's Health Resource Center: www.healthywomen.org
- North American Menopause Society: www.menopause.org
- National Vulvodynia Association: www.nva.org

PROGNOSIS

Lack of desire is most difficult type to treat with <50% success.

CODES

ICD10

- R37 Sexual dysfunction, unspecified
- F52.0 Hypoactive sexual desire disorder
- N94.1 Dyspareunia

CLINICAL PEARLS

- Female sexual dysfunction is a common, complex, multifactorial problem.
- Usually, patients with sexual dysfunction have a normal physical exam.
- Symptoms of sexual dysfunction peak during perimenopause between the ages of 45 and 64 years.
- Several therapies exist for treating sexual dysfunction in women, including behavioral therapy and medications.

SHOULDER PAIN

Elana R. Bannerman, MD • J. Herbert Stevenson, MD

BASICS

DESCRIPTION

- Shoulder pain is common and affects patients of all ages. Causes include acute trauma, overuse during sports, and activities of everyday living.
- Age plays an important role in determining the etiology of shoulder pain.
- Onset and characteristics of pain, weakness, mechanism of injury, and functional limitation help guide an accurate diagnosis.

EPIDEMIOLOGY

- Shoulder pain accounts for 16% of all musculoskeletal complaints.
- The lifetime prevalence of shoulder pain is ~70%.
- Predominant etiology varies with age:
  - <30 years: shoulder instability
  - >30 years: rotator cuff (RTC) disorder
    - 30 to 50 years: tendinopathy
    - 40 to 60 years: partial tear
    - >60 years: full-thickness tear
  - >60 years: glenohumeral osteoarthritis (OA)

Incidence

The incidence of shoulder pain is 7 to 25 cases/1,000 patients, with a peak incidence in the 4th to 6th decades.

ETIOLOGY AND PATHOPHYSIOLOGY

Pathology varies with cause:

- Trauma (fracture, dislocation, ligament/tendon tear, acromioclavicular [AC] separation)
- Overuse (RTC pathology, biceps tenosynovitis, bursitis, muscle strain, apophyseal injuries)
  - RTC disorders most commonly result from repetitive overhead activity,

leading to RTC impingement with a three-stage progression:
    - Stage I: tendinopathy
    - Stage II: partial RTC tear
    - Stage III: full-thickness RTC tear
  - Subacromial bursitis can occur with RTC disorders but is rarely an isolated diagnosis.
- Age-related: In pediatric athletes, instability and physeal injuries are more common. With increasing age, the incidence of AC and glenohumeral joint OA, adhesive capsulitis, and RTC tear rises.
- Rheumatologic: rheumatoid arthritis, polymyalgia rheumatica, fibromyalgia
- Referred pain: neck, gallbladder

RISK FACTORS

- Repetitive overhead activity
- Overhead and upper extremity weight-bearing sports (baseball, softball, swimming, tennis, volleyball)
- Weight lifting: acromioclavicular (AC) joint disorders
- Rapid increases in training frequency or load (often associated with improper technique)
- Muscle weakness or imbalance
- Trauma or fall onto the shoulder
- Diabetes, thyroid disorders and other autoimmune diseases, female gender, and age 40 to 60 years are risk factors for adhesive capsulitis.

GENERAL PREVENTION

- Maintain strength and range of motion (ROM).
- Avoid repetitive overhead activities (pitch counts).
- Proper technique (pitching, weight lifting)

DIAGNOSIS

HISTORY

- Pain characteristics
  - Superior pain: AC pathology, trapezius strain
  - Lateral/deltoid pain: RTC pathology (RTC pain typically does not extend

past elbow.)
  - Diffuse pain: RTC pathology, adhesive capsulitis, glenohumeral OA
  - Night pain: RTC pathology (pain laying on affected side), adhesive capsulitis, glenohumeral OA
  - Stiff shoulder: adhesive capsulitis, glenohumeral OA
  - Pain with cross-body activities: AC pathology
  - Pain with abduction/external rotation (reaching behind): shoulder instability, RTC pathology, glenohumeral OA
  - Pain with overhead activity: RTC pathology, AC pathology, labrum pathology, glenohumeral OA
  - Pain with turning neck, pain past elbow: cervical pathology
- Mechanism of injury
  - Forceful external rotation: traumatic shoulder instability/dislocation
  - Fall directly onto shoulder: AC joint sprain, clavicular fracture
  - Repetitive overhead activity: RTC pathology
  - Fall on outstretched hand (FOOSH): shoulder separation; forearm/wrist fracture
- Age
  - Shoulder instability (subluxation, dislocation, multidirectional instability) is the most common cause of shoulder pain in young athletes (<30 years old).
  - RTC disorders are the most common cause of shoulder pain in patients >30 years old. Severity of RTC disorder increases with age.
  - Older patients (>60 years old) commonly have OA.
  - Trauma in a young person <40 years is more commonly associated with dislocation/subluxation. In patients >40 years, trauma is more commonly associated with RTC tear.

PHYSICAL EXAM

- Observe face and shoulder movements as patient disrobes, moves arm, and shakes hand.
- Inspect for malalignment, muscle atrophy, asymmetry, erythema, ecchymosis, and swelling. Scapular winging suggests long thoracic nerve or muscular (trapezius, serratus anterior) dysfunction. Prominent scapular spine with scalloped infraspinatus fossa suggests infraspinatus atrophy.
- Palpate for tenderness, warmth, bony step-offs.

- Evaluate active and passive ROM and flexibility:
  - Decreased active AND passive ROM are more common with adhesive capsulitis.
  - Mildly decreased active and/or passive ROM may also indicate glenohumeral OA.
- Decreased active, full passive ROM: RTC pathology
- Evaluate for muscle strength including grip, biceps, triceps, and deltoid. Test RTC strength: supraspinatus (empty can test), infraspinatus/teres minor (resisted external rotation, external lag test), subscapularis (lift-off test, belly press, resisted internal rotation). Pain with RTC strength testing indicates RTC pathology. Weakness could suggest tear.
- Special tests
  - Neer, Hawkin tests: RTC impingement
  - Drop-arm test: RTC tear
  - Cross-arm adduction test: AC joint arthritis
  - Speed, Yergason tests: biceps tendinopathy
  - Apprehension, relocation test: anterior glenohumeral joint instability
  - Sulcus sign: inferior glenohumeral joint instability
  - O'Brien, clunk test: labral pathology
  - Spurling test: cervical pathology

DIFFERENTIAL DIAGNOSIS

- Fracture (clavicle, humerus, scapula), contusion
- RTC disorder: impingement, tear, calcific tendonitis
- Subacromial bursitis
- Scapulothoracic dyskinesis
- AC joint pathology (AC separation/OA, osteolysis)
- Biceps tenosynovitis or tear
- Acromial apophysitis or os acromiale
- Glenohumeral joint OA
- Glenohumeral joint instability (acute dislocation or chronic multidirectional instability)
- Adhesive capsulitis
- Labral tear or associated bony pathology
- Muscle strain (trapezius, deltoid, biceps)

- Cervical radiculopathy
- Other: autoimmune, rheumatologic, referred pain, septic joint (biliary/splenic, cardiac, pneumonia/lung mass)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Shoulder pain can be accurately diagnosed with a careful history and physical exam:
  - Adults with nontraumatic shoulder pain of <4 weeks duration may not require initial imaging.
- History of significant trauma, prolonged symptoms, or red flags (older age, fever, rest pain) suggest need for imaging.
- Plain radiographs are first line:
  - Assess for fracture, degenerative changes, signs of dislocation (Bankart, Hill-Sachs deformity), signs of large RTC tear (sclerosis, proximal migration of humeral head), anatomic deformities contributing to impingement, and masses (tumor, cyst).
  - Standard views: anteroposterior, scapular Y, axillary
- EMG study of the upper extremity may help differentiate referred cervical pain from a primary shoulder disorder.
- Obtain ECG if any suspicion for cardiac etiology.
- Serologic tests if autoimmune etiology is suspected.

Follow-Up Tests & Special Considerations

- CT scan can rule out occult fracture.
- MRI is gold standard for noninvasive soft tissue imaging, including RTC, biceps tendon.
- MR arthrogram may be necessary to assess for labral tears or small/partial RTC tears.
- Ultrasound (US) helps assess RTC tears, biceps tendinopathies, and AC joint disorders.

Diagnostic Procedures/Other

Consider diagnostic arthroscopy after noninterventional means have been exhausted if structural injury is suspected.

Test Interpretation

Depends on underlying diagnosis

- Tendinosis rather than tendonitis is common with stage I impingement.
- Capsular scarring is the hallmark of adhesive capsulitis.
- RTC tendon calcifications with calcific tendonitis

TREATMENT

Treatment is based on underlying diagnosis. In general, conservative therapy includes activity modification, analgesics, and/or anti-inflammatory medicines in association with appropriate rehabilitative programs.

MEDICATION

First Line

- Analgesics and anti-inflammatory medications for symptomatic relief:
  - Ibuprofen: 200 to 800 mg TID
  - Naproxen: 250 to 500 mg BID
  - Acetaminophen: not to exceed 3 g/day
- Corticosteroid injections (subacromial, glenohumeral, AC, subscapular bursa) acutely relieve pain due to RTC pathology, adhesive capsulitis, OA, or scapulothoracic dyskinesis (1)[A]. This can improve ability to engage in rehabilitative activities. US guidance improves accuracy of anatomic placement of corticosteroid injections. Long-term outcomes generally similar to conservative approaches

ISSUES FOR REFERRAL

Refer if etiology remains unclear, patient is not responsive to conservative care, for complicated or displaced fractures. Refer for full-thickness RTC tears >1 cm (acute or chronic) in patients <65 years old or any tear with significant changes in functional status. These tears have a high rate of progression, fatty infiltration, or retraction with nonoperative care (2).

ADDITIONAL THERAPIES

- Physical therapy can benefit persistent RTC disorders, adhesive capsulitis, and shoulder instability.

- Manual therapy and exercises may improve pain and increase function in RTC disease.
- Manual manipulative therapy (MMT) by chiropractors, osteopathic physicians, or physical therapists improves pain with adhesive capsulitis, RTC, and soft tissue disorders. In adhesive capsulitis, MMT is generally less effective than glucocorticoid injections at 6-week mark, but both have similar long-term outcomes. Acupuncture may improve short-term pain and function in RTC impingement (3)[A].
- Nitroglycerin patch may improve short-term pain in patients with RTC disease (4)[A].

SURGERY/OTHER PROCEDURES

- Surgery is recommended for shoulder pain caused by acute displaced fractures, large RTC tears (criteria as above). It also may be advised for multiple shoulder dislocation in patients <20 years of age. Surgery can be considered for shoulder pain unresponsive to conservative measures >3 to 6 months. Surgery is not more effective than active nonsurgical treatment in impingement syndrome (5)[A].
- Platelet-rich therapies need more conclusive evidence before routine use in treatment of MSK soft tissue injuries.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Acupuncture may help with acute shoulder pain. There is no conclusive evidence for the effectiveness of acupuncture.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Limit overhead activity to reduce impingement symptoms.

PATIENT EDUCATION

Refer to specific diagnosis for shoulder pain.

PROGNOSIS

Shoulder pain generally has a favorable outcome with conservative care, but

recovery can be slow, with 40–50% of patients complaining of persistent pain or recurrence at 12 months.

CODES

ICD10

- M25.519 Pain in unspecified shoulder
- S43.429A Sprain of unspecified rotator cuff capsule, init encntr
- M19.019 Primary osteoarthritis, unspecified shoulder

CLINICAL PEARLS

- RTC disorders (tendinopathy, tears) are the most common cause of shoulder pain in individuals >30 years of age.
- Shoulder instability (acute dislocation/subluxation or chronic instability) is the most common source of shoulder pain in individuals <30 years of age.
- Patients with diabetes are at increased risk for adhesive capsulitis.
- Most patients do well with a structured program of pain control and rehabilitation.

SINUSITIS

Chirag N. Shah, MD, FACEP • Patrick J. Rogers, DO

BASICS

DESCRIPTION

- Acute sinusitis is a symptomatic inflammation of ≥1 paranasal sinuses of <4 weeks' duration resulting from impaired drainage and retained secretions accompanied by obstruction, facial pain/pressure/fullness, or both. Because rhinitis and sinusitis usually coexist, "rhinosinusitis" is the preferred term.
- Disease is subacute when symptomatic for 4 to 12 weeks, recurrent acute when ≥4 annual episodes without persistent symptoms in between and chronic when symptomatic for >12 weeks.
- Uncomplicated rhinosinusitis has no extension of inflammation beyond paranasal sinuses and nasal cavity.
- System(s) affected: head/eyes/ears/nose/throat (HEENT), pulmonary

EPIDEMIOLOGY

- Affects one in eight adults accounting for >30 million individuals in the United States each year diagnosed with rhinosinusitis
- Diagnosis of acute bacterial rhinosinusitis remains the fifth leading reason for prescribing antibiotics.
- 0.5–2% of viral rhinosinusitis episodes have a bacterial superinfection.
- Viral cause in 90–98% of cases

Incidence

Incidence is highest in early fall through early spring (related to incidence of viral upper respiratory infection [URI]). Adults have two to three viral URIs per year; 90% of these colds are accompanied by viral rhinosinusitis. It is the fifth most common diagnosis made during family physician visits.

ETIOLOGY AND PATHOPHYSIOLOGY

- Important features
  - Inflammation and edema of the sinus mucosa

  - Obstruction of the sinus ostia
  - Impaired mucociliary clearance
- Secretions that are not cleared become hospitable to bacterial growth.
- Inflammatory response (neutrophil influx and release of cytokines) damages mucosal surfaces.
- Viral: vast majority of cases (rhinovirus; influenza A and B; parainfluenza virus; respiratory syncytial; adeno-, corona-, and enteroviruses)
- Bacterial (complicates 0.5–2% of viral cases)
  - More likely if symptoms worsen within 5 to 6 days after initial improvement
  - No improvement within 10 days of symptom onset
  - >3 to 4 days of fever >102°F and facial pain and purulent nasal discharge
  - *Streptococcus pneumoniae*, *Haemophilus influenzae*, and *Moraxella catarrhalis* are the most common bacterial pathogens.
  - Often overdiagnosed, which leads to overuse of and increasing resistance to antibiotics
  - Methicillin-resistant *Staphylococcus aureus* present in 0–15.9% of patients.
- Fungal: seen in immunocompromised hosts (uncontrolled diabetes, neutropenia, use of corticosteroids) or as a nosocomial infection

Genetics

No known genetic pattern

RISK FACTORS

- Viral URI
- Allergic rhinitis
- Asthma
- Cigarette smoking
- Dental infections and procedures
- Anatomic variations
  - Tonsillar and adenoid hypertrophy
  - Turbinate hypertrophy, nasal polyps
  - Cleft palate
- Immunodeficiency (e.g., HIV)
- Cystic fibrosis (CF)

GENERAL PREVENTION

- Hand washing to prevent transmission of viral infection
- Childhood vaccinations up to date
- Avoid close contacts with symptomatic individuals.
- Avoid smoking and exposure to second hand smoke.

DIAGNOSIS

- History and physical exam suggest and establish the diagnosis but are rarely helpful in distinguishing bacterial from viral causes.
- Use a constellation of symptoms rather than a particular sign or symptom in diagnosis.

HISTORY

- Symptoms somewhat predictive of bacterial sinusitis (1)[C]
  - Worsening of symptoms >5 to 6 days after initial improvement
  - Persistent symptoms for ≥10 days
  - Persistent purulent nasal discharge
  - Unilateral upper tooth or facial pain
  - Unilateral maxillary sinus tenderness
  - Fever
- Associated symptoms
  - Headache
  - Nasal congestion
  - Retro-orbital pain
  - Otalgia
  - Hyposomia
  - Halitosis
  - Chronic cough
- Symptoms requiring urgent attention
  - Visual disturbances, especially diplopia
  - Periorbital swelling or erythema
  - Altered mental status

PHYSICAL EXAM

- Fever
- Edema and erythema of nasal mucosa
- Purulent discharge
- Tenderness to palpation over sinus(es)
- Pain localized to sinuses when bending forward
- Transillumination of the sinuses may confirm fluid in sinuses (helpful if asymmetric; not helpful if symmetric exam).

Pediatric Considerations

- Sinuses are not fully developed until age 20 years. Maxillary and ethmoid sinuses, although small, are present from birth.
- Because children have an average of six to eight colds per year, they are at risk for developing sinusitis.
- Diagnosis can be more difficult than in adults because symptoms are often more subtle.

DIFFERENTIAL DIAGNOSIS

- Dental disease
- CF
- Wegener granulomatosis
- HIV infection
- Kartagener syndrome
- Neoplasm
- Headache, tension, or migraine

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic tests are not routinely recommended; no diagnostic tests can adequately differentiate between viral and bacterial rhinosinusitis (2)[C].

- None indicated in routine evaluation
- Routine use of sinus radiography discouraged because of the following:
  - ≥3 clinical findings have similar diagnostic accuracy as imaging.
  - Imaging does not distinguish viral from bacterial etiology.
- Limited coronal CT scan can be useful in recurrent infection or failure to respond to medical therapy.

DIAGNOSTIC PROCEDURES/OTHER

Sinus CT if signs suggest extrasinus involvement or to evaluate chronic rhinosinusitis

TEST INTERPRETATION

- Inflammation, edema, thickened mucosa
- Impaired ciliary function
- Metaplasia of ciliated columnar cells
- Relative acidosis and hypoxia within sinuses
- Polyps

TREATMENT

Most cases resolve with supportive care (treating pain, nasal symptoms). Antibiotics should be reserved for symptoms that persist >10 days, onset with severe symptoms (high fever, purulent nasal discharge, facial pain) for at least 3 to 4 consecutive days, or worsening signs/symptoms that were initially improving (1,2)[C].

GENERAL MEASURES

- Hydration
- Steam inhalation 20 to 30 minutes TID
- Saline irrigation (Neti pot) or nose drops
- Sleep with head of bed elevated.
- Avoid exposure to cigarette smoke or fumes.
- Avoid caffeine and alcohol.
- Antibiotics are indicated only when findings suggest bacterial infection.
- Analgesics, NSAIDs
- Acute viral sinusitis is self-limiting; antibiotics should not be used.

MEDICATION

First Line

- Decongestants
  - Pseudoephedrine HCl
  - Phenylephrine nasal spray (limited use)
  - Oxymetazoline nasal spray (e.g., Afrin) (not to be used >3 days)

- Analgesics
  - Acetaminophen
  - Aspirin
  - NSAIDs
- Antibiotics
  - Antibiotics have a slight advantage over placebo at 7 to 14 days (3)[A], yet most improve without therapy.
  - Reserve antibiotic use for patients with moderate to severe disease.
  - Choice should be based on understanding of antibiotic resistance in the community.
  - Infectious Disease Society of America recommends the following (1)[C]:
    - Start antibiotics as soon as clinical diagnosis of acute bacterial sinusitis is made.
    - Use amoxicillin-clavulanate rather than amoxicillin alone.
    - Amoxicillin-clavulanate 875/125 mg q12h; 2 g orally BID in geographic regions with high rates of resistant *S. pneumoniae*
    - Doxycycline: 100 mg PO BID an alternative to amoxicillin-clavulanate for initial therapy (adults only)
    - Trimethoprim-sulfamethoxazole (TMP/SMX) and 3rd generation cephalosporins not recommended due to high rate of resistance (1)[C]
    - Treat for 5 to 7 days in adults if uncomplicated bacterial rhinosinusitis (IDSA low-moderate-quality evidence). Treat for 10 to 14 days in children if uncomplicated bacterial rhinosinusitis (IDSA low-moderate-quality evidence).
  - American Academy of Pediatrics recommends the following (1)[C]:
    - Amoxicillin: 45 to 90 mg/kg/day in 2 divided doses if uncomplicated acute bacterial sinusitis in children
    - Amoxicillin-clavulanate: 80 to 90 mg/6.4 mg/kg/day in 2 divided doses for children with severe illness, recent antibiotics, or attending daycare
    - Levofloxacin: 10 to 20 mg/kg/day max 750mg/day if history of type 1 hypersensitivity to PCN (1)[C]
    - Clindamycin (30 to 40 mg/kg/day) + cefixime (8mg/kg/day in 2 divided doses) or cefpodoxime (10 mg/kg/day in 2 divided doses) (1)[C] for non-type 1 PCN allergy

    - Ceftriaxone: 50 mg/kg IM single dose if not able to tolerate oral meds (4) [C]
- Because allergies may be a predisposing factor, some patients may benefit from use of the following agents:
  - Oral antihistamines
    - Loratadine (Claritin), fexofenadine (Allegra), cetirizine (Zyrtec), desloratadine (Clarinex), or levocetirizine (Xyzal)
    - Chlorpheniramine (Chlor-Trimeton)
    - Diphenhydramine (Benadryl)
  - Leukotriene inhibitors (Singulair, Accolate), especially in patients with asthma
  - Nasal steroids (i.e., fluticasone [Flonase])

Second Line

- Levofloxacin (Levaquin): 750 mg/day for 5 days or moxifloxacin 400 mg/day for 5 to 7 days (adults only) (1)[C]
- If no response to first-line therapy after 72 hours
  - Broaden antibiotic coverage or switch to a different class, evaluate for resistant pathogens or other causes for treatment failure (i.e., noninfectious etiology) fluoroquinolones as above.
- *Note*: Bacteriologic failure rates of up to 20–25% are possible with use of azithromycin and clarithromycin.
- If lack of response to 3 weeks of antibiotics, consider the following:
  - CT scan of sinuses
  - Ear/nose/throat (ENT) referral

ISSUES FOR REFERRAL

Complications or failure of treatment

ALERT

- Meta-analyses have demonstrated no benefit of newer antibiotics over amoxicillin or doxycycline.
- Antibiotics recommendations vary with different guidelines. Patients seen by specialists are different from those in a primary care setting. Patients usually do not have complicated sinusitis in primary care setting.

- American Academy of Otolaryngology—Head and Neck Surgery Foundation (2)[C] recommends the following:
  - Consider watchful waiting without antibiotics in patients with uncomplicated mild illness (mild pain and temperature <101°F) with assurance of follow-up within 7 days.
- PCV-13 pneumococcal vaccine can be helpful in reducing chronic sinusitis in children (5)[B].
- Use of intranasal steroids small but significant improvement in symptoms when used alone or in combination with antibiotics (6)[A].
- Precautions
  - Decongestants can exacerbate hypertension.
  - Intranasal decongestants should be limited to 3 days to avoid rebound nasal congestion.

Pregnancy Considerations

- Nasal irrigation with saline, pseudoephedrine, most antihistamines, and some nasal steroids are safe during pregnancy and lactation.
- Antibiotics safe in pregnancy and lactation
  - Amoxicillin, amoxicillin-clavulanate, cephalosporins
- Antibiotic contraindicated: doxycycline, fluoroquinolones
- Antibiotic safe in lactation but not pregnancy: levofloxacin

SURGERY/OTHER PROCEDURES

- If medical therapy fails, consider sinus irrigation.
- Functional endoscopic sinus surgery is the preferred treatment for medically recalcitrant cases.
- Absolute surgical indications
  - Massive nasal polyposis
  - Acute complications: subperiosteal or orbital abscess, frontal soft tissue spread of infection
  - Mucocele or mucopyocele
  - Invasive or allergic fungal sinusitis
  - Suspected obstructing tumor
  - CSF rhinorrhea

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Hospitalization for complications (e.g., meningitis, orbital cellulitis or abscess, brain abscess)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Return if no improvement after 72 hours or no resolution of symptoms after 10 days of antibiotics.

PATIENT EDUCATION

- http://familydoctor.org/familydoctor/en.html
- https://www.nlm.nih.gov/medlineplus/

PROGNOSIS

Alleviation of symptoms within 72 hours with complete resolution within 10 to 14 days

COMPLICATIONS

- Serious complications are rare.
- Meningitis, orbital cellulitis, brain abscess
- Cavernous sinus thrombosis
- Osteomyelitis, subdural empyema

CODES

ICD10

- J01.90 Acute sinusitis, unspecified
- J01.00 Acute maxillary sinusitis, unspecified
- J01.20 Acute ethmoidal sinusitis, unspecified

CLINICAL PEARLS

- When bacterial infection is present, patients recover somewhat more quickly with antibiotics, but the majority will recover with symptomatic treatment alone, and accurate diagnosis of bacterial sinusitis is very difficult.

- Multiple meta-analyses have demonstrated *no* benefit of newer antibiotics over amoxicillin or doxycycline.
- Overall NNT to prevent 1 persistent case at follow-up = 15; harm due to antibiotic-associated diarrhea is similar.
- Significant patient symptom relief with nasal saline spray or drops or irrigation (Neti pot)

SJÖGREN SYNDROME

Mariya Milko, DO, MS • Rubaiya Mallay, DO, FACOI, ACR

BASICS

- Chronic inflammatory disorder characterized by lymphocytic infiltrates in exocrine organs
- Typically presents with diminished salivary and lacrimal gland function, resulting in sicca symptoms such as dry eyes (xerophthalmia), dry mouth (xerostomia), and parotid enlargement
- Extraglandular manifestations: arthralgia, myalgia, Raynaud phenomenon, pulmonary disease, GI disease, leukopenia, anemia, lymphadenopathy, vasculitis, renal tubular acidosis, lymphoma, CNS involvement with longitudinal transverse myelitis (>4 vertebral segments), and optic neuritis associated with anti-aquaporin-4 antibodies, PNS involvement with small fiber neuropathy
- Primary Sjögren: Not associated with other diseases; *HLA-DRB1*0301* and *HLA-DRB1*1501* are the most common.
- Secondary Sjögren: complication of other rheumatologic conditions, most commonly rheumatoid arthritis; associated with HLA-DR4
- First described by Swedish ophthalmologist Henrik Sjögren (1899–1986)

EPIDEMIOLOGY

Incidence

Annual incidence: ~4/100,000. Primary SS is one of the most common autoimmune diseases, affecting 1–4% of population.

- All races are affected
- Predominant sex: female > male (9:1)
- Predominant age: can affect patients of any age but is most common in the elderly; onset typically in the 4th to 5th decades of life

Prevalence

Sjögren syndrome (SS) affects 1 to 4 million people in the United States.

ETIOLOGY AND PATHOPHYSIOLOGY

- Multifactorial systemic autoimmune process characterized by infiltration of glandular tissue by CD4 T-lymphocytes
- Theorized that glandular epithelial cells present antigen to the T cells. Cytokine production then occurs. There is also evidence for B-cell activation, resulting in autoantibody production and an increased incidence of B-cell malignancies.
- Etiology is unknown. Estrogen may play a role because SS is more common in women. Exogenous factors such as viral proteins (EBV, HCV, HTLV-1) have also been implicated.

Genetics

- A familial tendency suggests a genetic predisposition.
- Associations in the HLA regions *HLA-DQA1*0501*, *HLA-DQB1*0201*, and *HLA-DRB*0301* are the strongest genetic risk factors for SS.

RISK FACTORS

There are no known modifiable risk factors.

GENERAL PREVENTION

- No known prevention. Complications can be prevented by early diagnosis and treatment.
- Oral health providers play a key role in early detection and management of symptoms resulting from salivary dysfunction (1)[C].

COMMONLY ASSOCIATED CONDITIONS

Secondary SS associated with rheumatoid arthritis, scleroderma, systemic lupus erythematosus (SLE), polymyositis, HIV, hepatitis C, MCTD, PBC, hypergammaglobulinemic purpura, necrotizing vasculitis, autoimmune thyroiditis, chronic active hepatitis, mixed cryoglobulinemia

Pregnancy Considerations

Pregnant SS patients with anti-SSA Abs have increased risk of delivering fetus with skin rash and 3rd-degree heart block.

DIAGNOSIS

- American College of Rheumatology Diagnostic Criteria (2)[A]: Individuals with signs/symptoms that may be suggestive of SS, who have at least two of the following three objective features:
  - Positive serum anti-SSA/Ro and/or anti-SSB/La or (positive rheumatoid factor and ANA titer—1:320)
  - Labial salivary gland biopsy exhibiting focal lymphocytic sialadenitis with a focus score 1 focus/4 mm^2
  - Keratoconjunctivitis sicca with ocular staining score >3 (assuming that individual is not currently using daily eye drops for glaucoma and has not had corneal surgery or cosmetic eyelid surgery in the last 5 years)
- Ocular signs and symptoms
  - Troublesome dry eyes daily for >3 months
  - Recurrent sandy/gritty ocular sensation
  - Use of tear substitute >3 times per day
- Oral signs and symptoms
  - Daily symptoms of dry mouth for ≥3 months
  - Recurrent feeling of swollen salivary glands
  - Need to drink liquid to help swallow dry foods
- Other manifestations: chronic arthritis, type 1 RTA, tubular interstitial nephritis, rheumatoid arthritis, vasculitis, vaginal dryness, pleuritis, pancreatitis

HISTORY

- Decreased tear production; burning, scratchy sensation in eyes
- Difficulty speaking/swallowing, dental caries, xerotrachea
- Enlarged parotid glands or intermittent swelling (bilateral)
- Dyspareunia; vaginal dryness

PHYSICAL EXAM

Common physical exam findings include:

- Eye exam: dry eyes (keratoconjunctivitis sicca), decreased tear pool in the lower conjunctiva, dilated conjunctival vessels, mucinous threads, and filamentary keratosis (slit-lamp examination)

- Mouth exam: dry mouth (xerostomia); decreased sublingual salivary pool (tongue may stick to the tongue depressor); frequent oral caries (sometimes in unusual locations such as the incisor surface and along the gum line); dark red tongue from prolonged xerostomia
- Ear, nose, and throat exam: parotid enlargement, submandibular enlargement
- Skin exam: nonpalpable or palpable vasculitic purpura (typically 2 to 3 mm in diameter and on the lower extremities)

DIFFERENTIAL DIAGNOSIS

- Causes of ocular dryness: hypovitaminosis A, decreased tear production unrelated to autoimmune process, chronic blepharitis or conjunctivitis, impaired blinking (i.e., due to Parkinson disease or Bell palsy), infiltration of lacrimal glands (i.e., amyloidosis, lymphoma, sarcoidosis), low estrogen levels
- Causes of oral dryness: anticholinergic medications, sialadenitis due to chronic obstruction, chronic viral infections (i.e., hepatitis C or HIV), radiation of head/neck
- Causes of salivary gland swelling: unilateral: obstruction, chronic sialadenitis, bacterial infection, neoplasm; bilateral (asymmetric): IgG4-related disease, HIV bilateral (symmetric): hepatic cirrhosis, DM, anorexia/bulimia, acromegaly, alcoholism, hypolipoproteinemia, chronic pancreatitis, acute or chronic viral infection (i.e., mumps, Epstein-Barr virus [EBV], coxsackievirus, echovirus, granulomatous diseases (i.e., tuberculosis, sarcoidosis)

DIAGNOSTIC TESTS & INTERPRETATION

The following tests can be used to support diagnosis:

- Schirmer test (<5-mm wetness after 5 minutes)
- Rose Bengal test (slit lamp)
- Minor salivary gland biopsy (gold standard)
- Auto antibodies: +ANAs (95%), +RF (75%)
- In primary SS: +anti-Ro (anti-SSA, 56%) and +anti-La (anti-SSB, 30%)

Initial Tests (lab, imaging)

Preliminary lab workup

- Basic labs: CBC with differential, BUN/creatinine (Cr), AST/ALT, ESR, C-reactive protein (CRP), urinalysis (UA)
- Special labs: ANA, rheumatoid factor (RF), anti-Ro/SSA, anti-La/SSB, ESR, CRP
- Anti-SSA and anti-SSB antibodies present in 33–74% and 23–52% of SS patients, respectively.
- Other auto antibodies-muscarinic receptor type 3 (M3R) and anti-α-fodrin are being explored with good specificity (3)[A].
- Initial imaging studies may include:
  - Imaging for xerostomia: salivary gland scintigraphy (insensitive but highly specific)
  - Parotid gland sialography (should not be used in acute parotitis)
  - MRI (correlates well with salivary gland biopsy)
- A novel diagnostic tool is Salivary Gland US (SGUS) which is noninvasive and highly specific for salivary gland involvement in SS (4)[A].

Diagnostic Procedures/Surgery

- Salivary gland biopsy: used to confirm suspected diagnosis of SS or to exclude other causes of xerostomia and bilateral glandular enlargement
- Parotid biopsy if malignancy is suspected
- Lymph node biopsy to rule out pseudolymphoma or lymphoma if suspected

Test Interpretation

- Salivary gland histology shows focal collections of lymphocytes; immunocytology shows CD4+ T cell lymphocyte predominance.
- SGUS parameters include:
  - Parenchymal nonhomogeneity—the most useful diagnostic marker with high specificity and good sensitivity (4)[A].
  - US inflammatory findings include hypoechoic and hyperechoic bands (4)[A].
  - Real-time sonoelastography (RTS) to quantify tissue rigidity and assess glandular damage (4)[A]

TREATMENT

- Treatment is primarily supportive.
- Treat sicca symptoms—dry eyes, dry mouth
- Avoid medications that may worsen oral dryness (i.e., anticholinergics).
- Promote good oral hygiene.
- Treat systemic manifestations.
- Address fatigue and pain.

MEDICATION

- Therapy for sicca symptoms: artificial tears and ocular lubricants (5)[C]
- Topical therapy for dry mouth: can be as simple as liberally drinking sips of water, trying sugar-free lemon drops or artificial saliva preparations such as Salivart, Saliment, Xero-Lube, MouthKote
- Immunosuppressive therapy such as hydroxychloroquine can be used for systemic symptoms; however, it has not shown any benefit in relieving refractory sicca symptoms.
- Evoxac (Cevimeline) may be prescribed for SS-associated xerostomia. It works by stimulating muscarinic cholinergic receptors to increase salivary gland secretion.
- Dry eyes are graded by severity of symptoms, conjunctival injection and staining, corneal damage, tear quality, and lid involvement. Artificial tears may be used; however, artificial tears with hydroxyethylcellulose or dextran are more viscous and can last longer.
- Acetaminophen or NSAIDs for arthralgias

First Line

- Xerostomia: sugar-free lozenges, especially malic acid, artificial saliva; pilocarpine 5 mg PO QID or cevimeline 30 mg PO TID
- Keratoconjunctivitis sicca: artificial tears and ocular lubricants for symptomatic relief, topical cyclosporine (Restasis), or autologous tears

Second Line

- Xerostomia: Interferon-alfa lozenges may enhance salivary gland flow.
- Keratoconjunctivitis sicca: topical glucocorticoids or topical NSAIDs (use

with caution)

- Immunosuppressive therapy: antimalarials (e.g., hydroxychloroquine) for arthralgias, lymphadenopathies, and skin manifestations; may then consider methotrexate or cyclosporine, which showed subjective improvement but no significant objective improvement
- Early studies show improvement in fatigue with rituximab (6)[B].
- For life-threatening extraglandular manifestations, cyclophosphamide (PO or IV), mycophenolate mofetil, and azathioprine are often used.

ISSUES FOR REFERRAL

- A rheumatologist can help with management of systemic manifestations or resistant symptoms.
- Oral health
- Ophthalmology, for grading of severity and management of xerophthalmia

ADDITIONAL THERAPIES

- Patients should use vaginal lubricants, such as Replens, for vaginal dryness. Vaginal estrogen creams can help in postmenopausal women. Be alert for and treat vaginal yeast infections.
- Xerostomia: small sips of water, good dental care
- Keratoconjunctivitis sicca: Conserve tears with side shields or ski/swim goggles, humidifiers, and moist washcloths.
- Dehydroepiandrosterone (DHEA) does not offer improvement in fatigue and well-being above placebo.

SURGERY/OTHER PROCEDURES

Keratoconjunctivitis sicca: If refractory to artificial tears, punctal occlusion is the treatment of choice.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Some studies show acupuncture benefits saliva production and symptoms of xerostomia.
- There is insufficient evidence to determine the effects of electrostimulation devices on dry mouth symptoms or saliva production in patients with Sjögren syndrome.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

May be required for extraglandular manifestations, such as cardiopulmonary disease, renal involvement, and CNS manifestations (e.g., optic neuritis, transverse myelitis, vasculitis, or ischemic stroke)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Frequency of follow-up depends on severity

Patient Monitoring

- Monitor for complications, systemic manifestations, and relief of symptoms.
- Medicolegal pitfalls: Monitor for parotid tumor or lymphoma.

PATIENT EDUCATION

In most cases, simple measures are adequate: humidifiers, sips of water, chewing gum, or artificial tears.

PROGNOSIS

- Hypocomplementemia is an independent risk factor for premature death.
- Primary SS is associated with increased risks of malignancy, non-Hodgkin lymphoma, and thyroid cancer.

COMPLICATIONS

Complications include dental caries, gum disease, dysphagia, salivary gland calculi, keratitis, conjunctivitis, and scarring of the ocular surface.

CODES

ICD10

- M35.00 Sicca syndrome, unspecified
- M35.02 Sicca syndrome with lung involvement
- M35.09 Sicca syndrome with other organ involvement

CLINICAL PEARLS

- Many symptoms of SS can be treated with simple interventions such as artificial tears and sugar-free lozenges.
- Consider lacrimal duct plugs for dry eyes.
- Consider SS in patients with unexplained lung disease and +ANA.
- Patients with primary SS may have an increased incidence of celiac disease because both disease share similar genetics.

SLEEP APNEA, OBSTRUCTIVE

Jeremy Golding, MD, FAAFP

BASICS

DESCRIPTION

- Obstructive sleep apnea (OSA) is defined as repetitive episodes of cessation of airflow (apnea) at the nose and mouth during sleep due to obstruction at the level of the pharynx.
  - Apneas often terminate with a snort/gasp.
  - Repetitive apneas produce sleep disruption, leading to excessive daytime sleepiness.
  - Associated with oxygen desaturation and nocturnal hypoxemia
  - Usual course is chronic.
- System(s) affected: cardiovascular; nervous; pulmonary
- Synonym(s): sleep apnea syndrome; nocturnal upper airway occlusion

EPIDEMIOLOGY

Incidence

- Predominant age: middle-aged men and women
- Predominant sex: male > female (2:1)

Prevalence

- Up to 4% in men, 2% in women
- Prevalence is higher in obese/hypertensive patients.

ETIOLOGY AND PATHOPHYSIOLOGY

OSA occurs when the naso- or oropharynx collapses passively during inspiration. Anatomic and neuromuscular factors contribute to pharyngeal collapse.

- Anatomic abnormalities such as increased soft tissue in the palate, tonsillar hypertrophy, macroglossia, and craniofacial abnormalities, predispose the airway to collapse by decreasing the area of the upper airway or increasing the pressure surrounding the airway.

- During sleep, decreased muscle tone in the naso- or oropharynx contributes to airway obstruction and collapse.
- Upper airway narrowing may be due to the following:
  - Obesity, redundant tissue in the soft palate
  - Enlarged tonsils/uvula
  - Low soft palate
  - Large/posteriorly located tongue
  - Craniofacial abnormalities
  - Neuromuscular disorders
  - Alcohol/sedative use before bedtime

RISK FACTORS

- Obesity
- Age >40 years
- Alcohol/sedative intake before bedtime
- Smoking
- Nasal obstruction (due to polyps, rhinitis, or deviated septum)
- Anatomic narrowing of nasopharynx (e.g., tonsillar hypertrophy, macroglossia, micrognathia, retrognathia, craniofacial abnormalities)
- Acromegaly
- Hypothyroidism
- Neurologic syndromes (e.g., muscular dystrophy, cerebral palsy)

GENERAL PREVENTION

Weight control and avoidance of alcohol and sedatives at night can help to prevent airway collapse.

COMMONLY ASSOCIATED CONDITIONS

- Common
  - Hypertension
  - Obesity
  - Daytime sleepiness
  - Metabolic syndrome
- Rare
  - Cardiac arrhythmias

- Cardiovascular disease
- Congestive heart failure
- Pulmonary hypertension
- Nasal obstructive problems

DIAGNOSIS

HISTORY

- Elicit a complete history of daytime and nighttime symptoms. Symptoms can be insidious and present for years.
- Daytime symptoms
  - Excessive daytime sleepiness (EDS) or fatigue (cardinal symptom) (1)
    - Mild symptoms are those that occur during quiet activities (e.g., reading, watching television).
    - More severe symptoms are those that occur during dynamic activities (e.g., work, driving).
  - Tired on morning awakening “nonrestorative sleep”
  - Sore/dry throat
  - Poor concentration, memory problems, irritability, mood changes, behavior problems (in children)
  - Morning headaches
  - Decreased libido
  - Depression
- Nighttime symptoms
  - Loud snoring (present in 60% of people with OSA)
  - Snort/gasp that arouses patient from sleep but not usually to full consciousness
  - Disrupted sleep
  - Witnessed apneic episodes at night

PHYSICAL EXAM

- OSA is commonly associated with obesity. It is unlikely to be found in those with normal body weight who do not snore (1).
- Focused head and neck exam

- Short neck with large circumference
- Oropharynx
  - Narrowing of the lateral airway wall
  - Tonsillar hypertrophy
  - Macroglossia
  - Micrognathia/retrognathia
  - Soft palate edema
  - Long/thick uvula
  - High, arched hard palate
- Nasopharynx
  - Deviated nasal septum
  - Poor nasal airflow

DIFFERENTIAL DIAGNOSIS

- Other causes of EDS such as the following:
  - Narcolepsy
  - Idiopathic daytime hypersomnolence
  - Inadequate sleep time
  - Depressive episodes with EDS
  - Periodic limb movements disorder
- Respiratory disorders with nocturnal awakenings such as the following:
  - Asthma
  - Chronic obstructive pulmonary disease
  - Congestive heart failure
- Central sleep apnea
- Sleep-related choking/laryngospasm
- Gastroesophageal reflux
- Sleep-associated seizures (temporal lobe epilepsy)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- When clinically indicated
  - Thyroid-stimulating hormone to evaluate hypothyroidism
  - CBC to evaluate anemia and polycythemia, which can indicate nocturnal hypoxemia.

  - Fasting glucose in obesity to evaluate for diabetes
  - Rare: arterial blood gases to evaluate daytime hypercapnia
- Cephalometric measurements from lateral head and neck radiographs aid in surgical treatment.

Diagnostic Procedures/Other

- The gold standard for OSA is polysomnography (PSG), a nighttime sleep study (1)[A].
  - Demonstrates severity of hypoxemia, sleep disruption, and cardiac arrhythmias associated with OSA and elevated end-tidal CO_2
  - Shows repetitive episodes of cessation/marked reduction in airflow despite continued respiratory efforts
  - Apneic episodes must last at least 10 seconds and occur 10 to 15 times per hour and cause decreased oxygen saturation to be considered clinically significant.
  - Complete PSG is expensive, and health insurance may not cover the cost.
- Multiple sleep latency testing is a diagnostic tool used to measure the time it takes from the start of a daytime nap period to the first signs of sleep (sleep latency). It provides an objective measurement of daytime sleepiness.
- The apnea-hypoapnea index (AHI) is defined as the total number of apneas and hypoapneas divided by the total sleep time in hours.
  - Mild OSA: AHI = 5 to 15
  - Moderate OSA: AHI = 15 to 30
  - Severe OSA: AHI >30
- Drugs that may alter the test results include benzodiazepines and other sedatives that can amplify the severity of apnea seen during the sleep study.
- Early data suggest that home-based diagnosis using portable monitoring devices may be an alternative to laboratory-based PSG if the test is of sufficient duration (2)[B].

TREATMENT

- Lifestyle modification is the most frequently recommended treatment for mild to moderate OSA. This includes weight loss, exercise, and avoidance of

alcohol, smoking, and sedatives, especially before bedtime. Weight loss has been shown to decrease the severity of symptoms in obese patients. Lifestyle modifications should be seen as adjunctive rather than curative therapy (3) [A], and a lack of improvement of symptoms with lifestyle modification should not preclude patients from receiving other therapy such as continuous positive airway pressure (CPAP).

- If OSA is present only when supine, keep the patient off his or her back when sleeping (e.g., tennis ball worn on back of nightshirt or using a sleep position trainer).
- The most effective therapy for mild, moderate, or severe OSA is CPAP (4)[A]. Treatment with CPAP uses a mask interface and a flow generator to prevent airway collapse, thus helping to prevent apnea, hypoxia, and sleep disturbance. Compared with inactive controls, CPAP significantly improves both objective (24-hour systolic and diastolic blood pressures) and subjective measures (Epworth Sleepiness Scale) in OSA patients with symptoms of daytime sleepiness. CPAP may also decrease the risk for atherosclerosis as well as improves insulin resistance in nondiabetic patients. Early data show that these benefits may not be seen in patients who do not have symptoms of daytime sleepiness.
- Several types of mask interfaces, including nasal masks, oral masks, and nasal pillows exist for CPAP therapy. Short-term data suggest that nasal pillows are the preferred interface in almost all patients. In patients with compliance difficulty, a different choice of interface may be appropriate.
- Oral appliances to treat OSA are available and often subjectively preferred by patients. Although oral appliances have been shown to improve symptoms compared with inactive controls, they are not as effective for reduction of respiratory disturbances as CPAP over short-term data. Treatment with oral appliances may be considered in patients who fail to comply with CPAP therapy.

MEDICATION

Medications are yet to be proven effective in treating OSA. Further studies in this area are needed.

First Line

Some short-term data found fluticasone nasal spray, mirtazapine, physostigmine, and nasal lubricant of some benefit; longer term studies needed.

ISSUES FOR REFERRAL

If sleep apnea is suspected, patient should be referred to a sleep specialist/neurologist for a sleep study evaluation.

SURGERY/OTHER PROCEDURES

Surgical corrections of the upper airway include alteration of the uvula and/or palate such as uvulopalatopharyngoplasty (UPPP), tracheostomy, and craniofacial surgery. Currently, no evidence supports the use of surgery for the treatment of OSA (5)[A].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

On admission, patients should continue to use CPAP/dental devices if they do so at home. They should bring in their own appliance and know their CPAP settings.

ONGOING CARE

Lifelong compliance with weight loss or CPAP is necessary for successful OSA treatment.

DIET

Overweight and obese patients should be encouraged to lose weight, and all patients must avoid weight gain. Weight loss alone could reduce symptoms of OSA.

PATIENT EDUCATION

- Weight loss and avoidance of alcohol and sedatives may reduce OSA symptoms particularly in severe cases.
- Significantly sleepy patients should not drive a motor vehicle/operate dangerous equipment.

PROGNOSIS

- EDS is reduced dramatically with appropriate apnea control.
- Lifelong compliance with weight loss or CPAP is necessary for effective treatment of OSA.
- If untreated, OSA is progressive.
- Significant morbidity and mortality with OSA usually due to motor vehicle accidents or are secondary to cardiac complications, including arrhythmias, cardiac ischemia, and hypertension.

COMPLICATIONS

Untreated OSA may increase the risk for development of hypertension, stroke, myocardial infarction, diabetes, cardiovascular disease, and work-related and driving accidents.

Pediatric Considerations

- The prevalence of pediatric OSA is 1–2% in children 4 to 5 years of age, and the peak incidence is between 3 and 6 years of age.
- Predominant sex: male = female
- Etiology: The most common cause is tonsillar hypertrophy. Additional causes are obesity and craniofacial abnormalities. OSA is also seen in children with neuromuscular diseases, such as cerebral palsy and spinal muscular atrophy, due to abnormal pharyngeal muscle control.
- Signs and symptoms
  - Nighttime: loud snoring, restlessness, and sweating
  - Daytime: hyperactivity and decreased school performance
  - EDS is not a significant symptom.
- Diagnosis: Gold standard is PSG. (PSG may be an even better tool in children due to lessened night-to-night variation. There is a lack of studies showing efficacy of home-based diagnostic studies vs. PSG in children.) Abnormal AHI is different in children: >1 to 2/hr is abnormal.
- Treatment: Surgery is the 1st-line treatment in cases due to tonsillar enlargement (reduces symptoms in 70%). Some data suggest improved academic performance if tonsillectomy is performed for OSA. For cases due to obesity/craniofacial abnormalities, patients can use CPAP treatment.

Geriatric Considerations

The presence of sleep apnea in the geriatric population may be associated with earlier onset of mild of cognitive impairment as well as Alzheimer dementia at an earlier age. The rate of decline of cognitive function may be slowed by the usage of CPAP.

CODES

ICD10

G47.33 Obstructive sleep apnea (adult) (pediatric)

CLINICAL PEARLS

- OSA is characterized by repetitive episodes of apnea often terminating in a snort/gasp.
- Laboratory PSG is the key to diagnosis.
- CPAP is the most effective form of treatment for both mild to moderate and moderate to severe OSA.
- Central sleep apnea may mimic OSA.

SLEEP DISORDER, SHIFT WORK

Chelsea Ma, MD • Ronald G. Chambers, Jr., MD, FAAFP • Cindy J. Chambers, MD, MAS, MPH

BASICS

DESCRIPTION

- The human system fundamentally relies on a natural circadian rhythm coordinated by the suprachiasmatic nucleus (SCN), an endogenous clock or pacemaker of the hypothalamus, which is responsible for linking the nervous system to the endocrine system (1).
- A shift in work schedule can desynchronize this circadian pacemaker with peripheral cells.
- The major environmental factor that can disrupt or reset the circadian rhythm is light at night (LAN) (1).
- Shift work disorder (SWD), classified as a circadian rhythm sleep disorder, is caused by a misalignment between the internal circadian rhythm and the required sleep–wake schedule due to erratic or nighttime shift work (2).
- Diagnostic criteria for SWD require that all criteria for circadian rhythm disorder be met in addition to specific SWD criteria (see below):
  - Criteria for circadian rhythm disorder:
    - Persistent/recurrent sleep disruption due to either an alteration in the circadian (24-hour) timekeeping system or misalignment between endogenous circadian rhythm and exogenous factors that affect sleep
    - Insomnia/excessive daytime sleepiness or both
    - Impairment in occupational, educational, or social functioning
  - Criteria for SWD:
    - Insomnia/excessive sleepiness, accompanied by reduced sleep time, associated with a recurring work schedule that overlaps with the usual time for sleep
    - Symptoms associated with shift work schedule are present for at least 3 months.
    - Sleep log or actigraphy monitoring (with sleep diaries) for at least 14

days demonstrates disturbed sleep (insomnia) and circadian and sleep-time misalignment
    - Sleep disturbance is not due to another current sleep disorder, mental disorder, medical disorder, substance use disorder, or medication use.

EPIDEMIOLOGY

Prevalence

- Shift workers include those who work night shifts, evening shifts, or rotating shifts and comprise approximately 15–25% of the workforce in the United States (2).
- SWD has been estimated to affect 10–23% of the presently 22 million American shift workers, with a prevalence estimate of approximately 2–5% of the general population (14.1% night shift workers and 8.1% of rotating shift workers) (3).

PATHOPHYSIOLOGY

- Circadian rhythms are evident in multiple biologic functions, including body temperature, hormone levels, blood pressure, metabolism, cellular regeneration, sleep–wake cycles, and DNA transcription and translation (2).
- Transcription factors involved in circadian rhythm generation collectively referred to as the “molecular clock,” control production of the many proteins that are expressed within a period of approximately 24 hours. This molecular clock is self-sustaining but requires resetting daily or it may become out of sync with environmental cues also called “zeitgebers” (2).
- The most powerful *zeitgeber*, or timekeeper, is light. Light transmitted from the retinohypothalamic tract of the eye to the SCN of the hypothalamus upregulates the production of the “clock gene” (PER) (2).
- Periods of darkness cause the SCN to induce the release of melatonin from the pineal gland, which can also help to reset the molecular clock (2).
- A dyssynchrony between the endogenous molecular clock and external cues (most notably light/dark cycles) is responsible for the development of circadian rhythm disorders and can have a severe impact on both physical and mental health (2).

RISK FACTORS

- Shift work, including night shifts, early morning shifts, or rotating shifts
- Younger age and “eveningness” (a.k.a. “night owls” rather than “morning larks”) may provide some protection from the development of SWD (2).

Genetics

No genetic predisposition has been described.

GENERAL PREVENTION

- Limit rotating shifts
- Use of bright light during shifts
- Scheduling brief, strategic 10- to 20-minute naps during shifts, if suitable

COMMONLY ASSOCIATED CONDITIONS

- Shift workers in general have impaired immediate free recall, decreased processing speed, and selective attention—impairments that may worsen with longer duration of shift work (2).
- Shift workers also have been shown to have a much higher risk of vehicular accidents, job-related injuries, absenteeism, and quality control errors (2).
- SWD has been associated with gastrointestinal (GI) disease, specifically peptic ulcer disease, cardiovascular disease (CVD), ischemic stroke, infertility, mood disorders and pregnancy complications (2,4).
- There is also evidence for possible increased risk of breast and prostate cancer. As such, the International Agency for Research on Cancer (IARC) has classified shift work that involves a circadian disruption as a probable carcinogen (1).

DIAGNOSIS

This is primarily a clinical diagnosis. However, there are some useful diagnostic aids.

HISTORY

- A careful history is critical to assess sleep disturbance including difficulty falling asleep, staying asleep, or nonrestorative sleep.
- Special attention should be paid to the following: (5)[C]
  - Sleep/wake habits

  - Degree of alertness or sleepiness
  - Sleep environment
  - Light exposure before, during, and after the shift.
  - Job related factors: length of shift, number of consecutive shifts, commute after shift.
  - Medications as well as over-the-counter (OTC) stimulants such as caffeine and energy drinks
  - Impact on social and domestic responsibilities (including drowsy driving)
- It is also essential to evaluate for symptoms of other sleep disorders, which often coexist and can exacerbate SWD such as the following:
  - Loud snoring and pauses in breathing during sleep (obstructive sleep apnea [OSA])
  - Sudden sleep attacks and leg symptoms (restless legs syndrome [RLS])
  - Falling asleep at inappropriate times, drop attacks and daytime fatigue (narcolepsy)

PHYSICAL EXAM

Evaluate for depression, GI disease, CVD and potential cancer risk, as well as signs of OSA such as obesity, a large neck, and a tight oropharynx (5)[C].

DIFFERENTIAL DIAGNOSIS

- Other primary sleep disorders: OSA, RLS, narcolepsy, and psychophysiologic insomnia.
- Other circadian rhythm sleep disorder such as delayed sleep phase disorder or jet lag syndrome. Distinguishing among these is challenging even for sleep specialists.

DIAGNOSTIC TESTS & INTERPRETATION

Given possible increased risk for CVD and cancer among shift workers, consider appropriate screenings.

Initial Tests (lab, imaging)

Fasting lipid panel, fasting glucose, age-appropriate cancer screenings

Diagnostic Procedures

- Evaluation of a sleep/wake diary that records the patient's sleep/wake habits,

including amount of sleep, naps during waking hours, and mood (1 to 2 weeks) (5)[C]
- Consider actigraphy (a mechanical device, often worn on the arm/leg, to measure movement): serves as a gross measure of time and amount of activity and rest (5)[C]
- Polysomnography, a measure of sleep duration and quality, is not typically used to diagnose SWD but may help rule out other sleep/wake disorders, such as sleep apnea and narcolepsy (2)[C].
- Several diagnostic tools are available, including the Multiple Sleep Latency Test (MSLT), the Morningness-Eveningness Questionnaire (MEQ), and the Epworth Sleepiness Scale (ESS) to help determine circadian misalignment (2)[C].

Test Interpretation

Typically sleep diaries and actigraph data reveal the following:

- Increased sleep latency
- Decreased total sleep time
- Frequent awakenings
- Notably, most people revert to nocturnal sleeping on their days off, such that every workweek, they start fresh in their attempt to shift their circadian rhythms to align with work schedules.

TREATMENT

- The only therapeutic modality deemed as “standard” by the American Academy of Sleep Medicine is planned (or prescribed) sleep schedules (6)[C].
- Other commonly used treatment strategies include optimizing sleep hygiene, bright light, melatonin, caffeine, and other stimulants as well as hypnotics and other medication sleep aids (discussed below).

GENERAL MEASURES

- Sleep hygiene: An important first step in approaching the treatment of sleep disorders is to educate the patient on proper sleep hygiene, including minimizing exposure to bright light before and during scheduled sleep periods (maintain a dark sleeping space, wear dark sunglasses following work shift,

wear eye mask to sleep), maintaining a quiet sleep environment (wear ear plugs to sleep, disconnect phone and doorbell), retraining core body temperature to shifted sleep/wake schedule (maintain cool sleeping quarters), and avoiding use of stimulants during second half of work shift (2)[C].

- Sleep time: Educate on need for protected time for sleep prior to and following work shifts with strategic use of naps where possible (5)[C].
- Address work/social/domestic factors: Treat psychosocial stress, depression, encourage healthy eating habits, limit substance use, increase exercise to at least 30 minutes 5 times per week (not within 2 to 4 hours of bedtime) (5)[C].
- Work-related interventions: If possible, reduce number of consecutive shifts (<4) or reduce shift duration (<12 hours), allow adequate time between shifts (>11 hours), move heavy workload outside circadian nadir (04:00 to 07:00) (5)[C].
- Bright light: Several studies have demonstrated that timed bright light and darkness can promote adaptation to night work (7)[C].
- Bright light therapy with conventional light/light boxes (10,000 lux preferable, but >1,000 lux will help) should be given 30 min/day during the night/early morning shift prior to the nadir of the core body temperature rhythm (7)[C].

MEDICATIONS

Sleep promoting medications:

- Melatonin may help shift circadian rhythms and can increase the quality and duration of sleep as well as increase alertness during the work shift.
- Ramelteon (Rozerem), a melatonin receptor agonist, is not FDA approved for the treatment of SWD but may be helpful in improving daytime sleep (2)[C].
- Antidepressants: Doxepin (tricyclic) and trazodone are FDA approved for the treatment of insomnia. Given at low doses, doxepin and trazodone can improve sleep without residual daytime impairment (2)[C].
- Intermediate-acting hypnotics such as zolpidem (Ambien) or eszopiclone (Lunesta) may be used (see below) but can cause postsleep sedation (2)[C].
- Suvorexant (Belsomra) is an orexin receptor antagonist approved by the FDA for insomnia in 2014.
- Wakefulness-promoting medications:
  - Modafinil (Provigil) and armodafinil (Nuvigil) are FDA approved for

excessive sleepiness in patients with SWD and can reduce daytime sleepiness and improve cognitive performance (2)[C].
  - Prophylactic caffeine use immediately prior to work shift and during work shift (5)[C].

First Line

Circadian shift/sleep promoting: Melatonin 3 mg PO or sublingual, 30 minutes before daytime sleep period. It should be taken only when the patient is home and able to go to bed (2)[C].

Second Line

- Wakefulness-promoting:
  - Modafinil initially 200 mg PO 1 hour prior to work shift
  - Armodafinil 150 mg PO 1 hour prior to work shift. Long-acting (12 to 16 hours, depending on food intake) and should be used judiciously in SWD as not to impede a patient's ability to sleep after the shift.
- Sleep promoting:
  - Nonbenzodiazepine hypnotics:
    - Zolpidem 5 to 10 mg or eszopiclone 1 to 3 mg immediately prior to bed. Eszopiclone is the only hypnotic approved for use over 35 days.
    - Suvorexant 10 to 20 mg PO 30 minutes prior to bed
  - Antidepressants
    - Doxepin (3 to 6 mg) and trazodone (25 to 150 mg), 1 to 2 hours prior to bed (2)[C]
  - Benzodiazepines: Estazolam, flurazepam, quazepam, temazepam, and triazolam are FDA-approved for the treatment of insomnia. However, they have high risk of tolerance and withdrawal and should be used cautiously for short-term treatment of insomnia (2)[C].
  - In general, hypnotics may improve daytime sleep but do not appear to improve sleep maintenance or nighttime alertness. They may also cause residual sedation during work hours, potentially worsening SWD symptoms (2)[C].

ISSUES FOR REFERRAL

Refer to a sleep specialist if there is suspicion of other primary sleep disorders or

dependence on hypnotics, alcohol, or stimulants.

ONGOING CARE

PATIENT EDUCATION

- Health care providers should discuss good sleep hygiene and advise on how to optimize the sleep environment.
- Shift workers who need to sleep in the daytime must take serious measures to ensure that their sleep environment is cool, dark, and quiet.
- Reserve bedroom for sleeping and intimacy only. Remove all televisions and telephones from bedroom.
- When going to sleep, turn clock away from bed and discourage prolonged reading in bed.
- Blackout shades are usually necessary in order to achieve the proper darkness.

- Sleep Diary: http://www.helpguide.org/life/pdfs/sleep_diary.pdf.

CODES

ICD10

G47.26 Circadian rhythm sleep disorder, shift work type

CLINICAL PEARLS

- SWD is associated with shortened and disturbed sleep, fatigue, decreased alertness, cognitive decrements, increased injuries and accidents, reproductive problems, and risks to cardiovascular and GI health. It has been classified as a probable carcinogen given possible association with breast and prostate cancer.
- The most important first diagnostic step in SWD is to obtain and evaluate a sleep diary.

SMELL AND TASTE DISORDERS

Beth K. Mazyck, MD • Daniel B. Kurtz, PhD

BASICS

DESCRIPTION

- The senses of smell and taste allow a full appreciation of the flavor and palatability of foods and also serve as a warning system against toxins, polluted air, smoke, and spoiled food.
- Physiologically, the chemical senses aid in normal digestion by triggering GI secretions. Smell/taste dysfunction may have a significant impact on quality of life.
- Loss of smell occurs more frequently than loss of taste, and patients frequently confuse the concepts of flavor loss (as a result of smell impairment) with taste loss (an impaired ability to sense sweet, sour, salty, or bitter).
- Smell depends on the functioning of CN I (olfactory nerve) and CN V (trigeminal nerve).
- Taste depends on the functioning of CNs VII, IX, and X. Because of these multiple pathways, total loss of taste (ageusia) is rare.
- Systems affected: nervous, upper respiratory

EPIDEMIOLOGY

Incidence

There are ~200,000 patient visits a year for smell and taste disturbances.

Prevalence

- Predominant sex: male > female. Men begin to lose their ability to smell earlier in life than women.
- Predominant age: Chemosensory loss is age dependent:
  - Age >80 years: 80% have major olfactory impairment; nearly 50% are anosmic.
  - Ages 65 to 80 years: 60% have major olfactory impairment; nearly 25% are anosmic.
  - Age <65 years: 1–2% have smell impairment.

- Estimated >2 million affected in the United States

ETIOLOGY AND PATHOPHYSIOLOGY

- Smell and/or taste disturbances:
  - Nutritional factors (e.g., malnutrition, vitamin deficiencies, liver disease, pernicious anemia)
  - Endocrine disorders (e.g., thyroid disease, diabetes mellitus, renal disease)
  - Head trauma
  - Migraine headache (e.g., gustatory aura, olfactory aura)
  - Sjögren syndrome
  - Toxic chemical exposure
  - Industrial agent exposure
  - Aging
  - Medications (see below)
  - Neurodegenerative diseases (e.g., multiple sclerosis, Alzheimer disease, cerebrovascular accident, Parkinson disease)
  - Infections (e.g., upper respiratory infection [URI], oral and perioral infections, candidiasis, coxsackievirus, AIDS, viral hepatitis, herpes simplex virus)
- Possible causes of smell disturbance:
  - Nasal and sinus disease (e.g., allergies, rhinitis, rhinorrhea)
  - Cigarette smoking
  - Cocaine abuse (intranasal)
  - Hemodialysis
  - Radiation treatment of head and neck
  - Congenital conditions
  - Neoplasm (e.g., brain tumor, nasal polyps, intranasal tumor)
  - Systemic lupus erythematosus (SLE)
  - Bell palsy
  - Oral/perioral skin lesion
  - Damage to CN I/V
  - Possible association with psychosis and schizophrenia
- Possible causes of taste loss:
  - Oral appliances
  - Dental procedures

  - Intraoral abscess
  - Gingivitis
  - Damage to CN VI, IX, or X
  - Stroke (especially frontal lobe)
- Selected medications that reportedly alter smell and taste:
  - Antibiotics: amikacin, ampicillin, azithromycin, ciprofloxacin, clarithromycin, doxycycline, griseofulvin, metronidazole, ofloxacin, tetracycline, terbinafine, β-lactamase inhibitors
  - Anticonvulsants: carbamazepine, phenytoin
  - Antidepressants: amitriptyline, doxepin, imipramine, nortriptyline
  - Antihistamines and decongestants: zinc-based cold remedies (Zicam)
  - Antihypertensives and cardiac medications: acetazolamide, amiloride, captopril, diltiazem, hydrochlorothiazide, nifedipine, propranolol, spironolactone
  - Anti-inflammatory agents: auranofin, gold, penicillamine
  - Antimanic drugs: lithium
  - Antineoplastics: cisplatin, doxorubicin, methotrexate, vincristine
  - Antiparkinsonian agents: levodopa, carbidopa
  - Antiseptic: chlorhexidine
  - Antithyroid agents: methimazole, propylthiouracil
  - Lipid-lowering agents: statins

Genetics

May be related to underlying genetically associated diseases (Kallmann syndrome, Alzheimer disease, migraine syndromes, rheumatologic conditions, endocrine disorders)

RISK FACTORS

- Age >65 years
- Poor nutritional status
- Smoking tobacco products

GENERAL PREVENTION

- Eat a well-balanced diet, with appropriate vitamins and minerals.
- Maintain good oral and nasal health, with routine visits to the dentist.

- Do not smoke tobacco products.
- Avoid noxious chemical exposures/unnecessary radiation.

Geriatric Considerations

- Elders are at particular risk of eating spoiled food or inadvertently being exposed to natural gas leaks owing to anosmia from aging.
- Anosmia also may be an early sign of degenerative disorders and has been shown to predict increased 5-year mortality (1)[B].

Pediatric Considerations

- Smell and taste disorders are uncommon in children in developed countries.
- In developing countries with poor nutrition (particularly zinc depletion), smell and taste disorders may occur.
- Delayed puberty in association with anosmia (± midline craniofacial abnormalities, deafness, or renal abnormalities) suggests the possibility of Kallmann syndrome (hypogonadotropic hypogonadism).

Pregnancy Considerations

- Pregnancy is an uncommon cause of smell and taste loss or disturbances.
- Many women report increased sensitivity to odors during pregnancy as well as an increased dislike for bitterness and a preference for salty substances.

COMMONLY ASSOCIATED CONDITIONS

URI, allergic rhinitis, dental abscesses

DIAGNOSIS

Smell and taste disturbances are symptoms; it is essential to look for possible underlying causes.

HISTORY

- Symptoms of URI, environmental allergies
- Oral pain, other dental problems
- Cognitive/memory difficulties
- Current medications
- Nutritional status, ovolactovegetarian

- Weight loss or gain
- Frequent infections (impaired immunity)
- Worsening of underlying medical illness
- Increased use of salt and/or sugar to increase taste of food
- Neurodegenerative disease

PHYSICAL EXAM

Thorough HEENT exam

DIFFERENTIAL DIAGNOSIS

- Epilepsy (gustatory aura)
- Epilepsy (olfactory aura)
- Memory impairment
- Psychiatric conditions

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

Consider (not all patients require all tests)

- CBC
- Liver function tests
- Blood glucose
- Creatinine
- Vitamin B_{12} level
- Thyroid-stimulating hormone (TSH)
- Serum IgE
- CT scanning is the most useful and cost-effective technique for assessing sinonasal disorders and is superior to an MRI in evaluating bony structures and airway patency. Coronal CT scans are particularly valuable in assessing paranasal anatomy (2)[B].

Follow-Up Tests & Special Considerations

Diagnosis of smell and taste disturbances is usually possible through history; however, the following tests can be used to confirm:

- Olfactory tests
  - Smell identification test: evaluates the ability to identify 40 microencapsulated scratch-and-sniff odorants (3)[B]

- Brief smell identification test (4)[B]
- Taste tests (more difficult because no convenient standardized tests are presently available): Solutions containing sucrose (sweet), sodium chloride (salty), quinine (bitter), and citric acid (sour) are helpful.
- An MRI is useful in defining soft tissue disease; therefore, a coronal MRI is the technique of choice to image the olfactory bulbs, tracts, and cortical parenchyma. Possible placement of an accessory coil (TMJ) over the nose to assist in imaging

TREATMENT

GENERAL MEASURES

- Appropriate treatment for underlying cause
- Quit smoking (5)[B].
- Treatment of underlying nasal congestion with nasal decongestants and/or nasal/oral steroids (6)[B]
- Surgical correction of nasal blockage/nasal polyps
- Some drug-related smell or taste loss or dysgeusias can be reversed with cessation of the offending medication, but it may take many months.
- Stop repeated oral trauma (e.g., appliances, tongue-biting behaviors).
- Proper nutritional and dietary assessment (2)[C]
- Formal dental evaluation

MEDICATION

- Treat underlying causes as appropriate. Idiopathic cases will often resolve spontaneously.
- Consider trial of corticosteroids topically (e.g., fluticasone nasal spray daily to BID) and/or systemically (e.g., oral prednisone 60 mg daily for 5 to 7 days) (6)[B].
- Zinc and vitamins (A, B complex) when deficiency is suspected

ISSUES FOR REFERRAL

- Consider referral to an otolaryngologist or neurologist for persistent cases.
- Referral to a subspecialist at a regional smell and taste center when complex

etiologies are suspected

SURGERY/OTHER PROCEDURES

If needed for treatment of underlying cause

ONGOING CARE

DIET

- Weight gain/loss is possible because the patient may reject food or may switch to calorie-rich foods that are still palatable.
- Ensure a nutritionally balanced diet with appropriate levels of nutrients, vitamins, and essential minerals.

PATIENT EDUCATION

- Caution patients not to overindulge as compensation for the bland taste of food. For example, patients with diabetes may need help in avoiding excessive sugar intake as an inappropriate way of improving food taste.
- Patients with chemosensory impairments should use measuring devices when cooking and should not cook by taste.
- Optimizing food texture, aroma, temperature, and color may improve the overall food experience when taste is limited.
- Patients with permanent smell dysfunction must develop adaptive strategies for dealing with hygiene, appetite, safety, and health.
- Natural gas and smoke detectors are essential; check for proper function frequently.
- Check food expiration dates frequently; discard old food.

PROGNOSIS

- In general, the olfactory system regenerates poorly after a head injury. Most patients who recover smell function following head trauma do so within 12 weeks of injury.
- Patients who quit smoking typically recover improved olfactory function and flavor sensation.
- Many taste disorders (dysgeusias) resolve spontaneously within a few years of onset.

- Phantosmias that are flow dependent may respond to surgical ablation of olfactory mucosa.
- Conditions such as radiation-induced xerostomia and Bell palsy generally improve over time.

COMPLICATIONS

- Permanent loss of ability to smell/taste
- Psychiatric issues with dysgeusias and phantosmia

CODES

ICD10

- R43.9 Unspecified disturbances of smell and taste
- R43.1 Parosmia
- R43.2 Parageusia

CLINICAL PEARLS

- Smell disorders are often mistaken as decreased taste by patients.
- Most smell loss is due to nasal passage obstruction.
- Actual taste disorders are often related to dental problems or medication side effects.
- Gradual smell loss is very common in the elderly; extensive workup in this population may not be indicated if no associated signs/symptoms are present but may be predictive of 5-year mortality.

SOMATIC SYMPTOM (SOMATIZATION) DISORDER

William G. Elder, PhD

BASICS

DESCRIPTION

- A pattern of one or more somatic symptoms recurring or persisting for >6 months that are distressing or result in significant disruption of daily life
- Conceptualization and diagnostic criteria for somatic symptom presentations were significantly modified with the advent of *DSM-5*. Somatic symptom disorder (SSD) is similar in many aspects to the former somatization disorder, which required presentation with multiple physical complaints, no longer based on symptoms counts; current diagnosis is based on the way the patient presents and perceives his or her symptoms.
- SSD now includes most presentations that would formerly be considered hypochondriasis. Hypochondriasis has been replaced by illness anxiety disorders, which is diagnosed when the patient presents with significant preoccupation with having a serious illness in the absence of illness-related somatic complaints.
- Somatization increases disability independent of comorbidity and individuals with SSD have health-related functioning that is two standard deviations below the mean.
- Symptoms may be specific (e.g., localized pain) or relatively nonspecific (e.g., fatigue).
- Symptoms sometimes may represent normal bodily sensations or discomfort that does not signify serious disease.
- Suffering is authentic. Symptoms are not intentionally produced or feigned.

EPIDEMIOLOGY

Incidence

- Usually, first symptoms appear in adolescence.
- Predominant sex: female > male (10:1)

- Type and frequency of somatic complaints may differ among cultures, so symptom reviews should be adjusted based on culture. More frequent in cultures without Western/empirical explanatory models.

Prevalence

- Expected 2% among women and <0.2% among men
- Somatization seen in up to 29% of patients presenting to primary care offices
- Somatic concerns may increase, but other features of the presentation decrease such that prevalence declines after age 65 years.

ETIOLOGY AND PATHOPHYSIOLOGY

Patients with SSD demonstrate different patterns of heart rate variability. Although this cannot be used to clinically, it does point to the differences in psychophysiology of SSD.

Genetics

Consanguinity studies and single nucleotide polymorphism genotyping indicate that both genetic and environmental factors contribute to the risk of SSD.

RISK FACTORS

- Child abuse, particularly sexual abuse, has been shown to be a risk factor for somatization.
- Symptoms begin or worsen after losses (e.g., job, close relative, or friend).
- Greater intensity of symptoms often occurs with stress.

COMMONLY ASSOCIATED CONDITIONS

Comorbid with other psychiatric conditions is yet to be determined but is likely to be 20–50% with anxiety, depression, or personality disorders.

DIAGNOSIS

- Determining that a somatic symptom is medically unexplained is unreliable, and it is inappropriate to diagnose a mental disorder solely because a medical diagnosis is not demonstrated. Rely on symptoms and presentation rather than ruling out medical causes in making the SSD diagnosis.
- Illness anxiety and somatic distress are independent but often co-occur.

HISTORY

- One or more somatic complaints, with sometimes a grossly positive review of symptoms
- SSD involves patient excessive thoughts, feelings, or behaviors associated with symptoms or associated health concerns manifested by at least one of the following:
  - Disproportionate and persistent thoughts about the seriousness of the symptoms
  - Persistent high level of anxiety about health or symptoms
  - Excessive time or energy devoted to symptoms or health concerns
- Diagnoses no longer rely on symptom counts, but common symptoms include:
  - Pain symptoms related to different sites such as head, abdomen, back, joints, extremities, chest, or rectum, or related to body functions such as menstruation, sexual intercourse, or urination
  - GI symptoms such as nausea, bloating, vomiting (not during pregnancy), diarrhea, intolerance of several foods
  - Sexual symptoms such as indifference to sex, difficulties with erection or ejaculation, irregular menses, excessive menstrual bleeding, or vomiting throughout all 9 months of pregnancy
  - Pseudoneurologic symptoms such as impaired balance or coordination, weak or paralyzed muscles, lump in throat or trouble swallowing, loss of voice, retention of urine, hallucinations, numbness (to touch or pain), double vision, blindness, deafness, seizures, amnesia or other dissociative symptoms, loss of consciousness (other than with fainting); none of these is limited to pain.
- Patients with SSD frequently use alternative treatments, which should be explored for their effects on health and physical functioning.

PHYSICAL EXAM

Physical exam remarkable for absence of objective findings to explain the many subjective complaints

DIFFERENTIAL DIAGNOSIS

- Other psychiatric illnesses must be ruled out:
  - Depressive disorders

  - Anxiety disorders
  - Schizophrenia
  - Other somatic disorders: illness anxiety disorder, conversion disorder
  - Factitious disorder
  - Body dysmorphic disorder
- Malingering
- General medical conditions, with vague, multiple, confusing symptoms, must be ruled out.
  - Systemic lupus erythematosus
  - Hyperparathyroidism
  - Hyper- or hypothyroidism
  - Lyme disease
  - Porphyria

DIAGNOSTIC TESTS & INTERPRETATION

Several screening tools are available that help to identify symptoms as somatic:

- Patient Health Questionnaire (PHQ)-15 (screens and monitors symptoms) (1) [B]
- Minnesota Multiphasic Personality Inventory (MMPI) (identifies somatization) (2)[B]

Initial Tests (lab, imaging)

- Laboratory test results do not support the subjective complaints.
- Imaging studies do not support the subjective complaints.

Test Interpretation

None are identified.

TREATMENT

GENERAL MEASURES

- The goal of treatment is to help the person learn to control the symptoms (3) [B].
- A supportive relationship with a sympathetic health care provider is the most important aspect of treatment:

  - Regular scheduled appointments should be maintained to review symptoms and the person's coping mechanisms (at least 15 minutes once a month).
  - Acknowledge and explain test results.
- The involvement of a single provider is important because a history of seeking medical attention and "doctor shopping" is common.
- Antidepressant or antianxiety medication and referral to a support group or mental health provider can help patients who are willing to participate in their treatment.
- Patients usually receive the most benefit from primary care providers who accept the limitations of treatment, listen to their patient's concerns, and provide reassurance.
- It is not helpful to tell patients that their symptoms are imaginary.

MEDICATION

Antidepressants (e.g., SSRIs) help to treat comorbid depression and anxiety (4) [C].

ISSUES FOR REFERRAL

- Discourage referrals to specialists for further investigation of somatic complaints.
- Referrals to support groups or to a mental health provider may be helpful.

ADDITIONAL THERAPIES

Treatments have not been evaluated for this recently reformulated disorder. However, there are numerous studies with positive outcomes for patients with various forms of somatization or medically unexplained symptoms.

- Treatment typically includes long-term therapy, which has been shown to decrease the severity of symptoms.
- Individual or group cognitive-behavioral therapy addressing health anxiety, health beliefs, and health behaviors has been shown to be the most efficacious treatment for somatoform disorders. Cognitive processes modified in therapy include patient tendencies to ruminate and catastrophize (5,6)[A].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patients should have regularly scheduled follow-up with a primary care doctor, psychiatrist, and/or therapist.

PATIENT EDUCATION

Encourage interventions that decrease stressful elements of the patient's life:

- Psychoeducational advice
- Increase in exercise
- Pleasurable private time

PROGNOSIS

- Chronic course, fluctuating in severity
- Full remission is rare.
- Individuals with this disorder do not experience any significant difference in mortality rate or significant physical illness.
- Patients with this diagnosis do experience substantially greater functional disability and role impairment than nonsomatizing patients (7).

COMPLICATIONS

- May result from invasive testing and from multiple evaluations that are performed while looking for the cause of the symptoms
- A dependency on pain relievers or sedatives may develop.

CODES

ICD10

- F45.9 Somatoform disorder, unspecified
- F45.20 Hypochondriacal disorder, unspecified
- F45.22 Body dysmorphic disorder

CLINICAL PEARLS

- With the advent of *DSM-5*, diagnosis is now based on a pattern of symptoms rather than an absence of medical explanation.
- A clue is accumulation of several diagnoses with >13 letters (e.g., chronic fatigue syndrome, fibromyalgia syndrome, reflex sympathetic dystrophy, temporomandibular joint syndrome, carpal tunnel syndrome, mitral valve prolapse).

- Inability of more than three physicians to make a meaningful diagnosis suggests somatization.
- Acknowledge the patient’s pain, suffering, and disability.
- Do not tell patients the symptoms are “all in their head.”
- Emphasize that this is not a rare disorder.
- Discuss the limitations of treatment while providing reassurance that there are interventions that will lessen suffering and reduce symptoms.

SPINAL STENOSIS

N. Wilson Holland, MD, FACP, AGSF • Birju B. Patel, MD, FACP, AGSF

BASICS

DESCRIPTION

Narrowing of the spinal canal and foramen:

- Spondylosis or degenerative arthritis is the most common cause of spinal stenosis, resulting from compression of the spinal cord by disc degeneration, facet arthropathy, osteophyte formation, and ligamentum flavum hypertrophy.
- The L4–L5 level is most commonly involved.

EPIDEMIOLOGY

The prevalence of spinal stenosis increases with age due to "wear and tear" on the normal spine.

Incidence

Symptomatic spinal stenosis affects up to 8% of the general population.

Prevalence

- The prevalence of spinal stenosis is high if assessed solely by imaging in elderly patients. Not all patients with radiographic spinal stenosis are symptomatic. The degree of radiographic stenosis does not always correlate with patient symptoms. Lumbar MRI shows significant abnormalities in 57% of patients >60 years.
- Predominant age: Symptoms develop in 5th to 6th decades (congenital stenosis is symptomatic earlier).

ETIOLOGY AND PATHOPHYSIOLOGY

- Spinal stenosis can result from congenital or acquired causes. Degenerative spondylosis is most common.
- Disc dehydration leads to loss of height with bulging of the disc annulus and ligamentum flavum into the spinal canal, increasing facet joint loading.
- Facet loading leads to reactive sclerosis and osteophytic bone growth, further

compressing spinal canal and foraminal elements.

- Other causes of acquired spinal stenosis include:
  - Trauma
  - Neoplasms
  - Neural cysts and lipomas
  - Postoperative changes
  - Rheumatoid arthritis
  - Diffuse idiopathic skeletal hyperostosis
  - Ankylosing spondylitis
  - Metabolic/endocrine causes-osteoporosis, renal osteodystrophy, and Paget disease

Genetics

No definitive genetic links

RISK FACTORS

Increasing age and degenerative spinal disease

GENERAL PREVENTION

There is no proven prevention for spinal stenosis. Symptoms can be alleviated with flexion at the waist:

- Leaning forward while walking
- Pushing a shopping cart
- Lying in flexed position
- Sitting
- Avoiding provocative maneuvers (back extension, ambulating long distances without resting)

DIAGNOSIS

HISTORY

- Helps distinguish spinal stenosis from other causes of back pain and peripheral vascular disease.
  - Insidious onset and slow progression are typical. Discomfort with standing, paresthesias, and weakness (often bilateral) (1)[C]

  - Symptoms *worsen with extension* (prolonged standing, walking downhill or downstairs).
  - Symptoms *improve with flexion* (sitting, leaning forward while walking, walking uphill or upstairs, lying in a flexed position).
- Neurogenic claudication (i.e., pain, tightness, numbness, and subjective weakness of lower extremities) may mimic vascular claudication.

PHYSICAL EXAM

Neurologic exam may be normal. Key exam areas:

- Examine gait (rule out cervical myelopathy or intracranial pathology).
- Loss of lumbar lordosis
- Evaluate range of motion of lumbar spine.
- Pain with extension of the lumbar spine is typical.
- Straight-leg raise test may be positive if nerve root entrapment is present.
- Muscle weakness is usually mild and involves the L4, L5, and (rarely) S1 nerve roots.
- About half of patients with symptomatic stenosis have a reduced or absent Achilles reflex. Some have reduced or absent patellar reflex.

DIFFERENTIAL DIAGNOSIS

- Vascular claudication. Symptoms of vascular claudication do not improve with leaning forward and usually abate with standing or rest.
- Disc herniation
- Cervical myelopathy

DIAGNOSTIC TESTS & INTERPRETATION

Generally a clinical diagnosis. Imaging (MRI is best) is used to stage severity and plan treatment.

Initial Tests (lab, imaging)

- CBC, ESR, C-reactive protein (if considering infection or malignancy)
- New back pain lasting >2 weeks or back pain accompanied by neurologic findings in patients >50 years generally warrants neuroimaging.
- MRI is the modality of choice.
- CT myelography is an alternative to MRI but is invasive and has higher risk of complications.

- Plain radiography helps exclude other causes of new back pain (e.g., malignant lytic lesions) but does not reveal the underlying pathology.
- Radiologic abnormalities in general do not correlate with the clinical severity.

Diagnostic Procedures/Other

Surgical decompression is definitive for patients who are symptomatic after nonoperative treatment:

- Spinal stenosis generally does not lead to neurologic damage.
- Surgery may be required for pain relief to increase mobility and improve quality of life.

Test Interpretation

Common radiographic findings include decreased disc height, facet hypertrophy, and spinal canal and/or foraminal narrowing.

TREATMENT

- In general, nonoperative interventions are preferred in the absence of progressive or debilitating neurologic symptoms:
  - Physical therapy, exercise, weight management, medications, and epidural steroid injections are options. There is insufficient evidence to definitively guide clinical practice.
  - Patients should understand that the benefits of surgery may diminish over time.
  - Rule out other neuropathies and peripheral vascular disease.
- Spinal decompression and physical therapy yield similar effects (2)[A].
- There is controversy about fusion being performed with decompression because of a future spondylolisthesis risk (3)[C].

MEDICATION

First Line

- Acetaminophen: caution in those with preexisting liver disease; increased warnings for hepatotoxicity; limit daily dosing in the elderly.
- NSAIDs: Consider potential for GI side effects, fluid retention, and renal failure.

Second Line

- Tramadol—currently a schedule IV controlled substance; has the potential to cause confusion, dizziness, lower seizure threshold, and increase fall risk in the elderly; should be used with caution
- The available evidence does not support the routine use of epidural steroid injections. Judicious injections may be reasonable in certain cases.
- Use opioids sparingly and only when other treatments have failed to control severe pain.

Geriatric Considerations

- Anti-inflammatory medications should be used with caution in the elderly due to the risks of GI bleeding, fluid retention, renal failure, and cardiovascular risks.
- Side effects of opioids include constipation, confusion, urinary retention, drowsiness, nausea, vomiting, and the potential for dependence and abuse.
- >10% of elderly lack Achilles reflexes.

ISSUES FOR REFERRAL

Patients in unremitting pain or with a neurologic deficit should see a neurosurgeon.

ADDITIONAL THERAPIES

- Patients with spinal stenosis are typically able to ride a bicycle (leaning forward tends to relieve symptoms).
- Aquatic therapy (helpful for muscle training and general conditioning)
- Strengthening of abdominal and back muscles
- Gait training
- While a brace or corset may help in the short term, use is not recommended for prolonged periods due to development of paraspinal muscle weakness.
- Encourage physical activity to prevent deconditioning.

SURGERY/OTHER PROCEDURES

- Surgery is indicated when symptoms persist despite conservative measures.
- Age alone should not be an exclusion factor for surgical intervention. Cognitive impairment, multiple comorbidities, and osteoporosis may increase the risk of perioperative complications in the elderly.

- Lumbar decompressive laminectomy is the mainstay of treatment. The traditional approach is laminectomy and partial facetectomy.
- Controversy exists about whether the decompression should be supplemented by a fusion procedure:
  - There is evidence that fusion (simple or complex), as opposed to decompression procedure alone, may be associated with higher risk of major complications, increased mortality, and increased resource use in the elderly.
- A less invasive alternative, known as interspinous distraction (X STOP implant), is an option (4)[B].
- The evidence for use of the Aperius interspinous implant device is inconclusive (5)[C].
- A unilateral partial hemilaminectomy combined with transmedial decompression may adequately treat stenosis with less morbidity in the elderly (6)[C].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Admission criteria/initial stabilization: acute or progressive neurologic deficit
- Discharge criteria: improved pain or after neurologic deficit has been addressed

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Follow up based on progression of symptoms.
- No limitations to activity; patients may be as active as tolerated. Exercise should be encouraged.

Patient Monitoring

Patients are monitored for improvement of symptoms and development of any complications.

DIET

Optimize nutrition for weight management.

PATIENT EDUCATION

- Activity as tolerated, if no other pathology is present (e.g., fractures)
- Patients should present for care if they develop progressive motor weakness and/or bladder/bowel dysfunction.
- Patients should know the natural history of the condition and how best to relieve symptoms.

PROGNOSIS

- Spinal stenosis is generally benign, but the pain can lead to limitation in ADLs and progressive disability.
- Surgery usually improves pain and symptoms in patients who fail nonoperative treatment.
- Surgical outcomes are similar in terms of pain relief and functional improvement for patients of all ages.

COMPLICATIONS

- Severe spinal stenosis can lead to bowel and/or bladder dysfunction.
- Surgical complications include infection, neurologic injury, chronic pain, and disability.

SEE ALSO

Algorithm: Low Back Pain, Acute

CODES

ICD10

- M48.00 Spinal stenosis, site unspecified
- M48.06 Spinal stenosis, lumbar region
- M48.04 Spinal stenosis, thoracic region

CLINICAL PEARLS

- Spinal stenosis typically presents as neurogenic claudication (pain, tightness, numbness, and subjective weakness of lower extremities), which can mimic vascular claudication.
- Flexion of the spine generally relieves symptoms associated with spinal stenosis.
- Spinal extension (prolonged standing, walking downhill, and walking downstairs) can worsen symptoms of spinal stenosis.
- Consider urgent surgery for patients with cauda equina/conus medullaris syndrome or progressive bladder dysfunction. Other patients with lumbar spinal stenosis typically do well with initial conservative management.

SPRAIN, ANKLE

Shane L. Larson, MD • Julia S. Fast, DO

BASICS

DESCRIPTION

The most common cause of ankle injury comprising a significant proportion of sports injuries:

- Types of ankle sprains: lateral, medial, and syndesmotic (or high ankle sprain)
  - Lateral ankle sprains are the most common, accounting for up to 89% of all ankle sprains (1):
    - In lateral ankle sprains, the anterior talofibular ligament (ATFL) is most likely to be injured.
    - The calcaneofibular ligament (CFL) is the second most likely ligament to be injured.
    - The posterior talofibular ligament (PTFL) is the least likely to be injured.
  - Medial ankle sprains (5–10%) result from an injury to the deltoid ligament.
  - Syndesmotic ("high ankle sprain") injuries account for 5–10% of ankle sprains.
    - The syndesmosis between the distal tibia and distal fibula bones consists of the anterior, posterior, and transverse tibiofibular ligaments and the interosseous ligament and interosseous membrane.
- Ankle sprains are classified according to the degree of ligamentous disruption:
  - Grade I: mild stretching of a ligament with possible microscopic tears
  - Grade II: incomplete tear of a ligament
  - Grade III: complete ligament tear

Geriatric Considerations

Increased risk of fracture in patients with preexisting bone weakness (osteoporosis/osteopenia)

Pediatric Considerations

- Increased risk of physeal injuries instead of ligament sprain because ligaments have greater tensile strength than physes

- Inversion ankle injuries in children may have a concomitant fibular physeal injury (Salter Harris type I or higher fracture).
- Consider tarsal coalition with recurrent ankle sprains.

EPIDEMIOLOGY

Incidence

- Ankle sprains are more common in childhood and adolescents, particularly in active individuals (2).
- 1/2 of all ankle sprains are sports related; highest incidence in indoor/court sports (basketball, volleyball, tennis), followed by football and soccer (3)
- Most common sports injury
- More common in males age <30 years and females >30 years old

Prevalence

- 25% of sports injuries in the United States
- 75% of all ankle injuries are sprains.

ETIOLOGY AND PATHOPHYSIOLOGY

- Lateral ankle sprains result from an inversion force with the ankle in plantar flexion.
- Medial ankle sprains are due to forced eversion while the foot is in dorsiflexion.
- Syndesmotic sprains result from eversion stress/extreme dorsiflexion along with internal rotation of tibia.

RISK FACTORS

- The greatest risk factor is a prior history of an ankle sprain (3–34% recurrence rate).
- Postural instability, gait alterations
- Joint laxity and decreased proprioception are not risk factors.

GENERAL PREVENTION

- Improve overall physical conditioning:
  - Training in agility and flexibility
  - Single-leg balancing
  - Proprioceptive training

- Taping and bracing may help prevent primary injury in selected sports (i.e., volleyball, basketball, football) or reinjury (4). Taping and bracing do not reduce sprain severity.
- Weight loss may help in overweight patients (4)[A].

COMMONLY ASSOCIATED CONDITIONS

- Contusions
- Fractures
  - Fibular head fracture/dislocation (Maisonneuve)
  - Fracture of the base of the 5th metatarsal
  - Distal fibula physeal fracture (includes Salter-Harris fractures in pediatric patients; most common type of pediatric ankle fracture)

DIAGNOSIS

HISTORY

- Elicit specific mechanism of injury (inversion vs. eversion)
- Popping/snapping sensation during the injury
- Previous history of ankle injuries
- Ability to ambulate immediately after the injury
- Rapid onset of pain, swelling, or ecchymosis
- Location of pain (lateral/medial)
- Difficulty bearing weight
- Past medical history of systemic disorders

PHYSICAL EXAM

- Timing: Initial assessment for laxity may be difficult due to pain, swelling, and muscle spasm. Repeating exam ~5 days after injury often improves sensitivity.
- Compare to uninjured ankle for swelling, ecchymosis, weakness, and laxity.
- Neurovascular exam
- Palpate ATFL, CFL, PTFL, and deltoid ligament for tenderness.
- Palpate lateral and medial malleolus, base of 5th metatarsal, navicular, and entire fibula.
  - High ankle sprain associated with fracture of proximal fibula

- Grade I sprain: mild swelling and pain; no laxity; able to bear weight/ambulate without pain
- Grade II sprain: moderate swelling and pain; mild laxity with firm end point noted; weight bearing/ambulation painful
- Grade III sprain: severe swelling, pain, and bruising; laxity with no end point; significant instability and loss of function/motion; unable to bear weight/ambulate
  - Swelling less sensitive for grade of tear in pediatric patient
- Special tests:
  - Anterior drawer test to check for ATFL laxity
  - Talar tilt test to check laxity in CFL (with inversion) or deltoid ligament (eversion)
  - Squeeze test: Compress tibia and fibula midcalf to check for syndesmotic injury; sensitivity 30%, specificity 93.5%
  - Dorsiflexion/external rotation test: Positive test is pain at syndesmosis with rotation; sensitivity 20%, specificity 85%

DIFFERENTIAL DIAGNOSIS

- Tendon injury
  - Tendinopathy/tendon tear
- Fracture and/or dislocation of the ankle/foot
- Hindfoot/midfoot injuries
- Nerve injury
- Contusion

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Ottawa Ankle Rules (nearly 100% sensitive, 30–50% specific) determine need for radiographs to rule out ankle fractures (patient must be 18 to 55 years; certain patients, e.g., diabetics with diminished sensation, may still need radiographs):
  - Pain in malleolar zone
  - Inability to bear weight (walk ≥4 steps) immediately and in the exam room
  - Bony tenderness at tip/posterior edge of the lateral/medial malleolus
    - Note: Ottawa rule for foot imaging: reported pain in the midfoot zone

AND pain with palpation of navicular or base of 5th metatarsal, OR inability to bear weight immediately and in the ER/office

  - Although Ottawa rules are highly sensitive, they should not overrule clinical judgment.
- If radiographs are indicated, obtain anteroposterior, lateral, and mortise views of the ankle.
  - Small avulsion fractures are associated with grade III sprains.
- Consider CT if radiographs are negative but occult fracture is suspected clinically.
- MRI is the gold standard for soft tissue imaging but is expensive and rarely necessary.
  - Syndesmotic ankle sprains: MRI is more sensitive.
- US is a good second-line imaging option with sensitivity comparable to MRI.

Follow-Up Tests & Special Considerations

If patient condition does not improve in 6 to 8 weeks, consider CT, MRI, or US. Failure to resolve could indicate an injury such as a fracture or osteochondral lesion of the talus.

TREATMENT

GENERAL MEASURES

- Most grade I, II, and III lateral ankle sprains can be managed conservatively.
- Conservative therapy: PRICE (protection, relative rest, ice, compression, elevation) (4)[A]
- Protection/compression: For grade I/II sprains, lace-up bracing is superior to air-filled/gel-filled ankle brace, which is superior to elastic bandage/taping to provide support and decrease swelling.
  - Note: The combination of air-filled brace and compression wrap is superior to each individual modality for return to preinjury joint function at 10 days and 1 month following grade I and II sprains.
  - Grade III sprains should have short-term immobilization (10 days) with below-the-knee cast, followed by a semirigid brace (air cast). If a patient refuses casting, a 10-day period of strict non–weight bearing with air cast

splint and elastic bandage is a comparable alternative if non–weight bearing is maintained.

- Rest: Initially, activity as tolerated. Early mobilization and physical therapy speed recovery/reduce pain:
  - Weight bearing, as tolerated
  - Consider crutches if unable to bear weight.
  - Initiate exercises as early as tolerated. Limit to pain-free range of motion.
  - Start mobilization by tracing the alphabet with the foot or toes.
  - Resistance exercises with an elastic band
- Ice: Ice for first 3 to 7 days reduces pain and decreases recovery time.
- Elevation: Elevate ankle to decrease swelling.

MEDICATION

- NSAIDs: preferably oral; topical forms (e.g., diclofenac 1% gel) may be used to minimize GI side effects. PRN NSAID dosing has similar outcomes to scheduled dosing with improved safety profile.
  - Example: naproxen 500 mg BID PRN
- Acetaminophen 650 mg q4–6h (max outpatient therapy dose: 3,250 mg/day)
- Opioids if severe pain

ISSUES FOR REFERRAL

- Malleolar/talar dome fracture
- Syndesmotic sprain
- Dislocation/subluxation
- Tendon rupture
- Ongoing instability
- Uncertain diagnosis

ADDITIONAL THERAPIES

Physical therapy:

- After the acute phase of the injury, patients with grade II or III sprain should start physical therapy as soon as possible to increase range of motion, strength, flexibility, and improve proprioceptive balance (wobble board/ankle disk).
- Functional rehabilitation prevents chronic instability and speeds healing.

- Athletes should undergo sport-specific rehabilitation before returning to play.

SURGERY/OTHER PROCEDURES

- Surgery is typically reserved for treatment of complicated recurrent sprains and certain syndesmotic sprains.
- Patients with chronic ankle instability who fail functional rehabilitation or with poor tissue quality may need anatomic repair/reconstructive surgery.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- After an ankle sprain, consider ankle-stabilizing orthoses (air stirrup braces, lace-up supports, athletic taping, etc.) for athletes participating in high-risk sports to prevent future ankle sprains.
- Moderate and severe sprains require ankle orthoses for ≥6 months during sports participation.
- Gradual return to play for athletes with a grade I lateral ankle sprain can generally be accomplished in 1 to 2 weeks; grade II sprain return to play time is 2 to 3 weeks; grade III sprain is approximately 4 weeks.
- Syndesmotic sprains take longer (~8 to 9 weeks) to heal than lateral ankle sprains.

Patient Monitoring

If athletes continue to have symptoms when they return to play or if a patient has pain for 6 to 8 weeks after injury, repeat examination and imaging.

PATIENT EDUCATION

- Crutch training
- Provide training on proper use of elastic bandages, brace, and/or orthoses.
- Demonstrate mobilization exercises (alphabet trace, towel grab).

PROGNOSIS

- Earlier physical therapy and mobilization with bracing allows for faster return to daily living and/or sports.
- Higher grade sprains, older patient age, and initial non–weight-bearing status

have poorer prognosis and longer recovery.
- Ligamentous strength does not return for months after the injury.

COMPLICATIONS

- Joint instability
- Intermittent swelling/pain if not properly treated
- Accumulation of cartilage damage, leading to degenerative changes
- 5–33% continue to have pain 1 year postinjury.

CODES

ICD10

- S96.919A Strain of unsp msl/tnd at ank/ft level, unsp foot, init
- S93.499A Sprain of other ligament of unspecified ankle, init encntr
- S93.419A Sprain of calcaneofibular ligament of unsp ankle, init

CLINICAL PEARLS

- Children are at an increased risk of physeal injuries because ligaments are stronger than physes.
- Conditioning, including proprioceptive training, before participating in sports and throughout the season helps to prevent ankle sprains.
- Functional rehabilitation, rather than total immobilization, is recommended for quicker return to sport and work.
- Patients who do not adequately rehabilitate an ankle sprain are at increased risk for recurrence and chronic ankle instability.
- If patient’s condition is not improving in 6 to 8 weeks, consider advanced imaging with CT, MRI, or US.

SPRAINS AND STRAINS

Elana R. Bannerman, MD • J. Herbert Stevenson, MD

BASICS

DESCRIPTION

- *Sprains* are complete or partial ligamentous injuries either within the body of the ligament or at the site of attachment to bone.
  - Classified as grade 1, 2, or 3 (AMA Ligament Injury Classification)
    - Grade 1: stretch injury without ligamentous laxity
    - Grade 2: partial tear with increased ligamentous laxity but firm end point on exam
    - Grade 3: complete tear with increased ligamentous laxity and no firm end point on exam
  - Usually secondary to trauma (e.g., falls, twisting injuries, motor vehicle accidents)
  - Physical exam is the key to accurate diagnosis.
- *Strains* are partial or complete disruptions of the muscle, muscle–tendon junction, or tendon.
  - Classified as
    - First degree: minimal damage to muscle, tendon, or musculotendinous unit
    - Second degree: partial tear to the muscle, tendon, or musculotendinous unit
    - Third degree: complete disruption of the muscle, tendon, or musculotendinous unit
  - Often associated with overuse injuries

Geriatric Considerations

More likely to see associated bony injuries due to decreased joint flexibility and increased prevalence of osteoporosis and osteopenia

Pediatric Considerations

- Sprains and strains account for 24% of pediatric injuries.

- 3 million pediatric sports injuries occur annually.
- Consider physeal/apophyseal injuries in the skeletally immature patient.

EPIDEMIOLOGY

Incidence

~80% of all U.S. athletes experience a sprain or strain at some point.

Prevalence

- Ankle sprains are among the most common injuries in primary care, accounting for ~30% of sports medicine clinic visits. Most ankle sprains are due to inversion injuries (lateral sprains) involving the anterior talofibular ligament; account for 650,000 annual ER visits in the United States
- Predominant age
  - Sprains: any age in physically active patient
  - Strains: usually 15 to 40 years of age
- Predominant sex: male > female for most; female > male for sprain of acromioclavicular ligament

ETIOLOGY AND PATHOPHYSIOLOGY

- Trauma, falls, motor vehicle accidents
- Excessive exercise; poor conditioning
- Improper footwear
- Inadequate warm-up and stretching before activity
- Prior sprain or strain

RISK FACTORS

- Prior history of sprain or strain is greatest risk factor for future sprain/strain.
- Change in or improper footwear, protective gear, or environment (e.g., surface)
- Sudden increase in training schedule or volume
- Tobacco use

GENERAL PREVENTION

- Appropriate warm-up and cool-down exercises
- Use proper equipment and footwear.
- Balance training programs improve proprioception and reduce the risk of

ankle sprains.
- Semirigid orthoses may prevent ankle sprains during high-risk sports, especially in athletes with history of sprain.
- Proprioception and strength training decrease injury risk; stretching does not.

COMMONLY ASSOCIATED CONDITIONS

- Effusions, hemarthrosis
- Stress, avulsion, or other fractures
- Syndesmotic injuries
- Contusions
- Dislocations/subluxations

DIAGNOSIS

HISTORY

- Obtain thorough description of mechanism of injury including activity, trauma, baseline conditioning, and prior musculoskeletal injuries.
- May describe feeling or hearing pop or snap

PHYSICAL EXAM

- Inspect for swelling, asymmetry, ecchymosis, and gait disturbance.
- Palpate for tenderness.
- Evaluate for decreased range of motion (ROM) of joint and joint instability/laxity.
- Evaluate for strength.
- Sprains
  - Grade 1: tenderness without laxity; minimal pain, swelling; little ecchymosis; can bear weight
  - Grade 2: tenderness with increased laxity on exam but firm end point; more pain, swelling; often ecchymosis; some difficulty bearing weight
  - Grade 3: tenderness with increased laxity on exam and no firm end point; severe pain, swelling; obvious ecchymosis; difficulty bearing weight

DIFFERENTIAL DIAGNOSIS

- Tendonitis

- Bursitis
- Contusion
- Hematoma
- Fracture
- Osteochondral lesion
- Rheumatologic process

DIAGNOSTIC TESTS & INTERPRETATION

- Ankle
  - Anterior drawer test assesses integrity of anterior talofibular ligament.
  - Talar tilt test assesses integrity of calcaneofibular ligament.
  - Squeeze test assesses for syndesmotic injury.
  - Palpate lateral and medial malleoli.
- Knee
  - Lachman and anterior drawer tests assess integrity of anterior cruciate ligament. Posterior drawer assesses integrity of posterior cruciate ligament.
  - Valgus/varus stress tests assess integrity of medial and lateral collateral ligaments, respectively.
- Shoulder
  - Positive apprehension test may indicate glenohumeral ligament sprain.
- Radiographs help rule out bony injury; stress views may be necessary. Obtain bilateral radiographs in children to rule out growth plate injuries.
- Use Ottawa foot and ankle rules (age 18 to 55 years) to determine if radiographs are necessary.
- Ankle films: required if pain in the malleolar zone *and*
  - Bone tenderness in posterior aspect distal 6 cm of tibia *or* fibula *or*
  - Unable to bear weight immediately or in emergency department
- Foot films: required if midfoot zone pain is present *and*
  - Bone tenderness at base of 5th metatarsal *or*
  - Bone tenderness at navicular *or*
  - Inability to bear weight immediately or in emergency department

Follow-Up Tests & Special Considerations

- CT scan if occult fracture is suspected
- MRI is the gold standard for imaging soft tissue structures, including muscle,

ligaments, and intra-articular structures. If tibiofibular syndesmotic disruption is suspected, MRI is highly accurate for diagnosis.

Diagnostic Procedures/Other

Surgery may be required for some partial and complete sprains depending on location, mechanism, and chronicity.

TREATMENT

GENERAL MEASURES

- Acute: *p*rotection, relative *r*est (activity modification), *i*ce, *c*ompression, *e*levation, *m*edications, *m*odalities (PRICEMM) therapy
- Ankle sprains: Compression stockings didn't affect pain, swelling, or time to pain-free walking but did show decreased time to return to sport (1)[B].
- Grade 1, 2 ankle sprain: functional treatment with brace, orthosis, taping, elastic bandage wrap
  - Ankle braces (lace-up, stirrup-type, air cast) are a more effective functional treatment than elastic bandages or taping (2)[A].
- Grade 3 ankle sprain: Short period of immobilization may be needed.
- Refer for early physical therapy.
- For high-level athletes with more extensive damage (e.g., biceps or pectoralis disruption), consider surgical referral.

MEDICATION

First Line

- Acetaminophen: not to exceed 3 g/day
- NSAIDs
  - Ibuprofen: 200 to 800 mg TID
  - Naproxen: 250 to 500 mg BID
  - Diclofenac: 75 mg BID
- Opioids may be needed acutely for severe pain.
- Acetaminophen and NSAIDs have similar efficacy in reducing pain after soft tissue injuries with less GI side effects; NSAIDs are better than narcotics.
- Topical diclofenac, ibuprofen, ketoprofen are effective for pain related to

strains and sprains, especially in gel form or patch (3)[A].

- Platelet-rich plasma injections may aid recovery in treatment of muscle strains, but more studies are needed.

ISSUES FOR REFERRAL

- ACL sprain in athletes/physically active
- Salter-Harris physeal fractures
- Joint instability especially chronic
- Tendon disruption (i.e., Achilles, biceps, ACL)
- Lack of improvement with conservative measures

ADDITIONAL THERAPIES

- Physical therapy is a useful adjunct after a sprain, particularly if early mobilization is crucial.
  - Proprioception retraining
  - Core strengthening
  - Eccentric exercises
  - Thera-Band exercises
- After hamstring strain, frequent daily stretching and progressive agility and trunk stabilization exercises may speed recovery and reduce risk of reinjury (4)[A]. Rehab protocols emphasizing eccentric/lengthening exercises are more effective than conventional exercises (5)[B].

SURGERY/OTHER PROCEDURES

- Casting and surgery are reserved for select partial and complete sprains. Need for surgery depends on the neurovascular supply to the injured area as well as the ability to attain full ROM and stability of the affected joint. The need for surgery also depends on activity level and patient preference.
- For primary management of acute lateral ankle sprains, there is no difference between surgical versus conservative therapy. Risks are increased with surgical intervention.
- Chronic ankle instability affects 10–20% of people who sustain an acute sprain. If conservative management fails and laxity is present, surgery is considered (6)[A].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

If the affected joint has full strength and ROM, the patient can advance activity as tolerated using pain as a guide for return to activity.

Patient Monitoring

After initial treatment, consider early rehabilitation. Limit swelling and work on increasing ROM.

DIET

Weight loss if obese

PATIENT EDUCATION

- Injury prevention through proprioceptive training and physical therapy
- ROM and strengthening exercises to restore functional capacity

PROGNOSIS

Favorable with appropriate treatment and rest. Duration of recovery depends on the severity of injury.

COMPLICATIONS

- Chronic joint instability
- Arthritis
- Muscle contracture

Tendinopathy

CODES

ICD10

- S93.409A Sprain of unsp ligament of unspecified ankle, init encntr
- S96.919A Strain of unsp msl/tnd at ank/ft level, unsp foot, init
- S43.50XA Sprain of unspecified acromioclavicular joint, initial encounter

CLINICAL PEARLS

For acute injury, remember PRICEMM:

- Protection of the joint

- Relative rest (activity modification)
- Apply ice
- Apply compression
- Elevate joint
- Medications for pain
- Other modalities as needed
- Wean out of brace as tolerated to strengthen stabilizing muscles.

SQUAMOUS CELL CARCINOMA, CUTANEOUS

Mercedes E. Gonzalez, MD, FAAD • Herbert P. Goodheart, MD

BASICS

- Squamous cell carcinoma (SCC) is a malignant epithelial tumor arising from epidermal keratinocytes. Cutaneous (nonmucous membrane) SCC is the second most common form of skin cancer.
- Lesions most frequently occur on sun-exposed sites of elderly, fair-skinned individuals. Most SCCs arise in actinic keratoses (*solar keratoses*). SCCs that develop from actinic keratoses are slow-growing, minimally invasive, and unaggressive. Thus, the prognosis of an SCC arising from an actinic keratosis is usually excellent because distant metastases are extremely rare.
- An SCC may also appear de novo without a preceding actinic keratosis or emerge from a preexisting human papillomavirus (HPV) infection (*verrucous carcinoma*).
- SCCs may develop from causes other than sun exposure such as within an old burn scar or on sites previously exposed to ionizing radiation.
- Metastases are more likely to occur in thicker tumors >6-mm deep (1). Other risk factors for metastases include lesions that arise on the ears, the vermilion border of the lips, or on mucous membranes. An SCC located on sites that received ionizing radiation on the skin of organ transplant recipients, in chronic inflammatory lesions (e.g., discoid lupus erythematosus), in long-standing scars or cutaneous ulcers (e.g., venous stasis ulcers), or other nonhealing wounds, also have an increased rate of metastasis.
- System(s) affected: skin/exocrine
- Synonym(s): squamous cell carcinoma of the skin; epidermoid carcinoma; prickle cell carcinoma

EPIDEMIOLOGY

- Predominant age: elderly population
- Predominant sex: males > females

- In the United States, >700,000 new cases each year

Incidence

- The escalating incidence in the United States is due to an increase in sun exposure in the general population, aging of the population, earlier and more frequent diagnosis of SCC, and the increase of immunosuppressed patients.
- The incidence is highest in Australia and in the Sun Belt of the United States.

ALERT

Bowen disease (SCC in situ) and frank SCC are two of the few skin cancers that should be considered in African Americans. Such non–sun-related SCCs tend to arise on the extremities de novo, in an old scar, or in a lesion of discoid lupus erythematosus.

ETIOLOGY AND PATHOPHYSIOLOGY

- Exact mechanisms are not established; however, SCC is thought to arise from a multistep process that begins with a single mutated keratinocyte.
- UV radiation damages skin cell nucleic acids (DNA), resulting in a mutant clone of the tumor suppressor gene, *p53*. This leads to an uncontrolled growth of skin cells containing a mutated *p53* gene. Additional mutations in genes controlling cellular proliferation and/or death lead to squamous cell dysplasia, which then progresses to SCC in situ and later invasive SCC that has the potential for metastasis.
- Cumulative UV radiation (including tanning salons, and psoralen-UV-A [PUVA] phototherapy) over a lifetime is the major etiologic factor in SCC (2) [A].
- A high prevalence of HPV DNA from SCC tissue has been noted in immunocompromised as well as immunocompetent specimens of SCC tissue (3).
- Other causative agents: ionizing radiation exposure, inorganic arsenic exposure, coal tar, and other oil derivatives
- Immunosuppression by medications or disease such as HIV/AIDS

Genetics

- Persons of Irish or Scottish ancestry have the highest prevalence of SCC.
- Caucasians with the red hair/fair skin phenotype (associated with certain

variant alleles of the human melanocortin-1 receptor [MC1R]) are predisposed to SCC.
- SCC is rare in people of African and Asian descent, although it is the most common form of skin cancer in these populations.

RISK FACTORS

- Older age
- Male sex: However, incidence is increasing in females due to lifestyle changes (e.g., suntan parlors, shorter dresses).
- Chronic sun exposure: SCC is noted more frequently in those with a greater degree of outdoor activity (e.g., farmers, sailors, gardeners).
- Patients with multiple actinic keratoses
- Personal or family history of skin cancer
- Northern European descent
- Fair complexion, fair hair, light eyes
- Poor tanning ability, with tendency to burn
- Organ transplant recipients, chronic immunosuppression
- Exposure to chemical carcinogens (e.g., arsenic, tar) or ionizing radiation
- Smoking (4)
- Therapeutic UV and ionizing radiation exposure
- Defects in cell-mediated immunity related to lymphoproliferative disorders (chronic lymphocytic leukemia [CLL], lymphoma)
- HPV infection
- Chronic scarring and inflammatory conditions
- Specific genodermatoses (e.g., xeroderma pigmentosum, oculocutaneous albinism, and dystrophic epidermolysis bullosa)

GENERAL PREVENTION

Sun-avoidance measures: sunscreens, hats, clothing, and sunglasses with UV protection; tinted windshields and side windows in cars; sun-protective garments

COMMONLY ASSOCIATED CONDITIONS

- Some investigators consider an actinic keratosis to be an early SCC, although relatively few ultimately are found to develop into an SCC.
- Actinic cheilitis and leukoplakia of the mucous membranes of the lips

- Cutaneous horn (see following discussion)
- Xeroderma pigmentosum albinism
- Immunosuppression
- Chronic skin ulcers, preexisting scars, burns

DIAGNOSIS

PHYSICAL EXAM

Lesions occur chiefly on chronically sun-exposed areas.

- Face and backs of the forearms and hands
- Bald areas of the scalp and top of ears in men
- The sun-exposed “V” of the neck as well as the posterior neck below the occipital hairline
- In elderly females, lesions tend to occur on the legs and other sun-exposed locations.
- In African Americans, equal frequency in sun-exposed and unexposed areas
- Clinical appearance
  - Generally slow-growing, firm, hyperkeratotic papules, nodules, or plaques
  - Most SCCs are asymptomatic, although bleeding, pain, and tenderness may be noted.
  - Lesions may have a smooth, verrucous, or papillomatous surface.
  - Varying degrees of ulceration, erosion, crust, or scale
  - Color is often red to brown, tan, or pearly (indistinguishable from basal cell carcinoma).
- Clinical variants of SCC
  - Bowen disease (SCC in situ): solitary lesion that resembles a scaly psoriatic plaque
  - Invasive SCC: often a raised, firm papule, nodule, or plaque. Lesions may be smooth, verrucous, or papillomatous, with varying degrees of ulceration, erosion, crust, or scale.
  - Cutaneous horn: SCC with an overlying cutaneous horn. A cutaneous horn represents a thick, hard, fingernail-like keratinization produced by the SCC. Bowen disease may also produce a cutaneous horn on its surface.
  - Erythroplasia of Queyrat refers to Bowen disease of the glans penis, which

manifests as one or more velvety red plaques.
  - Subungual SCC appear as hyperkeratotic lesions under the nail plate or on surrounding periungual skin, often mimicking warts (5).
  - Marjolin ulcer: an SCC evolving from a new area of ulceration or elevation at site of a scar or ulcer
  - HPV-associated SCC: virally induced. An SCC most commonly seen as a new or enlarging warty growth on penis, vulva, perianal area, or periungual region
  - Verrucous carcinoma: subtype of SCC that is extremely well differentiated, can be locally destructive, but rarely metastasizes. Lesions are "cauliflower-like" verrucous nodules or plaques.
  - Basaloid SCC: less common than typical SCC; seen more often in men aged 40 to 70 years

ALERT

Subungual SCC: Such lesions typically mimic warts.

DIFFERENTIAL DIAGNOSIS

- Actinic keratosis: Early SCC lesions may be clinically difficult, if not impossible, to distinguish from a precursor actinic keratosis.
- Basal cell carcinoma may be indistinguishable from an SCC, particularly if the lesion is ulcerated.
- Keratoacanthoma: This lesion also may be clinically and histopathologically impossible to differentiate from an SCC; it is considered by some to be a low-grade variant of an SCC.
- Verruca vulgaris: The appearance of common warts is often similar to that of SCC lesions.
- Seborrheic keratosis
- Pyoderma gangrenosum
- Venous stasis ulcer
- Chemical or thermal burn

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Surgical biopsy to ensure diagnosis: shave, punch, excisional, or incisional

biopsy

- Sentinel lymph node biopsy rarely is used to identify micrometastases in patients with high-risk SCC and clinically negative nodes. Whether the early detection of lymph node metastasis leads to enhanced survival in SCC is unknown.
- Patients with lymphadenopathy should be evaluated for metastases with CT scanning, MRI, US, or PET.

Test Interpretation

- Noninvasive SCC is characterized by an intraepidermal proliferation of atypical keratinocytes. Hyperkeratosis, acanthosis, and confluent parakeratosis are seen within the epidermis. Cellular atypia, including pleomorphism, hyperchromatic nuclei, and mitoses are prominent. Atypical keratinocytes may be found in the basal layer and often extend deeply down the hair follicles, but they do not invade the dermis.
- In the in situ type of SCC (Bowen disease), atypia involves the full thickness of the epidermis, but the basement membrane remains intact.
- An invasive SCC penetrates through the basement membrane into the dermis. It has various levels of anaplasia and may manifest relatively few to multiple mitoses and display varying degrees of differentiation, such as keratinization.
- Poorly differentiated tumors are clinically more aggressive. SCCs proliferate first by local invasion. Metastases, when they do occur, spread via local lymph ducts to local lymph nodes.

ALERT

Melanoma: An amelanotic melanoma and ulcerated melanoma may also be impossible to distinguish from an SCC.

TREATMENT

MEDICATION

First Line

- Total excision: preferred method for SCCs, permitting histologic diagnosis of the tumor margins

- Electrodesiccation and curettage (ED&C)
  - Best for small lesions (generally <1 cm) on flat surfaces (e.g., forehead, cheek) and SCC in situ (Bowen disease). ED&C may be used to treat superficially invasive SCCs that lack high-risk characteristics, but it is not appropriate for certain high-risk anatomic locations.
- Cryosurgery with LN_2 in selected lesions, such as SCC in situ
- Micrographic (Mohs) surgery is a microscopically controlled method of removing skin cancers that allows for controlled excision and maximum preservation of normal tissue. It has the highest cure rate (94–99%) of all surgical treatments. Mohs surgery may be indicated for the following:
  - Large, recurrent or invasive SCCs (e.g., to bone or cartilage)
  - Lesions with a poorly delineated clinical border
  - Locations where preservation of normal tissue is extremely important (e.g., tip of the nose, eyelids, ala nasi, ears, lips, and glans penis)
- Radiation therapy is a primary treatment option that is generally restricted to older patients who are physically debilitated or are unable to undergo or refuse to undergo excisional surgery.

Second Line

- Immunotherapy with topical imiquimod (Aldara) 5% cream has been successfully used for the treatment of SCC in situ (Bowen disease), actinic keratoses, genital warts, and superficial basal cell carcinomas (6)[A].
- Topical chemotherapy: topical formulations of 5-fluorouracil (5-FU) (6)[A]
- Intralesional 5-FU and bleomycin has also been used successfully to treat SCCs.
- Photodynamic therapy (PDT): PDT involves application of a photosensitizer (given topically or systemically) followed by exposure to a light source. Used primarily to treat large numbers of solar keratoses and is not recommended for treatment of invasive SCCs.
- In patients with multiple or recurrent SCCs, or those at high risk, such as organ transplant recipients, chemoprevention with systemic retinoids, such as acitretin, may be effective for reducing the number of new SCCs, treating existing SCCs, and reducing the risk of recurrence.

ADDITIONAL THERAPIES

For metastatic SCC, oral 5-FU has been used alone or in combination with SC interferon. More recently, epidermal growth factor receptor (EGFR) inhibitors, such as cetuximab (7)[C], are used in combination with systemic chemotherapy for metastatic disease.

SURGERY/OTHER PROCEDURES

- Complete lymphadenectomy of the draining nodal basin for high-risk tumors
- Metastatic disease requires aggressive management by a multidisciplinary team, involving plastic, ENT/maxillofacial, general, and onchologic surgeons.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Skin exam every month for 3 months, 6 months after treatment, and then yearly

PATIENT EDUCATION

Skin self-exam: Encourage sun-avoidance techniques, protective clothing, sunscreens, and so forth. Artificial tanning devices should be avoided.

PROGNOSIS

- For low-risk SCCs: a 90–95% cure rate with appropriate treatment
- Overall, head and neck lesions have better prognosis; however, lip and ear lesions metastasize more frequently when compared with other sites.
- The ability to produce scale (*keratinization*) indicates a tendency for a lesion to be more differentiated and less likely to metastasize.
- Softer, nonkeratinizing lesions are not as well differentiated and thus are more likely to spread.
- Lesions ≥2 cm are more likely to recur.
- SCCs that arise in areas of non–sun-exposed skin or have a greater tendency to metastasize
- An SCC arising on a mucous membrane or in a chronic ulcer should be regarded as potentially metastatic.
- Recurrence rate and mortality is greater in immunosuppressed patients, especially solid-organ transplant recipients.

- SCCs that are deeply invasive (≥6 mm in SC fat), or have perineural involvement, are more likely to metastasize.
- When SCC does metastasize, it usually occurs within several years from the time of diagnosis and involves draining lymph nodes.
- Once nodal metastasis of cutaneous SCC has occurred, the overall 5-year survival rate has historically been in the range of 25–35%.

COMPLICATIONS

- Untreated, an SCC becomes indurated, with a tendency to ooze, ulcerate, or bleed.
- Local recurrence
- Metastatic disease

CODES

ICD10

- C44.92 Squamous cell carcinoma of skin, unspecified
- C44.320 Squamous cell carcinoma of skin of unspecified parts of face
- C44.42 Squamous cell carcinoma of skin of scalp and neck

CLINICAL PEARLS

- SCCs that develop from actinic keratoses are generally unaggressive.
- Unlike most basal cell carcinomas, SCCs of the skin are associated with a risk of metastasis, especially those arising on mucous membranes, chronic ulcers, or in immunocompromised patients.
- A subungual SCC can easily be mistaken for a wart.

STRESS FRACTURE

Nandhini Veeraraghavan, MD, CAQSM, FAAFP

BASICS

DESCRIPTION

- Overuse injuries caused by cumulative microdamage from repetitive bone loading
- Stress fractures occur in different situations:
  - Fatigue fracture: abnormal stress applied to normal bone (e.g., young college athletes or new military recruits with increased physical activity demands and inadequate conditioning)
  - Insufficiency fracture: normal stress applied to structurally abnormal bone (e.g., femoral neck fracture in osteopenic bone)
  - Combination fracture: abnormal stress applied to abnormal bone (e.g., female long-distance runners with premature osteoporosis from female athletic triad)
- Weight-bearing bones of the lower extremity are most commonly affected at the following sites:
  - Tibia/fibula
  - Metatarsal bones
  - Navicular
  - Femoral neck
  - Pars interarticularis
- Less commonly affected sites:
  - Pelvis
  - Calcaneus
  - Ribs
  - Ulna
- High-risk stress fractures occur in zones of tension or areas with poor blood supply and are more likely to result in fracture displacement and/or nonunion. High-risk sites include the following:
  - Tension side of femoral neck

  - Anterior tibial diaphysis
  - Sesamoids
  - Pars interarticularis of lumbar spine (L4, L5)
  - 5th metatarsal at metaphyseal–diaphyseal junction
  - Proximal 2nd metatarsal
  - Medial malleolus
  - Tarsal navicular
  - Patella
  - Talar neck
- Synonym(s): march fracture; fatigue fracture

EPIDEMIOLOGY

Incidence

- Greatest incidence in 15- to 27-year-olds
- Females more commonly affected than males
- Affects 9–21% of track and field athletes annually
- Accounts for as many as 8% of visits to sports medicine and orthopedic clinics
- Occurs in <1% of general population

Prevalence

- Affects 5% of military recruits
- Affects 1–3% of college athletes

ETIOLOGY AND PATHOPHYSIOLOGY

- Bone is dynamic and constantly remodeling in response to applied physiologic stress.
- Repetitive loading or overuse causes microfractures that don’t heal due to imbalance between bone resorption and bone formation.
- If microdamage accumulates in excess of reparation, bony fatigue leads to stress fracture.

RISK FACTORS

- Intrinsic
  - Female athlete triad (low energy availability with or without disordered eating, menstrual dysfunction, and low bone mineral density)

  - History of previous stress fracture
  - History of osteoporosis, osteomalacia, rheumatoid arthritis, corticosteroid therapy
  - Skeletal malalignment: pes cavus, pes planus, leg length discrepancies, excessive forefoot varus, tarsal coalitions, prominent posterior calcaneal process, tight heel cords
  - Increased vertical loading rate (e.g., heel-to-toe running instead of forefoot striking)
  - Muscle fatigue and decreased lean muscle mass
  - Extremes of body size and composition
  - Previous inactivity or low aerobic fitness
- Extrinsic
  - Type of exercise—running, track and field, basketball, gymnastics, soccer, and dance are highest risk.
  - Rapid increase in mileage, running pace, or training volume
  - Inappropriate footwear
  - Hard training surface
  - Inadequate recovery or rest and training with fatigued muscle
- Tobacco use

GENERAL PREVENTION

- Avoid abrupt increases in physical activity (no more than 10% increase in load per week).
- Reduce intensity and duration of activity if new-onset pain.
- Proper footwear
- Increasing dynamic physical activity (jumping; plyometric training) increases bone density and resistance to mechanical stress.
- Decrease vertical loading rate either by switching to forefoot strike running or (if continuing with heel-to-toe strike) by using a heel pad insert.
- Shock-absorbing foot inserts may help.
- Increased calcium and vitamin D intake may reduce stress fractures in female runners and military recruits.

COMMONLY ASSOCIATED CONDITIONS

- Osteoporosis/osteopenia

- Female athlete triad
- Metabolic bone disorders

DIAGNOSIS

HISTORY

- Insidious onset of vague bony pain over period of weeks. Pain is typically worse with physical activity
- Rest initially relieves pain.
- If untreated, pain progresses and may occur earlier during training sessions or even at rest. Pain also becomes more localized.
- History of recent change in training intensity, alteration in training terrain, and/or footwear
- Assess dietary practices: energy availability, disordered eating, and weight fluctuations, calcium and vitamin D intake
- Assess menstrual history: menarche, oligomenorrhea, or amenorrhea.

PHYSICAL EXAM

- Height, weight, BMI, and any stigmata of disordered eating (cold extremities, hypercarotenemia, lanugo hair, calluses on back of fingers, poor oral hygiene, parotid gland hypertrophy, bradycardia, or orthostatic hypotension)
- Antalgic gait
- Point or percussion tenderness over injury site—a vibrating tuning fork over the fracture site may intensify pain.
- Swelling may be present.
- Specific tests:
  - Hop test for tibial stress fracture: with a stress fracture, the patient cannot hop on one leg 10 times; if able to perform test, consider shin splints (medial tibial stress syndrome).
  - Fulcrum test for femoral stress fracture: With patient seated, provoke pain by applying downward force on the distal femur while other hand uses the midthigh as fulcrum on femoral shaft (if clinical suspicion is high, defer or use only with extreme caution to avoid completing a femoral neck stress fracture).

  - Single-leg hyperextension (Stork) test for pars interarticularis fracture of lumbar spine: Stand on one leg and extend lumbar spine. Positive if painful on symptomatic side.
- Anatomic malalignment may be present (leg length discrepancy, pes planus/cavus).

DIFFERENTIAL DIAGNOSIS

- Shin splints (medial tibial stress syndrome—pain resolves with rest; stress fracture pain does not)
- Infection (osteomyelitis)
- Soft tissue injury (sprain, tendonitis, and periostitis)
- Compartment syndrome
- Bony fracture
- Neoplasm (osteoid osteoma)
- Entrapment syndromes
- Intermittent claudication

DIAGNOSTIC TESTS & INTERPRETATION

- None unless clinically indicated for suspected disease (e.g., female athlete triad, hyperparathyroidism, and vitamin D deficiency)
- Plain films:
  - First line in suspected stress fracture
  - Findings typically seen 2 to 8 weeks after pain onset
  - Sensitivity during early stages (1 to 2 weeks) may be as low as 10%.
  - May see periosteal callus, “gray cortex sign” (region of decreased cortical intensity), osteopenia, endosteal reaction, or ill-defined cortical margin
  - Severe cases may show discrete fracture.

Follow-Up Tests & Special Considerations

- MRI:
  - Gold standard for imaging stress fractures
  - Highly sensitive; more complete evaluation of exact anatomic location and extent of injury
- Bone scan:
  - Sensitive but nonspecific for stress fracture
  - Should not be used to assess healing

- CT scan:
  - Less sensitive than MRI or bone scan for early stress fractures but has an important role in evaluating occult fractures of foot, tibia, carpal scaphoid, and pars interarticularis
  - Can distinguish conditions (osteoid osteoma, malignancy, and osteomyelitis) that mimic stress fracture on bone scan
  - Bony detail provided by CT scan allows differentiation of complete versus incomplete fracture, especially if MRI is equivocal.
- US: not routinely used but may help to distinguish metatarsal stress fracture from other causes of metatarsalgia (e.g., Morton neuroma)
- Classification by radiographic grading (1)
- Grade I: normal x-ray, positive STIR short time inversion recovery (STIR) MRI
- Grade II: normal x-ray, positive STIR + positive T2-weighted MRI
- Grade III: discrete line or discrete periosteal reaction on x-ray, positive T1/T2-weighted MRI but with no definite cortical break
- Grade IV: fracture or periosteal reaction on x-ray, positive T1/T2-weighted fracture line.

TREATMENT

- Protection, rest, ice, compression, and elevation (PRICE) for acute pain and edema
- Decrease activity to the level of pain-free functioning.
- Consider temporarily immobilizing patients who have pain at rest or with gentle range of motion (ROM).
- If patients have pain with ambulation, use crutches with periodic walking trial to monitor readiness for nonaided (pain-free) ambulation.
- Pneumatic leg brace is effective in decreasing the return-to-play time for tibial shaft stress fracture.
- For low-risk stress fracture, slowly increase impact loading once ambulation and daily activities are pain free. Progression of activity depends on the individual and should be modified according to symptoms (2,3).
- High-risk fractures typically require immediate immobilization and a period

of non–weight-bearing. Many patients require early surgical intervention to avoid nonunion and facilitate earlier return to sport (4)[B].

- In bisphosphonate-associated femoral stress fracture, prophylactic nail fixation may avoid fracture completion, shorten hospital stay, and decrease subsequent morbidity (5)[C].

MEDICATION

First Line

- Calcium and vitamin D supplementation should be initiated when dietary intake is inadequate or deficiencies are found.
- Acetaminophen
- NSAIDs are beneficial for pain and inflammation but may adversely affect fracture healing and should, therefore, be used only sparingly.

ISSUES FOR REFERRAL

Orthopedic consultation for high-risk fractures, failure to improve with standard treatment, evidence of nonunion within 3 to 4 weeks, or inability to tolerate rehabilitation

ADDITIONAL THERAPIES

- Electrical stimulation may be an adjunct for delayed union and nonunion.
- Extracorporeal shock wave therapy (ESWT) and pulsed US may have potential benefit but require additional study.
- Physical therapy:
  - Correct training errors and inappropriate mechanics predisposing to stress fracture.
  - Strengthen surrounding musculature.
  - Encourage cross-training to maintain fitness.
  - Correct anatomic variations.
  - Antigravity treadmills

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Once the patient is pain free, low-impact training can start and be advanced

gently as tolerated.
- Once running has resumed, increase mileage slowly.

Patient Monitoring

Radiographs every 4 to 6 weeks to assess healing

PATIENT EDUCATION

- Gradually increase activity as long as pain free
- Rest and reevaluate if there is a recurrence of pain.
- Correct mechanical and training errors.
- Strengthen core muscles.

PROGNOSIS

- Young patients have a good prognosis.
- Older patients or those with metabolic bone disease often develop insufficiency fractures in other bones.
- Time to return to full activity:
  - Grade I: 3+ weeks
  - Grade II: 5+ weeks
  - Grade III: 11+ weeks
  - Grade IV: 14+ weeks

COMPLICATIONS

- Completion of fracture
- Delayed union
- Nonunion
- May require surgery with internal fixation

SEE ALSO

Algorithm: Foot Pain

CODES

ICD10

- M84.38XA Stress fracture, other site, initial encounter for fracture
- M84.369A Stress fracture, unsp tibia and fibula, init for fx
- M84.376A Stress fracture, unspecified foot, init encntr for fracture

CLINICAL PEARLS

- The diagnosis of stress fractures requires a high index of suspicion. X-rays are often negative initially.
- Identify and treat female athletic triad to prevent stress fractures.
- To help prevent stress fractures, gradually increase training volume and avoid sudden increases in high-impact activity or running mileage.
- High-risk fractures require immediate immobilization and non-weight bearing. Patients may also require early surgery.

STROKE, ACUTE

Scott A. Drummond, Jr., DO, DABR

BASICS

A cerebrovascular accident (CVA) is an infarction or hemorrhage in the brain.

DESCRIPTION

Stroke is the sudden onset of a focal neurologic deficit(s) resulting from either infarction or hemorrhage within the brain.

- Two broad categories: ischemic (thrombotic or embolic; 87%) and hemorrhagic (13%)
- Hemorrhage can be intracerebral or subarachnoid.
- System(s) affected: neurologic; vascular
- Synonym(s): CVA; cerebral infarct; brain attack
- Related terms: transient ischemic attack (TIA), a transient episode of neurologic dysfunction due to focal ischemia without permanent infarction on imaging (see topic "Transient Ischemic Attack (TIA)")

Pediatric Considerations

- Cardiac abnormalities (congenital heart disease, paradoxical embolism, rheumatic fever, bacterial endocarditis)
- Metabolic: homocystinuria, Fabry disease

EPIDEMIOLOGY

Incidence

Annual incidence in the United States is ~795,000.

Prevalence

- Prevalence in the United States: 550/100,000
- Predominant age: Risk increases >45 years of age and is highest during the 7th and 8th decades.
- Predominant sex: male > female at younger age, but higher incidence in women with age ≥75 years

ETIOLOGY AND PATHOPHYSIOLOGY

- 87% of stroke is ischemic, three main subtypes for etiology: thrombosis, embolism, and systemic hypoperfusion. Large vessel atherothrombotic strokes are commonly related to the origin of the internal carotid artery. Small vessel lacunar strokes are commonly due to lipohyalinotic occlusion. Embolic strokes are largely from a cardiac source (due to left atrial thrombus, atrial fibrillation, recent MI, valve disease, or mechanical valves) or ascending aortic atheromatous disease (>4 mm).
- 13% of stroke is hemorrhagic; most commonly due to HTN. Other causes include intracranial vascular malformations (cavernous angiomas, AVMs), cerebral amyloid angiopathy (lobar hemorrhages in elderly), and anticoagulation.
- Other causes include fibromuscular dysplasia (rare), vasculitis, or drug use (cocaine, amphetamines).

Genetics

Stroke is a polygenic multifactorial disease, with some clustering within families.

RISK FACTORS

- Uncontrollable: age, gender, race, family history/genetics, prior stroke or TIA
- Controllable/modifiable/treatable
  - Metabolic: diabetes, dyslipidemia
  - Lifestyle: smoking, cocaine use, amphetamine use
  - Cardiovascular: hypertension, atrial fibrillation, valvular heart disease, endocarditis, recent MI, severe carotid artery stenosis, hypercoagulable states, and patent foramen ovale

GENERAL PREVENTION

Smoking cessation, regular exercise, weight control to maintain nonobese BMI and prevent type 2 diabetes, use alcohol in moderation, control BP, and manage hyperlipidemia; use of antiplatelet agent such as aspirin, in high-risk persons; treatment of nonvalvular atrial fibrillation with dose-adjusted warfarin or dabigatran, apixaban, and rivaroxaban

COMMONLY ASSOCIATED CONDITIONS

Coronary artery disease is the major cause of death during the first 5 years after a stroke.

DIAGNOSIS

HISTORY

Acute onset of focal arm/leg weakness, facial weakness, difficulty with speech or swallowing, vertigo, visual disturbances, diminished consciousness; presence of vomiting and severe headache favor diagnosis of hemorrhagic stroke.

PHYSICAL EXAM

- Assess airway, breathing, and circulation (ABC).
- Anterior (carotid) circulation: hemiparesis/hemiplegia, neglect, aphasia, visual field defects
- Posterior (vertebrobasilar) circulation: diplopia, vertigo, gait and limb ataxia, facial paresis, Horner syndrome, dysphagia, dysarthria, alternating sensory loss

DIFFERENTIAL DIAGNOSIS

- Migraine (complicated)
- Postictal state (Todd paralysis)
- Systemic infection, including meningitis or encephalitis (infection also may uncover or enhance previous deficits)
- Toxic or metabolic disturbance (hypoglycemia, acute renal failure, liver failure, drug intoxication)
- Brain tumor, primary or metastases
- Head trauma, encephalopathy
- Other types of intracranial hemorrhage (epidural, subdural, subarachnoid)
- Trauma, septic emboli

DIAGNOSTIC TESTS & INTERPRETATION

Primarily used to narrow differential and identify etiology of stroke

Initial Tests (lab, imaging)

- Serum glucose level, including fingerstick testing (REQUIRED to exclude hypo- and hyperglycemia) (1)

- ECG
- CBC, including platelets
- Electrolytes, including BUN and creatinine
- Coagulation studies: PT, PTT, INR
- Markers of cardiac ischemia
- Emergent brain imaging with noncontrast CT (or brain MRI with diffusion weighted [DW-MRI]) to exclude hemorrhage can be lifesaving (1)[A].
- Subsequent multimodal CT (perfusion CT, CTA, unenhanced CT) or MRI to improve diagnosis of acute ischemic stroke

Follow-Up Tests & Special Considerations

Consider LFT, tox screen, blood alcohol, ABG, lumbar puncture if suspected subarachnoid hemorrhage (SAH), EEG if suspect seizures, blood type and cross.

- DW-MRI is more sensitive than CT for acute ischemic stroke, and MRI is also better than CT for diagnosis of posterior fossa lesions (2)[B].
- Emergent treatment (IV thrombolysis) should NOT be delayed to obtain advanced imaging studies. Generally, if symptomatic, an unenhanced brain CT is emergently performed to exclude hemorrhage, and thrombolytics are initiated immediately, unless contraindicated. A confirmatory MRI is not required in most cases, nor is the inherent delay in obtaining one recommended.
- Follow-up imaging of carotid vessels with Doppler ultrasound, CTA, or MRA of head and neck should be completed once treatment is initiated.
- Goal is therapy initiation within 60 minutes of presentation and initial examination.

Diagnostic Procedures/Other

Echocardiogram (transthoracic and/or transesophageal) in patients with increased suspicion for cardioembolic source. In cryptogenic stroke patients, prolonged ECG monitoring should be performed with a 30-day event monitor.

Test Interpretation

Early CT findings for ischemia: hyperdense MCA sign (increased attenuation of proximal portion of the MCA; is associated with thrombosis of MCA), loss of gray-white matter differentiation, sulcal effacement, loss of insular ribbon

TREATMENT

- BP closely monitored in the first 24 hours (1)[A]
  - Antihypertensives should be withheld unless systolic BP >220 mm Hg or diastolic BP >120 mm Hg, with a goal to lower BP by ~15% during first 24 hours if treatment is indicated. If thrombolytic therapy is to be initiated, BP must be <185/110 mm Hg prior to thrombolytics.
  - In acute spontaneous intracranial hemorrhagic stroke, goal for BP control is 160/90 mm Hg or target MAP 110 (see topic "Subarachnoid Hemorrhage" for details on BP management). With suspicion for elevated ICP, BP should be reduced with goal to keep cerebral perfusion pressure between 61 mm Hg and 80 mm Hg.
  - Antihypertensive medications should be restarted 24 hours after stroke onset for patients with a history of hypertension who are neurologically stable.

ALERT

Thrombolysis: IV thrombolysis should be discussed in eligible patients with measurable neurologic deficits that do not clear spontaneously, presenting within 3 to 4.5 hours of stroke symptom onset. Potential benefits are significant, but there are serious harms possible as well. Individualized discussion advised.

- Exclusion criteria for thrombolysis within 3 hours of onset include:
  - Symptoms suggestive of SAH
  - Head trauma or prior stroke within 3 months
  - MI within 3 months
  - GI or gastric ulcer hemorrhage within 21 days
  - Major surgery within 14 days
  - Arterial puncture at noncompressible site within 7 days
  - Any history of intracranial hemorrhage
  - Elevated BP (systolic >185 mm Hg and diastolic >110 mm Hg)
  - Active bleeding or acute trauma on examination
  - Taking anticoagulant and INR ≥1.7
  - Activated PTT not in normal range if heparin received during previous 48

hours; platelet count <100,000 mm^3
  - Blood glucose concentration <50 mg/dL
  - Seizure with postictal residual neurologic impairment
  - Multilobar infarction on CT (hypodensity >1/3 cerebral hemisphere)
  - Patient or family members not able to weigh and understand potential harms and benefits of treatment
- Extended exclusion criteria for thrombolysis within 4.5 hours include per AHA/ASA guidelines:
  - Age >80 years
  - All patients taking oral anticoagulants regardless of INR
  - National Institute of Health (NIH) Stroke Scale >25
  - History of stroke and diabetes
- Antiplatelet agents: Oral aspirin (initial dose, 325 mg) should be started within 24 to 48 hours (1)[A].

MEDICATION

First Line

- BP management (parameters under "Treatment") options include:
  - Labetalol 10 to 20 mg IV over 1 to 2 minutes, which may be repeated once
  - Nicardipine infusion 5 mg/hr, titrate up by 2.5 mg/hr at 5- to 15-minute intervals to maximum of 15 mg/hr; reduce to 3 mg/hr when target BP is reached
- Thrombolysis, IV administration of rtPA: Infuse 0.9 mg/kg, maximum dose 90 mg over 60 minutes with 10% of dose given as bolus over 1 minute.
  - Admit to ICU or stroke unit, with neurologic exams every 15 minutes during infusion, every 60 minutes for next 6 hours, then hourly until 24 hours after treatment.
  - Discontinue infusion and obtain emergent CT scan if severe headache, angioedema, acute hypertension, or nausea and vomiting develop.
  - Measure BP every 15 minutes for first 2 hours, every 30 minutes for next 6 hours, then every hour until 24 hours after treatment. Maintain BP <185/105. Follow-up CT at 24 hours before starting anticoagulants or antiplatelet agents.
- Antiplatelet: aspirin 325 mg/day within 48 hours or 24 to 48 hours after

thrombolytic therapy (1)[A]

Second Line

Carotid endarterectomy (CEA) for carotid artery stenosis rarely is indicated emergently. CEA is indicated for stenosis >70% ipsilateral to TIA or incomplete stroke lesion and may be indicated for 50–69% stenosis in carefully selected patients, depending on risk factors, and skill and experience of surgeons.

ISSUES FOR REFERRAL

Follow-up with neurologist 1 week after discharge, with subsequent follow-up based on individual circumstances

ADDITIONAL THERAPIES

- Prophylactic antibiotics are *not* recommended.
- Deep vein thrombosis (DVT) prophylaxis should be instituted for immobilized patients.
- Corticosteroids are *not* recommended for cerebral brain edema.
- Statin use should be continued without interruption following acute stroke (1) [B].
- At discharge, patient should be referred for physical therapy, occupational therapy, and speech therapy, as necessary.

SURGERY/OTHER PROCEDURES

- Ventricular drain may be placed for patients with acute hydrocephalus secondary to stroke (most commonly due to cerebellar stroke).
- Decompressive surgery is recommended for major cerebellar infarction; it should be considered for malignant middle cerebral artery infarction, especially if the patient is <60 years of age.
- Consider mechanical embolus removal with a cerebral infarction device in carefully selected patients, with evidence of potentially salvageable tissue on advanced imaging.

COMPLEMENTARY & ALTERNATIVE THERAPIES

Acupuncture starting within 30 days from stroke onset may improve neurologic functioning.

ADMISSION, INPATIENT, AND NURSING

CONSIDERATIONS

- Observe closely within first 24 hours for neurologic decline, particularly due to cerebral edema.
- Keep head of bed at least 30 degrees when elevated ICP is suspected. Patients with ischemic stroke may benefit from a horizontal bed position during the acute phase.
- Monitor cardiac rhythm for at least first 24 hours to identify any arrhythmias.
- Airway support and ventilatory assistance may be necessary due to diminished consciousness or bulbar involvement; supplemental oxygen should be reserved for hypoxic patients. Consider elective intubation for patients with malignant edema.
- Correct hypovolemia with normal saline.
- All patients should be kept NPO until a formal swallow evaluation has been performed; to reduce risk of aspiration pneumonia, maintain elevated head of bed to 30 degrees.
- Hypoglycemia can cause neurologic dysfunction; rapidly correct during initial evaluation.
- Hyperglycemia within first 24 hours after stroke is associated with poor functional outcomes and AHA/ASA guidelines: insulin treatment for patients with glucose levels >140 to 180 mg/dL (1)[C].
- In patients with ICH secondary to anticoagulant use, correction of an elevated INR is necessary with use of IV vitamin K and fresh frozen plasma or prothrombin concentrate complex. Factor VII infusion should be used in patients needing urgent surgical intervention (i.e., those with cerebellar hemorrhage who are neurologically deteriorating).
- DVT prophylaxis (1)[B]
- Maintain oxygen saturation >94% (1)[C].
- Early use of physical therapy and discharge planning for rehabilitation need and placement
- IV hydration with maintenance amounts of normal saline until swallowing status is assessed; monitor fluid balance closely.
- Regular neurologic exams more frequent in first 24 hours (every 1 to 2 hours)
- Fall precautions; frequent repositioning to prevent skin breakdown
- Discharge criteria: medically stable, adequate nutritional support, neurologic

status stable or improving

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Secondary prevention of stroke with aggressive management of risk factors
- Platelet inhibition using aspirin, clopidogrel, or aspirin plus extended-release dipyridamole (Aggrenox) based on physician and patient preference

Patient Monitoring

Follow-up every 3 months for 1st year, then annually.

DIET

Patients with impaired swallowing should receive nasogastric or percutaneous endoscopic gastrostomy feedings to maintain nutrition and hydration.

PATIENT EDUCATION

National Stroke Association (800-STROKES or http://www.stroke.org)

PROGNOSIS

Variable, depends on subtype and severity of stroke; NIH stroke scale may be used for prognosis.

COMPLICATIONS

- Acute: brain herniation, hemorrhagic transformation, MI, congestive heart failure, dysphagia, aspiration pneumonia, UTI, DVT, pulmonary embolism, malnutrition, pressure sores
- Chronic: falls, depression, dementia, orthopedic complications, contractures

CODES

ICD10

- I63.9 Cerebral infarction, unspecified
- I61.9 Nontraumatic intracerebral hemorrhage, unspecified
- I63.50 Cereb infrc due to unsp occls or stenos of unsp cereb artery

CLINICAL PEARLS

- Unless stroke is hemorrhagic or patient is undergoing thrombolysis, BP should not be lowered acutely to maintain perfusion of penumbra region.
- IV thrombolysis should be considered in eligible patients with neurologic deficits that do not clear spontaneously within 3 to 4.5 hours of symptom onset.
- DW-MRI is more sensitive than conventional CT for acute ischemic stroke. MRI is also better than CT for diagnosis of posterior fossa lesions.

SUBCONJUNCTIVAL HEMORRHAGE

Cara Marshall, MD

BASICS

DESCRIPTION

- Subconjunctival hemorrhage (SCH) is bleeding from small blood vessels underneath the conjunctiva, the thin clear skin covering the sclera of the eye.
- SCH is diagnosed clinically:
  - Flat, well-demarcated areas of extravasated blood can be seen just under the surface of the conjunctiva of the eye (red patch of blood sign).
  - SCH is more common in the inferior and temporal regions (1).
- Typically, SCH resolves spontaneously within 1 to 2 weeks.

EPIDEMIOLOGY

- Male = female; no gender predilection found
- Common; 3% rate of diagnosis in outpatient eye clinic (2)

Incidence

Incidence increases

- With increasing age
- In contact lenses wearers (5% of cases) (3)
- With systemic diseases such as diabetes, hypertension (HTN), and coagulation disorders
- During summer months, possibly due to trauma (2)

ETIOLOGY AND PATHOPHYSIOLOGY

- Direct trauma to the blood vessels of the conjunctiva from blunt or penetrating trauma
- Direct trauma to the conjunctiva from improper contact lens placement or improper cleaning
- Increased BP in the vessels of the conjunctiva from HTN or from the temporary increase in BP from a Valsalva type maneuver (e.g., vomiting)
- Damaged vessels from diabetes and atherosclerotic disease

- Increased bleeding tendencies from either thrombocytopenia or elevated prothrombin time (PT)/elevated international normalized ratio (INR) (4)
- Trauma to the eye
- Valsalva maneuvers causing sudden severe venous congestion such as coughing, sneezing, vomiting, straining, severe asthma or COPD exacerbation, weightlifting or childbirth/labor (1)
- HTN
- Atherosclerotic disease and diabetes
- Bleeding factors such as thrombocytopenia or elevated PT (from either disease or medication side effects)
- In patients age >60 years, HTN is the most common etiology.
- In patients age <40 years, trauma/Valsalva and contact lenses use are the most common etiologies.
- In patients age >40 years, conjunctivochalasis (redundant conjunctival folds) and presence of pinguecula are strongly associated (3).

RISK FACTORS

- Age
- Contact lenses wearer
- Systemic diseases
- Bleeding disorders (2)
- Recent cataract surgery

GENERAL PREVENTION

- Correct cleaning and maintenance of contact lenses.
- Protective eyewear in sports and hobbies
- Control of high BP
- Optimizing control of systemic diseases such as diabetes and atherosclerotic disease
- Control of PT/INR in patients on Coumadin therapy (5)

DIAGNOSIS

HISTORY

- Generally asymptomatic; usually the patient notices the redness in the mirror

or another person mentions it to the patient.
- There should be little to no pain involved (5)[C].
- Obtain history of trauma. SCH can occur 12 to 24 hours after orbital fracture (1).
- Obtain history of contact lenses usage or recent cataract, laser-assisted in situ keratomileusis (LASIK), or other ocular surgery (2)[C].
- Comprehensive past medical history to evaluate if at risk for systemic diseases or taking medications that might increase risk
- Obtain history for current systemic symptomatology.

PHYSICAL EXAM

- Evaluate BP to assess control (2)[C].
- Measure visual acuity; this should be normal in a simple SCH (5)[C].
- Verify that the pupils are equal and reactive to light and accommodation; this should be normal with an SCH (5)[C].
- There should be no discharge or exudate noted (5)[C].
- Look at sclera for a bright red demarcated patch.
  - Demarcated area is most often on inferior aspect of eye due to gravity (3)[C].
- If penetrating trauma is a consideration, do a gentle digital assessment of the integrity of the globe (4)[C].
- Slit-lamp exam should be performed if there is a history of trauma (1).

Geriatric Considerations

In older adults, the area of SCH will be more widespread across the sclera (3). Elastic and connective tissues are more fragile with age, and underlying conditions such as HTN and diabetes may contribute.

DIFFERENTIAL DIAGNOSIS

- Viral, bacterial, allergic, or chemical conjunctivitis (enterovirus and coxsackie virus most common) (1)[B]
- Foreign body to conjunctiva
- Penetrating trauma
- Acute angle glaucoma
- Iritis

- Recent ocular surgery
- Contact lenses induced
- Child abuse (particularly if bilateral in an infant or toddler) (1)
- May occur in newborns after vaginal delivery

DIAGNOSTIC TESTS & INTERPRETATION

- Typically no testing is indicated; SCH is a clinical diagnosis. If a foreign body is suspected, perform a fluorescein exam.
- Fluorescein exam of a patient with an SCH should show no uptake of staining (5)[C].
- If an orbital fracture is suspected, may obtain plain facial bone films or CT scan (4)[C]

Follow-Up Tests & Special Considerations

If history and physical exam suggest a bleeding etiology (5)[C]

- CBC
- PT/INR

ALERT

If a penetrating injury is suspected, may obtain a CT scan of the orbits but not an MRI (if object may be metal) (4)[C]

TREATMENT

GENERAL MEASURES

- Control BP.
- Control blood glucose.
- Control INR.
- Wear protective eyewear.

MEDICATION

No prescription medications are useful in treatment of SCH.

ISSUES FOR REFERRAL

- If a penetrating eye injury is suspected, send the patient to the emergency room for emergent ophthalmology consultation.

- If the patient complains of any decreased visual acuity or visual disturbances, refer to an ophthalmologist as soon as possible.
- If there is no resolution of SCH within 2 weeks, patient may need referral to an ophthalmologist.

ADDITIONAL THERAPIES

- Warm compresses
- Eye lubricants (5)[C]

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Follow up only if the area does not resolve within 2 weeks.
- If SCH recurs, then work up patient for systemic sources such as bleeding disorders (5)[C].

PATIENT EDUCATION

- Reassurance of the self-limited nature of the problem and typical time frame for resolution
- Education to return to clinic if the area does not heal or recurs
- Correct cleaning and maintenance of contact lenses

PROGNOSIS

Excellent

COMPLICATIONS

Rare

CODES

ICD10

- H11.30 Conjunctival hemorrhage, unspecified eye
- H11.31 Conjunctival hemorrhage, right eye
- H11.32 Conjunctival hemorrhage, left eye

CLINICAL PEARLS

- SCH is a clinical diagnosis. The condition is typically asymptomatic and will resolve spontaneously in 1 to 2 weeks.
- Always check BP in a patient with SCH, as HTN is a risk factor.
- Indications for immediate referral to an ophthalmologist are eye pain, change in vision, lack of pupil reactivity, and/or penetrating eye trauma.
- Reassurance and comfort measures are key.
- Contact lenses wearers should not wear contact lenses until the SCH resolves completely.

SUBSTANCE USE DISORDERS

S. Lindsey Clarke, MD, FAAFP

BASICS

DESCRIPTION

A substance use disorder manifests as any pattern of substance use causing significant physical, mental, or social dysfunction.

- Substances of abuse include the following:
  - Alcohol
  - Tobacco
  - Cannabinoids (marijuana)
  - Synthetic cannabinoids (Spice, K2, others); note: Increasingly, these are sold as liquid in eyedropper bottles for use with vaporizing devices (vape/hookah pens).
  - Prescription medications
    - CNS depressants (barbiturates, benzodiazepines, hypnotics)
    - Opioids and morphine derivatives (codeine, fentanyl, hydrocodone, hydromorphone, oxymorphone [Opana], meperidine, methadone, morphine, oxycodone)
    - Stimulants (amphetamines, methylphenidate)
    - Dextromethorphan
  - Stimulants (cocaine, amphetamines, methamphetamines, Khat)
  - Club drugs (MDMA [Ecstasy, Molly], PMMA [Superman], flunitrazepam, γ-hydroxybutyrate [GHB])
  - Opioids (heroin, opium, kratom, desomorphine [Krokodil])
  - Dissociative drugs (ketamine, phencyclidine [PCP])
  - Hallucinogens (lysergic acid diethylamide [LSD], salvia, ayahuasca, *N*,*N*-dimethyltrytamine [DMT])
  - Synthetic cathinones (bath salts, α-PVP [Flakka])
  - Inhalants (glue, paint thinners, nitrous oxide)
  - Anabolic steroids
- See also www.drugabuse.gov/drugs-abuse.

- System(s) affected: cardiovascular, endocrine/metabolic, CNS
- Synonym(s): drug abuse; drug dependence; substance abuse

Geriatric Considerations

- Alcohol is the most commonly abused substance, and abuse often goes unrecognized.
- Higher potential for drug interactions

Pregnancy Considerations

Substance abuse may cause fetal abnormalities, morbidity, and fetal or maternal death.

EPIDEMIOLOGY

Incidence

- Predominant age: 16 to 25 years
- Predominant sex: male > female

Prevalence

- 27 million (10.2%) Americans reported current illicit drug use in 2014.
- 9.4% for age 12 to 17 years; 22% for age 18 to 25 years
- One in five young adults currently use marijuana.

ETIOLOGY AND PATHOPHYSIOLOGY

Multifactorial, including genetic, environmental

Genetics

Substances of abuse affect dopamine, acetylcholine, γ-aminobutyric acid, norepinephrine, opioid, and serotonin receptors. Variant alleles may account for susceptibility to disorders.

RISK FACTORS

- Male gender, young adult
- Depression, anxiety
- Other substance use disorders
- Family history
- Peer or family use or approval
- Low socioeconomic status

- Unemployment
- Accessibility of substances of abuse
- Family dysfunction or trauma
- Antisocial personality disorder
- Academic problems, school dropout
- Criminal involvement

GENERAL PREVENTION

- Early identification and aggressive early intervention improve outcomes.
- Universal school-based interventions are modestly effective for preventing drug use among adolescents.

COMMONLY ASSOCIATED CONDITIONS

- Depression
- Personality disorders
- Bipolar affective disorder

ALERT

Prescription narcotic overdose is the leading cause of accidental death between the ages of 25 and 65 years in the United States; this correlates with increased prescribing of long-acting oxycodone (see http://www.cdc.gov/injury/wisqars/leading_causes_death.html).

DIAGNOSIS

Substance use disorder (*DSM-5* criteria): ≥2 of the following in past year, with severity based on number of criteria present:

- Missed work or school
- Use in hazardous situations
- Continued use despite social or personal problems
- Craving
- Tolerance (decreased response to effects of drug due to constant exposure)
- Withdrawal upon discontinuation
- Using more than intended
- Failed attempts to quit

- Increased time spent obtaining, using, or recovering from the substance
- Interference with important activities
- Continued use despite health problems

HISTORY

- History of infections (e.g., endocarditis, hepatitis B or C, TB, STI, or recurrent pneumonia)
- Social or behavioral problems, including chaotic relationships and/or employment
- Frequent visits to emergency department
- Criminal incarceration
- History of blackouts, insomnia, mood swings, chronic pain, repetitive trauma
- Anxiety, fatigue, depression, psychosis

PHYSICAL EXAM

- Abnormally dilated or constricted pupils
- Needle marks on skin
- Nasal septum perforation (with cocaine use)
- Cardiac dysrhythmias, pathologic murmurs
- Malnutrition with severe dependence

DIFFERENTIAL DIAGNOSIS

- Depression, anxiety, or other mental states
- Metabolic delirium (hypoxia, hypoglycemia, infection, thiamine deficiency, hypothyroidism, thyrotoxicosis)
- ADHD
- Medication toxicity

DIAGNOSTIC TESTS & INTERPRETATION

ALERT

Screening: a single question: “How many times in the past year have you used an illegal drug or used a prescription medication for nonmedical reasons?”: in primary care setting, resulted in sensitivity of 100% and specificity of ~75% (1)[B]

- CRAFFT questionnaire is superior to CAGE: cut down, annoyed by criticism,

guilty about drinking, eye-opener drinks for identifying alcohol use disorders in adolescents and young adults; sensitivity is 94% with ≥2 "yes" answers.
  - C: Have you ever ridden in a CAR driven by someone (including yourself) who was "high" or who had been using alcohol or drugs?
  - R: Do you ever use alcohol or drugs to RELAX, feel better about yourself, or fit in?
  - A: Do you ever use alcohol or drugs while you are ALONE?
  - F: Do you ever FORGET things you did while using alcohol or drugs?
  - F: Do your FAMILY or FRIENDS ever tell you that you should cut down on your drinking or drug use?
  - T: Have you gotten into TROUBLE while you were using alcohol or drugs?
- American Academy of Pediatrics also recommends the following brief screening tools for adolescents:
  - S2B1 (Screening to Brief Intervention)
  - BSTAD (Brief Screener for Tobacco, Alcohol, and Other Drugs)
- Blood alcohol concentration
- Urine drug screen (UDS) (order qualitative UDS, and if specific drug is in question, a quantitative analysis for specific drug; order confirmatory serum tests if you suspect false positive)
- Approximate detection limits
  - Alcohol: 6 to 10 hours
  - Amphetamines and variants: 2 to 3 days
  - Barbiturates: 2 to 10 days
  - Benzodiazepines: 1 to 6 weeks
  - Cocaine: 2 to 3 days
  - Heroin: 1 to 1.5 days
  - LSD, psilocybin: 8 hours
  - Marijuana: 1 day to 4 weeks
  - Methadone: 1 day to 1 week
  - Opioids: 1 to 3 days
  - PCP: 7 to 14 days
  - Anabolic steroids: oral, 3 weeks; injectable, 3 months; nandrolone, 9 months
- Liver transaminases

- HIV, hepatitis B and C screens
- Echocardiogram for endocarditis
- Head CT scan for seizure, delirium, trauma

TREATMENT

Determine substances abused early (may influence disposition).

GENERAL MEASURES

- Nonjudgmental, medically oriented attitude
- Motivational interviewing and brief interventions can overcome denial and promote change.
- Behavioral and cognitive therapy
- Community reinforcement
- Interventional counseling
- Self-help groups to aid recovery (Alcoholics Anonymous, other 12-step programs)
- Support groups for family (Al-Anon and Alateen)

MEDICATION

- Alcohol withdrawal: See "Alcohol Abuse and Dependence" and "Alcohol Withdrawal."
- Benzodiazepine or barbiturate withdrawal
  - Gradual taper preferable to abrupt discontinuation
  - Substitution of long-acting benzodiazepine (e.g., clonazepam) or phenobarbital
- Nicotine withdrawal: See "Tobacco Use and Smoking Cessation."
- Opioid dependence
  - Methadone: 15 to 40 mg/day PO; use restricted to inpatient settings and specially licensed clinics (2,3)[A]
  - Buprenorphine: 8 to 16 mg/day sublingually or as 6-month subdermal implant; may precipitate a more severe withdrawal if initiated too soon; use restricted to licensed clinics and certified physicians (3,4)[A]
  - Naltrexone: 50 mg PO daily, 100 mg PO every 2 days, or 150 mg PO every 3 days; must be opioid-free for 7 to 10 days

- Opioid withdrawal
  - Clonidine: 0.1 to 0.2 mg PO BID or TID for autonomic hyperactivity (5) [A]
- Stimulant withdrawal
  - No agent with clear benefit
  - Vaccine to treat cocaine addiction in development
  - Methylphenidate ER: titrated up to 54 mg/day PO might enhance abstinence in amphetamine-dependent patients
- Adjuncts to therapy
  - Use all medications in conjunction with psychosocial behavioral interventions.
  - Antiemetics, nonaddictive analgesics for opioid withdrawal
  - Nonhabituating antidepressants, mood stabilizers, anxiolytics, and hypnotics for comorbid mood and anxiety disorders and insomnia that persist after detoxification
- Contraindications
  - Buprenorphine in lactation
  - Naltrexone in pregnancy, liver disease
- Precautions: Clonidine can cause hypotension.
- Significant possible interactions
  - Buprenorphine and ketoconazole, erythromycin, or HIV protease inhibitors
  - Naltrexone and opioid medications (may precipitate or exacerbate withdrawal)

ISSUES FOR REFERRAL

- Consider addiction specialist, especially for opioid and polysubstance abuse.
- Maintenance therapy for opioid dependence (e.g., methadone) only in FDA-licensed clinics
- Psychiatrist for comorbid psychiatric disorders
- Social services

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Indications for inpatient detoxification
  - History of withdrawal symptoms (e.g., seizures)

  - Disorientation
  - Hallucinations or psychotic features
  - Threat of harm to self or others
  - Obstacles to close monitoring (follow-up)
  - Comorbid medical illness
  - Pregnancy
- For narcotic addiction and withdrawal
- Look for signs of severe infection (e.g., bacterial endocarditis).
- Maintenance until patient is taking fluids well by mouth
- Take frequent vital signs during withdrawal.
- Monitor for signs of drug use in the hospital.
- Discharge criteria
  - Detoxification complete
  - Rehabilitation plan in place

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Initially frequent visits to monitor for medical stability and adherence, then progressive follow-up intervals

Patient Monitoring

Verify patient's compliance with the substance abuse treatment program.

DIET

Patients often are malnourished.

PATIENT EDUCATION

- Substance Abuse and Mental Health Services Administration: http://www.samhsa.gov or 800-662-HELP (-4357) for information, treatment facility locator
- National Institute on Drug Abuse: http://www.drugabuse.gov/patients-families
- Alcoholics Anonymous: http://www.aa.org
- Narcotics Anonymous: http://www.na.org

PROGNOSIS

- Patients in treatment for longer periods (≥1 year) have higher success rates.
- Behavioral therapy and pharmacotherapy are most successful when used in combination.

COMPLICATIONS

- Serious harm to self and others: accidents, violence
- Overdoses resulting in seizures, arrhythmias, cardiac and respiratory arrest, coma, death
- Hepatitis, HIV, tuberculosis, syphilis
- Subacute bacterial endocarditis
- Malnutrition
- Social problems, including arrest
- Poor marital adjustment and violence
- Depression, schizophrenia
- Sexual assault (alcohol, flunitrazepam, GHB)

SEE ALSO

Alcohol Abuse and Dependence; Alcohol Withdrawal; Tobacco Use and Smoking Cessation

CODES

ICD10

- F19.10 Other psychoactive substance abuse, uncomplicated
- F10.10 Alcohol abuse, uncomplicated
- F12.10 Cannabis abuse, uncomplicated

CLINICAL PEARLS

- Substance use disorders are prevalent, serious, and often unrecognized in clinical practice. Comorbid psychiatric disorders are common.

- Substance abuse is distinguished by family, social, occupational, legal, or physical dysfunction that is caused by persistent use of the substance.
- Dependence is characterized by tolerance, withdrawal, compulsive use, and repeated overindulgence.
- Motivational interviewing, brief interventions, and a nonjudgmental attitude can help to promote a willingness to change behavior. Research shows the benefit of referring patients with alcohol dependence to an addiction specialist or treatment program.

SUICIDE

Irene Coletsos, MD • Harold J. Bursztajn, MD

BASICS

DESCRIPTION

Suicide and attempted suicide are significant causes of morbidity and mortality.

EPIDEMIOLOGY

- Predominant sex
  - Women *attempt* suicide 1.5 times more often than men. Men *complete* suicide 4 times more often than women. Men are more likely to choose a means with high lethality.
- Predominant age: adolescent (second leading cause of death in teenagers in the United States and the world. It is the 10th leading cause of death overall in the United States and the 15th leading cause of death in the world, per 2000–2016 CDC statistics [latest available]).
- Predominant race: 84% of people who complete suicides are white, non-Hispanic. Native Americans and Alaskan Native Americans have the next highest rate in the United States. Whites have twice the risk of suicide compared with African Americans.
- Marital status: single > divorced; widowed > married
- Worldwide, in of all countries, youths (ages 10 to 24 years) are the highest risk group.

Incidence

- In 2016, (based on latest available data from 2014) 10th leading cause of death in adults in the United States. Military service (not specifically active duty) is associated with increased risk. In 2009, 2010, 2012, and 2013, more soldiers died of suicide than in active duty, according to a congressional study and the National Center for Veterans.
- Worldwide, the 15th leading cause of death

RISK FACTORS

- “Human understanding is the most effective weapon against suicide. The greatest need is to deepen the awareness and sensitivity of people to their fellow man” (Shneidman, American Association of Suicidology).
- Be alert to a combination of “perturbation” (increased emotional disturbance) and “lethality” (having the potential tools to cause death).
- 80% who complete suicides had a previous attempt.
- 90% who complete suicide meet *Diagnostic and Statistical Manual* criteria for Axis I or II disorders: major depression, bipolar disorder, anorexia nervosa, panic disorder, borderline and antisocial personality disorders. Schizophrenia and acute onset of psychosis are also risk factors due to command hallucinations or even the negative affect or hopelessness that can accompany these states.
- Substance use (alcohol, hallucinogens, opioids)
- Family history of suicide
- Physical illness
- Despair: feeling unendurable emotional pain *and* has “given up” on self, feels without hope, and, consciously or unconsciously, unworthy of help
- Among teenagers: not feeling “connected” to their peers or family; being bullied; poor grades
- Psychosocial: recent loss: What may seem to be a small loss (to a medical provider) may be a devastating loss to the patient. *Patient-specific* factors need to be taken into account: social isolation, anniversaries, and holidays. Patients who attempt suicide also seem to have impaired decision-making skills and risk awareness and increased impulsivity, compared with patients who have never attempted suicide (1).
- If a patient is incompetent (e.g., too delusional) to inform providers about the potential for suicide, that puts the patient at increased risk; consider hospitalization.
- Access to lethal means: firearms, poisons (including prescription and nonprescription drugs)

GENERAL PREVENTION

- Know how to access resources 24/7 within and outside of the health care institution.
- Screen for risk factors and consider the overall clinical picture. Screening

instruments include the Patient Health Questionnaire-2 (PHQ-2), the PHQ-9, the Columbia Suicide Severity Rating Scale, Beck's Scale for Suicidal Ideation, Linehan's Reasons for Living Inventory, and Risk Estimator for Suicide.

- Treat underlying mental illness and substance abuse. Screen for possession of means of harm, including prescription and nonprescription drugs and firearms (encourage these patients to remove guns from their homes and to relinquish gun licenses).
- Women being treated for cancer, chronic obstructive pulmonary disease (COPD), heart disease, osteoporosis, or stroke were found to be at higher risk for suicide (even without a history of depression; neurologic illnesses [such as migraine, epilepsy, stroke]).
- Create a safety plan for patients at risk for suicide and their families, including education about how to access emergency care 24 hours a day.
- Public education about how to help others access emergency psychiatric care. Suicidal people may first confide in those they trust outside health care (e.g., family members, religious leaders, community elders, "healers," hairdressers, and bartenders).
- For the military: multiple resources: www.realwarriors.net. Suggested treatments include cognitive restructuring techniques (that their experience with adversity can be a source of strength) and help with problem solving; (so the service member does not feel like a "burden") therapeutic martial arts training; focus on Vets' helping others: "Power of 1" initiative (any "one" helpful contact could save a life).
- For teens, young adults, and their educators: suggestions and advice for students/families and educators: www.cdc.gov/healthyyouth/adolescenthealth; http://www.stopbullying.gov
- In developing world countries, pesticide ingestion is a common method of suicide. Limiting free access has led to reduced suicide rates.

DIAGNOSIS

HISTORY

- Depressed patients should be asked about ideation and about a plan:

  - "Have you ever felt that life isn't worth living? Do you ever wish you could go to sleep and not wake up? Are you having thoughts about killing yourself?"
- Use psychodynamic formulation, which combines mental state exam (i.e., behavior, mood, mental content, judgment), past history (i.e., What resources has the patient used in the past for support and are they currently available?), and history of current illness. If the patient is experiencing a loss, is under stress, and does not have access to a previously sustaining resource (e.g., a significant other, a pet, sports ability, a job), that patient is under increased risk for suicide.
- Prior attempts: precipitants, lethality, intent to die, precautions taken to avoid being rescued, reaction to survival (a patient who is upset that the suicide was not completed is at increased risk)
- History of psychiatric symptoms, substance abuse. Also note strengths, such as reasons to live, hopes for future, social supports. A patient without these is at increased risk.
- Collateral history is important (from friends, family, physicians). It may be appropriate to break confidentiality if patient is at imminent risk of suicide.

PHYSICAL EXAM

- Medical conditions: delirium, intoxication, withdrawal, medication side effects
- Psychosis: Observe for signs of/ask about command auditory hallucinations to kill oneself, delusional guilt, and persecutory delusions.
- In adults: Observe for signs of hopelessness/despair (see "Risk Factors").
- In teens: Screen for risk factors: substance abuse, bullying and social isolation (both common via electronic media), poor grades because teens may not appear depressed.

DIFFERENTIAL DIAGNOSIS

Differentiate between patients and pseudopatients (i.e., those who are using suicide threats and gestures to manipulate others).

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other

Brief tests that could be part of any medical/mental health assessment:

- PHQ-9: http://www.med.umich.edu/1info/FHP/practiceguides/depress/phq-9.pdf
- Columbia Suicide Severity Rating Scale, clinical instructions accessed at: http://www.cssrs.columbia.edu/scales_practice_cssrs.html
- Suicide Trigger Scale version 3 (STS-3), which measures a patient's "ruminative flooding" (self-critical, repetitive thoughts) and "frantic hopelessness" (feeling trapped, suicide is the only choice): http://www.ncbi.nlm.nih.gov/pmc/articles/PMC3443232/

TREATMENT

GENERAL MEASURES

- Patients expressing active suicidal thoughts or who made an attempt require immediate evaluation for risk factors, mental status, and capacity (to determine if they are able/or willing to inform treaters about suicidal intentions) as well as a formal psychiatric consultation. Careful primary care screening can be as effective at identifying risk as a psychological assessment.
- Cognitive therapy decreased reattempt rate in prior suicide attempters by half. (i) Establish therapeutic alliance. Have patient tell a story about recent suicidal thought or action. (ii) Help patient develop the skills needed to deal with the thoughts or feelings that trigger suicidal crises. (iii) Have patient imagine being in the situation that brought on the earlier crisis, but this time, guide that patient to practice problem-solving strategies—reinforcing the use of coping skills rather than suicidal actions (2)[B],(3).
- Psychotherapy with suicidal patients is a challenge even for the most experienced clinicians. The countertransference, a clinician's feelings toward a patient, can evolve into wanting to be rid of the patient. If the patient detects this, the risk of suicide is heightened. The clinician can avoid this by recognizing countertransference and bearing it within so that the patient remains unaware (4).
- Among military personnel: ACE campaign: Ask about suicidal thoughts; care for the person, including removing access to lethal weapons; "escort" the soldier for help: an emergency room, to calling 911, or a support hotline such

as (800) 273-TALK (8255); text: 838255

MEDICATION

- Psychopharmacology “is not a substitute for getting to know the patient” (5) [A].
- Patients are at increased risk of suicide at the outset of antidepressant treatment and when it is discontinued. Consider tapering/switching medical therapies rather than sudden discontinuation. Monitor carefully at these times.
- Anxiety, agitation, and delusions increasing in intensity are risk factors for suicide and should be treated aggressively.
- In patients with mood disorders, a meta-analysis of randomized controlled trials found that lithium reduced the risk of death by suicide by 60% (5)[A].
- Agitated or combative patients may require sedation with IV or IM benzodiazepines and/or antipsychotics. Clinical response is typically seen within 20 to 30 minutes if given IM/IV.

Pediatric Considerations

FDA posted black box warning for antidepressant use in the pediatric population after increased suicidality was noted. If risk of untreated depression is sufficient to warrant treatment with antidepressants, children must be monitored closely for suicidality.

First Line

ECGs before prescribing or continuing antidepressants or antipsychotics to look for QT prolongation

ISSUES FOR REFERRAL

Consider a psychiatric consult. All decisions regarding treatment must be carefully documented and communicated to all involved health care providers.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Inpatient hospitalization, if patient is suicidal with a plan to act or is otherwise at high risk; if immediate risk for self-harm, may be hospitalized involuntarily
- Immediately after a suicide attempt, treat the medical problems resulting from the self-harm before attempting to initiate psychiatric care.

- Order lab work (e.g., solvent screen, blood and urine toxicology screen, aspirin and acetaminophen levels). Patients may not disclose ingestions if they wish to succeed in their attempt or if they are undergoing mental status changes.
- Risk for self-harm continues even in hospital setting. Immediate search for and remove potentially dangerous objects, one-to-one constant observation, medication. Mechanical restraints only if necessary for patient safety.
- The period after transfer from involuntary to voluntary hospitalization is also a time of high risk.

Discharge Criteria

- No longer considered a danger to self/others
- Clinicians should be aware that a patient may *claim* that he or she is no longer suicidal in order to facilitate discharge—and complete the act. Look for clinical and behavioral signs that the patient truly is no longer in despair and is hopeful, such as improved appetite, sleep, engagement with staff, and group therapy. Clinicians should check with family and ancillary staff because patients may share more information with them than with doctors.
- Provide information about 24/7 resources.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Increase monitoring at the beginning of treatment, when changing medications, and on discharge.
- Educate family members and other close contacts/confidants to the warning signs of suicidality. For adults: despair/hopelessness, isolation, discussing suicide, stating that the world would be a “better place” without them, losses in areas key to the patient’s self-worth. For youths: may exhibit the same signs and symptoms, but one should be aware of these additional risks: history of abuse (e.g., sexual, physical), bullying in person or via electronic media (e.g., text messages or social Web sites), family stress, changes in eating and sleeping patterns, suicidality of friends, and giving away treasured items

- Make sure that the patient is willing to accept the type of follow-up offered. Do not assume that just setting it up is sufficient protection.
- Curtail access to firearms.
- Limiting the number of pills may be appropriate for an impulsive patient. However, clinicians may believe that by simply limiting the number of pills they prescribe, they are preventing further suicide attempts, an example of "magical thinking." Clinicians who find themselves thinking this way can take it as a warning sign that their patients may actually be at increased risk of suicide.

PATIENT EDUCATION

Patients who feel they are in danger of hurting themselves should consider one or several of these options:

- Call 911.
- Go directly to an emergency room.
- If already in counseling, contact that therapist immediately.
- Call the National Suicide Prevention Hotline at (800) 273-TALK (8255).
- Servicemen and servicewomen and their families can call (800) 796-9699; if there is no immediate answer, call (800) 273-TALK (8255); text 838255

PROGNOSIS

The key to a favorable course and prognosis is early recognition of risk factors, early diagnosis and treatment of a psychiatric disorder, and appropriate intervention and follow-up.

COMPLICATIONS

- According to the American Association of Suicidality (AAS), the grief process for significant others of suicide victims can be lifelong and can be expressed in emotions ranging from anger to despair. Survivors often attempt to shoulder the burden on their own because of the added guilt and shame of the nature of the attempted death or death.
- The AAS recommends the following:
  - Counseling: could include short-term behavioral therapy as well as psychotherapy; some therapy should focus on the survivors' relationships to their current and future significant others. Survivors often seek out life

partners as “replacements” for those they lost—could interfere with mourning (6).
  - Sympathetic listening by friends
  - Support during holidays
  - More self-help strategies: www.survivorsofsuicide.com

CODES

ICD10

- R45.851 Suicidal ideations
- T14.91 Suicide attempt
- Z91.5 Personal history of self-harm

CLINICAL PEARLS

- Key preventive measure is to listen to a patient and take steps to keep him or her safe. This could include immediate hospitalization. Questions to explore include, “Are you thinking of killing yourself?” “Who do you have to live for?” and “What should change so that you could live with your suffering?”
- Clozapine, lithium, and cognitive-behavioral therapy are associated with a reduction in the risk of suicide.
- Family members and contacts of people who have attempted or committed suicide suffer from reactions ranging from rage to despair. Their grief is often longer lasting and less well treated because of the shame and guilt associated with the act. Encourage them to discuss this and consider counseling.
- Resources for clinicians: www.suicidology.com; www.suicideassessment.com

SUPERFICIAL THROMBOPHLEBITIS

Emily M. Culliney, MD, FAAFP

BASICS

DESCRIPTION

- Superficial thrombophlebitis is venous inflammation with secondary thrombosis of a superficial vein.
- Most common in the lower extremities (60–80%), but can occur in the upper extremities/neck.
- Generally a benign and self-limiting process, but can be painful
- Traumatic thrombophlebitis types:
  - Injury
  - IV catheter related
  - Intentional (i.e., sclerotherapy)
- Aseptic thrombophlebitis types:
  - Primary hypercoagulable states: disorders with measurable defects in the proteins of the coagulation and/or fibrinolytic systems
  - Secondary hypercoagulable states: clinical conditions with a risk of thrombosis (venous stasis, pregnancy)
- Septic (suppurative) thrombophlebitis types:
  - Iatrogenic, long-term IV catheter use
  - Infectious, mainly syphilis and psittacosis
- Mondor disease
  - Rare presentation of anterior chest/breast veins of women
- System(s) affected: cardiovascular
- Synonym(s): phlebitis; phlebothrombosis

Geriatric Considerations

Septic thrombophlebitis is more common; prognosis is poorer.

Pediatric Considerations

Subperiosteal abscesses of adjacent long bone may complicate the disorder.

Pregnancy Considerations

- Associated with increased risk of aseptic superficial thrombophlebitis, especially during postpartum
- NSAIDs are contraindicated during pregnancy.

EPIDEMIOLOGY

- Predominant age
  - Traumatic/IV related has no predominate age/sex.
  - Aseptic primary hypercoagulable state
    - Childhood to young adult
- Aseptic secondary hypercoagulable state
  - Mondor disease: women, ages 21 to 55 years
  - Thromboangiitis obliterans onset: ages 20 to 50 years
- Predominant sex
  - Suppurative: male = female
  - Aseptic
    - Spontaneous formation: female (55–70%)
    - Mondor: female > male (2:1)

Incidence

- Septic
  - Incidence of catheter-related thrombophlebitis is 88/100,000 persons.
  - Develops in 4–8% if cutdown is performed
- Aseptic primary hypercoagulable state: antithrombin III and heparin cofactor II deficiency incidence is 50/100,000 persons.
- Aseptic secondary hypercoagulable state
  - In pregnancy, 49-fold increased incidence of phlebitis
  - Superficial migratory thrombophlebitis in 27% of patients with thromboangiitis obliterans

Prevalence

- Superficial thrombophlebitis is common.
- 1/3 of patients in a medical ICU develop thrombophlebitis that eventually progresses to the deep veins.

ETIOLOGY AND PATHOPHYSIOLOGY

- Similar to deep venous thrombosis. Virchow triad of vessel trauma, stasis, and hypercoagulability (genetic, iatrogenic, or idiopathic)
- Varicose veins play a primary role in etiology of lower extremity phlebitis
- Mondor disease pathophysiology not completely understood
- Less commonly due to infection (i.e., septic)
  - *Staphylococcus aureus, Pseudomonas, Klebsiella, Peptostreptococcus* sp.
  - *Candida* sp.
- Aseptic primary hypercoagulable state
  - Due to inherited disorders of hypercoagulability
- Aseptic secondary hypercoagulable states
  - Malignancy (Trousseau syndrome: recurrent migratory thrombophlebitis): most commonly seen in metastatic mucin or adenocarcinomas of the GI tract (pancreas, stomach, colon, and gallbladder), lung, prostate, and ovary
  - Pregnancy
  - Estrogen based oral contraceptives
  - Behçet, Buerger, or Mondor disease

Genetics

Not applicable other than hypercoagulable states

RISK FACTORS

- Nonspecific
  - Varicose veins
  - Immobilization
  - Obesity
  - Advanced age
  - Postoperative states
- Traumatic/septic
  - IV catheter (plastic > coated)
  - Lower extremity IV catheter
  - Cutdowns
  - Cancer, debilitating diseases
  - Burn patients
  - AIDS
  - IV drug use

- Aseptic
  - Pregnancy
  - Estrogen-based oral contraceptives
  - Surgery, trauma, infection
  - Hypercoagulable state (i.e., factor V, protein C or S deficiency, others)
- Thromboangiitis obliterans: persistent smoking
- Mondor disease
  - Breast cancer or breast surgery

GENERAL PREVENTION

- Avoid lower extremity cannulations/IV.
- Insert catheters under aseptic conditions, secure cannulas, and replace every 3 days.
- Avoid stasis and use usual deep vein thrombosis (DVT) prophylaxis in high-risk patients (i.e., ICU, immobilized)

COMMONLY ASSOCIATED CONDITIONS

- Frequently seen with concurrent DVT (6–53%)
- Symptomatic pulmonary embolism can also be seen concurrently (0–10%)
- Both DVT/PE can occur up to 3 months after onset of phlebitis.

DIAGNOSIS

HISTORY

Pain along the course of a vein

PHYSICAL EXAM

- Swelling, tenderness, redness along the course of a vein or veins
- May have a palpable cord along the course of the vein
- May look like localized cellulitis or erythema nodosum
- Fever in 70% of patients in septic phlebitis
- Sign of systemic sepsis in 84% of suppurative cases

DIFFERENTIAL DIAGNOSIS

- Cellulitis
- DVT

- Erythema nodosum
- Cutaneous polyarteritis nodosa
- Lymphangitis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

Often none necessary if afebrile, otherwise healthy

- Small or distal veins (i.e., forearms or below the knee): no recommended imaging
- If concern for more proximal extension: venous Doppler US to assess extent of thrombosis and rule out DVT

Follow-Up Tests & Special Considerations

- If suspicious for sepsis
  - Blood cultures (bacteremia in 80–90%)
  - Consider culture of the IV fluids being infused.
  - CBC demonstrates leukocytosis.
- Aseptic: evaluation for coagulopathy if recurrent or without another identifiable cause (e.g., protein C and S, lupus anticoagulant, anticardiolipin antibody, factor V and VIII, homocysteine)
- In migratory thrombophlebitis, have a high index of suspicion for malignancy.
- Repeat venous ultrasound to assess effectiveness of therapy.
  - If thrombosis is extending, more aggressive therapy required.

Test Interpretation

The affected vein is enlarged, tortuous, and thickened with endothelial damage and necrosis.

TREATMENT

GENERAL MEASURES

- Suppurative: consultation for urgent surgical venous excision
- Local, mild
  - Conservative management, antibiotics not useful
  - For varicosities

    - Compression stockings, maintain activities
  - Catheter/trauma associated
    - Immediately remove IV and culture tip.
    - Elevate with application of warm compresses.
    - If slow to resolve, consider LMWH.
- Large, severe, or septic thrombophlebitis
  - Inpatient care or bed rest with elevation and local warm compress
  - When the patient is ambulating, then start compression stockings or Ace bandages.

MEDICATION

First Line

- Best medication(s) and duration of treatment are not well-defined (1)[A].
- Localized, mild thrombophlebitis (usually self-limited)
  - NSAIDs and ASA for inflammation/pain to reduce symptoms and local progression .
  - Use of compression stockings can also provide symptomatic relief (2).

Second Line

- Septic/suppurative
  - May present or be complicated by sepsis
  - Requires IV antibiotics (broad spectrum initially) and anticoagulation
- Increasing evidence shows that LMWH/fondaparinux treatment can prevent extension of superficial venous thrombosis in addition to VTE prevention.
- Consider if thrombus present in the large veins or involving the long saphenous vein
  - To prevent venous thromboembolism (VTE), 4 weeks of LMWH; such as enoxaparin
  - 45 days of fondaparinux was found to reduce DVT and VTE by 85% (relative risk reduction) in one large study (3)[B].
- Superficial thrombophlebitis related to inherited or acquired hypercoagulable states is addressed by treating the related disease.

ISSUES FOR REFERRAL

Severely inflamed or very large phlebitis should be evaluated for excision.

SURGERY/OTHER PROCEDURES

- Septic
  - Surgical consultation for excision of the involved vein segment and involved tributaries
  - Drain contiguous abscesses.
  - Remove all associated cannula and culture tips.
- Aseptic: Manage underlying conditions.
  - Evaluate for saphenous vein ligation to prevent deep vein extension after acute phase resolved.
  - Consider referral for varicosity excision.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Septic: inpatient
- Aseptic: outpatient

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Septic: routine WBC count and differential. Target treatment based on culture results.
- Severe aseptic
  - Repeat venous Doppler US in 1 to 2 weeks to ensure no DVT and assess treatment effectiveness: Do not expect resolution, just nonprogression.
  - Repeat clotting studies.
- Local, mild thrombophlebitis typically resolves with conservative therapy and does not require specific monitoring unless there is a failure to resolve.

DIET

No restrictions

PATIENT EDUCATION

Review local care, elevation, and use of compression hose for acute treatment and prevention of recurrence.

PROGNOSIS

- Septic/suppurative
  - High mortality (50%) if untreated
  - Depends on treatment delay or need for surgery
- Aseptic
  - Usually benign course; recovery in 2 to 3 weeks
  - Depends on development of DVT and early detection of complications
  - Aseptic thrombophlebitis can be isolated, recurrent, or migratory.
  - Recurrence likely if related to varicosity or if severely affected vein not removed

COMPLICATIONS

- Septic: systemic sepsis, bacteremia (84%), septic pulmonary emboli (44%), metastatic abscess formation, pneumonia (44%), subperiosteal abscess of adjacent long bones in children
- Aseptic: DVT (6–53%), VTE (up to 10%), thromboembolic phenomena

SEE ALSO

Deep Vein Thrombophlebitis

CODES

ICD10

- I80.9 Phlebitis and thrombophlebitis of unspecified site
- I80.00 Phlbts and thombophlb of superfic vessels of unsp low extrm
- I80.8 Phlebitis and thrombophlebitis of other sites

CLINICAL PEARLS

- Mild superficial thrombophlebitis is typically self-limiting and responds well to conservative care.
- Lower extremity disease involving large veins or proximal saphenous vein may benefit from anticoagulation to prevent DVT.
- Septic thrombophlebitis requires admission for antibiotics and anticoagulation. If severe, consider surgical consultation for venous excision.

SYNCOPE

Joseph A. Spinner, MD • Santiago O. Valdes, MD, FAAP

BASICS

DESCRIPTION

- Transient loss of consciousness characterized by unresponsiveness, loss of postural tone, and spontaneous recovery; usually caused by cerebral hypoxemia
- System(s) affected: cardiovascular, nervous

EPIDEMIOLOGY

Incidence

- Up to 20% of adults will have ≥1 episode by age 75 years; 15% of children <18 years of age
- Accounts for 1–6% of hospital admissions and ~3% of emergency room visits

Prevalence

- Annual prevalence of fainting spells resulting in medical evaluation was 9.5/1,000 inhabitants.
- In institutionalized elderly (>75 years of age) is 6%

ETIOLOGY AND PATHOPHYSIOLOGY

- In some cases, vagal response leads to decreased heart rate.
- Systemic hypotension secondary to decreased cardiac output and/or systemic vasodilation leads to a drop in cerebral perfusion and resulting loss of consciousness.
- Cardiac (obstruction to outflow)
  - Aortic stenosis
  - Hypertrophic cardiomyopathy: most common cause of sudden cardiac death during exercise in young athletes
  - Pulmonary embolus
- Cardiac arrhythmias
  - Sustained ventricular tachycardia (VT)

  - Supraventricular tachycardia (SVT) (atrial fibrillation, atrial flutter, reentrant SVT)
  - Torsades de pointes (TdP)
  - Bradyarrhythmia
    - 2nd- and 3rd-degree AV block
    - Sick sinus syndrome
- Noncardiac
  - Reflex-mediated vasovagal (neurally mediated syncope [NMS]/neurocardiogenic): inappropriate vasodilation leading to neurally mediated systemic hypotension and decreased cerebral blood flow, situational (micturition, defecation, cough, pain, emotions, hair combing)
  - Orthostatic hypotension: Consider volume depletion, pregnancy, anemia, medications.
  - Drug induced: prescription or recreational
  - Neurologic: seizures, transient ischemic attack, disrupted cerebrospinal fluid
  - Metabolic: hypoglycemia
  - Carotid sinus hypersensitivity
- Vast majority of pediatric cases represent benign alterations in vasomotor tone
- NMS also most common cause in adult cases

Genetics

Specific cardiomyopathies and arrhythmias may be inherited (i.e., long QT syndrome, catecholaminergic polymorphic VT, Brugada syndrome, hypertrophic cardiomyopathy).

RISK FACTORS

- Heart disease (acquired or structural)
- Dehydration
- Drugs
  - Antihypertensives
  - Vasodilators (including calcium channel blockers, ACE inhibitors, and nitrates)
  - Phenothiazines
  - Antidepressants

- Antiarrhythmics
- Diuretics

GENERAL PREVENTION

See "Risk Factors."

COMMONLY ASSOCIATED CONDITIONS

See "Etiology and Pathophysiology."

DIAGNOSIS

HISTORY

- Careful history, physical exam, and an ECG are more important than other investigations in determining the diagnosis (1)[A].
- Make sure that the patient or witness (if present) is not talking about vertigo (i.e., sense of rotary motion, spinning, and whirling), seizure, or causes of fall without loss of consciousness. Onset of syncope is usually rapid, and recovery is spontaneous, rapid, and complete. Duration of episodes is typically brief (<60 seconds).
- Number of previous episodes: Benign causes of syncope tend to be associated with a single episode.
- Presence of prodromal symptoms: Consider NMS.
  - Elderly patients less likely to experience a prodrome
- Palpitations or during exercise: Consider cardiac.
- Position (supine: arrhythmia; erect: NMS, supine → erect: orthostatic hypotension)
- Prolonged syncope: Consider psychiatric, neurologic.
- Delayed recovery: Consider neurologic (postictal).
- Ask for family history of long QT syndrome, Implantable Cardioverter-Defibrillator (ICD), hypertrophic cardiomyopathy, or unexplained sudden cardiac death in young family members.
- Even after careful evaluation, including diagnostic procedures and special tests, the cause will be found in only 50–60% of the patients.

PHYSICAL EXAM

- BP and pulse, both lying and standing
  - Orthostatic: Drop in systolic BP >20 mm Hg or rise in HR of >30 bpm.
- Check for cardiac murmur or focal neurologic abnormality.

DIFFERENTIAL DIAGNOSIS

- Drop attacks
- Coma
- Vertigo
- Seizure disorder
- Psychiatric (conversion, somatization): lack hemodynamic and/or autonomic changes

DIAGNOSTIC TESTS & INTERPRETATION

- Goal is to identify life-threatening conditions or those associated with significant risk of injury (2).
- Comprehensive medical and family history, physical examination, and ECG should guide future testing (2).
- No one single test defines the cause of syncope (2).

Initial Tests (lab, imaging)

Consider (not all indicated in all individuals) the following:

- CBC
- Electrolytes, BUN, creatinine, glucose (rarely helpful if asymptomatic or presenting hours later)
- BNP level
- Cardiac enzymes (only if history suggestive of MI)
- D-dimer (for pulmonary embolism [PE] workup)
- Urine pregnancy and urine drug screen
- Initial cardiac or neuroimaging only if indicated
- Lung scan or helical CT scan of thorax if history and physical exam suggest PE

Follow-Up Tests & Special Considerations

- Injuries may occur in up to 1/3 of adult patients.
- If history and physical suggest ischemic, valvular, or congenital heart disease (2)

  - Exercise stress test (if syncope with exertion) (2)[C]
  - Echocardiogram (2)[B]
- ECG findings suggesting arrhythmia
  - Bifascicular block, AV block, sinus bradycardia <40 bpm or sinus pause >3 seconds, prolong QTc, preexcitation, alternating BBB
- If CNS disease suspected (2)[C]
  - EEG
  - Head CT scan
  - Head MRI/MRA if vascular cause is suspected
- ECG monitoring, either in hospital or ambulatory (Holter) (2)[C]
  - Useful in 4–15% of patients
  - Should be done in patients with preexisting heart disease, palpitations, or recurrent syncope
  - Arrhythmias frequently documented but not always causative
- Electrophysiologic studies (2)[C]
  - Should be done in patients with heart disease and recurrent syncope, although they may not show whether arrhythmia noted or induced during study is cause of syncope.
  - Induction of VT and dysfunction of His-Purkinje system are the two most common abnormalities.
  - Have been positive in 18–75% of patients
- Carotid hypersensitivity evaluation (3,4)[C]
  - Carotid hypersensitivity should be considered in patients >40 years old or with syncope during head turning, especially while wearing tight collars, and with neck tumors and neck scars.
  - The technique is not standardized; one side at a time is compressed gently for 20 seconds with constant monitoring of pulse and BP/ECG.
  - Atropine should be readily available.
- Tilt-table testing (2)[B]
  - Provocative test for vasovagal syncope
  - Often results are not reproducible
  - High false-positive rate
- Psychiatric evaluation (2)[C]: Anxiety, depression, and alcohol and drug abuse can be associated with syncope.

Diagnostic Procedures/Other

External event recorders or implantable loop recorders may be more helpful than short-term ambulatory monitoring. Helpful in selective patients with recurrent syncope, with yield of 32–80% (3,4)[B].

Test Interpretation

Depends on etiology and presence of underlying cardiac or neurologic conditions

TREATMENT

- Maintaining good hydration status and normal salt intake are initial therapy. Educate patients of the premonitory signs of syncope (3)[B].
- Majority of pediatric patients improve with nonpharmacologic measures

GENERAL MEASURES

- NMS: reassurance, education, behavior modification
- Elderly patients without previously recognized heart disease should be admitted if the physician thinks that the cause of syncope is likely cardiac.
- Patients without heart disease, especially young patients (age <60 years) can be worked up safely as outpatients.
- Prescribe antiarrhythmics for documented arrhythmias occurring simultaneously with syncope or symptoms of presyncope. Asymptomatic arrhythmias do not necessarily require treatment.
- The decision to treat patients on basis of arrhythmias or conduction abnormalities provoked or detected during EPS is even more problematic: Does the arrhythmia or conduction abnormality have anything to do with the patient’s symptoms?
- Most would treat patients with provoked sustained VT with an antiarrhythmic drug that suppressed arrhythmia during study.
- Rationale for such treatment: Recurrent syncope is less frequent in patients with positive EPS who are treated than it is in those who have negative EPS.

MEDICATION

First Line

- Geared toward specific underlying cardiac or neurologic abnormalities
- In cases of recurrent NMS (4)[B]
  - Mineralocorticoids (fludrocortisone)
  - α-Adrenergic agonists (midodrine)

Second Line

- SSRIs (paroxetine, sertraline, fluoxetine)
- Vagolytics (disopyramide)

ISSUES FOR REFERRAL

When cardiac or neurologic etiologies are suspected, obtain appropriate consultation, as indicated.

ADDITIONAL THERAPIES

For vasovagal/neurocardiogenic/NMS

- Counterpressure maneuvers, orthostatic training, and exercise have improved vasovagal symptoms and recurrence (3,5)[C].
- Head-up tilt sleeping (2)[C]
- Abdominal binders and/or support stockings (2)[C]

SURGERY/OTHER PROCEDURES

- ICD placement for patients with cardiac conditions with high risk of sudden death and/or recurrent syncope on medications (i.e., long QT syndrome, catecholaminergic polymorphic VT, hypertrophic cardiomyopathy) (2)[B]
- Many recommend pacemaker implantation in patients with the following:
  - 2nd- (Mobitz type II) and 3rd-degree heart block
  - HV intervals >100 ms
  - Pacing-induced infranodal block
  - Sinus node recovery time ≥3 seconds

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Patients with benign etiologies of syncope with negative ED workups are associated with benign outcomes, even in the presence of other risk factors (6)[B].
- Overwhelming majority of children who have completely recovered and

without red flags for cardiac or neurologic syncope can be followed as outpatients.

- Patients with suspected cardiac or neurologic cause for syncope or comorbidities (such as anemia or electrolyte abnormalities) should be admitted for evaluation.
- In adults: ROSE rule recommends hospital admission if any of the following is present: BNP level ≥300 pg/mL, bradycardia ≤50, + fecal occult blood, anemia with hemoglobin ≤9 g/dL, chest pain associated with syncope, ECG showing Q wave (not in lead III) or oxygen saturation ≤94% on room air (5)
- Close monitoring of BP and heart rate during initial presentation
- Discharge criteria
  - Attainment of hemodynamic stability
  - Satisfactory completion of workup for etiology
  - Adequate control of specific arrhythmia or seizure, if present

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Frequent follow-up visits for patients with cardiac causes of syncope, especially patients on antiarrhythmics
- Patients with an unknown cause of syncope rarely (5%) are diagnosed during the follow-up.

DIET

- No specific diet unless the patient has heart disease
- Increased fluid and salt intake to maintain intravascular volume in cases of recurrent NMS

PATIENT EDUCATION

- Reassure the patient that most cardiac causes of syncope can be treated, and patients with noncardiac causes do well, even if the cause of syncope is never discovered.
- Physical counterpressure maneuvers can prevent recurrences of vasovagal

syncope.

- Physician and patient should carefully consider whether the patient should continue to drive while syncope is being evaluated. Physicians should be aware of pertinent laws in their own states.

PROGNOSIS

- Cumulative mortality at 2 years
  - Low: young patients (<60 years of age) with noncardiac or unknown cause of syncope
  - Intermediate: older patients (>60 years of age) with noncardiac or unknown cause of syncope
  - High: patients with cardiac cause of syncope
- Independent predictors of poor short-term outcomes (5,6)[B]
  - Abnormal ECG
  - Shortness of breath
  - Systolic BP <90 mm Hg
  - Hematocrit <30%
  - Congestive heart failure

COMPLICATIONS

- Trauma from falling
- Death (see "Prognosis")

CODES

ICD10

R55 Syncope and collapse

CLINICAL PEARLS

- Careful history and physical exam is key to a diagnosis.
- Use the ECG/event-recorder to evaluate for arrhythmia.
- NMS is most common cause in children and adults.
- Injuries due to syncope are common.
- True neurologic causes of syncope are very rare.
- <2% of cases are caused by hyponatremia, hypocalcemia, hypoglycemia, or renal failure.

SYNCOPE, REFLEX (VASOVAGAL SYNCOPE)

Melinda Y. Kwan, DO, MPH • Norton Winer, MD

BASICS

Syncope is a reversible loss of consciousness and postural tone secondary to systemic hypotension and cerebral hypoperfusion due to vasodilation and/or bradycardia (rarely, tachycardia) with spontaneous recovery and no neurologic sequelae. The term syncope excludes seizures, coma, shock, or other states of altered consciousness.

DESCRIPTION

- Derived from the Greek term *syncopa*, meaning "to cut short"
- Sudden, transient loss of consciousness characterized by unresponsiveness, falling, and spontaneous recovery
- Common cause of syncope in all age groups, especially in patients with no evidence of neurologic or cardiac disease
- Four main types: vasovagal or neurocardiogenic syncope, situational syncope, orthostatic hypotension, carotid sinus hypersensitivity, and glossopharyngeal/trigeminal neuralgia syncope (uncommon) (1)

EPIDEMIOLOGY

- Mortality: cardiac-related syncope 20–30% and 5% in idiopathic syncope
- Age: any age

Incidence

- Ranges from 7.5% in children aged <18 years and 15% in adults aged >70 years
- 36–62% of all syncopal episodes
- 30% recurrence rate

Prevalence

22% in the general population

ETIOLOGY AND PATHOPHYSIOLOGY

Cause: an abnormal interaction of the normal mechanisms for maintaining BP and upright posture

- In normal individuals, upright posture results in venous pooling and transient decrease in BP.
- Neurally induced syncope may result from a cardioinhibitory response, a vasodepressor response, or a combination of the two.
- Increased cardiovagal tone leads to bradycardia or asystole and decreased peripheral sympathetic activity leads to venodilation and hypotension (2).
- Vasovagal syncope usually has a precipitating event, often related to fright, pain, panic, exercise, noxious stimuli, or heat exposure (2).
- Carotid sinus syncope is precipitated by position change, turning head, or wearing a tight collar (possible neck tumors or surgical scarring).
- Situational syncope is related to micturition, defecation, postexercise, cough, or swallow (3).
- Glossopharyngeal syncope is related to throat or facial pain (4).

Genetics

Vasovagal syncope: strong heritable component to the etiology of >20% of cases

RISK FACTORS

- Low-resting BP
- Age: older age
- Prolonged supine position with resulting deconditioning of autonomic control

GENERAL PREVENTION

Avoidance of precipitating events or situations. Optimization of diabetes mellitus (DM) control, elastic stockings, adequate hydration. Limited evidence suggests that polydipsia may reduce recurrences.

COMMONLY ASSOCIATED CONDITIONS

- Cardiopulmonary disorders: CHF, MI, arrhythmias, hypertrophic obstructive cardiomyopathy, HTN, PE pulmonary embolism
- Neurologic disorders: autonomic dysfunction, Shy-Drager, Parkinson disease, multiple system atrophy, transient ischemic attack, vertebrobasilar insufficiency, peripheral neuropathy
- Psychiatric disorders:

- Generalized anxiety disorder
- Panic disorder
- Major depression
- Alcohol dependence

DIAGNOSIS

HISTORY

- Evaluation of syncope and presyncope are the same.
- Important first to rule out cardiac syncope
- Neurally mediated syncope is preceded by blurred vision, palpitations, nausea, warmth, diaphoresis, or light-headedness, or there may be history of nausea, warmth, diaphoresis, or fatigue *after* syncope (5)[C].
- Vasovagal syncope
  - Three phases: prodrome, loss of consciousness, and postsyncope
  - Precipitating event or stimulus is usually identified, such as panic, fright, pain, or exercise.
  - Athletes may have after exertion (diagnosis of exclusion).
  - Position: *can be preceded by prolonged standing but can occur from any position; generally resolves when the patient becomes supine*
    - Preceding events: as discussed above
    - Prodrome: as listed above for neurally mediated syncope
  - Duration: generally brief (seconds to minutes)
  - Recovery: may be prolonged with persistent nausea, pallor, and diaphoresis but without neurologic change or confusion
- Carotid sinus syncope is precipitated by position change, after turning head, or wearing a tight collar.
- Situational syncope is related to micturition, defecation, or coughing.
- Glossopharyngeal syncope (less common) is related to throat or facial pain (4) [C]
  - Precipitating events or situations may include panic, pain, exercise, micturition, defecation, coughing, or swallowing.

PHYSICAL EXAM

- Vital signs, including orthostatics and bilateral BP
- Cardiac exam: volume status, murmurs, rhythm, carotid bruits
- Neurologic exam: signs of focal deficit
- Assess for occult blood loss, including guaiac.
- Dix-Hallpike to rule out benign paroxysmal vertigo

DIFFERENTIAL DIAGNOSIS

- Seizure
- Arrhythmia
- Hypoglycemia
- Cardiac syncope
- Cerebrovascular syncope
- Orthostatic hypotension
- Drop attacks
- Psychiatric illness

DIAGNOSTIC TESTS & INTERPRETATION

As indicated by history and physical, includes basic tests to rule out the three main reasons for syncope: hypoglycemia, arrhythmia, and anemia

Initial Tests (lab, imaging)

- Blood sugar
- ECG should be ordered for all patients. Abnormal ECG findings are common in patients with cardiac syncope.
- CBC to rule out anemia
- Head CT, MRI/MRA, carotid ultrasound only in patients whose history or physical exam suggests a neurologic cause of syncope
  - The 2007 American College of Emergency Physicians (ACEP) Guidelines for diagnostic testing for syncope are as follows (6):
    - *Level A recommendations*: standard 12-lead ECG
    - *Level B recommendations*: none specified
    - *Level C recommendations*: laboratory testing and investigations, including echocardiography or head CT, to be performed only if indicated by specific findings in the history or physical examination

Follow-Up Tests & Special Considerations

- 24-hour Holter monitoring only in patients with a high probability of cardiac cause of syncope and/or abnormal ECG findings
- A low hemoglobin without obvious cause of bleed would warrant a guaiac, CT head to rule out subarachnoid hemorrhage (SAH), CT abdomen to rule out retroperitoneal bleed.
- Negative imaging will prompt workup for alternative causes.
- Stroke, bleed, or carotid stenosis will require appropriate disease-oriented management.
- EEG only when history or physical exam is very suggestive of seizure activity
- Implantable loop recorder

Diagnostic Procedures/Other

- Head-up tilt table testing:
  - Contraindicated in patients with known cardiac or neurovascular disease or in pregnancy
  - Indicated for recurrent syncope or single episode accompanied by injury or risk to others (e.g., pilots, surgeons)
  - Uses positional changes to reproduce symptoms
  - Positive tests are diagnostic for vasovagal syncope.
- Carotid sinus massage, only in a monitored setting (i.e., BP and HR monitoring, IV access):
  - Contraindicated in patients with carotid disease (careful auscultation prior to massage is essential)
  - Pressure at the angle of the jaw for 5 seconds with simultaneous ECG monitoring
  - Positive tests (causing syncope or cardiac pause >3 seconds) are diagnostic of carotid sinus syncope.
- Psychiatric evaluation: to rule out anxiety, depression, and alcohol abuse

TREATMENT

Therapy is primarily for recurrent syncope. Situational syncope will not warrant any treatment.

GENERAL MEASURES

Recognition and avoidance of precipitating events or situations; medical management is based on small, nonrandomized clinical trials.

First Line

- Nonpharmacologic treatment
  - Includes patient counseling
    - Development of coping skills
    - Increased salt and fluid intake
  - Moderate exercise training
    - Isometric muscle contractions
      - Leg crossing and buttocks clenching
      - Intense gripping of the hands and tensing of the arms
      - These maneuvers increase cardiac output and arterial blood pressure (7).
  - Tilt-table training
    - Progressively prolonged periods of enforced upright posture

Second Line

- α-Agonists are mainly used for orthostatic hypotension.
  - Midodrine is commonly used. It increases peripheral vascular resistance and venous return. Side effects include HTN, paresthesia, urinary retention, “goose bumps,” hyperactivity, dizziness, tremor, and nervousness.
- SSRIs: Paroxetine and fluoxetine are SSRIs useful in treating neurocardiogenic/vasovagal syncope.
  - Serotonin affects BP and HR via the central nervous system. Serotonin decreases a sympathetic withdrawal response to rapid increases in serotonin levels.
  - Side effects include weight gain, nausea, anxiety, sexual dysfunction, and insomnia.
- Mineralocorticoids: Fludrocortisone has been found helpful mainly in orthostatic hypotension.
  - Helpful in renal sodium absorption and increasing the vasoconstrictive peripheral vascular response
  - Adverse reactions include fluid retention, HTN, CHF, peripheral edema, and hypokalemia.

- β-Blockers: Metoprolol, atenolol, or pindolol are mainly used for postural tachycardia syndrome (POTS).
  - Block peripheral vasodilators and ventricular mechanoreceptor stimulation.
  - Stabilization of HR and BP
  - Side effects: hypotension and bradycardia (with worsening of syncope), fatigue, depression, and sexual dysfunction
  - Contraindicated in asthma

ISSUES FOR REFERRAL

Neurology or cardiology, as needed

ADDITIONAL THERAPIES

Use of support/pressure stockings

COMPLEMENTARY & ALTERNATIVE MEDICINE

These include treatments for underlying heart disease or precipitating factors like anxiety. None of these are proven therapies.

- Nutrition and supplements: omega-3 fatty acids, multivitamin, CoQ10, acetyl-L-carnitine, α-lipoic acid, and L-arginine
- Herbs: Green tea (*Camellia sinensis*), bilberry (*Vaccinium myrtillus*), ginkgo (*Ginkgo biloba*)
- Homeopathy: Carbo vegetabilis, opium, sepia
- Acupuncture: It may precipitate fainting.

SURGERY/OTHER PROCEDURES

Pacemaker placement may be of use in patients with frequent neurocardiogenic/vasovagal syncope that is refractory to other therapies (3)[C].

- Prevents prolonged bradycardia or asystole during syncopal episodes
- Long-term effect
- Invasive placement procedure

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

2007 ACEP guidelines mandate that the patient be admitted if (6):

- *Level B recommendations*
  - Admit patients with syncope and evidence of heart failure or structural

heart disease.
  - Admit patients with syncope and high-risk factors.
- High-risk stratification is based on the following factors:
  - Older age and associated comorbidities
  - Abnormal ECG, hematocrit (Hct) 30 (if obtained)
  - History or presence of heart failure, coronary artery disease, or structural heart disease
- Additional causes to admit
  - Syncope occurring during exercise
  - Syncope causing severe injury
  - Family history of sudden death
- IV fluids to stabilize HR and BP
- Isotonic crystalloids, as needed
- Vital sign monitoring
- Discharge when hemodynamically stable and workup satisfactory

ONGOING CARE

DIET

- Increased salt intake may be helpful if not contraindicated (2)[C].
- Maintain fluid intake.

PATIENT EDUCATION

- To identify and avoid precipitating events or situations
- Avoid dehydration, alcohol consumption, warm environments, tight clothing, and long periods of standing motionless.
- Recognize presyncopal symptoms.
- Use behaviors, such as lying down, to avoid syncope.

PROGNOSIS

May be recurrent but not life-threatening

COMPLICATIONS

May result in injury from fall

CODES

ICD10

R55 Syncope and collapse

CLINICAL PEARLS

- History should include a careful analysis of the events preceding the attack.
- It is important to rule out cardiologic or neurologic pathology.
- Prodrome is often present.
- Recovery may be prolonged, with persistent symptoms but no neurologic deficit or confusion.
- Patient counseling to avoid precipitating situations or events is the first-line treatment.
- Pregnant females can have reflex syncope when moving from supine to lateral decubitus or upright positions.

SYNDROME OF INAPPROPRIATE ANTIDIURETIC HORMONE SECRETION (SIADH)

Elise J. Barney, DO

BASICS

DESCRIPTION

- A syndrome of abnormal production of antidiuretic hormone (ADH), despite low serum osmolality, leading to hyponatremia and inappropriately elevated urine osmolality
  - Resulting abnormal urinary free water retention leads to dilutional hyponatremia (total body sodium levels may be normal or near normal, but the patient's total body water is increased).
  - Often secondary to medications but may be associated with an underlying disorder, such as neoplasm, pulmonary disorder, or CNS system disease
- Synonym(s): syndrome of inappropriate secretion of ADH; syndrome of inappropriate antidiuresis

EPIDEMIOLOGY

Incidence

- Often found in the hospital setting, where incidence can be as high as 35%
- Predominant age: elderly
- Predominate sex: females > males

ETIOLOGY AND PATHOPHYSIOLOGY

- Drugs:
  - Antidepressants (e.g., monoamine oxidase inhibitors [MAOIs], tricyclics, SSRIs)
  - Antineoplastic drugs (e.g., vincristine, vinblastine, cisplatin, cyclophosphamide)
  - Antipsychotic agents (e.g., phenothiazines, thioridazine, haloperidol)
  - Analgesics (e.g., NSAIDs)

  - Antiepileptics (e.g., carbamazepine, oxcarbazepine, valproic acid)
  - Oral hypoglycemics (e.g., chlorpropamide, metformin)
  - Others (e.g., vasopressin, DDAVP, oxytocin, ciprofloxacin, α-interferon, ecstasy)
- Neoplasms (ectopic ADH production):
  - Bronchogenic carcinoma
  - Hodgkin disease
  - Mesothelioma
  - Oat cell carcinoma of the lung
  - Pancreatic carcinoma
  - Small cell carcinoma of the lung
  - Thymoma
- Pulmonary conditions:
  - Asthma/COPD
  - Atelectasis
  - Cystic fibrosis
  - Positive pressure mechanical ventilation
  - Pneumonia
  - Pulmonary tuberculosis (TB)
  - Sarcoidosis
- Neurologic causes:
  - Acute porphyria
  - CNS injury (i.e., SAH, trauma, stroke)
  - CNS lupus
  - Encephalitis
  - Epilepsy
  - Guillain-Barré syndrome
  - Meningitis
  - Multiple sclerosis
- Other:
  - HIV infection
  - Hypothyroidism, myxedema
  - Rocky Mountain spotted fever
- Idiopathic

Genetics

- 10% of patients have X-linked mutation of V2R.
- Polymorphisms in TPRV4 gene

RISK FACTORS

- Use of predisposing drugs
- Advanced age
- Postoperative status
- Institutionalization

GENERAL PREVENTION

- Search for cause, if unknown.
- Reduce/change medications, if drug-induced.
- Lifelong restriction of fluid intake

COMMONLY ASSOCIATED CONDITIONS

See “Etiology.”

DIAGNOSIS

HISTORY

Symptoms:

- Fatigue
- Anorexia
- Nausea
- Vomiting
- Diarrhea
- Headaches
- Unsteady gait
- Falls
- Myalgias/weakness
- Increased thirst
- Confusion
- Seizures, coma

PHYSICAL EXAM

- Euvolemic state
- Mild/moderate hyponatremia (serum Na 125 to 135 mEq/L)
  - Slow cognition and reaction times
  - Hyporeflexia
  - Ataxia
- Severe hyponatremia (serum Na <125 mEq/L)
- Altered mental status
- Lethargy
- Seizures
- Psychosis
- Coma
- Death

DIFFERENTIAL DIAGNOSIS

- Intravascular volume depletion and thiazide-induced
- Appropriate ADH secretion secondary to decreased effective arterial blood volume (e.g., congestive heart failure [CHF], nephrotic syndrome, liver cirrhosis)
- Low solute intake hyponatremia
  - “Tea and toast” diet
  - Beer potomania
- Psychogenic polydipsia
  - Intake usually >10 L/day
  - Diuresis occurs when intake is stopped.
- Endocrinopathies
  - Addison disease
  - Hypothyroidism
- Translocational hyponatremia: caused by hyperglycemia, mannitol, sucrose, glycine
- Pseudohyponatremia
  - Lab artifact caused by hyperlipidemia, paraproteinemias, administration of IVIG
  - Labs using flame photometry or indirect potentiometry susceptible
- Postoperative complications:
  - Caused by nonosmotic release of ADH, probably mediated by pain

afferents
  - ADH stimulated by pain, nausea, vomiting, and hypotension
- Cerebral salt-wasting syndrome (hyponatremia, extracellular fluid depletion, CNS insult)

DIAGNOSTIC TESTS & INTERPRETATION

- Serum Na level: low
- Serum urea level: normal to low
- Serum osmolality: low
- Urine osmolality: high; urine osmolality >100 mOsm/kg H_2O (1)
- Urine Na concentration: high; urine Na >30 mEq/L (1)
- Fractional excretion of Na >0.5 % (1)
- Serum ADH level: high (not clinically useful)
- Not usually required for diagnosis but to assess for other concerns:
  - Serum uric acid
  - Serum glucose; creatinine
  - Thyroid function
  - Morning cortisol

TREATMENT

GENERAL MEASURES

- Treatment of the underlying cause is essential.
- Requires frequent monitoring (see "Patient Monitoring")
- Fluid restriction (usually <1,000 mL/day) is the main treatment (2)[C].
- Avoid isotonic saline, as this can worsen the hyponatremia.
- Mild asymptomatic hyponatremia (serum Na >125 mEq/L [>125 mmol/L]): Restrict fluid and treat underlying cause.
- Severe or with neurologic manifestations
  - Hypertonic saline (3% normal saline) bolus
  - Loop diuretics in conjunction with above
  - Restrict free water intake.
  - Increase oral solute intake.
  - Calculate urine/plasma electrolyte ratio ([urine Na + K] / [serum Na +

serum K]) to determine efficacy of fluid restriction; ineffective if ratio >1 (3) and may need pharmacologic therapy.
  - Increase serum Na slowly with hypertonic saline by 4 to 6 mEq/L over 4 to 6 hours (not to exceed 8 mEq/L in a 24-hour period) (1,4).
- Acute (<48 hours duration)
  - Can initially correct rapidly but 24-hour goal is same as in chronic hyponatremia (4)

MEDICATION

- If severe or neurologic symptoms: IV 3% sodium chloride to increase serum Na cautiously (5)[B]:
  - If serum Na <120 mEq/L or severe neurologic symptoms; consider bolus of hypertonic saline to increase serum Na by 4 to 6 mEq/L over the first 4 to 6 hours.
- Sodium chloride (NaCl) oral tablets
- Oral urea is an option but limited due to bitter taste.
- Loop diuretics: furosemide (Lasix) + potassium replacement
- Vasopressin-2 receptor antagonist (the vaptans: tolvaptan, conivaptan) (5)
  - Good efficacy and safety profiles in the treatment of moderate hyponatremia due to SIADH
  - Liberal fluid intake encouraged
  - Must be initiated in hospital setting
  - Cost may limit long-term use.
  - Avoid tolvaptan in patients with liver disease.
- Demeclocycline (limited use) (6)[C]
  - Blocks ADH at renal tubule; produces nephrogenic diabetes insipidus
  - Dosage for long-term management: 300 to 600 mg PO BID
  - Onset of action within 1 week; therefore, not best for acute management
  - Adverse effects of GI intolerance and nephrotoxicity limit its use.
  - Paucity of evidence for efficacy
- Contraindications: Avoid fluids in CHF, nephrotic syndrome, or cirrhosis. Avoid tolvaptan in patients with cirrhosis due to possible liver injury.
- Precautions: Overly rapid correction (>10 mEq/L/day) can increase risk for osmotic demyelination syndrome (ODS):

- Permanent CNS damage in pons leading to quadriplegia and pseudobulbar palsy
- Increased risk in women, alcoholics, malnutrition, hypoxia, chronic hyponatremia of <110 mEq/L, and hypokalemia

ALERT

Increase Na levels slowly, no more than 8 mEq/L/24 hr, to prevent ODS (1)[C].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Careful continuous clinical and laboratory monitoring of hyponatremic state during acute phase:
  - Hourly urine output
  - Urine Na
  - Serum Na and potassium (K) every 4 to 6 hours if moderate/severe, then daily once stable
  - Goal sodium increase is <8 mEq/L until Na reaches 130 mEq/L (1,4)[C].
- Chronic management: Treat underlying cause; continue fluid restriction and NaCl tablets as needed.

DIET

Increase protein/solute intake and decrease water intake.

PATIENT EDUCATION

Diet and fluid restrictions

PROGNOSIS

- Higher morbidity and mortality in hospitalized patients with hyponatremia (7)
- Higher risk of ICU admission and increased risk of 30-day hospital readmission in hyponatremic patients (7)
- If symptomatic (seizure, coma): high mortality due to cerebral edema if serum Na <120 mEq/L

COMPLICATIONS

- Falls and hip fractures (8)
- Cerebral edema (see “Prognosis”)
- Osmotic demyelination with overcorrection (see “Treatment” precautions): central pontine and extrapontine irreversible myelinolysis (4)
- Chronic hyponatremia
- Chronic hyponatremia is associated with osteoporosis (8)[C].

Hyponatremia

CODES

ICD10

E22.2 Syndrome of inappropriate secretion of antidiuretic hormone

CLINICAL PEARLS

- Treatment of the underlying cause is a key. Review all medications for potential culprits.
- Nephrology consultation is recommended in moderate to severe hyponatremia or if hypertonic saline indicated.
- Fluid restriction is the mainstay of treatment in SIADH. Fluid restriction fails to correct hyponatremia and Na wasting in salt-losing renal disease.
- Cerebral salt wasting is a controversial disease entity and is similar to SIADH. However, patients with SIADH are euvolemic, whereas patients with cerebral salt wasting are hypovolemic. The only real way to establish the diagnosis is through fluid restriction. Serum urate and fractional excretion of urate will be corrected with fluid restriction in SIADH but will not correct in cerebral salt wasting.
- CPM is a cerebral demyelination syndrome that causes quadriplegia, pseudobulbar palsy, seizures, coma, and death. It is caused by an overly rapid rate of Na correction.
- Safe correction of hyponatremia is important. Online calculators are available: www.medcalc.com/sodium.html.

SYPHILIS

Melissa Badowski, PharmD • Mahesh C. Patel, MD

BASICS

DESCRIPTION

- A chronic, systemic infectious disease caused by *Treponema pallidum*
- Transmitted sexually by direct contact with an active lesion, vertically (maternal–fetal), and via blood transfusions
- Untreated disease includes four overlapping stages.
  - Primary: single (usually) painless chancre at point of entry; appears in 10 to 90 days; chancre heals without treatment in 3 to 6 weeks
  - Secondary: appears 2 to 8 weeks after primary chancre; nonpuritic rash on palms or soles of feet, mucous membrane lesions, headache, fever, lymphadenopathy, alopecia
  - Latent: seroreactive without evidence of disease
    - Early latent: acquired within the last year
    - Late latent: exposure >12 months prior to diagnosis
  - Tertiary (late): Serology may be negative (fluorescent treponemal antibody absorption [FTA-ABS] test typically positive).
    - Gumma, cardiovascular, and late neurosyphilis; may be fatal
  - Neurosyphilis: *any* type of CNS involvement; can occur at *any* stage
    - Psychosis, delirium, dementia
- Syphilis can affect nearly every organ/tissue.

Pediatric Considerations

In noncongenital cases, consider child abuse.

Pregnancy Considerations

- All pregnant patients should be screened with venereal disease research laboratory test (VDRL) or rapid plasma reagin (RPR) test early in pregnancy. If high exposure risk, repeat at 28 weeks and at delivery (1,2)[A].
- The same nontreponemal test used for initial screening should be used for follow-up (1,2)[A].

EPIDEMIOLOGY

Incidence

- Syphilis rate decreased until 2000; has increased (primarily in men) since (3) [A]
- In 2014: 6.3/100,000. Highest for men aged 25 to 29 years and women aged 20 to 24 years (3)[A]
  - Men: 11.7/100,000
  - Women: 1.1/100,000
- Congenital: 11.6 cases/100,000 live births (3)[A]
- Ocular
- Race/ethnicity (3)[A]
  - Male (per 100,000 population)
    - Whites, non-Hispanic: 6.5
    - Blacks, non-Hispanic: 34.5
    - Hispanics: 13.9
    - Asians: 5.6
    - American Indians/Alaska natives: 10.5
    - Native Hawaiians/Pacific Islanders: 12.0
  - Female (per 100,000 population)
    - Whites, non-Hispanic: 0.5
    - Blacks, non-Hispanic: 4.6
    - Hispanics: 1.1
    - Asians: 0.2
    - American Indians/Alaska natives: 4.8
    - Native Hawaiians/Pacific Islanders: 0.8

Prevalence

- Predominant sex: male (91%) > female (9%) (3)[A]
- Greatest increase in men having sex with men (MSM) (3)[A]

ETIOLOGY AND PATHOPHYSIOLOGY

T. pallidum enters through intact mucous membranes or breaks in skin. The organism quickly enters the lymphatics to cause systemic disease. Highly infectious; exposure to as few as 60 spirochetes is associated with ~50% chance

of infection.

RISK FACTORS

MSM, multiple sexual partners, exposure to infected body fluids, IV drug use, transplacental transmission, adult inmates, high-risk sexual behavior, HIV positive

GENERAL PREVENTION

Education regarding safe sex; condoms reduce but do not eliminate transmission (4)[A]

COMMONLY ASSOCIATED CONDITIONS

HIV infection, hepatitis B, other STIs

DIAGNOSIS

HISTORY

- As the “great imitator,” a high index of suspicion is often required.
- Previous sexual contact with partner with known infection or high-risk sexual behavior
- Genital lesions (chancre—primary syphilis)
- Rash, alopecia, malaise, headache, anorexia, nausea, fatigue (secondary syphilis)
- Mental status changes (tertiary syphilis)

PHYSICAL EXAM

Signs/symptoms depend on stage

- Primary: single (occasionally multiple), usually painless ulcer (chancre) in groin or at other point of entry; regional adenopathy
- Secondary
  - Rash: skin/mucous membranes
    - Rough, red-brown macules, usually on palms and soles
    - May appear with chancre or after it has healed
    - Condyloma lata
    - Alopecia
  - Nonspecific symptoms: fever, adenopathy, malaise, headache, hair loss

- Tertiary
  - Focal neurologic findings (hearing loss, visual loss)
  - Gummas (skin, mucous membranes, other organ systems)

DIFFERENTIAL DIAGNOSIS

- Primary: chancroid, lymphogranuloma venereum, granuloma inguinale, condyloma acuminata, herpes simplex, Behçet syndrome, trauma, carcinoma, mycotic infection, lichen planus, psoriasis, fungal infection
- Secondary: pityriasis rosea, drug eruption, psoriasis, lichen planus, viral exanthema, Stevens-Johnson syndrome
- Positive serology, asymptomatic: previously treated syphilis/other spirochetal disease (yaws, pinta)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Dark-field microscopy demonstrating *T. pallidum* spirochetes in lesion exudate/tissue biopsy: gold standard but difficult and not very sensitive (5)[A]
- Nontreponemal tests (VDRL/RPR) (3,5)[A]
  - Primary screening test: positive within 7 days of exposure
  - Nonspecific, false-positive results common; must confirm diagnosis with treponemal tests
  - Positive test should be quantified and titers followed regularly after treatment.
    - Titers usually correlate with disease activity; 4-fold change is clinically significant.
    - Titers decrease with time/treatment; following adequate treatment for primary/secondary disease, a 4-fold decline is typical within 6 to 12 months.
    - Absence of a 4-fold decline suggests potential treatment failure.
    - ~15% of appropriately treated patients do not have a 4-fold decline in titer 12 months after treatment. Management is unclear, repeat HIV testing and/or CSF examination and continue to follow titers.
    - With appropriate treatment, titers should become negative (see serofast reaction).
    - Titers of patients treated in latent stages decline more gradually.

- Prozone phenomenon: negative results from high titers of antibody; test with diluted serum
- Serofast reaction: persistently positive results years after successful treatment; new infection diagnosed by 4-fold rise in titer
- Conditions that may alter treponemal testing (all stages of syphilis can have a false-negative RPR result, especially in primary syphilis)
  - Pregnancy, autoimmune disease, mononucleosis, malaria, leprosy, viral pneumonia, cardiolipin antigens, injection drug use, acute febrile illness, HIV infection; elderly can have false-positive results.

- Treponemal tests (*confirmatory test after positive nontreponemal screening test*): FTA-ABS, TP-PA (*T. pallidum particle agglutination*) (5)[A]:
  - Confirmatory test; not used for screening
  - Usually positive for life after treatment
  - Titers of no benefit
  - 15–25% of patients treated during primary stage revert to serologic nonreactivity after 2 to 3 years.
- Lumbar puncture indicated for (5)[A]:
  - Neurologic, ocular, or auditory manifestations
  - Some experts advise LP in all secondary and early latent cases—even without neurologic symptoms
  - HIV-positive patients with late latent/latent of unknown duration
  - Patients with late latent/latent of unknown duration if nonpenicillin therapy planned
  - Treatment failures
  - Other evidence of active tertiary syphilis is present (e.g., aortitis, gumma, iritis)
  - Children to rule out neurosyphilis
  - VDRL, not RPR, used on CSF; may be negative in neurosyphilis; highly specific but insensitive
  - Send CSF for protein, glucose, and cell count.
  - Monitor resolution with cell count at 6 months along with serologies (see “Patient Monitoring”).
  - Negative FTA-ABS or microhemagglutination (MHA)-TP on CSF excludes neurosyphilis (highly sensitive).

- Positive FTA-ABS or MHA-TP on CSF is not diagnostic because of high false-positive rate.
- Traumatic tap, tuberculosis (TB), pyogenic/aseptic meningitis can all result in false-positive VDRL.

TREATMENT

GENERAL MEASURES

- Advise patients to notify partners and to avoid intercourse until treatment is complete (5)[A].
- Test for HIV (3,5)[A].
- Management of sexual contacts (5)[A]
  - Presumptively treat partners exposed within 90 days of diagnosis.
  - Presumptively treat partners exposed >90 days before diagnosis if serologic results are not available immediately and follow-up is uncertain.
  - Presumptively treat those exposed to a patient diagnosed with syphilis of unknown duration who has high treponemal titers (>1:32).
  - Long-term sex partners of patients with latent infection should be evaluated clinically (including serologies) and treated accordingly.

MEDICATION

ALERT

Bicillin L-A should be used instead of Bicillin C-R (combination benzathine–procaine penicillin) when penicillin G benzathine is indicated.

First Line

Parenteral penicillin G is the drug of choice. The formulation is determined by the disease stage and clinical presentation.

- Primary, secondary, and early latent <1 year (5)[A]
  - Benzathine penicillin G 2.4 million Units IM × 1 dose
  - Penicillin-allergic patients: doxycycline 100 mg PO BID for 2 weeks, or tetracycline 500 mg PO QID for 2 weeks, or ceftriaxone 1 to 2 g IM or IV daily for 10 to 14 days
    - Azithromycin 2 g PO × 1 dose (early syphilis only; should not be used in

HIV, MSM, or pregnancy)
    - Resistance and treatment failures have been noted in several U.S. regions.
- Late latent/latent of unknown duration and tertiary without evidence of neurosyphilis (5)[A]
  - Benzathine penicillin G 2.4 million units IM weekly × 3 doses
  - Penicillin-allergic patients: Attempt desensitization and treatment with penicillin or doxycycline 100 mg PO 2 BID for 28 days, or tetracycline 500 mg PO QID for 28 days; compliance may be an issue.
- Ocular or neurosyphilis (5)[A]
  - Aqueous crystalline penicillin G 3 to 4 million units IV q4h as continuous infusion for 10 to 14 days
  - Alternative: Procaine penicillin G 2.4 million units IM daily in conjunction with probenecid 500 mg PO QID × 10 to 14 days (if compliance can be ensured)
  - Penicillin-allergic patients: Attempt desensitization and treat with penicillin; ceftriaxone 2 g/day IM or IV for 10 to 14 days.
  - If late latent, latent of unknown duration, or tertiary in addition to neurosyphilis, consider also treating as recommended for late latent after completion of neurosyphilis treatment.
- Congenital (5)[A]
  - Aqueous crystalline penicillin G 50,000 units/kg/dose IV q12h for the first 7 days of life and q8h thereafter for a total of 10 days, or procaine penicillin G 50,000 units/kg/dose IM daily for 10 days
  - If negative CSF serologies, normal physical exam, and titer: maternal titer, then 50,000 units/kg benzathine penicillin G IM in single dose
  - If >1 day of drug is missed, restart course.
  - Children (after newborn period): aqueous crystalline penicillin G 50,000 units/kg/dose IV q4–6h for 10 days; late latent, 50,000 units/kg IM as 3 doses at 1-week intervals
  - For contacts without symptoms: Treat as primary disease after serologies are obtained.
  - HIV-infected and pregnant patients may show poor response to recommended IM doses. Use IV therapy for all treatment failures in these patients.

  - Do not give benzathine or procaine penicillins IV.
- Children (after newborn period) (5)[A]: aqueous crystalline penicillin G 50,000 U/kg/dose IV q4–6h × 10 days; late latent, 50,000 U/kg IM as three doses at 1-week intervals
- Pregnancy (5)[A]
  - Treatment is the same as for nonpregnant patients.
  - Some recommend 2nd dose of 2.4 million units benzathine penicillin G 1 week after initial dose in 3rd trimester or with primary, secondary, or early latent syphilis.
  - Penicillin sensitivity: no proven alternatives to penicillin available for treatment during pregnancy
  - Penicillin-allergic patients: Desensitize and treat with penicillin.
  - HIV-infected pregnant patients may show poor response to recommended IM doses. Use IV therapy for all treatment failures in these patients.
- Treat contacts without symptoms as primary disease after obtaining serologies.
- History of penicillin allergy:
  - Confirmed IgE-mediated reaction: desensitization
  - Questionable history of IgE-mediated hypersensitivity: penicillin skin testing if major and minor penicillin determinants available
- Precautions (5)[A]
  - HIV-infected and pregnant patients may show poor response to recommended IM doses. Use IV therapy for all treatment failures in these patients.
  - Do not give benzathine or procaine penicillins IV.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Clinical and serologic evaluation 6 to 12 months after treatment; if >1 year duration, check at 24 months (5)[A].
- In HIV-infected persons, clinical and serologic evaluation at 3, 6, 9, 12, and 24 months after therapy (5)[A]

Patient Monitoring

- Use VDRL or RPR test to monitor therapy: 4-fold rise (two dilutions) in titer indicates new infection, whereas failure to decrease 4-fold (two dilutions) in 6 to 12 months may indicate treatment failure (although definitive criteria for cure not established); always use same test (preferably same lab) (5)[A].
- Urge retreatment for persistent clinical signs or recurrence, 4-fold rise in titers, or failure of initially high titer to decrease 4-fold by 6 to 12 months.
- Neurosyphilis: Repeat lumbar puncture every 6 months to check for normalization of CSF cell count (± CSF-VDRL and protein evaluation) (5) [A].

PATIENT EDUCATION

No intimate contacts until 4-fold titer drop

PROGNOSIS

- Excellent in all cases except patients with late syphilis complications and with HIV infection
- Syphilis in HIV-infected patient
  - Treatment same as for HIV-negative patients
  - More often false-negative treponemal and nontreponemal tests or unusually high titers
  - Response to therapy less predictable
  - Early syphilis: increased risk of neurosyphilis and higher rates of treatment failure
  - Late neurosyphilis: harder to treat; can occur up to 20+ years after infection

COMPLICATIONS

- Membranous glomerulonephritis
- Paroxysmal cold hemoglobinemia
- Meningitis and tabes dorsalis
- Cardiovascular aneurysms; valvular damage
- Irreversible organ damage
- Jarisch-Herxheimer reaction
  - Fever, chills, headache, myalgias, new rash
  - Common when starting treatment (of primary/secondary disease; less

common with tertiary) owing to lysis of treponemes
  - Should not be confused with drug reaction
  - Managed with analgesics and antipyretics

CODES

ICD10

- A53.9 Syphilis, unspecified
- A51.0 Primary genital syphilis
- A53.0 Latent syphilis, unspecified as early or late

CLINICAL PEARLS

- Screen all HIV-positive patients and patients with high-risk sexual behaviors

for syphilis.

- Penicillin remains the treatment of choice for syphilis.
- Syphilis rates are rising—particularly among MSM.

TARSAL TUNNEL SYNDROME

Jeff Wang, MD, MPH • J. Herbert Stevenson, MD

BASICS

DESCRIPTION

A compression neuropathy of the posterior tibial nerve as it passes behind the medial malleolus and under the flexor retinaculum (laciniate ligament) in the medial ankle (the tarsal tunnel)

Pregnancy Considerations

- Tarsal tunnel syndrome can occur during pregnancy, typically secondary to local compression caused by fluid retention and volume changes (1).
- Care is supportive. Most cases resolve after pregnancy.

EPIDEMIOLOGY

- Women are slightly more affected than men (56%).
- All postpubescent ages are affected.

ETIOLOGY AND PATHOPHYSIOLOGY

- The posterior tibial nerve passes through the tarsal tunnel, which is formed by three osseus structures—sustentaculum tali, medial calcaneus, and medial malleolus—covered by the laciniate ligament.
- Compression of the posterior tibial nerve within the tarsal tunnel results in decreased blood flow, ischemic damage, and resultant symptoms (1).
- Chronic compression can destroy endoneurial microvasculature, leading to edema and (eventually) fibrosis and demyelination (2).
- Increased pressure in the tarsal tunnel is caused by a variety of mechanical and biochemical mechanisms. The specific cause for compression is identifiable in only 60–80% of patients (1).
- Three general categories: trauma, space-occupying lesions, deformity (1)
  - Trauma including displaced fractures, deltoid ligament sprains, or tenosynovitis
  - Varicosities

  - Hindfoot varus or valgus
  - Fibrosis of the perineurium
- Other causes:
  - Osseous prominences
  - Ganglia; lipoma; neurolemmoma
  - Inflammatory synovitis
  - Pigmented villonodular synovitis
  - Tarsal coalition
  - Accessory musculature
- In patients with systemic disease (e.g., diabetes), the “double crush” syndrome refers to the development of a second compression along the same nerve at a site of anatomic narrowing in patients with previous proximal nerve damage (3).
- Tarsal tunnel decompression may improve sensory impairment and restore protective sensation in diabetic peripheral neuropathies if there is nerve entrapment at the tarsal tunnel.

RISK FACTORS

- Tarsal tunnel syndrome is associated with certain occupations and activities involving repetitive weight bearing on the foot and ankle (jogging, dancing).
- Other possible risk factors include (4):
  - Diabetes
  - Systemic inflammatory arthritis
  - Connective tissue disorders
  - Obesity
  - Varicosities
  - Heel varus or valgus
  - Bifurcation of the posterior tibial nerve into medial and lateral plantar nerves proximal to the tarsal tunnel

DIAGNOSIS

Tarsal tunnel syndrome is largely a clinical diagnosis, characterized by pain and paresthesias in a predictable distribution along the medial aspect of the ankle and

plantar surface of the foot (1).

HISTORY

- History of trauma (may be trivial) to the foot precipitating pain
- Pain behind medial malleolus radiating to the longitudinal arch and plantar aspect of foot including the heel
- Tightness, burning, tingling, and numbness (1)
- Pain usually worsens during standing or activity.
- Pain radiates proximally up the medial leg (Valleix phenomenon) in 33% of patients with severe compression.
- Some patients have substantial night pain (may be related to venostasis).
- Symptoms improve with rest, wearing loose footwear, and elevation.
- In advanced nerve compression, motor involvement may cause weakness, atrophy, and digital contractures of the intrinsic foot muscles (4).

ALERT

Other systemic neuropathies (diabetes, alcoholism, HIV, drug reactions) present with similar symptoms.

PHYSICAL EXAM

- Foot alignment
  - Examine for hindfoot varus or valgus deformity.
  - Exaggerating heel dorsiflexion, inversion, or eversion may reproduce symptoms by stretching or compressing the posterior tibial nerve.
- Palpate the tarsal tunnel and the course of the tibial nerve for tenderness and swelling.
- Tinel sign: Percussion over the the tibial nerve may reproduce paresthesias that radiate distally.
- Valleix sign: Percussion over the tibial nerve may produce paresthesias that radiate proximally.
- Cuff test: Inflating a pneumatic cuff engorges varicosities and reproduces symptoms.
- Compression test: Applying pressure to the tarsal tunnel for 60 seconds may reproduce symptoms.
- Sensory examination

  - The medial calcaneal nerve usually is spared, but numbness and altered sensation may be present in the distribution of the medial or lateral plantar nerves.
  - Vibratory sensation and two-point discrimination are decreased early in the disease process.
- Motor examination
  - Intrinsic foot muscle weakness (difficult to assess)
  - Rarely, weakness of toe plantar flexion may be present.
  - Atrophy of the abductor hallucis or abductor digiti minimi may be seen late in the disease process.

DIFFERENTIAL DIAGNOSIS

- Peripheral neuropathies (diabetes, alcoholism, HIV, or drug related)
- Inflammatory arthritis (rheumatoid arthritis)
- Morton neuroma
- Metatarsalgia
- Subtalar joint arthritis
- Tibialis posterior tendinitis/dysfunction
- Plantar fasciitis
- Plantar callosities
- Peripheral vascular disease
- Lumbar radiculopathy
- Proximal injury or compression of the tibial branch of the sciatic nerve

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

Routine lab tests help rule out other conditions that may mimic tarsal tunnel syndrome, including diabetic neuropathy, rheumatoid arthritis, thyroid dysfunction, or other systemic illnesses (5).

- Routine weight-bearing radiographs, followed by CT (if necessary) to assess for fracture or structural abnormality
- Consider evaluation of lumbar spine x-ray if double crush (injury to lumbar nerve results in compensatory injury to posterior tibial nerve) is suspected (5).
- MRI: helps assess the tarsal tunnel for soft tissue masses or other sources of nerve compression before surgery (1)

- Ultrasound: Gaining importance and with several advantages over MRI (6); can assess for tenosynovitis, ganglia, varicose veins, or lipomas (1)

Pediatric Considerations

MRI is recommended for evaluating pediatric tarsal tunnel syndrome to exclude neoplastic mass.

Diagnostic Procedures/Other

Electrodiagnostic studies

- Electromyography (EMG) of the intrinsic muscles of the foot can confirm the diagnosis of tarsal tunnel syndrome (7). A normal EMG does not exclude the diagnosis (false-negative rate is ~10%) (1).
- Nerve conduction studies may reveal slowed conduction of the tibial nerve.
- Evaluate for proximal nerve compression, including a lumbar radiculopathy or a double crush phenomenon.

TREATMENT

Conservative management is recommended, except for acute onset tarsal tunnel syndrome or in the setting of a known space-occupying lesion (excluding synovitis).

MEDICATION

First Line

- Analgesics and anti-inflammatory medications
- Local corticosteroid injection
- Medications that alter neurogenic pain (tricyclic antidepressants, antiepileptic drugs, nerve blockers)

ADDITIONAL THERAPIES

- Rest/immobilization
- Taping and bracing
- Orthotics or shoe modification
- Physical therapy to strengthen the intrinsic and extrinsic muscles of the foot and to restore the medial longitudinal arch
- Other modalities (stretching, US, massage, icing)

- Compression stockings to decrease swelling
- Weight loss for obese patients

SURGERY/OTHER PROCEDURES

- Surgery is indicated (1,2,8).
  - If nonoperative measures fail following a 3- to 6-month trial
  - In the setting of acute tarsal tunnel syndrome
  - If a space-occupying lesion is identified
- The surgical outcome is dependent on technique and postoperative management. 50–95% of cases have good to excellent outcomes.
- At the time of surgery, assess focal swelling, scarring, or nerve abnormalities and look for a pathologic source of compression.
- Postoperative management includes:
  - Non–weight-bearing splint until incision heals (2 to 3 weeks), followed by progressively increased weight-bearing and range of motion exercises
  - Rest, ice, compression, elevation to limit swelling

ONGOING CARE

PATIENT EDUCATION

- Discuss conservative and surgical options based on individual patient circumstance and preference.
- A decision about surgical intervention should be made with a clear understanding risks, benefits, and potential adverse outcomes.

PROGNOSIS

Surgery is most helpful for:

- Patients with a positive Tinel sign (3)[B]
- Young patients
- Short period between occurrence of symptoms and surgery <1 year (9)[B].
- Localized space-occupying lesion (1)
- No motor neuron involvement

COMPLICATIONS

- The main adverse outcome is an unsuccessful surgical intervention

characterized by lack of improvement or recurrence of symptoms (1).

- Causes for a failed tarsal tunnel release include (10):
  - Incorrect diagnosis
  - Incomplete release
  - Adhesive neuritis (external scar formation)
  - Intraneural damage (systemic disease, direct nerve injury)
  - Failure to treat all sources of nerve compression in a double crush phenomenon
- Electrodiagnostic studies are rarely helpful in determining the cause of a failed tarsal tunnel release.
- Results with surgical revision are poorer than those for the primary surgical release.

SEE ALSO

Algorithm: Foot Pain

CODES

ICD10

- G57.50 Tarsal tunnel syndrome, unspecified lower limb
- G57.51 Tarsal tunnel syndrome, right lower limb
- G57.52 Tarsal tunnel syndrome, left lower limb

CLINICAL PEARLS

- Tarsal tunnel syndrome typically presents with pain and tingling of the medical ankle and plantar foot.
- Tinel sign is the most sensitive and specific physical examination test for diagnosing tarsal tunnel.
- EMG cannot independently diagnose tarsal tunnel syndrome; it is used to confirm a clinical diagnosis.
- Conservative management is recommended, except for patients with an acute

onset tarsal tunnel syndrome or known space-occupying lesion.

TELOGEN EFFLUVIUM

Quratulanne H. Jan, MD • Arham K. Barakzai, MD

BASICS

Diffuse hair loss or hair thinning; most often an acute self-limited process

DESCRIPTION

Telogen effluvium (TE) is a transient condition in which there is a premature conversion of a significant proportion of anagen (growth phase) hairs into telogen (resting phase) hairs resulting in increased shedding of these resting hair follicles and the clinical appearance of moderate to severe hair thinning.

- Five proposed types of TE (1)
  - Immediate anagen release: a highly common form, lasting 3 to 4 weeks, in which follicles meant to remain in anagen phase enter telogen prematurely due to a signal, including high fever, drug induced, or stress
  - Delayed anagen release: occurs most often postpartum, in which a large group of hair follicles that have remained in the anagen phase for an extended period all together enter the telogen phase, resulting in hair loss
  - Short anagen: a somewhat speculative type, in which at least 50% of the hair follicles have an idiopathic shortening of the anagen phase, resulting in a corresponding doubling of the follicles in the telogen phase
  - Immediate telogen release: Normal resting club hairs remain within the hair follicle until an unknown signal causes their release, initiating the anagen stage to begin. In this type, the resting club hairs are prematurely released, ending the telogen phase abruptly and causing diffuse shedding.
  - Delayed telogen release: in this type, the presence of increased visible light, whether it be a seasonal or environmental change, is thought to end a prolonged telogen phase and initiate the anagen phase, resulting in diffuse shedding of hair follicles.

EPIDEMIOLOGY

Incidence

Second most common cause of alopecia

Prevalence

Unknown

ETIOLOGY AND PATHOPHYSIOLOGY

- The hair cycle consists of two predominant phases. The anagen (growth phase) and the telogen (resting phase), lasting ~3 years and 3 months, respectively. On the scalp, ~10–15% of hairs are in the telogen phase normally. Due to the presence of some types of external/internal stress, there may be an increase in the percentage of telogen hairs. As new anagen hairs emerge, these telogen hair follicles are forced out. The preceding event usually occurs 2 to 3 months prior to the appearance of hair loss.
- It is hypothesized that substance P plays a key role in the pathogenesis of TE through various mechanisms (2,3). Studies have been conducted on human hair follicles in vitro and mice hair follicles in vivo, which support this theory.
- Role of substance P includes the following (4):
  - Upregulation of substance P receptor, NK1, at the gene and protein level, leading to premature catagen development and hair growth inhibition
  - Upregulation of nerve growth factor (NGF) and subsequently its hair apoptosis–producing receptor, p75NTR
  - Downregulation of hair growth–promoting receptor, TrkA
  - Upregulation of major histocompatibility class (MHC) I and β_2-microglobulin resulting in loss of hair follicle immune-privilege
  - Increase in tumor necrosis factor-α release by mast cells resulting in hair keratinocyte apoptosis
- Decreased cortisol levels in chronic stress states may also enhance the effects of substance P (5).

RISK FACTORS

- Infection
- Trauma
- Major surgery
- Thyroid disorder
- Febrile illness
- Malignancy
- Allergic contact dermatitis (6)

- Iron deficiency anemia (7,8)
- Excess vitamin A (1)
- Protein-calorie restriction (1)
- End-stage liver or renal disease
- Hormonal changes (including pregnancy, delivery, and estrogen-containing medications) (1)
- Chronic stress
- Drug induced (β-blockers, anticonvulsants, antidepressants, anticoagulants, retinoids, ACE-inhibitors, etc.) (1)
- Immunizations

DIAGNOSIS

HISTORY

- Commonly, an inciting event 2 to 6 months previous
- Fear of becoming bald
- Patients often present with bags of hair to emphasize the severity of their hair loss.

PHYSICAL EXAM

- Decreased density of hair on the scalp, most commonly involving the crown
- In rare cases of chronic TE, there is hair loss of eyebrows and pubic region.
- May be able to demonstrate diffuse shedding of hair when running fingers through scalp
- Shed hairs are telogen hairs, which have a small bulb of unpigmented or pigmented keratin on the root end.
- May affect nail growth, resulting in the appearance of Beau lines, which are transverse grooves on the nails of the hands and feet

DIFFERENTIAL DIAGNOSIS

- Hypothyroidism
- Hyperthyroidism
- Alopecia areata (diffuse pattern)
- Androgenetic alopecia
- Drug-induced alopecia

- Systemic lupus erythematosus
- Secondary syphilis
- Trichotillomania

DIAGNOSTIC TESTS & INTERPRETATION

Most often, TE is a clinical diagnosis of exclusion. Blood work may be collected primarily to rule out other possible causes of hair loss and/or to identify a possible cause for TE.

Initial Tests (lab, imaging)

If indicated:

- CBC, ferritin
- TSH
- Creatinine
- Consider hepatic enzymes.
- Consider RPR/VDRL.

Diagnostic Procedures/Other

- Hair pull test: unreliable; performed by gently pulling 25 to 30 hairs from various sites on a patient's scalp. Each pull should elicit <5 normal club hairs; increased quantity may indicate possibility of TE (1).
- Hair clip test: Performed by cutting 25 to 30 hairs from the patient's scalp and examining them under a microscope. A negative test (not indicative of TE) will demonstrate <10% of hair shafts of small diameter. A positive test will demonstrate >10% of hair shafts of small diameter (1).
- Trichogram: ~50 hairs are plucked from the patient's scalp, and the number of telogen and anagen hairs present are counted. In TE, there will be >10% of hairs in the telogen phase.
- Scalp biopsy: rarely needed; it is recommended that several 4-mm punch biopsies be obtained, all horizontally embedded to determine an accurate anagen-to-telogen ratio. Histologically, catagen-to-telogen hairs have numerous apoptotic cells in the outer sheath epithelium. >12–15% of hair follicles in telogen phase is consistent with TE (1,9).

TREATMENT

TE is a benign, self-limited process. Identify and correct underlying cause. Patient should be reassured that full hair growth will occur in ~6 months to 1 year. No treatment is required.

MEDICATION

- Minoxidil stimulates hair regrowth via arteriolar smooth muscle vasodilation; not effective in TE
- Oral zinc therapy: New medication that may have benefits for patients with TE through various mechanisms all essential to hair growth, including the following (10)[C]:
  - Cofactor for enzymes needed in nucleic acid and protein synthesis and cell division
  - Inhibition of the catagen phase by blocking certain enzymes involved in hair apoptosis
  - Involved in hair growth regulation via hedgehog signaling

COMPLEMENTARY & ALTERNATIVE MEDICINE

Nigella Sativa (black cumin) essential oil has also been studied and may be beneficial (11).

CODES

ICD10

L65.0 Telogen effluvium

CLINICAL PEARLS

- TE is a self-limited form of nonscarring alopecia; most often acute.
- TE is due to a premature conversion of a significant proportion of anagen (growth phase) hairs into telogen (resting phase) hairs, resulting in increased shedding of these resting hair follicles and the clinical appearance of moderate to severe hair thinning and loss when growth resumes.

- There are many potential causes of TE, both emotional and physiologic. Often it is hard to determine the etiology, but eliminating the stressor often is the key to resolving TE and stimulating new hair growth.
- No treatment is needed. Patient should be reassured that complete hair regrowth will occur in 6 months to 1 year.

TEMPOROMANDIBULAR JOINT DISORDER (TMD)

Jessica Johnson, MD, MPH • Benjamin N. Schneider, MD

BASICS

DESCRIPTION

- Syndrome characterized by
  - Pain and tenderness involving the muscles of mastication and surrounding tissues
  - Sound, pain, stiffness, or grating in the temporomandibular joint (TMJ) with movement
  - Limitation of mandibular movement with possible locking or dislocation
  - Recent research suggests that TMD is a complex disorder with multiple causes consistent with a biopsychosocial model of illness (1)[B].
- System(s) affected: musculoskeletal
- Synonym(s): TMJ syndrome; TMJ dysfunction; myofascial pain–dysfunction syndrome; bruxism; orofacial pain

EPIDEMIOLOGY

Incidence

- Symptoms more common in ages 30 to 50 years
- Predominant sex: female > male (4:1)

Prevalence

General prevalence is 6–12% in both adults and older children. Up to 1/2 of the population have at least one sign or symptom of TMD, but most are not limited by symptoms, and <1:4 seek medical or dental treatment.

ETIOLOGY AND PATHOPHYSIOLOGY

- Pathophysiology is multifactorial, involving anatomic, behavioral, emotional, and cognitive factors.
- The American Academy of Orofacial Pain categorizes TMD according to

three anatomic origins of pain. The change in name from TMJ to TMD emphasizes that most patients suffer from muscular and not articular pain.

- Muscle disorders involving the muscles of mastication
  - Occlusomuscular dysfunction (bruxism)
  - Masticatory muscle spasm
  - Myositis
  - Myofibrosis
  - Poorly fitting oral devices (dentures, splints, etc.)
  - Contracture
  - Neoplasia
- Articular disorders of the joint
  - Congenital disorders
  - Inflammatory disorders: synovitis, arthritides, capsulitis, ankyloses
  - Avascular necrosis (rare)
  - TMJ disk derangement, osteoarthritis
  - Hyper- or hypomobile TMJ
  - TMJ trauma: condylar fractures, dislocation
- Cranial bone disorder including the mandible
  - Congenital and developmental disorders
  - Acquired disorders (fracture, neoplasm)

Genetics

Research is ongoing in gene polymorphisms associated with TMD and other pain disorders. These include the catechol O-methyltransferase gene (COMT), which is thought to be associated with changes in pain responsiveness.

RISK FACTORS

- Macrotrauma to the face, jaw, and neck, including cervical whiplash injuries and hyperextension of jaw
- Rheumatologic and degenerative conditions involving the TMJ
- Psychosocial stress and poor adaptive capabilities
- Repetitive microtrauma from dental malocclusion, including inappropriate dental treatment
- Link with bruxism and jaw/teeth clenching is inconsistent.

GENERAL PREVENTION

- Elimination of tension-causing oral habits
- Reduction in overall muscle tension

COMMONLY ASSOCIATED CONDITIONS

Craniomandibular disorders, somatization disorder, somatoform pain disorder, other chronic pain syndromes, fibromyalgia, juvenile idiopathic arthritis, tension headache, sleep disturbance, tobacco use

DIAGNOSIS

- TMD is a clinical diagnosis, and localized pain is the unifying feature.
- Several research classification systems exist. Most share several of the history and physical findings listed below.

HISTORY

- Facial and/or TMJ pain
- Locking/catching of jaw; decreased range of motion
- TMJ noises: clicking, grinding, popping
- Headache, earache, neck pain

PHYSICAL EXAM

- Facial symmetry, muscle hypertrophy, intraoral exam
- Palpation of muscles of mastication may reproduce pain.
- Test jaw range of motion (opening, closing, lateral, protrusive) and masticatory muscle strength.
  - Maximal (pain-free) jaw opening with interincisal distance <40 mm is suggestive of joint rather than muscle pathology if accompanied by other signs and symptoms (normal 35 to 55 mm).
  - Deviation to the affected side is common.
- Muscle tenderness and restricted pain-free opening are most consistent distinguishing signs.
- There may be tenderness over the TMJ.
- Clicking or crepitus of jaw with opening

DIFFERENTIAL DIAGNOSIS

- Condylar fracture/dislocation
- Trigeminal neuralgia
- Dental or periodontal conditions
- Neoplasm of the jaw, orofacial muscles, or salivary glands
- Acute, nondental infection: parotitis, sialadenitis, otitis, mastoiditis
- Jaw claudication: giant cell arteritis
- Migraine or tension type headache
- Ramsay-Hunt syndrome (zoster auricular syndrome)

DIAGNOSTIC TESTS & INTERPRETATION

- There are no labs to rule in TMD.
- Blood work may be useful to rule out other conditions (CBC, CMP, ESR, CRP).

Initial Tests (lab, imaging)

- TMD is a clinical diagnosis based primarily on history and physical exam.
- Often, a poor correlation is found between pain severity and pathologic changes seen in joint or muscle tissues. Consider the following for severe or treatment-resistant cases, with MR or CT more useful as part of surgical workup:
  - Panoramic dental radiographs are a good first-line screen.
  - CT scan allows fine detail of bony structures, preferred for trauma.
  - US: Effusion and findings correlate with MRI and subjective pain.
  - MRI: noninvasive study for disc position; more sensitive than US; can help determine need for surgical management

Diagnostic Procedures/Other

- Local anesthetic nerve block can differentiate orofacial pain of articular versus muscular origin.
- Arthroscopy can be diagnostic for cartilage and bony pathology.

Test Interpretation

Positive findings include:

- Condylar head displacement
- Anterior disc displacement
- Posterior capsulitis

- Loosening of disc and capsular attachments
- Chondroid metaplasia of disc leading to disc perforation and degeneration

TREATMENT

Signs and symptoms will abate without intervention in most patients. 50% report improvement in 1 year and 85% by 3 years. With conservative therapy, symptoms resolve in 75% of cases within 3 months.

- Therapeutic exercises, especially if displacement is present, including formal physical therapy
- Psychosocial interventions, including cognitive-behavioral therapy with or without biofeedback (2)[A]
- Behavior modification to eliminate tension-relieving oral habits (2)[A]
- Occlusal adjustment cannot be recommended for the management or prevention of TMD, as there is an absence of evidence from RCTs that occlusal adjustment treats or prevents TMD (3)[A].
- Insufficient evidence exists either for or against the use of stabilization splint therapy for the treatment of TMD (4)[A].
- The American Dental Association recommends a “less is often best” stepwise approach and offers the following stepwise progression for therapy:
  - Eating softer foods
  - Avoiding chewing gum and nail biting
  - Modifying pain with heat or ice
  - Relaxation techniques including meditation and biofeedback
  - Exercises to strengthen jaw muscles
  - Medications
  - Night guards and orthotics

MEDICATION

First Line

- Acetaminophen
- Naproxen: stronger evidence than for other NSAIDs
- Topical methylsalicylate
- Gabapentin

- Ibuprofen, if osteoarthritis is suspected (5)[B]

Second Line

- Muscle relaxants
- Tricyclic antidepressants, SSRIs, or SNRIs
- Acupuncture
- Opiates should be reserved for perioperative or severe or recalcitrant cases (5)[B].
- Ineffective medications (5)[B]
  - The following medications when compared with placebo in RCTs were shown to be ineffective in improving pain and should not be used for the treatment of TMD:
    - Benzodiazepines
    - Topical capsaicin
    - Diclofenac
    - Celecoxib

ADDITIONAL THERAPIES

Joint and muscle injections

- There is very limited evidence to recommend for or against injections into or around the TMJ. Proposed therapies include steroids, hyaluronic acid, local anesthetics, and, recently, botulinum toxin.
- Steroids given >3 times annually may accelerate degenerative changes.
- Injections into inferior space or double spaces have better effect than superior space injections alone.
- Recent studies suggest that botulinum toxin type A (Botox) injections may be successful in cases that have failed first-line pharmacologic therapy (6)[B].

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Glucosamine may be effective if pain is secondary to osteoarthritis of the TMJ (5)[B].
- Multiple electronic diagnostic and treatment modalities are currently marketed to patients; however, the scientific literature does not support the use of electronic diagnostic and treatment devices for TMD at this time.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Relax jaw by disengaging teeth.
- Avoid wide, uncontrolled opening, such as yawning.
- Stress management and behavior modification counseling may be helpful.
- Be aware of any teeth-clenching or grinding habits.

Patient Monitoring

- Ongoing assessment of clinical response to conservative therapies (NSAIDs, behavior modification, occlusal splints) is necessary.
- Surgical procedure (arthroplasty, joint replacement) to correct disc displacement or replace a damaged disc may be indicated only if the patient has not responded to conservative treatment.

DIET

Soft diet to reduce chewing

PROGNOSIS

- With conservative therapy, symptoms resolve in 75% of cases within 3 months.
- Patients benefit most from a comprehensive treatment approach including the following (7):
  - Restoration of normal muscle function
  - Pain control
  - Stress management
  - Behavior modification

COMPLICATIONS

- Secondary degenerative joint disease
- Chronic TMJ dislocation
- Loss of joint range of motion
- Depression and chronic pain syndromes
- Secondary headache disorder

Headache, Tension

CODES

ICD10

- M26.60 Temporomandibular joint disorder, unspecified
- M26.62 Arthralgia of temporomandibular joint
- M26.63 Articular disc disorder of temporomandibular joint

CLINICAL PEARLS

- The condition called TMD actually designates a number of potential underlying joint and muscle conditions involving the jaw.
- Characteristics of all are pain and functional limitation.
- TMD is a clinical diagnosis with limited utility of imaging.
- Cognitive-behavioral therapy reduces pain, depression, and limitation of function.
- Exercises may improve function and pain.
- Evidence is lacking to support occlusion correction or splinting.
- Naproxen, gabapentin, topical methylsalicylate, glucosamine, amitriptyline, acupuncture, and botulinum toxin injections have some evidence of efficacy.

TESTICULAR MALIGNANCIES

Huy Tan Tran, MD, LCDR, MC, USN

BASICS

DESCRIPTION

- Testicular cancer accounts for 1% of all cancers in men; it is the most common solid malignancy in men aged 15 to 34 years (1).
- An estimated 8,720 new cases were diagnosed, and an estimated 380 deaths occurred in the United States in 2016 (2).
- Treatment produces an overall 5-year survival of 95.4%; for African American patients, this 5-year survival rate is alarmingly lower but has improved from 86% to 90% (2).

ETIOLOGY AND PATHOPHYSIOLOGY

95% of all malignant tumors arising in the testes are germ cell tumors (GCTs), which are subclassified as follows:

- Seminomatous GCTs: most common type overall
- Nonseminomatous GCTs (NSGCTs): These include embryonal cell carcinoma, choriocarcinoma, yolk sac tumor, teratomas, or often multiple cell types; these are more clinically aggressive tumors.

RISK FACTORS

- Cryptorchidism is the most firmly established risk factor: Relative risk of testicular cancer in all patients with cryptorchidism is 3 to 8, with a lower relative risk of 2 to 3 in those undergoing orchiopexy by age 12 years; in patients with unilateral cryptorchidism, the relative risk of testicular cancer in the contralateral normally descended testis is negligible (3).
- Personal history of testicular cancer
- Use of muscle building supplements
- Positive family history for testicular cancer
- Testicular dysgenesis
- Klinefelter syndrome
- Caucasian race

- HIV infections

GENERAL PREVENTION

No evidence that screening for testicular cancer is effective (4)

DIAGNOSIS

HISTORY

- A painless solid testicular mass is pathognomonic for testicular cancer.
- Clinical symptoms of epididymitis or orchitis that do not respond to treatment warrant further evaluation.
- Gynecomastia can be a rare systemic endocrine manifestation of testicular neoplasm.

PHYSICAL EXAM

- Testicular exam: Palpate for size, consistency, and nodules; masses do not transilluminate; a firm, hard, or fixed area should be considered suspicious.
- Lymph node and abdominal exam
- Gynecomastia

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- α-Fetoprotein (AFP), β-human chorionic gonadotropin (β-hCG), lactate dehydrogenase (LDH), creatinine, chemistry profile, complete blood count, liver enzymes, chest x-ray (CXR), and testicular ultrasound (US)
- Tumor markers AFP, β-hCG, and LDH are used to assist with diagnosis, prognosis, assessing treatment outcome, and monitoring for relapse:
  - AFP
    - Produced by nonseminomatous testicular cancer and is therefore associated with this histologic type
    - Those with a histologically “pure” testicular seminoma and an elevated AFP are assumed to possess an undetected focus of nonseminoma tumor.
  - β-hCG
    - May be associated with both seminomatous or nonseminomatous tumors
    - Hypogonadism and marijuana use may cause benign elevations of β-hCG.

- LDH is less specific than AFP.
- Testicular US is the initial study.
- If an intratesticular mass is identified, measure serum AFP, LDH, and β-hCG and order a CXR.
- CT scan of the abdomen/pelvis, positron emission tomography (PET) scan, MRI of the brain, and bone scan are used for staging and metastases evaluation as clinically indicated.

Diagnostic Procedures/Other

- Radical inguinal orchiectomy is the primary procedure for diagnosis and treatment.
- Testicular biopsy may be rarely considered if a suspicious intratesticular abnormality is identified on US; however, testicular microcalcification on US without any other abnormality can simply be observed and does not demand a biopsy.
- For those with unilateral testicular cancer, contralateral testicular biopsy is not routinely performed but should be considered when there is a cryptorchid testis, marked testicular atrophy, or a suspicious US for intratesticular abnormalities.

Test Interpretation

Clinical staging (5):

- Stage 0: carcinoma in situ
- Stage IA: tumor limited to testis and epididymis without vascular/lymphatic invasion; tumor may invade into the tunica albuginea but not the tunica vaginalis; normal serum tumor markers
- Stage IB: tumor limited to testis and epididymis with vascular/lymphatic invasion or tumor extending through tunica albuginea with involvement of tunica vaginalis; tumor invades the spermatic cord with or without vascular/lymphatic invasion; tumor invades the scrotum with or without vascular/lymphatic invasion; no lymph node involvement or distant metastasis; normal serum tumor markers
- Stage IS: any tumor with elevated serum tumor markers but no nodal involvement or metastasis
- Stage IIA: any tumor with lymph node mass/masses <2 cm

- Stage IIB: any tumor with lymph node mass/masses 2 to 5 cm
- Stage IIC: any tumor with lymph node mass >5 cm
- Stage IIIA: any tumor/lymph node presence; with nonregional nodal or pulmonary metastasis; either serum tumor markers normal or with mild elevation
- Stage IIIB: any tumor/lymph node presence; no distant metastasis or nonregional nodal involvement or pulmonary metastasis; with moderately elevated serum tumor markers
- Stage IIIC: any tumor/lymph node presence; with or without any metastasis; with greatly elevated serum tumor markers

DIFFERENTIAL DIAGNOSIS

Epidermoid cyst, epididymitis, hernia, hydrocele, hematoma, lymphoma, orchitis, spermatocele, testicular torsion, varicocele

TREATMENT

GENERAL MEASURES

- Seminoma: Specifics are noted in the National Comprehensive Cancer Network guidelines (1):
  - Stages IA, IB: Options may include surveillance (preferred) (for low tumor load malignancy, i.e., pT1–pT3), single-agent carboplatin, or radiotherapy (2)[A].
  - Stage IS: repeat elevated serum tumor marker and abdominal/pelvic CT scan (2)[A]
  - Stage IIA: radiotherapy to include para-aortic and ipsilateral iliac lymph nodes (preferred) or primary chemotherapy (2)[A]
  - Stage IIB: primary chemotherapy (preferred) or radiotherapy in select nonbulky cases to include para-aortic and ipsilateral iliac lymph nodes (2)[A]
  - Stages IIC, III
    - Good risk (any primary site and no nonpulmonary visceral metastases and normal AFP with any β-hCG or LDH): primary etoposide and cisplatin (EP) or bleomycin, etoposide, and cisplatin (BEP) chemotherapy (1)

    - Intermediate risk (any primary site and nonpulmonary visceral metastases and normal AFP with any β-hCG or LDH): primary BEP chemotherapy (1)
- Nonseminoma: Tumors with both seminomatous and nonseminomatous histology are managed as nonseminomatous. See “National Comprehensive Cancer Network guidelines” (1):
  - Stage IA: nonseminomatous surveillance protocol (preferred) or nerve-sparing retroperitoneal lymph node dissection (RPLND) (2)[A]
  - Stage IB: nerve-sparing RPLND or primary BEP chemotherapy (2)[A]; for T2 only can enter nonseminomatous surveillance protocol (2)[B]
  - Stage IS: primary chemotherapy followed by response evaluation:
    - Complete response, negative tumor markers: nonseminomatous surveillance protocol (2)[A]
    - Partial response, negative tumor markers: surgical resection of all residual masses (2)[A]
    - Incomplete response: consider second-line therapy (2)[A]
  - Stage IIA
    - Negative tumor markers: nerve-sparing RPLND (2)[A] or primary chemotherapy (2)[B]
    - Persistent marker elevation: primary chemotherapy followed by response evaluation
    - Complete response, negative tumor markers: nonseminomatous surveillance protocol (2)[A] or bilateral RPLND +/− nerve-sparing in select cases (2)[B]
    - Partial response, negative tumor markers: surgical resection of all residual masses (2)[A]
    - Incomplete response: Consider second-line therapy (2)[A].
  - Stage IIB
    - Negative tumor markers: primary chemotherapy or nerve-sparing RPLND in highly selected cases (2)[A]
    - Persistent marker elevation: primary chemotherapy followed by response evaluation
      - Complete response, negative tumor markers: nonseminomatous surveillance protocol (2)[A] or bilateral RPLND +/− nerve-sparing in

selected cases (2)[B]
    - Partial response, negative tumor markers: surgical resection of all residual masses (2)[A]
    - Incomplete response: Consider second-line therapy (2)[A].
  - Stage IIC: primary chemotherapy followed by response evaluation as per stages IIA and IIB (2)[A]
  - Stages IIIA, IIIB and IIIC: primary chemotherapy depending on risk profile, which is based on tumor, metastases, and postorchiectomy serum tumor markers (2)[A]
- Brain metastases: primary chemotherapy +/− radiotherapy, +/− surgery, as clinically indicated

MEDICATION

First Line

Primary chemotherapy regimens for GCTs:

- EP: Etoposide 100 mg/m^2/day IV on days 1 to 5, cisplatin 20 mg/m^2/day IV on days 1 to 5; repeat every 21 days (1)[A].
- BEP: Etoposide 100 mg/m^2/day IV on days 1 to 5, cisplatin 20 mg/m^2/day IV on days 1 to 5; bleomycin 30 U/dose IV weekly on days 1, 8, and 15 or days 2, 9, and 16; repeat every 21 days (1)[A].
- VIP: Etoposide 75 mg/m^2/day IV on days 1 to 5; mesna 120 mg/m^2 slow IV push before ifosfamide on day 1, then mesna 1,200 mg/m^2 IV continuous infusion on days 1 to 5; ifosfamide 1,200 mg/m^2/day on days 1 to 5; cisplatin 20 mg/m^2/day IV on days 1 to 5, repeat every 21 days (1)[A].

Second Line

- These agents are considered in patients who do not respond to first-line therapy or those who experience a recurrence: carboplatin, cisplatin, etoposide, ifosfamide, mesna, paclitaxel, and vinblastine (1)[A].
- Gemcitabine, oxaliplatin, and paclitaxel are used in palliative chemotherapy regimens (1)[A].

ADDITIONAL THERAPIES

Consider sperm banking before treatment that may compromise fertility; rarely covered by insurance

SURGERY/OTHER PROCEDURES

- Radical inguinal orchiectomy: primary treatment for testicular cancer for all patients; prosthesis can be inserted at this time.
- RPLND identifies nodal metastases and provides accurate pathologic staging of the retroperitoneum.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Pure seminoma: Specifics are noted in the National Comprehensive Cancer Network guidelines (1),(2)[A]:
  - Stages IA, IB: in general, H&P, optional tumor markers, every 3 to 6 months for 1 years, every 6 to 12 months for years 2 to 33, then annually for years 4 to 5; abdominal/pelvic CT at 3, 6, and 12 months then every 6 to 12 months for years 2 to 3, every 12 to 24 months for years 4 to 5; CXR, as clinically indicated; less frequent if adjuvant therapy is given
  - Stage IS: Repeat elevated serum tumor marker and assess with abdominal/pelvic CT scan for evaluable disease.
  - Stages IIA, IIB (select): in general, H&P, optional tumor markers every 3 months for year 1, every 6 months for years 2 to 5; abdominal/pelvic CT at 3 and 6 to 12 months, then annually for years 2 to 3, then as clinically indicated; CXR every 6 months for years 1 to 2
  - Stages IIB (select), IIC, and III: Check all serum tumor markers along with chest, abdominal, and pelvic CT:
    - Residual mass 0 to 3 cm and normal serum tumor markers: H&P, AFP, β-hCG, LDH, CXR every 2 months for year 1, every 3 months for year 2, every 6 months for years 3 to 4, then annually; abdominal/pelvic CT scan at 3 to 6 months then as clinically indicated, PET scans as clinically indicated
    - Residual mass >3 cm and normal serum tumor markers: PET scan 6 weeks after chemotherapy:
      - Negative PET scan: abdominal/pelvic CT scans every 6 months for year 1, then annually for 5 years

        - Positive PET scan: Consider RPLND or second-line chemotherapy or radiotherapy.
    - Any recurrence: Treat according to extent of disease at relapse.
- Nonseminoma: Specifics are noted in the National Comprehensive Cancer Network guidelines (1):
    - Stages IA and IB on surveillance only: H&P, AFP, β-hCG, LDH, every 2 months for year 1, every 3 months for year 2, every 4 to 6 months for year 3, every 6 months for year 4, annually thereafter; CXR and abdominal/pelvic CT depending on IA or IB
    - Follow-up after complete response to chemotherapy and RPLND in general: H&P, AFP, β-hCG, LDH every 2 to 3 months for years 1 to 2, every 6 months for years 3 to 5, annually thereafter; abdominal/pelvic CT every 6 months for year 1, annually for year 2, as clinically indicated thereafter
    - Follow-up after RPLND only: H&P, AFP, β-hCG, LDH, CXR every 2 months for year 1, every 3 months for year 2, every 4 months for year 3, every 6 months for year 4, annually thereafter; abdominal/pelvic CT at 3 to 4 months and, as clinically indicated, thereafter; CXR every 2 to 4 months year 1, 3 to 6 months year 2, annually thereafter

PROGNOSIS

>90% of patients diagnosed are cured, including 70–80% with advanced tumors (1).

COMPLICATIONS

- Surgical: hematoma, hemorrhage, infection, and infertility
- Radiotherapy: radiation enteritis and infertility
- Late complications (6):
    - Cardiovascular toxicity and second malignancies each have a 25-year risk of about 16% in those treated with chemotherapy and/or radiotherapy.
    - Risk for secondary malignancies remains increased for at least 35 years after treatment.
    - Increased incidence of metabolic syndrome occurs and is likely associated with lower testosterone levels.
    - Other late complications associated with chemotherapy, depending on the

regimen, include chronic neurotoxicity, ototoxicity, renal function impairment, and pulmonary fibrosis.

- The incidence of late relapse in treated testicular cancer is now estimated to be 2–6%; the time to late relapse ranges from 2 to 32 years, with a median of 6 years (6).

CODES

ICD10

- C62.90 Malig neoplasm of unsp testis, unsp descended or undescended
- C62.00 Malignant neoplasm of unspecified undescended testis
- C62.10 Malignant neoplasm of unspecified descended testis

CLINICAL PEARLS

- Testicular cancer is the most common solid organ tumor in men aged 15 to 34 years.
- Testicular US is initial imaging of choice for testicular pathology.
- Radical inguinal orchiectomy is used for both diagnosis and treatment, with possible radiotherapy or chemotherapy as adjuvant treatment.
- 96% overall survival at 10 years after diagnosis and treatment

TESTICULAR TORSION

Jonathan Green, MD • Michael P. Hirsh, MD, FACS, FAAP

BASICS

DESCRIPTION

- Twisting of testis and spermatic cord, resulting in acute ischemia and loss of testis if unrecognized:
  - Intravaginal torsion: occurs within tunica vaginalis, only involves testis and spermatic cord
  - Extravaginal torsion: involves twisting of testis, cord, and processus vaginalis as a unit. Typically seen in neonates.
- System(s) affected: reproductive

Geriatric Considerations

Rare in this age group

Pediatric Considerations

Peak incidence at age 14 years

EPIDEMIOLOGY

Incidence

- ~1/4,000 males before age 25 years
- Predominant age:
  - Occurs from newborn period to 7th decade
  - 65% of cases occur in 2nd decade, with peak at age 14 years.
  - 2nd peak in neonates (in utero torsion usually occurs around week 32 of gestation).

ETIOLOGY AND PATHOPHYSIOLOGY

- Twisting of spermatic cord causes venous obstruction, edema of testis, and arterial occlusion.
- “Bell clapper” deformity is most common anatomic anomaly predisposing to intravaginal torsion:

  - High insertion of the tunica vaginalis on the spermatic cord, resulting in increased testicular mobility within tunica vaginalis
  - Bilateral in ~80% of patients
- No clear anatomic defect is associated with extravaginal testicular torsion:
  - In neonates, the tunica vaginalis is not yet well attached to scrotal wall, allowing torsion of entire testis including tunica vaginalis.
- Usually spontaneous and idiopathic
- 20% of patients have a history of trauma.
- 1/3 have had prior episodic testicular pain.
- Contraction of cremasteric muscle or dartos may play a role and is stimulated by trauma, exercise, cold, and sexual stimulation.
- Increased incidence may be due to increasing weight and size of testis during pubertal development.
- Possible alterations in testosterone levels during nocturnal sex response cycle; possible elevated testosterone levels in neonates.
- Testis must have inadequate, incomplete, or absent fixation within scrotum.
- Torsion may occur in either clockwise or counterclockwise direction.

Genetics

- Unknown
- Familial testicular torsion, although previously rarely reported, may involve as many as 10% of patients.

RISK FACTORS

- May be more common in winter
- Paraplegia
- Previous contralateral testicular torsion

DIAGNOSIS

HISTORY

- Acute onset of pain, often during period of inactivity
- Onset of pain usually sudden but may start gradually with subsequent increase in severity.
- Nausea and vomiting are common:

  - Presence may increase the likelihood of testicular torsion versus other differential diagnoses.
- Prior history of multiple episodes of testicular pain with spontaneous resolution in an episodic crescendo pattern may indicate intermittent testicular torsion.

PHYSICAL EXAM

- Scrotum is enlarged, red, edematous, and painful.
- Testicle is swollen and exquisitely tender.
- Testis may be high in scrotum with a transverse lie.
- Absent cremasteric reflex

DIFFERENTIAL DIAGNOSIS

- Torsion appendix testis (this may account for 35–67% of acute scrotal pain cases in children)
- Epididymitis (8–18% of acute scrotal pain cases)
- Orchitis
- Incarcerated or strangulated inguinal hernia
- Acute hydrocele
- Traumatic hematoma
- Idiopathic scrotal edema
- Acute varicocele
- Epididymal hypertension (venous congestion of testicle or prostate due to sexual arousal that does not end in orgasm)
- Testis tumor
- Henoch-Schönlein purpura
- Scrotal abscess
- Leukemic infiltrate

DIAGNOSTIC TESTS & INTERPRETATION

- Doppler US may confirm testicular swelling but is diagnostic by demonstrating lack of blood flow to the testicle; PPV of 89.4% (1,2)[B].
- In boys with intermittent, recurrent testicular torsion, both Doppler US and radionuclide scintigraphy findings will be normal (2)[B].

Diagnostic Procedures/Other

- Doppler US flow detection demonstrates absent or reduced blood flow with torsion and increased flow with inflammatory process (reliable only in first 12 hours) (2)[B]
- Radionuclide testicular scintigraphy with technetium-99m pertechnetate demonstrates absent/decreased vascularity in torsion and increased vascularity with inflammatory processes (including torsion of appendix testes) (3)[C].

Test Interpretation

- Venous thrombosis
- Tissue edema and necrosis
- Arterial thrombosis
- Decreased Doppler flow also seen in hydrocele, abscess, hematoma or scrotal hernia (2)
- Sensitivity of radionuclide testicular scintigraphy is decreased relative to ultrasonography because hyperemia in the torsed testicle can mimic flow (3).

TREATMENT

- Manual reduction: Best performed by experienced physician; may be successful, facilitated by lidocaine 1% (plain) injection at level of external ring:
  - Difficult to determine success of manual reduction, especially after giving local anesthesia
  - Manual reduction might require sedation and the entire process may delay definitive treatment.
  - Even if successful, must always be followed by surgical exploration, urgently but not emergently (4)[C]
- Surgical exploration via scrotal approach with detorsion, evaluation of testicular viability, orchidopexy of viable testicle, orchiectomy of nonviable testicle (1)[B].
- In boys with a history of intermittent episodes of testicular pain, scrotal exploration is warranted with testicular fixation if abnormal testicular attachments are confirmed (1)[B].

GENERAL MEASURES

Early exam is crucial because necrosis of the testicle can occur after 6 to 8 hours (5)[C].

SURGERY/OTHER PROCEDURES

Operative testicular fixation of the torsed testicle after detorsion and confirmation of viability:

- At least 3- or 4-point fixation with nonabsorbable sutures between the tunica albuginea and the tunica vaginalis (1)[B]
- Excision of window of tunica albuginea with suture to dartos fascia (1,6)[B]
- Any testis that is not clearly viable should be removed (1)[B].
- Testes of questionable viability that are preserved and pexed invariably atrophy (1)[B]
- Bilateral testicular fixation is recommended by many surgeons (1)[B].
- Contralateral testicle frequently has similar abnormal fixation and should be explored (1)[B],(4)[C].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Postoperative visit at 1 to 2 weeks
- Yearly visits until puberty may be needed to evaluate for atrophy.

DIET

Regular

PATIENT EDUCATION

Possibility of testicular atrophy in salvaged testis with depressed sperm counts. Importantly, fertility rates in patients with one testicle remain excellent.

PROGNOSIS

- Testicular salvage:
  - Salvage is related directly to duration of torsion (85–97% if within 6 hours, 20% after 12 hours <10% if >24 hours) (5).
  - The degree of torsion is related to testicular salvage:

    - The median degree of torsion is <360 in patients who are explored and orchidopexy performed.
    - The median degree of torsion is 540 in patients who undergo exploration and require orchiectomy (7).
- 80–94% may have depressed spermatogenesis related to duration of ischemic injury (possibly related to autoimmune-mediated injury) (5).
- Up to 45% of patients undergoing orchiopexy for testicular torsion will develop atrophy of testicle.

COMPLICATIONS

- Possible testicular atrophy
- Abnormal spermatogenesis
- Infertility:
  – Fertility rates with one testicle remain excellent.
  – Nearly 36% of patients who experience torsion have sperm counts <20 million/mL (3).

CODES

ICD10

- N44.00 Torsion of testis, unspecified
- N44.01 Extravaginal torsion of spermatic cord
- N44.03 Torsion of appendix testis

CLINICAL PEARLS

- The diagnosis of testicular torsion is usually made by physical exam. Patients with suspected torsion should be taken to the OR without delay. If diagnosis is in question, a testicular Doppler US may be done to evaluate blood flow.
- Although testicular necrosis may be present within 6 to 8 hours of torsion, this is highly variable.
- Infertility can be a problem even if the testicle is viable. Autoimmune antibodies may be produced, and they may affect subsequent fertility.

TESTOSTERONE DEFICIENCY

Michael Lao, MD • Gregory Murphy, MD • Stanton C. Honig, MD

BASICS

DESCRIPTION

- Testosterone (T) is a critical anabolic hormone involved in various key metabolic pathways.
- It is the principle circulating androgen in males.
- Critical in modulating bodily processes of the cardiovascular, reproductive, hematologic, central nervous, and musculoskeletal systems
- Testosterone deficiency (TD), or hypogonadism, is characterized by low levels of T, often in addition with signs and symptoms attributed to low T levels.
- No universally accepted threshold of T concentration to distinguish eugonadal from hypogonadal men, but the FDA definition is T <300 ng/dL.
- Clinically, TD is divided into primary and secondary.
- T levels can be affected by disruptions to the medical conditions that influence the hypothalamic–pituitary–testis axis, age, and medical comorbidities.
- T levels correlates with overall health and may be associated with sexual dysfunction
- T levels decline by 1% per year after age 40 years.
- Special consideration is needed for men with low T who desires future fertility.
- Synonym(s): hypogonadism, hypoandrogenism, androgen deficiency, and low T

EPIDEMIOLOGY

Incidence

- Overall incidence increases with age.
- Symptomatic TD in United States ages 30 to 79 years is 5.6%.
- 481,000 new cases in United States in men 40 to 69 years

Prevalence

- Estimates of TD vary widely, but typically 20% of men over 60 years, 30% over 70 years, and 50% over 80 years of age.
- 2 to 4 million men in United States

ETIOLOGY AND PATHOPHYSIOLOGY

- Normal hypothalamic–pituitary–testis axis:
  - Hypothalamus produces GnRH, which stimulates pituitary to produce follicle-stimulating hormone (FSH) and luteinizing hormone (LH).
  - LH stimulates Leydig cells to produce T; responsible for 90% of the body's T
  - T inhibits LH and GnRH through negative feedback at level of hypothalamus and pituitary.
- Primary hypogonadism: Testes produces insufficient amount of T; FSH/LH levels are elevated.
- Secondary hypogonadism: low T from inadequate production of LH
- Normal aging process
- Congenital syndromes: cryptorchidism, Klinefelter, hypogonadotropic hypogonadism
- Acquired: cancer, trauma, orchiectomy, steroid use
- Infectious: mumps orchitis, HIV, tuberculosis
- Systemic: Cushing, hemochromatosis, autoimmune, severe illness (e.g., renal and liver disease), metabolic syndrome, obesity, obstructive sleep apnea
- Drugs and medications: LHRH agonists (leuprolide), corticosteroids, ethanol, ketoconazole ethanol spironolactone, marijuana, opioids, cimetidine, SSRIs
- Elevated prolactin: prolactinoma, dopamine antagonists (e.g., neuroleptics and metoclopramide)

Genetics

- Usually normal
- Klinefelter: XXY karyotype
- Kallmann syndrome: abnormal GnRH secretion due to abnormal hypothalamus development

RISK FACTORS

- Obesity, diabetes, COPD, depression, thyroid disorders, malnutrition, alcohol,

stress
- Chronic infections or inflammatory diseases
- Medications that affect T production or metabolism
- Undescended testicles
- Trauma, cancer, testicular radiation, chemotherapy, disorders of the pituitary and/or hypothalamus

GENERAL PREVENTION

General health maintenance and treatment of obesity

COMMONLY ASSOCIATED CONDITIONS

- Infertility, erectile dysfunction, low libido
- Poorer health outcomes
- Osteopenia/osteoporosis and fractures
- Diabetes and insulin resistance, metabolic syndrome
- Increased body weight, adiposity
- Sleep disturbance and depressed mood, poor concentration, irritability

DIAGNOSIS

HISTORY

Check for

- Congenital and developmental abnormalities
- Infertility, loss of libido, erectile dysfunction (1)[A]
- Depression, fatigue, difficulty with concentration
- Decreased muscle strength, energy level
- Increase in body fat, development of diabetes
- Bone fractures from relatively minor trauma
- Testicular trauma, infection, radio- or chemotherapy
- Decrease in testicle size or consistency
- Headaches or vision changes suggesting pituitary dysfunction
- Medications

PHYSICAL EXAM

- Infancy: ambiguous genitalia

- Puberty
  - Impaired growth of penis, testicles
  - Lack of secondary male characteristics
  - Gynecomastia, eunuchoid habitus
- Adulthood
  - Decreased muscular development, visceral fat distribution; body habitus changes to suggest corticosteroid excess
  - Presence of gynecomastia
  - Skin changes to suggest hemochromatosis
  - Eunuchoid habitus
- Genitourinary exam
  - Small and/or soft testicles

DIFFERENTIAL DIAGNOSIS

- Delayed puberty
- Obesity
- Normal aging
- Prior anabolic steroid abuse

DIAGNOSTIC TESTS & INTERPRETATION

- T levels vary widely; they are subject to diurnal, seasonal, and age-related variations. There are multiple assays, each with unique characteristics. Measurement should be obtained between 6 to 10 AM. Confirmation with a second measurement may be necessary. Whether total T or free T most closely correlates with symptomatic deficiency is unclear. Free T with total T is generally preferred. Measurements should not be obtained during acute or subacute illness. T circulates in blood primary bound to SHBG or to albumin. Only 2–3% of total T is found free. Free and albumin-bound T is considered bioavailable. Laboratory findings must be interpreted in the appropriate clinical setting. Bioavailable T is considered most important, but assays are not readily available and calculated bioavailable T is not reliable.
- Lower limit of normal in most reference laboratories for total testosterone is 280 to 300 ng/dL (9.8 to 10.4 nmol/L). The lower limit of normal for free testosterone is 5 to 9 pg/mL (0.17 to 0.31 nmol/L).

Initial Tests (lab, imaging)

- In symptomatic individuals, morning T level is initial test. Morning timing is more important for younger men in whom there is more diurnal variation. If initial morning testosterone is low, and confirmed on repeat test, further evaluation is appropriate (2)[A].
- Endocrine evaluation should include LH and FSH to differentiate between primary versus secondary hypogonadism. Consider estradiol and prolactin levels.
- If primary hypogonadism of unknown origin and physical exam reveals abnormalities, consider obtaining karyotype (e.g., Klinefelter), especially if severe testis atrophy exists.
- If secondary hypogonadism, evaluation may consist of prolactin, iron saturation, pituitary function testing, and/or MRI of pituitary.
- Imaging is not helpful in the initial diagnosis of TD.
- No evidence to support screening for TD in the general population

Follow-Up Tests & Special Considerations

- Routine blood work to measure T response to interventions (e.g., hematocrit, prostate-specific antigen [PSA])
- Dual-emission x-ray absorptiometry (DEXA) to measure bone mineral density in men with severe TD or fracture from minimal trauma
- Pituitary MRI: if there is elevation of prolactin more than twice the upper limit of normal or LH/FSH below normal range

TREATMENT

Testosterone replacement therapy (TRT) has been shown to effectively ameliorate many symptoms of TD. TRT is recommended for symptomatic men (e.g., low libido and/or erectile dysfunction, low energy level, constitutional symptoms) with low T levels ≤300 ng/dL obtained in the morning. Not recommended for older men with low T levels in absence of signs or symptoms

GENERAL MEASURES

- Confirm suspicion.
- Obtain hematocrit, PSA in men >40 years, prolactin, LH/FSH, SHBG,

estradiol if obese.

- Baseline physical exam including digital rectal exam, and International Prostate Symptom Score (IPSS)
- Correction of underlying cause
- Considerations
  - Is future fertility an issue? Different treatment strategies are used in men of reproductive age and/or interest.
  - Current evidence fails to demonstrate that higher serum T is associated with greater risk of prostate cancer development (3)[A].
  - Safety of T therapy in existing prostate cancer is still uncertain and contraindicated in package insert.
  - 2010 Endocrine Guidelines: Patients with organ-confined prostate cancer who have undergone radical prostatectomy and have been disease free for ≥2 years after surgery with undetectable PSA may be considered for T replacement on an individualized basis. Lack of data from randomized trials precludes a general recommendation.
  - T therapy should not be used in men with hematocrit >54%, untreated obstructive sleep apnea, uncontrolled CHF, severe lower urinary tract symptoms with an IPSS >19 (4)[A].
  - T therapy is not recommended for: mood or strength improvement in otherwise healthy men, or asymptomatic men with low T measurements (4)[A]
  - Carefully weigh risks and benefits in men at elevated cardiovascular risk (4,5)[A].
  - Clinicians can consider starting short-term T therapy as an adjunctive in men with HIV and low T to promote weight maintenance and gains in lean body mass and strength.

MEDICATION

ALERT

Avoid contact with females or children (see package insert) in patients applying gel preparations.

- Oral therapy is not recommended due to significant hepatotoxicity.

- The FDA has cautioned that testosterone is approved for men with confirmed low testosterone by laboratory testing and caused by certain medical conditions, NOT solely due to aging.
- Despite prior data showing no clear association between TRT and CV disease, there have been several recent papers suggesting that TRT use puts patients at an increased risk for CV disease. These papers have been criticized widely for being flawed due to comparison of unequal groups, short and inaccurate endpoints, flawed laboratory testing, erroneous exclusion criteria, and atypical statistical analysis. Despite this, an FDA panel concluded that there is a possible increased CV risk associated with testosterone use.
- TRT (FDA approved)
  - Topical gels/solutions: most common
    - Multiple FDA-approved formulations
    - Most frequently prescribed in United States
    - Mimics normal daily circadian rhythm
    - Good absorption, but 15–20% are nonresponders
    - Transfer concern to children and women
    - Gel application: arms, back, axilla, and groin
  - Testosterone pellets (Testopel)
    - Minor office procedure with mild discomfort
    - Long-acting formulation, 3 to 4 months
    - 1–2% risk of infection or pellet extrusion
  - Transdermal patch (Androderm)
    - Achieves less robust levels
    - Convenient over gels, no risk of transference
    - High incidence of skin irritation
  - Testosterone cypionate and enanthate (short acting)
    - Injectable (IM), inexpensive
    - Inconvenient: injections every 1 to 3 weeks
    - Starting dose: 100 mg/week or 200 mg/2 weeks
    - Roller coast effect: Levels rise and fall.
  - Testosterone undecanoate (long acting)
    - Injectable, expensive, convenient
    - Small risk of oil embolism, needs observation in office for 30 minutes

postinjection
    - Given approximately every 8 to 12 weeks
  - Buccal application (Striant)
    - Adheres to gum line, irritation in 16.3%
    - Poor compliance, every 12 hours application
  - Nasal gel (Natesto)
    - Levels overdosing schedule are variable.
    - TID dosing, nasal irritation
- Off-label treatment
  - Human chorionic gonadotropin (hCG)
    - Structure similar to LH, mimics its actions
    - 3 times per week starting at 1,500 IU SC
    - Poor compliance
    - Maintenance of testicular volume and fertility
    - Used in men wanting to preserve fertility
  - Clomiphene citrate: oral agent
    - Increases T by interfering with negative feedback, resulting in increased LH and FSH
    - Starting dose of 25 mg daily 3 to 7 times weekly
    - Used in men wanting to preserve fertility
  - Aromatase inhibitors (Arimidex): oral agent
    - Blocks conversion of T to estradiol
    - Does not negatively impact spermatogenesis and testicular volume
    - Utilized in cases of low T/estradiol ratio
  - Combination TRT with low dose hCG may preserve and support fertility in hypogonadal men hoping for future paternity.

ISSUES FOR REFERRAL

- PSA >4 ng/mL or >3 ng/mL in high-risk individuals, and/or abnormal prostate exam, worsening symptoms of BPH (IPSS >19) should be referred to urology.
- Worsening CHF, OSA, polycythemia should be referred to the appropriate providers.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Necessary to monitor effectiveness of therapy as well as for adverse effects: initially 3 to 6 months after treatment initiation and then annually
- Measure hematocrit at baseline, at 3 to 6 months, and then annually. If hematocrit >54% or symptomatic, stop therapy until hematocrit decreases to a safe level. Treatment includes phlebotomy, blood donation, or adjustment of dose.
- Evaluate patient for hypoxia, sleep apnea, or gynecomastia.
- Monitor bone mineral density after 1 to 2 years of therapy in men with osteoporosis or low trauma fracture.
- Recent meta-analysis of randomized trials did not show aggravation of LUTS after TRT. Men with mild to moderate IPSS did not have significant changes compared to placebo. However, most men with IPSS >19 (severe) were excluded.
- Prostate exam done regularly every 6 to 12 months.
- Refer to urology when increase in PSA >0.7 ng/mL within any 12-month period of T treatment or detection of prostatic abnormality on prostate exam.

DIET

Healthy diet and weight reduction if obese

PATIENT EDUCATION

- TD is chronic and likely to need lifelong therapy.
- T replacement comes with many risks, and it is very important to regularly monitor outcomes.
- Women and children must not be allowed to come in contact with TRT gel products.

PROGNOSIS

- Sustained reversal of symptoms can be achieved when serum levels of T fall in the normal range.
- Adverse health outcomes seen in many with chronically low levels of T such

as osteoporosis

COMPLICATIONS

Complications of testosterone replacement

- Decreased testicular volume, azoospermia in 40% of patients on TRT, infertility
- Fluctuations in mood or libido
- Gynecomastia and growth of breast cancer
- Acne and oily skin
- Erythrocytosis (increased hematocrit)
- Exacerbation of sleep apnea
- Hepatotoxicity with prolonged oral use
- Possible prostate enlargement with or without worsening symptoms of BPH
- Unknown cardiovascular risks

CODES

ICD10

- E29.1 Testicular hypofunction
- E89.5 Postprocedural testicular hypofunction

CLINICAL PEARLS

- Testosterone deficiency is common, and prevalence increases with age.
- Testosterone deficiency can have negative adverse impact on many bodily systems.
- Symptomatic men with sexual dysfunction, obesity, and metabolic diseases should be tested for testosterone deficiency and treated.
- Initial test of choice is a morning total and free testosterone; if low, repeat measurements.
- TRT in the appropriately selected population can increase lean mass, reduce fat mass, increase bone density, improve libido, and improve erections.

THALASSEMIA

Herbert L. Muncie, Jr., MD • Garland Edward Anderson, II, MD

BASICS

DESCRIPTION

- A group of inherited hematologic disorders that affect the synthesis of adult hemoglobin tetramer (HbA) (1,2)[C]
- α-Thalassemia is due to a deficient synthesis of α-globin chain, whereas β-thalassemia is due to a deficient synthesis of β-globin chain:
  - The synthesis of the unaffected globin chain proceeds normally.
  - This unbalanced globin chain production causes unstable hemoglobin tetramers, which leads to hypochromic, microcytic RBCs, and hemolytic anemia.
- α-Thalassemia is more common in persons of Mediterranean, African, and Southeast Asian descent, whereas β-thalassemia is more common in patients of African and Southeast Asian descent.
- Types
  - Thalassemia (minor) trait (α or β): absent or mild anemia with microcytosis and hypochromia
  - α-Thalassemia major with hemoglobin Barts usually results in fatal hydrops fetalis (fluid in ≥2 fetal compartments secondary to anemia and fetal heart failure).
  - α-Thalassemia intermedia with hemoglobin H (hemoglobin H disease): results in moderate hemolytic anemia and splenomegaly
  - β-Thalassemia major: results in severe anemia, growth retardation, hepatosplenomegaly, bone marrow expansion, and bone deformities. Transfusion therapy is necessary to sustain life.
  - β-Thalassemia intermedia: Milder disease; transfusion therapy may not be needed or may be needed later in life.
- Other variants include hemoglobin E/β-thalassemia in Southeast Asians, which often mimics the severity of α-thalassemia major; delta thalassemia;

hemoglobin H Constant Spring.
- System(s) affected: hematologic/lymphatic/immunologic, cardiac, hepatic
- Synonym(s): Mediterranean anemia; hereditary leptocytosis; Cooley anemia

Pediatric Considerations

- *β*-Thalassemia major causes symptoms during early childhood, usually starting at 6 months of age, and requires periodic transfusions to sustain life.
- Newborn's cord blood or heel stick should be screened for hemoglobinopathies with hemoglobin electrophoresis or comparably accurate test, although this primarily detects sickle cell disease.

Pregnancy Considerations

- Preconception genetic counseling is advised for couples at risk for having a child with thalassemia and for parents or other relatives of a child with thalassemia (3)[A].
- Once pregnant, a chorionic villus sample at 10 to 11 weeks' gestation or an amniocentesis at 15 weeks' gestation can be done to detect point mutations or deletions with polymerase chain reaction (PCR) technology.

EPIDEMIOLOGY

Incidence

- Occurs in ~4.4/10,000 live births
- Predominant age: Symptoms start to appear 6 months after birth with *β*-thalassemia major.
- Predominant sex: male = female

Prevalence

- Worldwide, ~200,000 people are alive with *β*-thalassemia major and <1,000 patients are in the United States.
- In the worldwide population, an estimated 1.5% are *β*-thalassemia carriers and 5% *α*-thalassemia carriers (4).

ETIOLOGY AND PATHOPHYSIOLOGY

Unknown; it is unclear how the imbalance of *β*-globulin in *α*-thalassemia and *α*-globin in *β*-thalassemia results in ineffective red blood cell genesis and hemolysis.

Genetics

- Inherited in an autosomal recessive pattern.
- α-Thalassemia results from a deletion of ≥1 of the 4 genes, 2 on each chromosome 16, responsible for α-globin synthesis. 1-gene deletion is a silent carrier state, 2-gene deletion is the trait, 3-gene deletion results in hemoglobin H, and 4-gene deletion results in hemoglobin Bart, causing fatal hydrops fetalis.
- Nondeletional forms do occur rarely. Hemoglobin H Constant Spring is the most common nondeletional form.
- β-Thalassemia is caused by any of >200-point mutations and, very rarely, deletions on chromosome 11; 20 alleles account for >80% of the mutations.
- Significantly disparate phenotype with the same genotype occurs because β-globin chain production can range from near-normal to absent.

RISK FACTORS

Family history of thalassemia

GENERAL PREVENTION

- Prenatal information: genetic counseling regarding partner selection and information on the availability of diagnostic tests during the pregnancy
- Complication prevention
  - For offspring of adult thalassemia patients, an evaluation for thalassemia by 1 year of age
  - Severe forms
    - Avoid exposure to sick contacts.
    - Keep immunizations up to date.
  - Promptly treat bacterial infections. (After splenectomy, patients should maintain a supply of an appropriate antibiotic to take at the onset of symptoms of a bacterial infection.)
  - Dental checkups every 6 months
  - Avoid activities that could increase the risk of bone fractures.

COMMONLY ASSOCIATED CONDITIONS

See “Complications.”

DIAGNOSIS

Thalassemia (minor) trait has no signs or symptoms.

HISTORY

- Poor growth
- Excessive fatigue
- Cholelithiasis
- Pathologic fractures
- Shortness of breath

PHYSICAL EXAM

- Pallor
- Splenomegaly
- Jaundice
- Maxillary hyperplasia/frontal bossing due to massive bone marrow expansion
- Dental malocclusion

DIFFERENTIAL DIAGNOSIS

- Iron deficiency anemia
- Other microcytic anemias: lead toxicity, sideroblastic
- Other hemolytic anemias
- Other hemoglobinopathies

DIAGNOSTIC TESTS & INTERPRETATION

Special tests

- Bone marrow aspiration to evaluate for causes of microcytic anemia is rarely needed.
- Multiple indices have been evaluated to discriminate β-thalassemia trait from iron deficiency anemia, yet none is sensitive enough to exclude β-thalassemia.
- Hemoglobin: usual range 10 to 12 g/dL with thalassemia trait and 3 to 8 g/dL with β-thalassemia major before transfusions.
- Hematocrit
  - 28–40% in thalassemia trait
  - May fall to <10% in β-thalassemia major
- Peripheral blood

  - Microcytosis (MCV <70 fl)
  - Hypochromia (MCH <20 pg)
  - High percentage of target cells
  - Reticulocyte count is elevated.
- Red cell distribution width (RDW)
  - A normal RDW with a microcytic hypochromic anemia is almost always thalassemia trait.
  - The RDW can be elevated in ~50% of thalassemia trait patients. This is in contrast to iron deficiency anemia, where the RDW is almost always elevated (90%).
- Hemoglobin electrophoresis
  - In α-thalassemia trait, no recognizable electrophoretic pattern occurs in adults.
  - However, in the neonatal period, 3–10% of trait patients will have hemoglobin H or hemoglobin Bart at birth, which would confirm α-thalassemia.
  - If HbA_2 is below normal (<2.5%) with a normal HbF level, the diagnosis is α-thalassemia intermedia (HbH disease).
  - In the neonatal period with β-thalassemia trait, the electrophoresis is normal. However, in adults, elevated HbA_2 levels (>4%) may be present but are usually normal (5)[C].
  - β-Thalassemia major or intermedia has elevated HbA_2, elevated HbF, and reduced or absent HbA.
- DNA analysis
  - α-Thalassemia can definitively be diagnosed with genetic testing of hemoglobin A1 and A2 (for deletions and point mutations), but this is not routinely done due to the high cost.
  - High-performance liquid chromatography
  - Cost-effective primary screening tool for children and adolescents (6)[C]
  - Equivocal results should be confirmed with DNA analysis.

Pediatric Considerations

For children, calculate Mentzer index (mean corpuscular volume/RBC count).

- <13: suggests thalassemia

- >13: suggests iron deficiency anemia
- Liver iron concentrations can be assessed with MRI (FerriScan).

TREATMENT

- Outpatient for mild cases
- Inpatient for transfusion therapy

GENERAL MEASURES

- Mild cases (trait or minor) require no therapy.
- Thalassemia intermedia: No therapy is necessary unless hemoglobin falls to a level that causes symptoms; then transfusion therapy is needed. Decision is based on patient's quality of life.
- Iron supplements should not be given unless iron deficiency occurs and is confirmed with low ferritin. Supplements increase the risk of iron overload.
- Thalassemia major
  - A regular transfusion schedule to increase posttransfusion hemoglobin to 13.0 to 14.0 g/L and maintain a mean hemoglobin level of at least 9.3 g/dL (1.4 mmol/L)
  - Patients require >8 transfusion events per year. An event may be multiple transfused units.
  - Iron overload (7)[C]
    - Patients receiving transfusion therapy increase total body iron 4 times the normal amount.
    - Therapy is iron chelation. (See "Medication.")

MEDICATION

Thalassemia intermedia and major: folic acid supplements (1 mg/day)

First Line

β-Thalassemia major

- Iron chelation with deferoxamine (Desferal)
  - Usually continuous SC or IV infusion
  - Acute toxicity: initial—1,000 mg IV, may be followed by 500 mg every 4 hours for 2 doses; subsequent doses of 500 mg every 4 to 12 hours based on

response (max 6,000 mg/day)
  - Chronic: 20 to 40 mg/kg over 8 to 12 hours daily
  - Usually started by 5 to 8 years of age
  - Treatment lasts 3 to 5 years to reach serum ferritin <1,000 ng/mL.
- Deferasirox (Exjade): 20 to 30 mg/kg/day PO acceptable alternative; approved for transfusion and non–transfussion-dependent patients with hepatic iron concentrations ≥5 mg/g of dry weight and serum ferritin >300 μg/L; renal and hepatic monitoring is recommended.

Second Line

Chelation with deferiprone (Ferriprox) 25 mg/kg TID PO initially is an acceptable alternative for patients who have not responded to deferoxamine; may provide more cardioprotection. A drawback is weekly CBC because ∼1% of patients develop agranulocytosis.

ISSUES FOR REFERRAL

Thalassemia major usually requires hematology consult.

ADDITIONAL THERAPIES

β-Thalassemia intermedia

- Hydroxyurea may improve hemoglobin 1 to 2 g/dL.
- Psychological support seems appropriate for this chronic disease. However, no conclusions can be made regarding specific psychological therapies.

SURGERY/OTHER PROCEDURES

- Splenectomy
  - May be needed if hypersplenism causes an increase in the transfusion requirements (>180 to 200 mL/kg/year) (8)[C]
  - Defer surgery until patient is at least 4 years of age (due to increased infection risk).
  - Administer pneumococcal polyvalent-23 vaccine 1 month before splenectomy. Children should complete their pneumococcal conjugate vaccine series before surgery.
  - Daily penicillin prophylaxis, 250 mg BID, after splenectomy for 2 years for all patients and for children until age 16 years.
- Bone marrow transplantation with HLA-identical related donor stem cells in

children before developing hepatitis or iron overload has high likelihood of remission but may impair fertility.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Thalassemia trait requires no restrictions.
- β-Thalassemia major
  - Avoid strenuous activities (e.g., football, soccer).
  - Acceptable activity levels will be determined on an individual basis depending on the severity of the disorder.

Patient Monitoring

- Thalassemia-trait patients require no special follow-up.
- For β-thalassemia major, lifelong monitoring is necessary because the therapy and disease progression have numerous potential complications.

DIET

- Thalassemia trait requires no restrictions.
- β-Thalassemia major
  - Limit intake of iron-rich foods (e.g., red meats such as liver and some cereals).

PATIENT EDUCATION

Printed patient information available from Cooley Anemia Foundation, 330 7th Ave. Suite 900, New York, NY 10001; http://www.thalassemia.org or http://www.cooleysanemia.org

PROGNOSIS

- Outlook varies depending on type.
- Thalassemia-trait patients live a normal lifespan.
- β-Thalassemia major patients live an average of 17 years and usually die by age 30 years.
- Iron overload causes most of the morbidity and mortality:
  - Cardiac events are the primary cause of death.

- Myocardial iron deposition is best assessed with MRI T2 (9)[C].
- Effective iron chelation improves longevity.

COMPLICATIONS

- Chronic hemolysis
- Susceptibility to infections after splenectomy
- Infections from blood transfusion
- Jaundice
- Leg ulcers
- Cholelithiasis
- Osteoporosis and low-trauma fractures
- Impaired growth rate
- Delayed or absent puberty
- Hypogonadism
- Hepatic siderosis
- Splenomegaly
- Cardiac disease from iron overload
- Thromboembolic phenomenon
- Aplastic and megaloblastic crises
- Increased risk of hematologic and abdominal cancer (10)
- Increased risk of dementia (11)

CODES

ICD10

- D56.9 Thalassemia, unspecified
- D56.1 Beta thalassemia
- D56.0 Alpha thalassemia

CLINICAL PEARLS

- Thalassemia (group of inherited hematologic disorders that affect the synthesis of adult hemoglobin tetramer) is a genetic condition; hemoglobin

will not improve over time.

- α-Thalassemia is due to a deficient synthesis of the α-globin chain, whereas β-thalassemia is due to a deficient synthesis of the β-globin chain.
- Hemoglobin electrophoresis is needed for genetic counseling but not to make the diagnosis of thalassemia minor when evaluating a patient with mild hypochromic, microcytic anemia, and normal serum ferritin.
- Anemia from thalassemia minor is not due to inadequate iron availability or iron storage. Therefore, iron supplements will not improve the anemia and could be harmful due to GI distress and iron overload. If coexisting iron deficiency is proven, then iron therapy is appropriate.

THORACIC OUTLET SYNDROME

Muhammad Imran Khan, MD • Najm Hasan Siddiqui, MD

BASICS

DESCRIPTION

- A constellation of symptoms that affects the head, neck, shoulders, and upper extremities caused by compression of the neurovascular structures (i.e., brachial plexus and subclavian vessels) at the thoracic outlet, specifically in the area superior to the 1st rib and posterior to the clavicle
- Three forms of thoracic outlet syndrome (TOS) have been described: neurogenic, vascular (containing venous and arterial symptoms), and nonspecific (includes traumatic and secondary to certain provocative movements).
- Synonym(s): scalenus anticus syndrome; cervical rib syndrome; costoclavicular syndrome

Pregnancy Considerations

Generalized tissue fluid accumulations and postural changes may aggravate symptoms.

EPIDEMIOLOGY

Incidence

- Predominant age
  - Neurogenic type (95%): 20 to 60 years
  - Venous type (4%): 20 to 35 years
  - Arterial type (1%; atherosclerosis): young adult or >50 years
- Predominant sex
  - Neurogenic type: female > male (3.5:1)
  - Venous type: male > female
  - Arterial type: male = female
- No objective confirmatory tests are available to measure true incidence.
- Estimated 3 to 8/1,000 cases for neurogenic type

- Incidence of other TOS types is unclear.

ETIOLOGY AND PATHOPHYSIOLOGY

The interscalene triangle area is reduced in TOS and may become smaller during certain shoulder and arm movements. Fibrotic bands, cervical ribs, and muscle variations may further narrow the triangle. Trauma or provocative movements affecting the lower brachial plexus have strong implications in TOS pathogenesis.

- Three known causes of TOS: anatomic, traumatic/repetitive movement activities, and neurovascular entrapment
  - Anatomic: Variations in the anatomy of the neck scalene muscles may be responsible for presentations of the neurologic type of TOS and may involve the superior border of the 1st rib. Cervical ribs also have been implicated as a cause of neurologic TOS, with subsequent neuronal fibrosing and degeneration associated with arterial hyalinization in the lower trunk of the brachial plexus. Fibrous bands to cervical ribs are often congenital.
  - Trauma or repetitive movement activities: Motor vehicle accidents with hyperextension injury and resulting fibrosis, including fibrous bands to the clavicle; musicians who maintain prolonged positions of shoulder abduction or extension may be at increased risk.
  - Neurovascular entrapment: occurring in the costoclavicular space between the 1st rib and the head of the clavicle

RISK FACTORS

- Trauma, especially to the shoulder girdle
- Presence of a cervical rib
- Posttraumatic, exostosis of clavicle or 1st rib, postural abnormalities (e.g., drooping of shoulders, scoliosis), body building with increased muscular bulk in thoracic outlet area, rapid weight loss with vigorous physical exertion and/or exercise, pendulous breasts
- Occupational exposure: computer users; musicians; repetitive work involving shoulders, arms, hands
- Young, thin females with long necks and drooping shoulders

GENERAL PREVENTION

Consider observation or further evaluation in patients with cervical ribs.

COMMONLY ASSOCIATED CONDITIONS

- Paget–von Schrötter syndrome: thrombosis of subclavian vein
- Gilliatt-Sumner hand: neurogenic atrophy of abductor pollicis brevis

DIAGNOSIS

HISTORY

- Neurologic type, upper plexus (C4–C7)
  - Pain and paresthesias in head, neck, mandible, face, temporal area, upper back/chest, outer arm, and hand in a radial nerve distribution
  - Occipital and orbital headache
- Neurologic type, lower plexus (C8–T1)
  - Pain and paresthesias in axilla, inner arm, and hand in an ulnar nerve distribution, often nocturnal
  - Hypothenar and interosseous muscle atrophy
- Venous type: arm claudication, cyanosis, swelling, distended arm veins
- Arterial type: digital vasospasm, thrombosis/embolism, aneurysm, gangrene

PHYSICAL EXAM

- Positive Adson maneuver (head rotation to the affected side with cervical extension and then deep inhalation); test is positive if paresthesias occur or if radial pulse is not palpable during maneuver.
- Tenderness to percussion or palpation of supraclavicular area
- Worsening of symptoms with elevation of arm, overhead extension of arms, or with arms extended forward (e.g., driving a car, typing, carrying objects); prompt disappearance of symptoms with arm returning to neutral position
- Morley test
  - Brachial plexus compression test in the supraclavicular area from the scalene triangle
  - Positive with reproduction of an aching sensation and typical localized paresthesia
- Hyperabduction test: diminishment of radial pulse with elevation of arm

above the head

- Military maneuver (i.e., costoclavicular bracing): When patient elevates chin and pushes shoulders posteriorly in an extreme “at-attention” position, symptoms are provoked.
- 1-minute Roos test
  - A thoracic outlet shoulder girdle stress test
  - Shoulders and arms are braced in a 90-degree abducted and externally rotated position; patient is required to clench and relax fists repetitively for 1 minute.
  - A positive test reproduces the symptom.

DIFFERENTIAL DIAGNOSIS

- Cervical disk or carpal tunnel syndrome
- Orthopedic shoulder problems (shoulder strain, rotator cuff injury, tendonitis)
- Cervical spondylitis
- Ulnar nerve compression at elbow and hand
- Multiple sclerosis
- Spinal cord tumor/disease
- Angina pectoris
- Migraine
- Complex regional pain syndromes
- C3–C5 and C8 radiculopathies

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

CBC, ESR, and C-reactive protein (CRP) determination may rule out underlying inflammatory conditions.

- Radiograph (chest, C-spine, shoulders) (1)[C] may reveal elongated C7 transverse process or a cervical rib, Pancoast tumor, or healed clavicle fracture.
- Nerve conduction studies and electromyography (EMG)
- CT scan or MRI, although MRI is the method of choice when searching for nerve compression
- Improved high-resolution MRN and tractography are valuable tools for identifying the source of nerve compression in patients with neurogenic TOS

and can augment current diagnostic modalities for this syndrome (2)[B].
- Contrast-enhanced 3D MRA using provocative arm positioning allows excellent imaging of the arteries and veins on both sides and thus provides a noninvasive imaging alternative to digital subtraction angiography in patients with suspected vascular TOS (3)[B].
- Doppler and duplex US if vascular obstruction is suspected
- Arteriogram and venogram have limited roles; useful when symptoms suggestive of arterial insufficiency or ischemia, or in planning surgical intervention (4)[C].

Diagnostic Procedures/Other

No indicated procedures; anesthetic anterior scalene block may relieve pressure by scalene muscles on the brachial plexus, making this type of block diagnostic and potentially therapeutic, but it poses the risk of procedural damage to the brachial plexus.

Test Interpretation

Systematic results of biopsy have not been reported. There is no indication for biopsy unless to investigate another underlying condition.

TREATMENT

GENERAL MEASURES

- Conservative management usually involves approaches to reduce and redistribute pressure and traction through the use of physiotherapy or prosthesis.
- Interscalene injections of botulinum toxin have been shown to decrease symptoms of TOS (5)[C]. A single, CT-guided Botox injection into the anterior scalene muscle may offer an effective, minimally invasive treatment for NTOS (6)[A].
- Physical therapy will develop strength in pectoral girdle muscles and achieve normal posture (1)[C].
- Severe cases may use taping, adhesive elastic bandages, moist heat, TENS, or US but should not substitute active exercise and correction of posture and

muscle imbalance (7)[B].

MEDICATION

- No firm evidence exists for any approach to the four types of TOS.
- Physical therapy is the first-line treatment (7)[B].
- Anti-inflammatory (ibuprofen)
  - Adult dose: 400 to 800 mg PO q8h; not to exceed 3,200 mg/day
  - Pediatric dose
    - <12 years: 10 mg/kg/dose every 6 to 8 hours
    - >12 years: as in adults
  - Contraindications: documented hypersensitivity, active PUD, renal or hepatic impairment, recent use of anticoagulants, hemorrhagic conditions
- Neuropathic pain: Tricyclic antidepressants, carbamazepine, gabapentin, phenytoin, pregabalin; muscle relaxants such as baclofen, metaxalone, or tizanidine may be helpful.
- Severe pain: Consider opiates for brachial plexus nerve block, steroid injections.

ISSUES FOR REFERRAL

- Neurologic, anesthesiologic, orthopedic, vascular surgery referral(s) may be indicated depending on the type of pathologic condition.
- Physical and rehabilitation physicians

SURGERY/OTHER PROCEDURES

- Operative if vascular involvement is present and/or loss of function or lifestyle occurs secondary to severity of symptoms and if conservative therapy fails after 2 to 3 months (1)[C]
- Resection of 1st rib or cervical ribs via transaxillary (preferred with good to excellent outcome 80% of patients), supraclavicular (good to excellent outcome 80% of patients), posterior approaches (reserved for complicated TOS due to necessity of large muscle incision). Excellent results were seen in patients who underwent first rib resection in all three forms of TOS (8)[A].
- Transaxillary 1st rib resection (TFRR) may provide better pain relief than supraclavicular neuroplasty of the brachial plexus (SNBP); although, overall, both treatment options have generally positive outcomes (9)[B].

- Transaxillary approach provides a good exposure and cosmetics in patients with TOS. It should be considered as the gold standard in the management of TOS (10)[B].
- Supraclavicular scalenectomy (11)[C]
- Isolated pectoral minor tenotomy (PMT) is a low-risk outpatient procedure that is effective for the treatment of selected patients with disabling NTOS, with early outcomes similar to supraclavicular decompression + PMT (12)[A].
- Excision of adhesive bands, anterior scalenectomy (13)[B]

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Conservative, outpatient, nonpharmacologic treatment is reasonable first-line therapy except in cases of thromboembolic phenomena and acute ischemia, symptoms of chronic vascular occlusion, stenosis, arterial dilatation, or progressive neurologic deficit (7)[B].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Correct improper posture, practice proper posture, exercises to strengthen shoulder elevator and neck extensor muscles, stretching exercises for scalene muscles, support bra for women with pendulous breasts, breast reduction surgery in selected cases; sleep with arms below chest level, avoid/reduce prolonged hyperabduction.

Patient Monitoring

Office follow-up visits every 3 to 4 weeks

PATIENT EDUCATION

Physical therapy, postural exercises, ergonomic workstation

PROGNOSIS

Follow-up from surgery at mean of 7.5 years showed that functional results were excellent, good, fair, and poor in 87 (49.4%), 61 (34.6%), 14 (8%), and 14 (8%) procedures, respectively (14).

Durable long-term functional outcomes can be achieved predicated on a highly selective approach to the surgical management of patients with TOS. A majority of operated patients will not require adjunctive procedures or chronic narcotic use (15).

COMPLICATIONS

- Postoperative shoulder, arm, hand pain, and paresthesias in 10%
- Patients who will have symptomatic recurrences at 1 month to 7 years postoperatively (usually within 3 months): 1.5–2%
- Patients who will have brachial plexus injury, probably due to intraoperative traction: 0.5–1%
- Reoperation is indicated for symptomatic recurrence with long posterior remnant of 1st rib (posterior approach) or with disrupted fibrous adhesions (transaxillary approach).
- Venous obstruction or arterial emboli; usually responds to thrombolytics

CODES

ICD10

G54.0 Brachial plexus disorders

CLINICAL PEARLS

- Consider breast reduction for patients with pendulous breasts.
- Avoid opiate dependence.
- Consider pain clinic referral if there are nonsurgical causes.

THROMBOPHILIA AND HYPERCOAGULABLE STATES

Kirsten Vitrikas, MD

BASICS

DESCRIPTION

- An inherited or acquired disorder of the coagulation system predisposing an individual to thromboembolism (the formation of a venous, or less commonly, an arterial blood clot) (1)
- Venous thrombosis typically manifests as deep venous thrombosis (DVT) of the lower extremity in the legs or pelvis and pulmonary embolism (PE) (1).
- System(s) affected: cardiovascular, nervous, pulmonary, reproductive, hematologic
- Synonym(s): hypercoagulation syndrome; prothrombotic state

EPIDEMIOLOGY

- An inherited thrombophilic defect or risk can be detected in up to 50% of patients with venous thromboembolism (VTE).
- Factor V Leiden is the most common inherited thrombophilia (1/2 of all currently characterizable inherited thrombophilia cases involve the factor V Leiden mutation), and it is present in its heterozygous form in up to ~20% of patients with a first VTE.
- Heterozygous prothrombin G20210A mutation, the second most common inherited thrombophilia, is present in up to ~8% of patients with VTE.

Incidence

First-time thromboembolism

- ~100/100,000/year among the general population
- <1/100,000/year in those age <15 years
- ~1,000/100,000/year in those age ≥85 years

Prevalence

- 40–80% of lower extremity orthopedic procedures can result in DVT if

prophylaxis is not used.
- VTE accounts for ~1.2 to 4.7 deaths per 100,000 pregnancies.

ETIOLOGY AND PATHOPHYSIOLOGY

- Virchow triad as a cause of VTE includes blood stasis, vascular endothelial injury, and abnormalities in circulating blood constituents (i.e., hypercoagulability).
- An imbalance between the hemostatic and fibrinolytic pathways leads to thrombus formation.
- VTE is considered to be the result of genetic tendencies with other acquired risks.
- Upper extremity DVT: >60% are associated with venous catheters. Malignancy is an additional significant risk (2).

Genetics

- The most common genetic thrombophilias (factor V Leiden, prothrombin G20210A, proteins C and S, and antithrombin III deficiency) are inherited in an autosomal dominant pattern.
- Homozygous mutations generally have a higher risk of VTE.
- Factor V Leiden/activated protein C (aPC) resistance is the most common inherited thrombophilia.
  - 2–5% prevalence among Caucasians; rare in African Americans or Asians
  - aPC does not cleave factor Va, so thrombin formation continues.
  - Other acquired risks are synergistic (3).
- Prothrombin gene mutation G20210A: prevalence 6% among Caucasians. Heterozygous carriers have increased risk of thrombosis.
- Hyperhomocysteinemia: 5–6% among the general population; increases risk of coronary artery disease/myocardial infarction, cerebrovascular accident, and DVT/PE; acquired in those with folate, vitamin B_{12}, and vitamin B_6 deficiencies
- Antithrombin deficiency: <0.2% among the general population; produced in the liver; acquired deficiency in disseminated intravascular coagulation (DIC), sepsis, liver disease, nephrotic syndrome
- Protein C and S deficiencies: 0.5% and 1% incidences, respectively, among the general population. Homozygotes and heterozygotes are hypercoagulable.

Vitamin K–dependent, produced in the liver. Protein C inactivates Va and VIIIa. Protein C may become an acquired deficiency in liver disease, sepsis, DIC, acute respiratory distress syndrome, and after surgery. Protein S is a cofactor for protein C, and it may become an acquired deficiency with oral contraceptive pill (OCP) use, pregnancy, liver disease, sepsis, DIC, HIV, and nephrosis.

RISK FACTORS

- Acquired risk factors
  - Immobilization or prolonged travel
  - Trauma
  - Surgery, especially orthopedic
  - Malignancies (especially pancreatic, ovarian, brain, and lymphoma)
  - Pregnancy
  - Acute medical illness
  - Exogenous female hormones/oral contraceptives
  - Obesity
  - Nephrotic syndrome
  - Antiphospholipid syndrome (APS) and lupus anticoagulant
  - Myeloproliferative disorders (polycythemia vera, essential thrombocythemia)
  - Hyperviscosity syndromes (sickle cell, paraproteinemias)
  - Hyperhomocysteinemia secondary to vitamin deficiencies (B_6, B_{12}, folic acid)
  - Tamoxifen, thalidomide, lenalidomide, bevacizumab, L-asparaginase, erythropoietic stimulating agents
  - Previous thromboembolism
- Established genetic factors
  - Factor V Leiden
  - Prothrombin G20210A mutation
  - Protein C deficiency
  - Protein S deficiency
  - Antithrombin III deficiency
- Rare genetic factors

  - Dysfibrinogenemia
  - Hyperhomocysteinemia (methylene tetrahydrofolate reductase mutation)
- Indeterminate factors
  - Elevated factor VIII
- Age: >60 years
- Gender: men
- Race: Incidence is higher among African Americans.

GENERAL PREVENTION

- Consider medication prophylaxis in any hospitalized patient with VTE risk factors; hospitalized patients should be encouraged to ambulate as soon as possible (4)[A].
- Consider mechanical prophylaxis in patients at increased risk for VTE in whom anticoagulation may be contraindicated (4)[A].
- Consider prophylaxis with low-molecular-weight heparin (LMWH) plus aspirin in pregnant patients with APS or other thrombophilia.
- Consider prophylaxis using LMWH in patients with solid tumors who have additional risk factors for VTE.
- Prophylaxis with unfractionated heparin (UFH) or LMWH should be considered in patients with genetic or acquired risks of thrombosis and an anticipated additional risk, such as the immobilization associated with surgery.
- Use caution with procoagulant medicines (e.g., OCPs) in asymptomatic individuals who have a known hereditary predisposition.

COMMONLY ASSOCIATED CONDITIONS

Advanced age, cancer, pregnancy, obesity, prior history of thrombosis, surgery, immobilization

DIAGNOSIS

HISTORY

Consider prothrombotic assessment for the following:

- Thrombosis at an unusual anatomic site or recurrent thromboses
- Family history suggesting multiple individuals affected with VTE
- Recurrent pregnancy loss

PHYSICAL EXAM

- DVT: swelling, pain, warmth, and redness, usually of one extremity
- PE: dyspnea, pleurisy, hemoptysis, hypoxia, tachycardia
- Postthrombotic syndrome: pain, swelling, pigmentation, and/or ulceration

DIAGNOSTIC TESTS & INTERPRETATION

Testing for thrombophilias is not recommended unless it will affect management (2,5,6)[B]. Testing should be delayed until after the initial 3 months of anticoagulation (2,5,6)[B].

Initial Tests (lab, imaging)

- CBC
- aPC profile: ≤2.0 implies factor V Leiden mutation; 95–100% are factor V Leiden-positive; false-positive finding in pregnancy or with use of OCPs, confirm with factor V Leiden mutation testing or consider factor V Leiden mutation testing up front.
  - aPC resistance may be unreliable while taking LMWH or UFH.
- Prothrombin G20210A genetic assay
- ATIII functional assay
  - Will be low with acute thrombosis and on heparin therapy. May be falsely high on dabigatran, apixaban, edoxaban, and rivaroxaban
- Protein C functional assay
  - May be low with acute thrombosis; will be lower on warfarin, dabigatran, apixaban, edoxaban, and rivaroxaban
- Protein S antigen and functional assay and free S
  - May be low with acute thrombosis; will be lower on warfarin, dabigatran, apixaban, edoxaban, and rivaroxaban
- Antiphospholipid antibodies: phospholipid-dependent tests and anticardiolipin antibodies, lupus anticoagulant
  - May be unreliable on heparin
- Consider evaluation for subclinical malignancy in an unprovoked thrombosis in those >40 years of age or at greater risk.
- Consider homocysteine level, although treatment of hyperhomocysteinemia (vitamins B_{12} and B_6, folate) does not alter the thrombophilic risk.

Follow-Up Tests & Special Considerations

Dysfibrinogenemia and plasminogen deficiency are very rare causes of thrombophilia.

TREATMENT

MEDICATION

First Line

- Newer oral anticoagulants: apixaban, dabigatran, edoxaban, and rivaroxaban are now recommended over vitamin K antagonists for long-term oral anticoagulation (6)[B].
- Parenteral anticoagulation: LMWH has largely replaced UFH as first-line therapy for VTE.
  - Enoxaparin (Lovenox): 1 mg/kg SC BID for at least 5 days (with concomitant warfarin) until international normalized ratio (INR) has reached 2 for at least 24 hours; adjust dose for renal disease.
    - Enoxaparin is preferred in patients with active cancer for a minimum of 6 months (can dose at 1.5 mg/kg SC daily), after which time the patient can be reevaluated to continue treatment (4).
    - Adverse reactions: bleeding, heparin-induced thrombocytopenia (HIT) <0.5% incidence, bone loss (uncommon)
    - Reversal: Stop LMWH.
  - UFH: 80 U/kg or 5,000 U IV bolus, then 18 U/kg/hr or 1,000 U/hr to target the activated partial thromboplastin time (aPTT) to a corresponding anti-Xa level of 0.3 to 0.7 U/mL. The first aPTT should be checked 6 hours after initial therapy and adjusted per standard heparin nomograms, aiming for an adequate level within 24 hours. Transition to warfarin is similar to the recommendations for enoxaparin.
    - SC UFH is an alternative and can be given as 5,000 U IV (once) followed by 250 U/kg SC BID, or 250 U/kg bolus followed by 250 U/kg BID (monitored as for IV UFH), or 333 U/kg once followed by 250 U/kg SC BID (unmonitored).
    - Adverse reactions: bleeding, HIT 3% incidence, bone loss (long-term use)

    - Reversal: Stop heparin, protamine.
- Oral factor Xa inhibitors
  - Rivaroxaban (Xarelto): 15 mg twice daily for 21 days then 20 mg once daily. Not recommended in morbidly obese patients due to lack of data (6) [C]
  - Apixaban (Eliquis): 10 mg twice daily for 7 days, then 5 mg twice daily. Can be used without need for preceding heparin therapy, less renal clearance than other oral anticoagulants
  - Edoxaban (Savaysa): 60 mg daily. Requires treatment with heparin for 5 days prior to initiation, needs adjustment for renal impairment. Not recommended if creatinine clearance >95 mL/min. Adjust dose to 30 mg in patients <60 kg or if using verapamil, quinidine, macrolides, or oral antifungals.
- Direct thrombin inhibitors
  - Dabigatran (Pradaxa): 150 mg twice daily after 5 to 10 days of parenteral anticoagulation. Reversal agent: idarucizumab (Andexanet) newly available. May be dialyzable (6)[C]
- Vitamin K antagonist
  - Warfarin (Coumadin): 10 mg/day initially and adjust to INR 2 to 3 for at least 3 months, potentially indefinitely in those with high risk of recurrence, recurrent or unprovoked VTE
    - Warfarin requires careful and frequent monitoring because of many drug–drug and drug–diet (e.g., vitamin K) interactions.
    - Adverse reactions: bleeding, skin necrosis (rare and early in course)
    - Reversal: four-factor prothrombin complex concentrate (PCC); fresh frozen plasma and/or vitamin K
- Pregnancy: low-dose aspirin and/or LMWH or UFH; warfarin is contraindicated.

Second Line

Usually indicated when contraindication to heparin or LMWH, such as heparin-associated thrombosis and thrombocytopenia, if there is an inability to use IV drugs, or renal failure. Direct oral anticoagulants may become first line as more clinical experience is developed.

- Factor Xa inhibitors

  - Fondaparinux (Arixtra): acute VTE/PE. Weight <50 kg: 5 mg/day SC; weight 50 to 100 kg: 7.5 mg/day SC; weight >100 kg: 10 mg/day SC; use for 5 to 9 days until oral anticoagulation is therapeutic.
    - Prophylaxis: 2.5 mg/day SC
    - Dose adjustments: needed for renal insufficiency; if creatinine clearance is <30 mL/min, use is contraindicated.
- Direct thrombin inhibitors:
  - Argatroban: liver metabolized; may be dose-adjusted in liver dysfunction; therapeutic dose based on aPTT

SURGERY/OTHER PROCEDURES

- Consider systemic thrombolysis for unstable cases (e.g., massive PE with hypotension).
- Inferior vena cava filter
  - Reduces short-term risk of PE in those with contraindications to anticoagulation (e.g., GI bleeding, cerebral hemorrhage)
  - May increase long-term risk of recurrent DVT
  - Used for patients with multiple episodes of recurrent thromboembolism despite therapeutic anticoagulation and contraindication to anticoagulation

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Avoid significant risk for trauma (e.g., contact sports, climbing a ladder).

Patient Monitoring

Monitor warfarin as frequently as needed to maintain an INR goal of 2 to 3.

DIET

Vitamin K–stable diet if patient is taking warfarin

PATIENT EDUCATION

- Assume that any drug may enhance or attenuate the warfarin effect.
- Increase the frequency of monitoring following any medication change to ensure therapeutic anticoagulation and to avoid overanticoagulation,

especially with antibiotics.
- Many drugs may modulate warfarin effect: alcohol, antibiotics, aspirin, NSAIDs, acetaminophen.

PROGNOSIS

- Anticoagulation should be continued for 3 months and consideration of longer in those with unprovoked VTE.
- Patients with a provoked VTE (i.e., surgery, hospitalization) not receiving chronic anticoagulation have risks of recurrence of 7% (year 1), 16% (year 5), and 23% (year 10).
- Patients with an unprovoked VTE not receiving chronic anticoagulation have risks of recurrence of 15% (year 1), 41% (year 5), and 53% (year 10).
- Currently, there are no data from randomized, controlled trials or controlled clinical trials about the benefits of thrombophilia testing to decrease the risk of recurrent VTE (1).

COMPLICATIONS

Venous or arterial thrombosis; bleeding in anticoagulated patients

CODES

ICD10

- D68.59 Other primary thrombophilia
- D68.51 Activated protein C resistance
- D68.2 Hereditary deficiency of other clotting factors

CLINICAL PEARLS

- Factor V Leiden (resistance to aPC) is the most common inherited thrombophilia, with a prevalence of 2–7% in the U.S. Caucasian population.
- Test patients for thrombophilias only if it will affect management of the condition.
- Rule out malignancy, especially in those >50 years of age.

THROMBOTIC THROMBOCYTOPENIC PURPURA

Palni R. Patel, PharmD, RPh • Paul Beninger, MD, MBA

BASICS

DESCRIPTION

- An acute syndrome of microangiopathic hemolytic anemia (MAHA) and consumptive thrombocytopenia with deposition of hyaline thrombi in terminal arterioles and capillaries leading to ischemic multiorgan damage
- Thrombotic thrombocytopenic purpura (TTP) is characterized by MAHA and thrombocytopenia, with or without the following signs and symptoms (1):
  - Neurologic symptoms
  - Renal dysfunction
  - Fever
  - Most patients do not show the historic pentad of MAHA, thrombocytopenia, renal dysfunction, neurologic abnormalities, and fever because treatment is initiated before the pentad can develop.

EPIDEMIOLOGY

Incidence

- Predominant age: 18 to 49 years
- Predominant sex: female > male (3:1)
- Incidence ratio in blacks to whites is 7:1.
- The age–sex–race standardized incidence of clinically suspected TTP is 8 million/year and 2 million/year in those with ADAMTS13 levels <10% (2).

ETIOLOGY AND PATHOPHYSIOLOGY

- In TTP, the aggregating agent responsible for platelet thrombi is unusually large von Willebrand factor (UL vWF) multimers, which are far larger than those found in normal plasma.
- A metalloproteinase, ADAMTS13, which normally enzymatically cleaves UL vWF multimers to prevent clumping within vessels, is deficient, defective, or

absent, allowing UL vWF to react with platelets. This leads to the endothelial cell damage and disseminated thrombi characteristic of TTP.

- Arterioles most often affected are in the brain, kidney, pancreas, heart, and adrenal glands. Lungs and liver are relatively spared.
- In familial TTP, patients have an inherited deficiency of ADAMTS13 (1).
- In acquired idiopathic TTP, autoantibodies are directed against the metalloproteinase ADAMTS13 (1,3).
- Endothelial injury, either directly from a drug/toxin or indirectly via platelet/neutrophil activation, has been proposed as a cause of secondary TTP especially in those without ADAMTS13 deficiency.
  - Drug induced (see "Risk Factors")
  - Hematopoietic cell transplantation

Genetics

TTP is most often an acquired disorder. A congenital form of inherited TTP (Schulman-Upshaw syndrome) is due to a mutation at the ADAMTS13 metalloproteinase gene locus on chromosome 9q34. This rare form of TTP has an autosomal-recessive pattern of inheritance (4).

RISK FACTORS

- Pregnancy and oral contraceptives
- AIDS and early symptomatic HIV infection
- Autoimmune disease
  - Antiphospholipid antibody syndrome
  - Systemic lupus erythematosus
  - Scleroderma
- Cancer
- Hematopoietic stem cell transplantation
- Drug toxicity
  - Cancer chemotherapy
    - Mitomycin C and gemcitabine
    - Bleomycin and cisplatin
    - Bevacizumab
  - Calcineurin inhibitors
    - Tacrolimus and cyclosporine

- Immune mediated
  - Quinine and quinidine
  - Ticlopidine and clopidogrel

COMMONLY ASSOCIATED CONDITIONS

- TTP/HUS/atypical HUS (hemolytic uremic syndrome) have similar presentations with MAHA and thrombocytopenia and multiorgan involvement.
- TTP generally presents with minimal renal involvement and may have neurologic abnormalities, whereas the opposite is more characteristic of HUS/atypical HUS.
- However, patients with HUS and TTP may have both prominent renal and neurologic manifestations, often making the diagnosis unclear, hence the historical hybrid name “TTP-HUS.”
- ADAMTS13 levels are diminished in adults with familial or acquired idiopathic TTP but are normal in children diagnosed with HUS following infection with *Escherichia coli* (particularly type O157:H7), so-called Shiga toxin-HUS, and in “atypical HUS,” is also called complement mediated thrombotic microangiopathy reflecting the pathophysiology which is related to complement dysregulation.

DIAGNOSIS

- Most common symptoms are nonspecific: nausea, vomiting, weakness, abdominal pain, fatigue, fever
- Related to thrombocytopenia
  - Easy bruising, purpura, or petechiae
  - Epistaxis, menorrhagia, bleeding gums
  - GI bleeding
  - Intracranial hemorrhage
  - Visual symptoms due to retinal hemorrhage
- Related to hemolytic anemia (MAHA): jaundice, fatigue
- Related to end-organ ischemia
  - Neurologic: CNS symptoms occur in 50%.

    - Often fluctuating symptoms
    - Headache
    - Altered mental status: Spectrum runs from behavioral/personality changes to obtundation/stupor/coma.
    - Seizures
    - Stroke
  - Renal: hematuria, oliguria, or anuria
  - Cardiac: arrhythmia, myocardial infarction, heart failure

HISTORY

- Generally acute onset of symptoms but subacute in about 1/4 of patients
- It is important to assess for potential underlying causes or risk factors (see discussion earlier).

PHYSICAL EXAM

- Fever
- Mental status/neurologic: confusion, coma, stupor, weakness
- HEENT: retinal hemorrhage, scleral icterus, epistaxis
- Abdomen/GI: nonspecific tenderness
- Skin: jaundice, petechiae, purpura, ecchymoses

DIFFERENTIAL DIAGNOSIS

- HUS and atypical HUS: See "Commonly Associated Conditions."
- Antiphospholipid antibody syndrome: prolonged partial thromboplastin time (PTT) and presence of lupus anticoagulant
- Systemic lupus erythematosus
- Malignant hypertension (HTN): diastolic >130 mm Hg, papilledema, retinal hemorrhages
- Pregnancy-associated preeclampsia/eclampsia or hemolysis, elevated liver enzyme levels, and low platelet HELLP levels: low ATIII levels
- Disseminated intravascular coagulation
  - Prolonged prothrombin time (PT)/PTT, low fibrinogen
  - Low factors V and VIII
  - Secondary to sepsis/shock or widely disseminated malignancy
- Idiopathic thrombocytopenic purpura (ITP)

  - No hemolysis, normal lactate dehydrogenase (LDH) and bilirubin
  - Presence of antiplatelet antibodies
- Malignancy-associated microangiopathy
- Evan syndrome (autoimmune hemolytic anemia and thrombocytopenia): positive direct Coombs test
- Sclerodermal kidney

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- CBC
  - Hemoglobin (decreased): average is 8 to 10 g/dL
  - Platelets decreased: typically in the 10 to 30,000 range
- Reticulocyte count (increased)
- Haptoglobin decreased (hemolysis)
- Peripheral smear
  - Schistocytes (prominent, >1% of RBCs)
  - Helmet cells, RBC fragments
  - Nucleated RBCs
  - Polychromasia (reticulocytosis)
- Coagulation studies
  - Normal in most; mild elevation in 15%
  - Fibrinogen normal
- Coombs test: negative direct Coombs test
- Electrolytes, BUN/creatinine: mild elevation of BUN and creatinine (creatinine <3 mg/dL)
- Liver function studies: increased indirect bilirubin (hemolysis)
- LDH: 5 to 10 times normal
- Urinalysis
  - Proteinuria, microscopic hematuria
  - Positive dipstick for large blood but minimal RBCs on microscopic exam
- ECG: sinus tachycardia, heart block
- Troponin: increased if cardiac involvement
- HIV, hepatitis A, B, C testing: Exclude underlying viral precipitant.
- Pregnancy test

- Pretreatment ADAMTS13 activity level of <10% is useful in distinguishing acquired or familial TTP from other disorders.
- Head CT/MRI scan: performed if mental status changes are present to rule out possible intracranial hemorrhage or ischemic changes

Test Interpretation

Biopsy of affected organs shows platelet thrombi within or beneath damaged endothelium. However, biopsy is rarely obtained because the diagnosis is made on clinical grounds and laboratory findings.

TREATMENT

ALERT

- Prompt treatment of TTP is necessary due to the high mortality (90%).
- In the absence of another apparent cause, the dyad of MAHA and thrombocytopenia is sufficient to begin treatment for TTP while the workup proceeds (1,3):
  - Plasma exchange transfusion (PEX) is the cornerstone of treatment of classic TTP (3)[A].
  - PEX replaces deficient or defective metalloproteinase (ADAMTS13) and removes UL vWF and antimetalloproteinase antibodies.
  - PEX should begin immediately and continued daily.
  - Optimal PEX duration is variable. Convention is to continue for 2 days after platelet count is ≥150,000, then consider tapering (5)[C].
  - Fresh frozen plasma: temporary measure until PEX can be initiated (3)[B]

MEDICATION

First Line

- Glucocorticoids may be of benefit in some patients. British guidelines recommend its use for all patients (5)[B].
  - Steroids may work by suppressing the autoantibodies inhibiting ADAMTS13 activity.
  - Use may be in patients with severe ADAMTS13 deficiency, in the setting of exacerbation when PEX is stopped or in relapse after remission.

  - Little benefit of steroids when used as monotherapy
  - Doses: prednisone 1 to 2 mg/kg/day and taper once in remission or methylprednisolone 1 g/day IV for 3 days
- Rituximab, an anti-CD20 antibody that deletes B cells, may reduce relapse when given in conjunction with PEX and steroids (6).
  - Dose: 375 mg/m^2 IV weekly for 4 weeks

Second Line

The following medications are used in refractory cases:

- Rituximab (5)[B]
- Vincristine, cyclophosphamide, cyclosporine
- Intravenous immunoglobulin (IVIG) (3)
- Bortezomib (7)[C],(8)

ISSUES FOR REFERRAL

- Hematology or blood bank for PEX
- Nephrology for dialysis
- Cardiology for presence of significant heart block or ischemia
- Neurosurgery for intracranial hemorrhage

SURGERY/OTHER PROCEDURES

Splenectomy is reserved for severe, refractory cases (9).

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- ABCs, oxygen, IV access, telemetry
- Volume resuscitation if hypotensive/actively bleeding
- Packed RBCs can be transfused safely.
- Platelet transfusion may be used for the treatment of hemorrhage.
- Discharge on normalization and stabilization of neurologic symptoms, LDH, platelets, and renal function

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- No maintenance therapy is required. After PEX is discontinued, blood counts should be monitored over a few months. If testing results remain normal, testing interval can be lengthened.
- Promptly evaluate any symptoms of relapse.

PATIENT EDUCATION

- On discharge, advise patients to self-monitor for signs of relapse (e.g., fever, headache, bruising).
- Patients should be advised about prolonged periods of fatigue following the acute phase.
- See National Heart, Lung and Blood Institute Web site: http://www.nhlbi.nih.gov/health/health-topics/topics/ttp

PROGNOSIS

- Most patients recover fully from idiopathic TTP when treated promptly:
  - 30-day mortality is 10% in those who receive PEX.
  - 70% respond within 14 days; 90% respond within 28 days.
  - 80% survival in patients with idiopathic TTP treated with PEX (10)
- Initial LDH and platelet counts are not predictive of the patient's response to treatment.
- Final platelet count and LDH or the length or intensity of treatment does not predict relapse.
- Low levels of ADAMTS13 activity during remission are associated with higher risk of relapse (11).
- In patients with severe ADAMTS13 deficiency, the risk of relapse is estimated to be 41% at 7.5 years, with the greatest risk being in the 1st year.

COMPLICATIONS

- Patients may experience mild cognitive impairments in attention, concentration, and memory following ≥1 episodes of TTP.
- Complications of PEX include the following:
  - Central line infections and hemorrhage
  - Citrate toxicity
  - Hypersensitivity reactions to frequent plasma exposure
  - Electrolyte abnormalities

CODES

ICD10

- M31.1 Thrombotic microangiopathy
- D69.42 Congenital and hereditary thrombocytopenia purpura
- D69.3 Immune thrombocytopenic purpura

CLINICAL PEARLS

- The diagnosis of TTP is made clinically; common symptoms are nonspecific: nausea; vomiting; weakness; abdominal pain; fatigue; fever; and easy bruising, purpura, or petechiae.
- The historical pentad of fever, neurologic symptoms, renal dysfunction, MAHA, and thrombocytopenia is not present in most patients.
- The dyad of MAHA and thrombocytopenia is sufficient to initiate treatment with PEX.
- Do not wait for results of ADAMTS13 determination to initiate therapy.

THYROID MALIGNANT NEOPLASIA

Mohannad Al-Tarakji, MD • Jowhara Al-Qahtani, MD • AbdulHakeem AlTabib, MD

BASICS

DESCRIPTION

Thyroid malignant neoplasia is an autologous growth of thyroid nodules with potential for metastases.

- Papillary thyroid carcinoma (PTC)
  - Most common variety, 60–70% of thyroid tumors
  - Peak incidence in the 3rd to 4th decades
  - 3 times more common in women
  - May be associated with radiation exposure
  - Metastasizes by lymphatic route (30% at time of diagnosis)
  - Multicentric in ≥20%, especially in children
  - Higher risk in patients with Hashimoto thyroiditis
  - Evidence for overdetection "overdiagnosis" of PTC includes increased numbers of smaller size tumors and improved or unchanged survival.
  - Many different histologic variants have been described for the thyroid PTC.
  - Thyroid tumors currently diagnosed as noninvasive encapsulated follicular variant of papillary thyroid carcinoma (EFVPTC) have a very low risk of adverse outcome and should be termed "noninvasive follicular thyroid neoplasms with papillary-like nuclear features" (NIFTP). This reclassification will affect a large population of patients worldwide and result in a significant reduction in psychological and clinical consequences associated with the diagnosis of cancer.
- Follicular carcinoma
  - 10–20% of thyroid tumors
  - Peak incidence in 5th decade of life
  - Incidence has been decreasing because of the addition of dietary iodine.
  - Metastasizes by the hematogenous route
- Hürthle cell carcinoma (variant of follicular with poorer prognosis)

  - 2–3% of thyroid malignancies
  - Usually in patients >60 years old
  - No gender difference
  - Radioresistant
  - Variant of follicular carcinoma with worse prognosis
- Medullary thyroid carcinoma (MCT)
  - Arises from parafollicular cells, C cells
  - Multiple endocrine neoplasia (MEN) syndromes (MEN2A, MEN2B, FMTC). Prevalence of MEN2 is 1:30,000.
  - MCT associated with MEN2B occur in childhood, those with MEN2A occur in young adults, and those with FMTC occur at middle age.
  - 3–4% of all thyroid tumors
  - 25–35% are associated with MEN syndromes (2A more common than 2B), which can be familial or sporadic.
  - Calcitonin is a chemical marker.
  - *RET* proto-oncogene mutation is screened; family members who carry the *RET* gene should consider early prophylactic thyroidectomy.
- Anaplastic carcinoma
  - 3% of thyroid tumors
  - Most aggressive form of thyroid neoplasia
  - More common in females
  - Usually in patients >60 years old
- Other: lymphoma, sarcoma, or metastatic (renal, breast, or lung)
- System(s) affected: endocrine/metabolic
- Synonym(s): follicular carcinoma of the thyroid; papillary carcinoma of the thyroid; Hürthle cell carcinoma of the thyroid; anaplastic cell carcinoma of the thyroid

Geriatric Considerations

Risk of malignancy increases at >60 years old.

Pediatric Considerations

- >60% of thyroid nodules are malignant.
- <2% of thyroid malignancies occur in children and adolescents.
- Increasing tumor size, extrathyroidal extension, and multifocal disease are

independent factors associated with nodal metastases in pediatric differentiated thyroid cancer which require careful preoperative evaluation for evidence of lateral cervical lymph node metastases and intraoperative evaluation of the central compartment, with consideration of central lymphadenectomy.

EPIDEMIOLOGY

Incidence

- 12.9/100,000 per year in the United States
- Deaths: 0.5/100,000 per year in the United States
- In 2015, estimated 62,450 new cases and 1,950 deaths from thyroid cancer in the United States
- Predominant age: usually >40 years old
- Predominant sex: female > male (2.6:1) prevalence
- Lifetime risk of developing thyroid cancer is 1.1%.
- In 2011, 566,708 patients living with thyroid cancer in the United States

ETIOLOGY AND PATHOPHYSIOLOGY

Genetics

- Familial polyposis of the colon, Turcot syndrome, and Gardner syndrome with the *APC* gene (5q21)
- Medullary: autosomal dominant with MEN syndrome
- *BRAF* mutation (rare in children)
- *RET* oncogene (more common in children)

RISK FACTORS

- Family history
- Neck irradiation (6 to 2,000 rads): papillary carcinoma
- Iodine deficiency: follicular carcinoma
- MEN2: medullary carcinoma; autosomal dominant
- Previous history of subtotal thyroidectomy for malignancy: anaplastic carcinoma
- Asian race
- Female gender

GENERAL PREVENTION

- Physical exam in high-risk group
- Calcium infusion or pentagastrin-stimulated calcitonin test screening in high-risk MEN patients
- Screen for *RET* proto-oncogene in groups at-risk for MCT.

COMMONLY ASSOCIATED CONDITIONS

Medullary carcinoma: pheochromocytoma, hyperparathyroidism, ganglioneuroma of the GI tract, neuromata of mucosal membranes

DIAGNOSIS

HISTORY

- Change in voice (hoarseness)
- Positive family history
- Neck mass
- Dysphagia
- Dyspnea
- Cough
- Difficulty swallowing

PHYSICAL EXAM

- Neck mass: If fixed to surrounding tissue, this finding suggests advanced disease.
- Cervical adenopathy
- Inspection for mucosal neuromas and marfanoid habitus as this finding is suggestive of MEN IIb

DIFFERENTIAL DIAGNOSIS

- Multinodular goiter
- Thyroid adenoma
- Thyroglossal duct cyst
- Thyroiditis
- Thyroid cyst
- Ectopic thyroid
- Dermoid cyst

DIAGNOSTIC TESTS & INTERPRETATION

- US: Solid mass and microcalcifications are more suspicious of malignancy.
- CT scan and MRI can be useful to evaluate large substernal masses and recurrent soft tissue masses.
- Medullary carcinoma: calcitonin level (normal <30 pg/mL [300 ng/L]), pentagastrin stimulation test, and *RET* proto-oncogene
- Thyroglobulin (TG) level: postoperative tumor marker
- DNA content of tumors from biopsy specimen: Diploid content has a better prognosis.
- Thyroid function tests usually normal
- Thyroid scan: 12–15% of cold nodules are malignant; rate is higher in patients <40 years of age, and those with microcalcifications on US.^{18}F-FDG positron-emission tomographic scan can help if the cytology is inconclusive; helpful with recurrent disease when patient has a negative 131I scan and an elevated TG level

Diagnostic Procedures/Other

- Fine-needle aspiration (FNA)
- Surgical biopsy/excision
- Laryngoscopy if vocal cord paralysis is suspected

Test Interpretation

- Papillary: psammoma bodies, anaplastic epithelial papillae
- Follicular: anaplastic epithelial cords with follicles
- Hürthle cell: large eosinophilic cells with granular cytoplasm
- Medullary: large amounts of amyloid stroma
- Anaplastic: small cell and giant cell undifferentiated tumors

TREATMENT

MEDICATION

Postoperatively, will require thyroid hormone replacement: Goal is to keep TSH <0.1 mU/L.

- Levothyroxine (T_4, Synthroid) 100 to 200 μg/day

- Liothyronine (T_3, Cytomel) 50 to 100 μg/day

GENERAL MEASURES

- Most cases of thyroid cancer are managed surgically and medically with a good prognosis (1)[C].
- Palliative support has a role in case of advanced thyroid malignancy (1)[C].
- Papillary/follicular: ^{131}I thyroid remnant ablation
- Medullary: Vandetanib has been tried in patients with advanced disease (2) [B].
- Anaplastic: Doxorubicin and cisplatin have achieved partial remission in some patients.
- Recurrent tumor: Sorafenib has been used in patients with recurrent disease.

ADDITIONAL THERAPIES

- External beam radiation for advanced disease
- ^{131}I is used in high-risk patients with papillary and follicular tumors. The role is to ablate remnant thyroid tissue to improve specificity of future TG assays.

SURGERY/OTHER PROCEDURES

- Papillary carcinoma: lobectomy with isthmectomy (if lesion <1 cm) or total thyroidectomy and removal of suspicious lymph nodes; total thyroidectomy for tumors >1 cm (3)[B]
- Follicular carcinoma and Hürthle cell: total thyroidectomy and removal of suspicious lymph nodes
- Medullary carcinoma: total thyroidectomy with central node dissection; unilateral or bilateral modified radical neck dissection if lateral nodes are histologically positive
- Anaplastic carcinoma: aggressive en bloc thyroidectomy; tracheostomy often required; not responsive to ^{131}I

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- 10–30% of initially disease-free patients will develop recurrence and/or

metastases. 80% recur in neck and 20% with distant metastases. Lung is most common site of distant metastases.

- Thyroid scan at 6 weeks and administration of ^{131}I for any visible uptake; any evidence of residual thyroid tissue (after total thyroidectomy) or lymph node disease noted on scan is treated with radioactive iodine.
- At 6 months and then yearly, the patient should have a thyroid scan and chest x-ray.
- Papillary and follicular: A TG level should be done yearly. Recombinant human thyroid-stimulating hormone (rhTSH)–stimulated TG level may be more sensitive.
- Medullary: Calcitonin level should be done yearly with pentagastrin stimulation.
- The thyroid scan and TG level should be done with the patient in the hypothyroid state induced by 6-week withdrawal of levothyroxine or 2- to 3-week withdrawal of liothyronine.
- Decreased incidence of recurrence when TSH is suppressed

DIET

Avoid iodine deficiency.

PATIENT EDUCATION

National Cancer Institute: (301) 496-5583; http://www.cancer.gov

PROGNOSIS

- Taken together: 5-year survival of thyroid cancer is 97.8%.
- Favorable factors: female, multifocality, regional LN involvement
- Adverse factors: age >45 years, follicular histology, primary tumor >4 cm, extrathyroid extension, distant metastases
- Papillary carcinoma: 10-year overall survival is 93%; 30-year cancer-related death rate of 6%
- Follicular carcinoma: 10-year overall survival is 85%; histologically, microinvasive tumors parallel papillary tumor results, whereas grossly invasive tumors do far worse; 30-year cancer-related death rate of 15%
- Hürthle cell carcinoma: 93% 5-year survival rate and 83% survival rate overall; grossly invasive tumor survival <25%

- Medullary carcinoma: negative nodes, 90% 5-year survival rate and 85% 10-year survival rate; with positive nodes, 65% 5-year survival rate and 40% 10-year survival rate. Prognosis worse for MEN2B compared to MEN2A. Overall 10-year survival is 75%.
- Anaplastic carcinoma: survival unexpected. Long-term survivors should have original pathology reexamined.

COMPLICATIONS

- Recurrence of tumor is 10–30%; 80% recur in neck, and 20% recur distally.
- Hoarseness from tumor invasion or operative injury to recurrent laryngeal nerve
- Hypoparathyroidism from operative injury to parathyroid glands

SEE ALSO

Multiple Endocrine Neoplasia (MEN) Syndromes

CODES

ICD10

C73 Malignant neoplasm of thyroid gland

CLINICAL PEARLS

- Standard workup for a patient suspected of having a thyroid cancer is a physical exam, TSH level, neck US, and FNA.
- TG levels can be elevated in several thyroid disorders. Its usefulness comes once the diagnosis of cancer has been made. It serves as a better marker for recurrent disease.
- ~2% of the normal population will have a positive ^{18}F-FDG positron-emission tomographic scan, so it is more useful for postresection follow-up.
- FNA results will be benign, malignant, indeterminate, or nondiagnostic. More helpful in planning initial surgical approach.

THYROIDITIS

Pradeepa P. Vimalachandran, MD, MPH

BASICS

DESCRIPTION

Inflammation of the thyroid gland that may be painful or painless

- Thyroiditis with thyroid pain
  - Subacute granulomatous thyroiditis (nonsuppurative thyroiditis, de Quervain thyroiditis, or giant cell thyroiditis): self-limited; viral URI prodrome, symptoms and signs of thyroid dysfunction (variable)
  - Infectious/suppurative thyroiditis
- Bacterial, fungal, mycobacterial, or parasitic infection of the thyroid
- Most commonly associated with *Streptococcus pyogenes*, *Staphylococcus aureus*, and *Streptococcus pneumoniae*
  - Radiation-induced thyroiditis: from radioactive iodine therapy (1%) or external irradiation for lymphoma and head/neck cancers
- Thyroiditis with no thyroid pain
  - Hashimoto (autoimmune) thyroiditis (chronic lymphocytic thyroiditis): most common etiology of chronic hypothyroidism; autoimmune disease; 90% of patients with high-serum antithyroid peroxidase (TPO) antibodies
  - Postpartum thyroiditis: episode of thyrotoxicosis, hypothyroidism, or thyrotoxicosis followed by hypothyroidism in the 1st year postpartum or after spontaneous/induced abortion in women who were without clinically evident thyroid disease before pregnancy.
  - Painless (silent) thyroiditis (subacute lymphocytic thyroiditis): mild hyperthyroidism, small painless goiter, and no Graves ophthalmopathy/pretibial myxedema
  - Riedel (fibrous) thyroiditis: rare inflammatory process involving the thyroid and surrounding cervical tissues; associated with various forms of systemic fibrosis; presents as a firm mass in the thyroid commonly associated with compressive symptoms (dyspnea, dysphagia, hoarseness, and aphonia) caused by local infiltration of the advancing fibrotic process with

hypocalcemia and hypothyroidism
  - Drug-induced thyroiditis: interferon-α, interleukin-2, amiodarone, kinase inhibitors, or lithium

EPIDEMIOLOGY

- Subacute granulomatous thyroiditis: most common cause of thyroid pain; peaks during summer; incidence: 3/100,000/year; female > male (4:1); peak age: 40 to 50 years
- Suppurative thyroiditis: commonly seen with preexisting thyroid disease/immunocompromise
- Hashimoto thyroiditis: peak age of onset, 30 to 50 years; can occur in children; primarily a disease of women; female > male (7:1)
- Postpartum thyroiditis: female only; occurs within 12 months of pregnancy in 8–11% of pregnancies; occurs in 25% with type 1 diabetes mellitus; incidence is affected by genetic influences and iodine intake.
- Painless (silent) thyroiditis: female > male (4:1) with peak age 30 to 40 years; common in areas of iodine sufficiency
- Reidel thyroiditis: female > male (4:1); highest prevalence age 30 to 60 years

ETIOLOGY AND PATHOPHYSIOLOGY

- Hashimoto disease: Antithyroid antibodies may be produced in response to an environmental antigen and cross-react with thyroid proteins (molecular mimicry). Precipitating factors include infection, stress, sex steroids, pregnancy, iodine intake, and radiation exposure.
- Subacute granulomatous thyroiditis: probably viral
- Postpartum thyroiditis: autoimmunity-induced discharge of preformed hormone from the thyroid
- Painless (silent) thyroiditis: autoimmune

Genetics

Autoimmune thyroiditis is associated with the CT60 polymorphism of cytotoxic T-cell lymphocyte–associated antigen 4. Also associated with HLA-DR4, -DR5, and -DR6 in whites

RISK FACTORS

- Hashimoto disease: family history of thyroid/autoimmune disease, personal

history of autoimmune disease (type 1 diabetes, celiac disease), high iodine intake, cigarette smoking, selenium deficiency
- Subacute granulomatous thyroiditis: recent viral respiratory infection or HLA B35
- Suppurative thyroiditis: congenital abnormalities (persistent thyroglossal duct/piriform sinus fistula), greater age, immunosuppression
- Radiation-induced thyroiditis: high-dose irradiation, younger age, female sex, preexisting hypothyroidism
- Postpartum thyroiditis: smoking, history of spontaneous/induced abortion
- Painless (silent) thyroiditis: iodine-deficient areas

GENERAL PREVENTION

Selenium may decrease inflammatory activity in pregnant women with autoimmune hypothyroidism and may reduce postpartum thyroiditis risk in those positive for TPO antibodies.

COMMONLY ASSOCIATED CONDITIONS

Postpartum thyroiditis: family history of autoimmune thyroid disease; HLA-DRB, -DR4, and -DR5

DIAGNOSIS

HISTORY

- Hypothyroid symptoms (e.g., constipation, heavy menstrual bleeding, fatigue, weakness, dry skin, hair loss, cold intolerance)
- Hyperthyroid symptoms (e.g., irritability, heat intolerance, increased sweating, palpitations, loose stools, disturbed sleep, and lid retraction)
- Subacute granulomatous thyroiditis: sudden/gradual onset, with preceding upper respiratory infection/viral illness (fever, fatigue, malaise, anorexia, and myalgia are common); pain may be limited to thyroid region or radiate to upper neck, jaw, throat, or ears.
- Classic triphasic course (thyrotoxic, hypothyroid, recovery) but variable in the following: subacute, silent, and postpartum thyroiditis (1)[C]

PHYSICAL EXAM

- Examine thyroid size, symmetry, and nodules.
  - Hashimoto disease: 90% have a symmetric, diffusely enlarged, painless gland, with a firm, pebbly texture; 10% have thyroid atrophy.
  - Postpartum thyroiditis: painless, small, nontender, firm goiter (2 to 6 months after delivery)
  - Reidel thyroiditis: rock-hard, wood-like, fixed, painless goiter, often accompanied by symptoms of esophageal/tracheal compression (stridor, dyspnea, a suffocating feeling, dysphagia, and hoarseness)
- Signs of hypothyroid: delayed relaxation phase of deep tendon reflexes, nonpitting edema, dry skin, alopecia, bradycardia
- Signs of hyperthyroid: moist palms, hyperreflexia, tachycardia/atrial fibrillation

DIFFERENTIAL DIAGNOSIS

Simple goiter; iodine-deficient/lithium-induced goiter; Graves disease; lymphoma; acute infectious thyroiditis; oropharynx and trachea infections; thyroid cancer; amiodarone; contrast dye; amyloid

DIAGNOSTIC TESTS & INTERPRETATION

- Thyroid-stimulating hormone (TSH), anti-TPO antibodies
- Hashimoto disease
  - High titers of anti-TPO antibodies
  - New subtype: IgG4 thyroiditis, which is histopathologically characterized by lymphoplasmacytic infiltration, fibrosis, increased numbers of IgG4-positive plasma cells, and high serum IgG4 levels; more closely associated with rapid progress, subclinical hypothyroidism, higher levels of circulating antibodies, and more diffuse low echogenicity (2)[C]
- Subacute granulomatous thyroiditis
  - High T_4, T_3; low TSH during early stages and elevated later; TSH varies with phase (1)[C].
  - High thyroglobulin; normal levels of anti-TPO and antithyroglobulin antibodies (present in 25%, usually low titers)
  - Elevated erythrocyte sedimentation rate (ESR) (usually >50 mm/hr) and C-reactive protein; mild anemia and slight leukocytosis; LFTs are frequently abnormal during initial hyperthyroid phase and resolve over 1 to 2 months.

- Suppurative thyroiditis
  - In the absence of preexisting thyroid disease, thyroid function is normal, but hyper-/hypothyroidism may occur.
  - Elevated ESR and WBC with marked increase in left shift
  - Fine-needle aspiration (FNA) of the lesion with Gram stain and culture is the most useful diagnostic test.
- Postpartum thyroiditis (3)[B]
  - Anti-TPO antibody positivity is the most useful marker for the prediction of postpartum thyroid dysfunction.
  - Women known to be anti-TPO-Ab+ should have TSH measured at 6 to 12 weeks' gestation and at 6 months postpartum or as clinically indicated.
  - Thyrotoxic phase occurs 1 and 6 months postpartum (most commonly at 3 months) and usually lasts only 1 to 2 months.
  - Hypothyroidism occurs between 3 and 8 months (most commonly at 6 months).
  - Most patients (80%) have normal thyroid function at 1 year; 30–50% of patients develop permanent hypothyroidism within 9 years.
  - High thyroglobulin, normal ESR
- Painless (silent) thyroiditis
  - Hyperthyroid state in 5–20%: averages 3 to 4 months, and total duration of illness is <1 year, followed by hypothyroidism and then a return to normal state; some have primary/subclinical hypothyroidism.
  - ~50% have anti-TPO antibodies (1)[C].
- Reidel thyroiditis (4)[C]
  - Hypothyroidism due to extensive replacement of the gland by scar tissue. Anti-TPO antibodies are present in 2/3 of patients along with low radioactive iodine uptake (RAIU).
- Drug-induced thyroiditis
  - Hyper-/hypothyroidism, low RAIU, and variable presence of anti-TPO antibodies
- US: shows variable heterogeneous texture, hypoechogenic in subacute, painless (silent), and postpartum thyroiditis
- Thyroid RAIU scan: decreased in all forms of thyroiditis but not helpful in establishing diagnosis of Hashimoto disease. High RAIU in hashitoxicosis,

Graves disease

- Random urine iodine measurement may be helpful to distinguish from other causes of low RAIU.
  - Urine iodine <500 μg/L (subacute granulomatous thyroiditis)
  - Urine iodine >1,000 μg/L (in patients with exposure to excess exogenous iodine/radiocontrast material)

Diagnostic Procedures/Other

- Hashimoto with a dominant nodule should have FNA to rule out thyroid carcinoma.
- Open biopsy is necessary for a definitive diagnosis of Reidel thyroiditis.

Test Interpretation

- Hashimoto disease: lymphocytic infiltration with formation of Askanazy (Hürthle) cells, oxyphilic changes in follicular cells, fibrosis, thyroid atrophy
- Subacute granulomatous thyroiditis: giant cells, mononuclear cell (granulomatous) infiltrate
- Postpartum thyroiditis: lymphocytic infiltration, occasional germinal centers, disruption and collapse of thyroid follicles
- Painless (silent) thyroiditis: lymphocytic infiltration, but without fibrosis, Askanazy cells, and extensive lymphoid follicle formation

TREATMENT

GENERAL MEASURES

Analgesics for pain; corticosteroids for severe granulomatous thyroiditis

MEDICATION

- Hashimoto disease (2)[C]
  - If hypothyroid/goitrous: levothyroxine (1.7 μg/kg/day for adults <50 years of age). If no cardiac complications and no adrenal insufficiency, 1/2 replacement dose and increase to full replacement in 10 days.
    - If >50 years of age or heart disease and/or adrenal insufficiency, begin with 25 μg/day and titrate to TSH of lower limit normal range.
- If thyrotoxic and symptomatic: propylthiouracil and propranolol

- An elevated TSH level in a woman who is pregnant or attempting to become pregnant is an indication for thyroid replacement.
- Subacute granulomatous thyroiditis
  - Anti-inflammatory agents for 2 to 8 weeks (NSAIDs or aspirin)
  - Pain with no improvement in 2 to 3 days after NSAID use: prednisone 40 mg/day; should result in pain relief in 1 to 2 days; if not, question diagnosis.
  - Severe pain: prednisone 40 to 60 mg/day discontinued over 4 to 6 weeks. If pain recurs, increase dose for several weeks and then taper.
  - Symptomatic hyperthyroidism: β-blockers while thyrotoxic (propranolol 40 to 120 mg/day)
  - Symptomatic hypothyroid phase: Levothyroxine, as mentioned earlier, target TSH in the normal range.
- Suppurative thyroiditis
  - Parenteral empiric, broad-spectrum antibiotics, and surgical drainage
- Painless (silent) thyroiditis
  - No treatment needed.
  - If symptomatic during hyperthyroid state, treat with β-blocker (propranolol 40 to 120 mg/day).
  - Prednisone shortens the period of hyperthyroidism. Monitor TSH every 4 to 8 weeks to confirm resolution.
  - Treat hypothyroid symptoms and asymptomatic patients with TSH >10 mU/L with levothyroxine (50 to 100 μg/day), to be discontinued after 3 to 6 months.
- Postpartum thyroiditis (5)[C]
  - Treat symptomatic hyper-/hypothyroid state. Most do not need treatment.
  - Caution in breastfeeding mothers because β-blockers are secreted into breast milk.
  - For symptomatic hypothyroidism, treat with levothyroxine. Otherwise, remonitor in 4 to 8 weeks. Taper replacement hormone after 6 months if thyroid function has normalized.
- Reidel thyroiditis (4)[C]
  - Corticosteroids in early stages but controversial thereafter. Prednisone 10 to 20 mg/day for 4 to 6 months, possibly continued thereafter if effective
  - Long-term anti-inflammatory medications to arrest progression and

maintain a symptom-free course
  - Tamoxifen 10 to 20 mg twice daily as monotherapy or in conjunction with prednisone reduces mass size and clinical symptoms.
  - Methotrexate is used with some success.
  - Reduction of goiter seen with a combination of mycophenolate mofetil (1 g BID) and 100 mg/day prednisone
  - Debulking surgery is limited to isthmusectomy to relieve constrictive pressure when total thyroidectomy is not possible.
- Drug-induced thyroiditis
  - Discontinue offending drug.

SURGERY/OTHER PROCEDURES

Enlarged painful thyroid or tracheal compression

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Hashimoto disease: Repeat thyroid function tests every 3 to 12 months.
- Subacute granulomatous thyroiditis: Repeat thyroid function tests every 3 to 6 weeks until euthyroid, then every 6 to 12 months.
- Postpartum thyroiditis: Check TSH annually.
- Reidel thyroiditis: CT of cervical mediastinal region is recommended.
- TSH every 6 months in patients on amiodarone

Pregnancy Considerations

- Avoid radioisotope scanning if possible.
- Keep TSH maximally suppressed.
- If using RAIU scan, discard breast milk for 2 days because RAI is secreted in breast milk.

PROGNOSIS

- Hashimoto disease: persistent goiter; eventual thyroid failure
- Subacute granulomatous thyroiditis: 5–15% hypothyroid beyond a year: Some with eventual return to normal; remission may be slower in the elderly;

recurrence rate: 1–4% after a year

- Painless (silent) thyroiditis: 10–20% hypothyroid beyond a year; recurrence rate 5–10% (much higher in Japan)
- Postpartum thyroiditis: 15–50% hypothyroid beyond a year; women may be euthyroid/continue to be hypothyroid at the end of 1st postpartum year. 70% recurrence rate in subsequent pregnancies; substantial risk exists for later development of hypothyroidism/goiter.

SEE ALSO

Hyperthyroidism; Hypothyroidism, Adult

CODES

ICD10

- E06.9 Thyroiditis, unspecified
- E06.1 Subacute thyroiditis
- E06.0 Acute thyroiditis

CLINICAL PEARLS

- TSH elevation above the normal range indicates a hypothyroid state; suppressed TSH indicates hyperthyroid state. Follow up with free T_3/T_4 determination.
- Follow patients on thyroid replacement with periodic TSH level.

TINEA (CAPITIS, CORPORIS, CRURIS)

Elisabeth L. Backer, MD

BASICS

DESCRIPTION

- Superficial fungal infections of the skin/scalp; various forms of dermatophytosis; the names relate to the particular area affected (1).
  - Tinea cruris: infection of crural fold and gluteal cleft
  - Tinea corporis: infection involving the face, trunk, and/or extremities; often presents with ring-shaped lesions, hence the misnomer *ringworm*.
  - Tinea capitis: infection of the scalp and hair; affected areas of the scalp can show characteristic black dots resulting from broken hairs.
- Dermatophytes have the ability to subsist on protein, namely keratin.
- They cause disease in keratin-rich structures such as skin, nails, and hair.
- Infections result from contact with infected persons/animals
  - Zoophilic infections are acquired from animals.
  - Anthropophilic infections are acquired from personal contact (e.g., wrestling) or fomites.
  - Geophile infections are acquired from the soil.
- System(s) affected: skin; exocrine
- Synonym(s): jock itch; ringworm

EPIDEMIOLOGY

Incidence

- Tinea cruris
  - Predominant age: any age; rare in children
  - Predominant sex: male > female
- Tinea corporis
  - Predominant age: all ages
  - Predominant sex: male = female
- Tinea capitis
  - Predominant age: 3 to 9 years; almost always occurs in young children

– Predominant sex: male = female

Prevalence

Common worldwide

Pediatric Considerations

- Tinea cruris is rare prior to puberty.
- Tinea capitis is common in young children.

Geriatric Considerations

Tinea cruris is more common in the geriatric population due to an increase in risk factors.

Pregnancy Considerations

Tinea cruris and capitis are rare in pregnancy.

ETIOLOGY AND PATHOPHYSIOLOGY

Superficial fungal infection of skin/scalp

- Tinea cruris: Source of infection is usually the patient's own tinea pedis, with agent being transferred from the foot to the groin via the underwear when dressing; most common causative dermatophyte is *Trichophyton rubrum*; rare cases caused by *Epidermophyton floccosum* and *T. mentagrophytes*.
- Tinea corporis: most commonly caused by *T. rubrum*; *T. tonsurans* most often found in patients with tinea gladiatorum.
- Tinea capitis: *T. tonsurans* found in 90% and *Microsporum* sp. in 10% of patients

Genetics

Evidence suggests a genetic susceptibility in certain individuals.

RISK FACTORS

- Warm climates; summer months and/or copious sweating; wearing wet clothing/multiple layers (tinea cruris)
- Daycare centers/schools/confined quarters (tinea corporis and capitis)
- Depression of cell-mediated immune response (e.g., individuals with atopy or AIDS)
- Obesity (tinea cruris and corporis)

- Direct contact with an active lesion on a human, an animal, or rarely, from soil; working with animals (tinea corporis)

GENERAL PREVENTION

- Avoidance of risk factors, such as contact with suspicious lesions
- Fluconazole or itraconazole may be useful in wrestlers to prevent outbreaks during competitive season.

COMMONLY ASSOCIATED CONDITIONS

Tinea pedis, tinea barbae, tinea manus

DIAGNOSIS

HISTORY

- Lesions range from asymptomatic to pruritic.
- In tinea cruris, acute inflammation may result from wearing occlusive clothing; chronic scratching may result in an eczematous appearance.
- Previous application of topical steroids, especially in tinea cruris and corporis, may alter the overall appearance causing a more extensive eruption with irregular borders and erythematous papules. This modified form is called *tinea incognito*.

PHYSICAL EXAM

- Tinea cruris: well-marginated, erythematous, half-moon–shaped plaques in crural folds that spread to upper thighs; advancing border is well defined, often with fine scaling and sometimes vesicular eruptions. Lesions are usually bilateral and do not include scrotum/penis (unlike with *Candida* infections) but may migrate to perineum, perianal area, and gluteal cleft and onto the buttocks in chronic/progressive cases. The area may be hyperpigmented on resolution.
- Tinea corporis: scaling, pruritic plaques characterized by a sharply defined annular pattern with peripheral activity and central clearing (ring-shaped lesions); papules and occasionally pustules/vesicles present at border and, less commonly, in center.
- Tinea capitis: commonly begins with round patches of scale (alopecia less

common). In its later stages, the infection frequently takes on patterns of chronic scaling with either little/marked inflammation or alopecia. Less often, patients will present with multiple patches of alopecia and the characteristic black-dot appearance of broken hairs. Extreme inflammation results in kerion formation (exudative, pustular nodulation).

DIFFERENTIAL DIAGNOSIS

- Tinea cruris
  - Intertrigo: inflammatory process of moist-opposed skin folds, often including infection with bacteria, yeast, and fungi; painful longitudinal fissures may occur in skin folds.
  - Erythrasma: diffuse brown, scaly, noninflammatory plaque with irregular borders, often involving groin; caused by bacterial infection with *Corynebacterium minutissimum*; fluoresces coral red with Wood lamp
  - Seborrheic dermatitis of groin
  - Psoriasis of groin (“inverse psoriasis”)
  - Candidiasis of groin (typically involves the scrotum)
  - Acanthosis nigricans
- Tinea capitis
  - Psoriasis
  - Seborrheic dermatitis
  - Pyoderma
  - Alopecia areata and trichotillomania
  - Aplasia cutis congenital
- Tinea corporis
  - Pityriasis rosea
  - Eczema (nummular)
  - Contact dermatitis
  - Syphilis
  - Psoriasis
  - Seborrheic dermatitis
  - Subacute systemic lupus erythematosus (SLE)
  - Erythema annulare centrifugum
  - Erythema multiforme; erythema migrans
  - Impetigo circinatum

– Granuloma annulare

DIAGNOSTIC TESTS & INTERPRETATION

Wood lamp exam reveals no fluorescence in most cases (*Trichophyton* sp.); 10% of infections, those caused by *T. rubrum* will fluoresce with a green light.

Initial Tests (lab, imaging)

- Potassium hydroxide (KOH) preparation of skin scrapings from dermatophyte leading border shows characteristic translucent, branching, rod-shaped hyphae.
- Arthrospores can be visualized within hair shafts. Spores and/or hyphae may be seen on KOH exam.

Follow-Up Tests & Special Considerations

- Reevaluate to assess response, especially in resistant/extensive cases
- Fungal culture using Sabouraud dextrose agar/dermatophyte test medium

Test Interpretation

- Skin scrapings show fungal hyphae in epidermis.
- Arthrospores found in hair shafts; spores and/or hyphae seen on KOH exam.

TREATMENT

GENERAL MEASURES

- Careful handwashing and personal hygiene; laundering of towels/clothing of affected individual; no sharing of towels/clothes/headgear
- Evaluate other family members, close contacts, or household pets.
- Avoid predisposing conditions such as hot baths and tight-fitting clothing (boxer shorts are better than briefs).
- Keep area as dry as possible (talcum/powders may be beneficial).
- Itching can be alleviated by OTC preparations such as Sarna or Prax.
- Topical steroid preparations should be avoided (see “Tinea Incognito”), unless absolutely needed to control itching and only after definitive diagnosis and initiation of antifungal treatment.
- Nystatin should be avoided in tinea infections but is indicated for cutaneous candidal infections.

- Avoid contact sports (e.g., wrestling) temporarily while starting treatment.

MEDICATION

First Line

- Tinea cruris/corporis (2)[C]
  - Topical azole antifungal compounds
    - Terbinafine 1% (Lamisil): OTC inexpensive and effective compound; can be applied once or BID for 1 to 2 weeks
    - Econazole 1% (Spectazole), ketoconazole (Nizoral): usually applied BID for 2 to 3 weeks
    - Butenafine 1% (Mentax): applied once daily for 2 weeks; also very effective. To prevent relapse, use for 1 week after resolution.
- Tinea capitis (3)[A]
  - PO griseofulvin for *Trichophyton* and *Microsporum* sp.; microsized preparation available; dosage 10 to 20 mg/kg/day (max 1,000 mg); taken BID or as a single dose daily for 6 to 12 weeks
  - PO terbinafine can be used for *Trichophyton* sp. at 62.5 mg/day in patients weighing 10 to 20 kg; 125 mg/day if weight 20 to 40 kg; 250 mg/day if weight >40 kg; use for 4 to 6 weeks.
  - PO itraconazole can be used for *Microsporum* sp. and matches griseofulvin efficacy while being better tolerated. Dosage of 3 to 5 mg/kg/day, but most studies have used 100 mg/day for 6 weeks in children >2 years of age.

Second Line

Tinea cruris/corporis

- Oral antifungal agents are effective but not indicated in uncomplicated tinea cruris/corporis cases. They can be used for resistant and extensive infections or if the patient is immunocompromised. If topical therapy fails, consider possible oral therapy. Griseofulvin can be given 500 mg/day for 1 to 2 weeks.
- The following oral regimens have been reported in medical literature as being effective but currently are not specifically approved by FDA for tinea cruris:
  - PO terbinafine (Lamisil): 250 mg/day for 1 week
  - PO itraconazole (Sporanox): 100 mg BID once and repeated 1 week later
  - PO fluconazole (Diflucan): 150 mg once per week for 4 weeks
- Topical terbinafine 1% solution has been studied recently and appears

effective as a once-daily application for 1 week.
- Oral antifungals have many interactions including warfarin, OCPs, and alcohol; advise checking for drug interactions prior to use; contraindicated in pregnancy. Monitor for liver toxicity when using oral antifungals.

ISSUES FOR REFERRAL
Refer if disease is nonresponsive/resistant, especially in immunocompromised host.

ADDITIONAL THERAPIES
Treatment of secondary bacterial infections

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Reevaluate response to treatment.

Patient Monitoring
Liver function testing prior to therapy and at regular intervals during course of therapy for patients requiring oral terbinafine, fluconazole, itraconazole, and griseofulvin.

PATIENT EDUCATION
Explain the causative agents, predisposing factors, and prevention measures.

PROGNOSIS
- Excellent prognosis for cure with therapy in tinea cruris and corporis.
- In tinea capitis, lesions will heal spontaneously in 6 months without treatment but scarring is more likely.

COMPLICATIONS
- Secondary bacterial infection
- Generalized, invasive dermatophyte infection
- Secondary eruptions called dermatophytid reactions may occur at distant sites.

CODES

ICD10

- B35.0 Tinea barbae and tinea capitis

- B35.4 Tinea corporis
- B35.6 Tinea cruris

CLINICAL PEARLS

- Tinea corporis is characterized by scaly plaque, with peripheral activity and central clearing.
- Tinea cruris is characterized by erythematous plaque in crural folds usually sparing the scrotum. Treatment of concomitant tinea pedis is advised.
- Tinea capitis is a fungal infection of the scalp affecting hair growth. Topical therapy is ineffective for this infection.

TINEA PEDIS

Elisabeth L. Backer, MD

BASICS

DESCRIPTION

- Superficial infection of the feet caused by dermatophytes
- Most common dermatophyte infection encountered in clinical practice
- Often accompanied by tinea manuum, tinea unguium, and tinea cruris
- Two clinical forms: acute and chronic; both are contagious
- System(s) affected: skin/exocrine
- Synonym(s): athlete's foot

EPIDEMIOLOGY

- Predominant age: 20 to 50 years, although can occur at any age (1)[C]
- Predominant gender: male > female

Prevalence

4% of population

Pediatric Considerations

Rare in younger children; common in teens

Geriatric Considerations

Elderly are more susceptible to outbreaks because of immunocompromise and impaired perfusion of distal extremities.

ETIOLOGY AND PATHOPHYSIOLOGY

Superficial infection caused by dermatophytes that thrive only in nonviable keratinized tissue.

- *Trichophyton mentagrophytes* (acute)
- *Trichophyton rubrum* (chronic)
- *Trichophyton tonsurans*
- *Epidermophyton floccosum*

Genetics

No known genetic pattern

RISK FACTORS

- Hot, humid weather
- Sweating
- Occlusive/tight-fitting footwear
- Immunosuppression
- Prolonged application of topical steroids

GENERAL PREVENTION

- Good personal hygiene
- Wearing rubber or wooden sandals in community showers, bathing places, locker rooms
- Careful drying between toes after showering or bathing; blow-drying feet with hair dryer may be more effective than drying with towel.
- Changing socks and shoes frequently
- Applying drying or dusting powder
- Applying topical antiperspirants
- Putting on socks before underwear to prevent infection from spreading to groin

COMMONLY ASSOCIATED CONDITIONS

- Hyperhidrosis
- Onychomycosis
- Tinea manuum/unguium/cruris/corporis

DIAGNOSIS

HISTORY

- Itchy, scaly rash on foot, usually between toes; may progress to fissuring/maceration in toe web spaces.
- May be associated with onychomycosis and other tinea infections

PHYSICAL EXAM

- Acute form: self-limited, intermittent, recurrent; scaling, thickening, and fissuring of sole and heel; scaling or fissuring of toe webs; or pruritic

vesicular/bullous lesions between toes or on soles

- Chronic form: most common; slowly progressive, pruritic erythematous erosion/scales between toes, in digital interspaces; extension onto soles, sides/dorsum of feet (moccasin distribution); if untreated, may persist indefinitely
- Other features: strong odor, hyperkeratosis, maceration, ulceration
- Tinea pedis may occur unilateral or bilateral.
- Seconday eruptions called dermatophytid reactions may occur at distant sites.

DIFFERENTIAL DIAGNOSIS

- Interdigital type: erythrasma, impetigo, pitted keratolysis, candidal intertrigo
- Moccasin type: psoriasis vulgaris, eczematous dermatitis, pitted keratolysis
- Inflammatory/bullous type: impetigo, allergic contact dermatitis, dyshidrotic eczema (negative KOH examination of scrapings), bullous disease

DIAGNOSTIC TESTS & INTERPRETATION

Wood lamp exam will not fluoresce unless complicated by another fungus, which is uncommon: *Malassezia furfur* (yellow to white), *Corynebacterium* (red), or *Microsporum* (blue-green).

Initial Tests (lab, imaging)

Testing is not needed in typical presentation.

- Direct microscopic exam (potassium hydroxide) of scrapings of the lesions
- Culture (Sabouraud medium)

Test Interpretation

- Potassium hydroxide preparation: septate and branched mycelia
- Culture: dermatophyte

TREATMENT

Treatment is generally with topical antifungal medications for up to 4 weeks and is more effective than placebo:

- Acute treatment
  - Aluminum acetate soak (Burow solution; Domeboro, one pack to one quart warm water) to decrease itching and acute eczematous reaction

  - Antifungal cream of choice BID after soaks
- Chronic treatment:
  - Antifungal creams BID, continuing for 3 days after the rash is resolved: terbinafine 1% (possibly most effective topical), clotrimazole 1%, econazole 1%, ketoconazole 2%, tolnaftate 1%, etc. (2)[A]
  - May try systemic antifungal therapy; see below (consider if concomitant onychomycosis or after failed topical treatment)

GENERAL MEASURES

- Soak with aluminum chloride 30% or aluminum subacetate for 20 minutes BID.
- Careful removal of dead/thickened skin after soaking or bathing
- Treatment of shoes with antifungal powders
- Avoidance of occlusive footwear
- Chronic or extensive disease or nail involvement requires oral antifungal medication and systemic therapy.

MEDICATION

For use when topical therapy has failed

First Line

- Systemic antifungals (3)[A]:
  - Itraconazole (Sporanox): 200 mg PO BID for 7 days (cure rate >90%)
  - Terbinafine (Lamisil): 250 mg/day PO for 14 days
- If concomitant onychomycosis:
  - Itraconazole: 200 mg PO BID for first week of month for 3 months. Liver function testing is recommended.
  - Terbinafine: 250 mg/day PO for 12 weeks, or pulse dosing: 500 mg/day PO for first week of month for 3 months. Not recommended if creatinine clearance is <50 mL/min.
- Pediatric dosing options:
  - Griseofulvin: 10 to 15 mg/kg/day or divided
  - Terbinafine:
    - 10 to 20 kg: 62.5 mg/day
    - 20 to 40 kg: 125 mg/day

    - >40 kg: 250 mg/day
- Itraconazole: 5 mg/kg/day
- Fluconazole: 6 mg/kg/week
- Contraindications: itraconazole, pregnancy Category C
- Precautions: All systemic antifungal drugs may have potential hepatotoxicity.
- Significant possible interactions: Itraconazole requires gastric acid for absorption; effectiveness is reduced with antacids, H_2 blockers, proton pump inhibitors, etc. Take with acidic beverage such as soda if on antacids.

Second Line

- Systemic antifungals: griseofulvin 250 to 500 mg of microsize BID daily for 21 days
- Contraindications (griseofulvin):
  – Patients with porphyria, hepatocellular failure
  – Patients with history of hypersensitivity to griseofulvin
- Precautions (griseofulvin):
  – Should be used only in severe cases
  – Periodic monitoring of organ-system functioning, including renal, hepatic, and hematopoietic
  – Possible photosensitivity reactions
  – Lupus erythematosus, lupus-like syndromes, or exacerbation of existing lupus erythematosus has been reported.
- Significant possible interactions (griseofulvin):
  – Decreases activity of warfarin-type anticoagulants
  – Barbiturates usually depress griseofulvin activity.
  – May potentiate effect of alcohol, producing tachycardia and flush

ISSUES FOR REFERRAL

If extensive or resistant disease, especially in immunocompromised host

ADDITIONAL THERAPIES

- Treatment of secondary bacterial infections
- Treatment of eczematoid changes

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Avoid sweating feet.

Patient Monitoring

Evaluate for response, recognizing that infections may be chronic/recurrent.

DIET

No restrictions

PATIENT EDUCATION

See "General Prevention."

PROGNOSIS

- Control but not complete cure
- Infections tend to be chronic with exacerbations (e.g., in hot weather).
- Personal hygiene and preventive measures such as open-toed sandals, careful drying, and frequent sock changes are essential.

COMPLICATIONS

- Secondary bacterial infections (common portal of entry for streptococcal infections, producing lymphangitis/cellulitis of lower extremity)
- Eczematoid changes

SEE ALSO

Dermatitis, Contact; Dyshidrosis

CODES

ICD10

B35.3 Tinea pedis

CLINICAL PEARLS

- Treatment is generally with topical antifungal medications for up to 4 weeks.
- Tinea pedis is often recurrent/chronic in nature.
- Careful drying between toes after showering or bathing helps prevent recurrences. (Blow drying feet with hair dryer may be more effective than drying with towel.)
- Socks should be changed frequently. Put on socks before underwear to prevent infection from spreading to groin (tinea cruris).
- Dusting and drying powders (containing antifungal agents) may prevent recurrences.

TINEA VERSICOLOR

Elisabeth L. Backer, MD

BASICS

DESCRIPTION

- Rash due to a common superficial mycosis with a variety of colors and changing shades of color, predominantly present on trunk and proximal upper extremities; macules are usually hypopigmented, light brown, or salmon-colored; fine scale is often apparent. It is not a dermatophyte infection.
- System(s) affected: skin/exocrine
- Synonym(s): pityriasis versicolor

EPIDEMIOLOGY

Incidence

- Common, occurs worldwide, especially in tropical climates, where prevalence can reach 50 %
- Predominant age: teenagers and young adults
- Predominant sex: male = female

Pediatric Considerations

Usually occurs after puberty (except in tropical areas); facial lesions are more common in children.

Geriatric Considerations

Not common in the geriatric population

ETIOLOGY AND PATHOPHYSIOLOGY

Inhibition of pigment synthesis in epidermal melanocytes, leading to hypomelanosis; in the hyperpigmented type, the melanosomes are large and heavily melanized (1).

- Saprophytic yeast: *Pityrosporum orbiculare* (also known as *P. ovale*, *Malassezia furfur*, or *M. ovalis*), which is a known colonizer of all humans
- Development of clinical disease associated with transformation of *Malassezia* from yeast cells to pathogenic mycelial form due to host and/or external

factors.
- Not linked to poor hygiene

Genetics
Genetic predisposition may exist.

RISK FACTORS
- Hot, humid weather
- Use of topical skin oils
- Hyperhidrosis
- HIV infection/immunosuppression
- High cortisol levels (Cushing, prolonged steroid administration)
- Pregnancy
- Malnutrition
- Oral contraceptives

GENERAL PREVENTION
- Recheck and treat again each spring prior to tanning season.
- Avoid skin oils.

DIAGNOSIS

HISTORY
- Asymptomatic scaling macules on trunk
- Possible mild pruritus
- More prominent in summer
- Sun tanning accentuates lesions because infected areas do not tan.
- Periodic recurrences are common.

PHYSICAL EXAM
- *Versicolor* refers to the variety and changing shades of colors. Color variations can exist between individuals and also between lesions.
- Sun-exposed areas: Lesions are usually white/hypopigmented.
- Covered areas: Lesions are often brown or salmon-colored.
- Distribution (sebum-rich areas): chest, shoulders, back (also face and intertriginous areas)

  - Face is more likely to be involved in children.
- Appearance: small individual macules that frequently coalesce
- Scale: fine, more visible with scraping

DIFFERENTIAL DIAGNOSIS

Other skin diseases with discolored macules and plaques, including the following:

- Pityriasis alba/rosea ("Christmas tree-like" distribution visible in *P. rosea*)
- Vitiligo (presents without scaling)
- Seborrheic dermatitis (more erythematous; thicker scale)
- Nummular eczema
- Secondary syphilis
- Erythrasma
- Mycosis fungoides

DIAGNOSTIC TESTS & INTERPRETATION

Wood lamp: yellow to yellow-green fluorescence or pigment changes

Initial Tests (lab, imaging)

- Direct microscopy of scales with 10% potassium hydroxide (KOH) preparation to visualize hyphae and spores ("spaghetti and meatballs" pattern)
- Routine lab tests are usually not necessary.
- Fungal culture is not useful.

Test Interpretation

- Short, stubby, or Y-shaped hyphae
- Small, round spores in clusters on hyphae

TREATMENT

GENERAL MEASURES

- Apply prescribed topical medications to affected skin with cotton balls.
- Pigmentation may take months to fade or fill in.
- Repeat treatment each spring prior to sun exposure; some may require repeated treatment during the summer as prophylaxis.
- Patients who fail topical treatment can be treated with an oral/systemic

medication.

MEDICATION

Topical antifungal therapy is the treatment of choice in limited disease. Evidence is generally of poor quality, but data suggest that longer durations of treatment and higher concentrations of active agents produce greater cure rates (2)[A].

First Line

- Ketoconazole 2% shampoo applied to damp skin and left on for 5 minutes for 1 to 3 days *or*
- Selenium sulfide shampoo 2.5% (Selsun):
  - Allowed to dry for 10 minutes prior to showering: daily for 1 week *or*
  - Allowed to remain on body for 12 to 24 hours prior to showering: once a week for 4 weeks *or*
- Clotrimazole 1% topical (Lotrimin) BID for 2 to 4 weeks *or*
- Miconazole 2% (Micatin, Monistat) BID for 2 to 4 weeks *or*
- Ketoconazole 2% (Nizoral) cream BID for 2 to 4 weeks *or*
- Terbinafine (Lamisil) 1% solution BID for 1 week *or*
- Terbinafine (Lamisil Derm Gel) once daily for 1 week
- Cure rates of topical antiyeast preparations typically 70–80%; healing continues after active treatment. Resumption of even pigmentation may take months.
- Contraindications: Ketoconazole is contraindicated in pregnancy.
- Newer preparations: 2.25% selenium sulfide foam; ketoconazole 2% gel

Second Line

- Use for extensive disease or nonresponders
- Oral fluconazole 300 mg once weekly for 2 weeks (3)[A]
- Itraconazole 200 mg/day PO for 1 week; cure rate >90% (3)[A]
- Oral ketoconazole is no longer recommended by FDA due to risks of hepatotoxicity, adrenal insufficiency, and drug–drug interactions.
- Oral terbinafine or griseofulvin is not effective.
- Pramiconazole has been studied but is not yet available for clinical use.

ISSUES FOR REFERRAL

- If resistant to treatment

- If extensive disease occurs in immunocompromised host

ONGOING CARE

- Ketoconazole 2% or selenium sulfide 2.5% shampoo can be used weekly for maintenance or monthly for prophylaxis.
- Itraconazole 400 mg once monthly during the warmer months of the year can also reduce recurrences.

FOLLOW-UP RECOMMENDATIONS

Warn patients that whiteness will remain for several months after treatment.

Patient Monitoring

- Recheck and treat again each spring prior to tanning season.
- Failure to respond should prompt reassessment or dermatology referral.
- Resistance to treatment, frequent recurrences, or widespread disease may point to immunodeficiency.

PATIENT EDUCATION

For patient education materials favorably reviewed on this topic, contact American Academy of Dermatology, 930 N. Meacham Road, P.O. Box 4014, Schaumberg, IL 60168-4014; (708) 330-0230.

PROGNOSIS

- Duration of lesions months/years
- Recurs almost routinely because this yeast is a known human colonizer
- Pigmentary changes may take months to resolve.

CODES

ICD10

B36.0 Pityriasis versicolor

CLINICAL PEARLS

- Noncontagious macules of varying colors, with fine scale
- Recurrence in summer months
- More apparent after tanning. Skin areas with fungal infection do not tan; thus, hypopigmented areas become more visible.
- Warn patients that whiteness will remain for several months after treatment.

TINNITUS

Donna I. Meltzer, MD

BASICS

DESCRIPTION

- Tinnitus is a perceived sensation of sound in the absence of an external acoustic stimulus; often described as a ringing, hissing, buzzing, or whooshing
- Derived from the Latin word *tinnire*, meaning “to ring”
- May be heard in one or both ears or centrally within the head
- Two types: subjective (most common) and objective tinnitus
- Subjective tinnitus: perceived only by the patient; can be continuous, intermittent, or pulsatile
- Objective tinnitus: audible to the examiner; usually pulsatile; <1% cases (1)
- Primary tinnitus: idiopathic with or without sensorineural hearing loss (SNHL) (2)
- Secondary tinnitus: associated with a specific cause (other than SNHL)

EPIDEMIOLOGY

Prevalence

- Tinnitus reported by 35 to 50 million adults in United States; although underreported, 12 million seek medical care.
- Affects 10–15% of adults
- Prevalence increases with age, peaks in sixth decade and then decreases with increased age
- Prevalence of 13–53% in general pediatric population
- Ethnic: whites > blacks and Hispanics
- Gender: males > females

Incidence

- Incidence increasing in association with excessive noise exposure
- Higher rates of tinnitus in smokers, hypertensives, diabetics, and obese patients

ETIOLOGY AND PATHOPHYSIOLOGY

- Precise pathophysiology is unknown; numerous theories have been proposed. Cochlear damage from ototoxic agents or noise exposure damage hair cells so that the central auditory system compensates, resulting in hyperactivity in cochlear nucleus and auditory cortex. Animal models have identified brain abnormalities resulting in increased firing and synchrony in auditory cortex.
- Causes of subjective tinnitus are the following:
  - Otologic: hearing loss, cholesteatoma, cerumen impaction, otosclerosis, Ménière disease, vestibular schwannoma
  - Ototoxic medications: anti-inflammatory agents (aspirin, NSAIDs); antimalarial agents, antimicrobial drugs (aminoglycosides); antineoplastic agents, loop diuretics, miscellaneous drugs (antiarrhythmics, antiulcer, anticonvulsants, antihypertensives); psychotropic drugs; anesthetics (1)
  - Somatic: temporomandibular joint (TMJ) dysfunction, head or neck injury
  - Neurologic: multiple sclerosis, spontaneous intracranial hypertension, vestibular migraine, type I Chiari malformation
  - Infectious: viral, bacterial, fungal
- Causes of objective tinnitus: patulous eustachian tube
  - Vascular: aortic or carotid stenosis, venous hum, arteriovenous fistula or malformation, vascular tumors, high cardiac output state (anemia)
  - Neurologic: palatal myoclonus, idiopathic stapedial muscle spasm

Genetics

Minimal genetic component

RISK FACTORS

- Hearing loss (but can have tinnitus with normal hearing)
- High-level noise exposure
- Advanced age
- Use of ototoxic medications
- Otologic disease (otosclerosis, Ménière disease, cerumen impaction)
- Anxiety and depression associated with increased odds of tinnitus

GENERAL PREVENTION

- Avoid loud noise exposure and wear appropriate ear protection to prevent

hearing loss.
- Monitor ototoxic medications and avoid prescribing more than one ototoxic agent concurrently.

COMMONLY ASSOCIATED CONDITIONS

- SNHL caused by presbycusis (age associated hearing loss) or prolonged loud noise exposure
- Conductive hearing loss due to cerumen, otosclerosis, cholesteatoma
- Psychological disorders: depression, anxiety, insomnia, suicidal ideation
- Despair, frustration, interference with concentration and social interactions, work hindrance

DIAGNOSIS

HISTORY

- Onset gradual (presbycusis) or abrupt (following loud noise exposure)
- Timing: can be continuous (hearing loss) or intermittent (Ménière disease)
- Pattern: nonpulsatile > pulsatile (often vascular cause)
- Location: bilateral > unilateral (vestibular schwannoma, cerumen, Ménière disease)
- Pitch: high pitch (with SNHL) > low pitch (Ménière disease)
- Associated symptoms: hearing loss, headache, noise intolerance, vertigo, TMJ dysfunction, neck pain
- Exacerbating factors: loud noise; jaw, head, or neck movements
- Alleviating factors: hearing aid, position change, medications
- Medication use (prescription, OTC, supplements)
- Hearing and past noise exposure (occupational, military, recreational)
- Psychosocial history (depression, sleep habits)
- Impact of tinnitus: Tinnitus Handicap Inventory, Tinnitus Functional Index

PHYSICAL EXAM

- HEENT, neck, neurologic, and vascular examinations
- Ear: cerumen impaction, effusion, cholesteatoma
- Check hearing; air and bone conduction testing with 512- or 1,024-Hz tuning fork (Weber and Rinne tests)

- Eye: funduscopic exam for papilledema (intracranial hypertension) or visual field change (mass)
- TMJ: Palpate for tenderness and crepitus with movement.
- Cranial nerve, Romberg test (equilibrium), finger to nose, gait; assess for nystagmus.
- Auscultate for bruits or murmurs over ear canal, periauricular areas, orbit, neck, chest.

DIFFERENTIAL DIAGNOSIS

Pulsatile tinnitus: carotid stenosis, aortic valve disease, AV malformation, high cardiac output state (anemia, hyperthyroidism), paraganglioma (glomus tumor)
Nonpulsatile tinnitus: auditory hallucinations

DIAGNOSTIC TESTS & INTERPRETATION

- Tinnitus is a symptom; no objective test to confirm diagnosis
- Pure tone audiometry (air and bone conduction)
- Speech discrimination testing
- Tympanometry
- Auditory brainstem response (ABR); less sensitive and specific than MRI for diagnosis of vestibular schwannoma (1)
- Carotid Doppler ultrasonography (neck bruit)

Initial Tests (lab, imaging)

- Little evidence to support lab testing other than targeted lab studies based on history and physical exam. Use clinical judgment and consider the following:
- CBC
- BUN/creatinine, fasting glucose, lipid panel
- Thyroid-stimulating hormone
- Newer guidelines advise against imaging studies unless have one or more of the following: unilateral or pulsatile tinnitus, focal neurologic abnormality, or asymmetric hearing loss (2)
- Nonpulsatile tinnitus: MRI with or without contrast, MRI auditory canal (for vestibular schwannoma)
- Pulsatile tinnitus: Contrast-enhanced temporal bone CT, MRI, MRA/MRV, CTA/CTV, carotid ultrasound, and conventional angiography all have been

used to work up pulsatile tinnitus (3).
- Cerebral angiography is gold standard for diagnosis of suspected dural arteriovenous fistula.

Follow-Up Tests & Special Considerations

Consider HIV, RPR, autoimmune panel, Lyme test, vitamin B_{12} level.

Diagnostic Procedures/Other

Electronystagmography (vestibular testing for Ménière disease)

TREATMENT

GENERAL MEASURES

- Individualize treatment based on the severity of tinnitus and impact on function
- Reassure patient.
- Manage treatable pathology.
- Education, relaxation therapy, cognitive-behavioral therapy (CBT)
- Hearing aids (corrects hearing and might mask tinnitus); can be tried even if there is minimal hearing loss; no evidence to support or refute the use of hearing aids (4)[B]
- Protect hearing against future loud noise.
- Masking sound devices or generators on discontinuation might have decreased tinnitus (residual inhibition).
- Discontinue ototoxic medications.

MEDICATION

No pharmacologic agent has been shown to cure or consistently alleviate tinnitus.

First Line

- Antidepressants (SSRIs or TCAs): probably help with psychological distress. Newer review states insufficient evidence that antidepressant drug therapy improves tinnitus (5)[B].
- Melatonin decreases tinnitus intensity and improves sleep quality; most

effective in men, those without depression or prior treatment, and those with more severe bilateral tinnitus (6)[B].

Second Line

- Anticonvulsants: may have a small effect (of doubtful clinical significance) on tinnitus (7)[A].
- Benzodiazepines help reduce tinnitus distress, but regular use discouraged.
- No difference between gabapentin and control group in patients with isolated tinnitus (8)[B]
- Higher caffeine intake associated with lower incidence of tinnitus in women (9)[B]

ISSUES FOR REFERRAL

- Audiologist for comprehensive hearing evaluation and management
- Otolaryngologist, neurologist, or neurosurgeon depending on pathology
- Dental referral for TMJ treatment and dental orthotics (splint, night guard)
- Therapists for CBT, biofeedback, education, and relaxation techniques

ADDITIONAL THERAPIES

- Sound therapy (masking): Patients wear low-level noise generators to mask the tinnitus noise; commonly used but no strong evidence for its efficacy (10)[B]; optional therapy (2)[C]
- CBT employs relaxation exercises, coping strategies, and deconditioning techniques to reduce arousal levels and reverse negative thoughts about tinnitus. Depression and severity of tinnitus improved with CBT (11)[A].
- Tinnitus retraining therapy (TRT) combines counseling, education, and acoustic therapy (soft music, sound machine) to minimize bothersome nature of tinnitus; often requires a team approach and up to 2 years of therapy; might be more effective than sound masking (12)[B]
- Transcranial magnetic stimulation (TMS): a noninvasive method to stimulate neurons in the brain by rapidly changing magnetic fields; insufficient data to support long-term safety of repetitive TMS (13)[B]
- Botulism toxin (for palatal myoclonus)
- Intratympanic steroid injections not recommended (2)[C]

SURGERY/OTHER PROCEDURES

- Cochlear implants (for severe SNHL)
- Ablation of cochlear nerve (destroys hearing)
- Epidural stimulation of secondary auditory cortex with implanted electrodes suppressed tinnitus in small subset of patients.
- Otosclerosis: stapedectomy surgery with implantation of ossicular prosthesis
- Severe Ménière disease not alleviated by medications: installation of endolymphatic shunt, labyrinthectomy, or vestibular neurectomy
- Auditory neoplasms: surgical resection/radiation
- Pulsatile tinnitus due to atherosclerotic carotid artery disease: carotid endarterectomy

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Zinc supplements might improve tinnitus in those with zinc deficiency. One study in elderly did not demonstrate effectiveness of zinc treatment (14)[B].
- Ginkgo biloba has not been shown effective in recent review (15)[B].
- One evidence-based practice guideline does not recommend Ginkgo biloba, melatonin, zinc, or other dietary supplements for treatment of persistent, bothersome tinnitus (2)[C].
- Acamprosate (used to treat alcohol dependence): not recommended (2)[C]
- Hypnosis (unknown effectiveness)
- Acupuncture (unknown effectiveness)

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Not applicable

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Audiologist: for hearing evaluation and therapy
- Counseling as needed for psychological distress
- Family physician: as needed for support and guidance

PATIENT EDUCATION

- Help patients understand the relatively benign nature of tinnitus.

- Self-help groups
- American Tinnitus Association: (800) 634-8978; http://www.ata.org/
- National Institute on Deafness and Other Communication Disorders: (800) 241-1044; http://www.nidcd.nih.gov/Pages/default.aspx
- American Academy of Family Physicians: http://familydoctor.org

PROGNOSIS

- Tinnitus persisted in 80% of older patients and increased in severity in 50% (1).
- Focus on managing tinnitus and reducing severity, not curing.

CODES

ICD10

- H93.19 Tinnitus, unspecified ear
- H93.11 Tinnitus, right ear
- H93.12 Tinnitus, left ear

CLINICAL PEARLS

- People have different levels of tolerance to tinnitus. It may affect sleep, concentration, and emotional state. Many patients with chronic tinnitus have depression.
- To keep tinnitus from worsening, avoid loud noises and minimize stress.
- Optimal management may involve multiple strategies.

TOBACCO USE AND SMOKING CESSATION

Felix B. Chang, MD, DABMA, FAAMA

BASICS

DESCRIPTION

- Use of tobacco of any form
- *Smokeless tobacco* refers to tobacco products that are sniffed, sucked, or chewed.
- Nicotine sources: cigars, pipes, water pipes, hookahs, and cigarettes

EPIDEMIOLOGY

Incidence

- 2.4 million new smokers annually in the United States (2.6% initiation rate)
- 58.8% of new smokers are <18 years of age (5.8% initiation rate for teens).

Prevalence

- 443,000 deaths annually in the United States
- Cigarette smoking among adults in the United States: 21.3% of adults in 2012 to 2013
- Highest among those aged 18 to 25 years (40.8%)
- Adults aged >25 years (28.5%)
- Race: highest among whites (22.1%) and African Americans (21.3%) and is lower among Hispanics (14.6%) and Asians (12%)
- Gender: male > female (21.5% vs. 17.3%)
- Inversely proportional to education level

ETIOLOGY AND PATHOPHYSIOLOGY

- Addiction due to nicotine's rapid stimulation of the brain's dopamine system (teenage brain especially susceptible)
- Atherosclerotic risk due to adrenergic stimulation, endothelial damage, carbon monoxide, and adverse effects on lipids
- Direct airway damage from cigarette tar
- Carcinogens in all tobacco products

RISK FACTORS

- Presence of a smoker in the household
- Easy access to cigarettes
- Comorbid stress and psychiatric disorders
- Low self-esteem/self-worth
- Poor academic performance
- Boys: high levels of aggression and rebelliousness
- Girls: preoccupation with weight and body image

GENERAL PREVENTION

- Most first-time tobacco use occurs before high school graduation.
- The AAFP's Tar Wars program has targeted 4th and 5th graders successfully.
- Smoking bans in public areas and workplaces
- Restriction of minors' access to tobacco
- Restrictions on tobacco advertisements
- Raising prices through taxation
- Media literacy education
- Tobacco-free sports initiatives

COMMONLY ASSOCIATED CONDITIONS

- Coronary artery disease
- Cerebrovascular disease
- Peripheral vascular disease
- Abdominal aortic aneurysm (AAA)
- COPD
- Cancer of the lip, oral cavity, pharynx, larynx, lung, esophagus, stomach, pancreas, kidney, bladder, cervix, and blood
- Pneumonia, osteoporosis
- Periodontitis
- Alcohol use
- Depression and anxiety
- Reduced fertility

Pregnancy Considerations

Women who smoke or are exposed to secondhand smoke during pregnancy have

increased risks of miscarriage, placenta previa, placental abruption, premature rupture of membranes, preterm delivery, low-birth-weight infants, and stillbirth.

Pediatric Considerations

- Secondhand smoke increases the risk of the following in infants and children:
  - Sudden infant death syndrome
  - Acute upper and lower respiratory tract infections
  - More severe exacerbations of asthma
  - Otitis media and need for tympanostomies
- Nicotine passes through breast milk, and its effects on the growth and development of nursing infants are unknown.

DIAGNOSIS

HISTORY

- Ask about tobacco use and secondhand smoke exposure at every physician encounter.
- Type and quantity of tobacco used
- Pack years = packs/day × years
- Awareness of health risks
- Assess interest in quitting.
- Identify triggers for smoking.
- Prior attempts to quit: method, duration of success, reason for relapse

PHYSICAL EXAM

- General: tobacco smoke odor
- Skin: premature face wrinkling
- Mouth: nicotine-stained teeth; inspect for suspicious mucosal lesions.
- Lungs: crackles, wheezing, increased or decreased volume
- Vessels: carotid or abdominal bruits, abdominal aortic enlargement, peripheral pulses, stigmata of peripheral vascular disease

DIAGNOSTIC TESTS & INTERPRETATION

- CXR for patients with pulmonary symptoms or signs of cancer but not for screening

- The USPSTF recommends one-time screening US for AAA in men ≥65 years of age who ever smoked (number needed to screen to prevent 1 AAA = 500).

Diagnostic Procedures/Other

PFTs for smokers with chronic pulmonary symptoms, such as wheezing and dyspnea

TREATMENT

Both behavioral counseling and pharmacotherapy benefit patients who are trying to quit smoking especially when used in combination.

ALERT

Provider recommending smoking cessation at *every clinical visit* improves cessation rates.

GENERAL MEASURES

- Behavioral counseling includes the 5 As:
  - Ask about tobacco use at every office visit.
  - Advise all smokers to quit.
  - Assess the patient's willingness to quit.
  - Assist the patient in his or her attempt to quit.
  - Arrange follow-up.
- Patients ready to quit smoking should set a quit date within the next 2 weeks. No difference in success rates between patients who taper prior to their quit date and those who stop abruptly
- Success increased with a quitting partner, such as a spouse, friend, or coworker, to provide mutual encouragement.

MEDICATION

First Line

- Varenicline (Chantix): 0.5 mg/day PO for 3 days, then 0.5 mg BID for 4 days, then 1 mg BID for 11 weeks (1)[A]:
  - Start 1 to 4 weeks prior to smoking cessation and continue for 12 to 24 weeks.

- Superior to placebo and to bupropion; number needed to treat = 7
- May be combined with nicotine replacement therapy
- S/E: nausea, insomnia, headache, depression, suicidal ideation; safety not established in adolescents or patients with psychiatric or cardiovascular disease; pregnancy Category C

- Bupropion SR (Zyban): 150 mg PO for 3 days, then 150 mg BID:
  - Start 1 week prior to smoking cessation and continue for 7 to 12 weeks.
  - Twice as effective as placebo
  - Drug of choice for patients with depression or schizophrenia
  - May be combined with varenicline and nicotine replacement therapy (NRT) in men who smoke >1 PPD
  - S/E: tachycardia, headache, nausea, insomnia, dry mouth; contraindicated in patients who have seizure disorders or anorexia/bulimia; pregnancy Category C (1),(2)[A]
- NRT (e.g., patch, gum, lozenge, inhaler, nasal spray) (1),(2)[A]:
  - Improves quit rates by 50–70% versus placebo
  - Over-the-counter
  - Patch (NicoDerm CQ 21, 14, and 7 mg):
    - 1 patch q24h
    - Start with 21 mg if smoking ≥10 cigarettes/day; otherwise, start with 14 mg.
    - 6 weeks on initial dose, then taper
    - 2 weeks each on subsequent doses
    - No proven benefit beyond 8 weeks
  - E-cigarettes
    - Contain less nicotine than cigarette
    - Considered less “dangerous” than tobacco but not as well studied as other NRT (3)[B]
    - Conflicting data on whether teen use increases or decreases risk to cigarette progression
  - Gum (Nicorette, 2 and 4 mg):
    - Use 4 mg if smoking ≥25 cigarettes/day.
    - Chew 1 piece q1–2h for 6 weeks, then 1 piece q2–4h for 3 weeks, then 1 piece q4–8h for 3 weeks.

- May use in combination with bupropion; monitor for hypertension.
- S/E: headache, pharyngitis, cough, rhinitis, dyspepsia; all mainly with inhaler and spray forms
- Pregnancy Category D

Second Line (1)[A]

- Nortriptyline: 25 to 75 mg/day PO or in divided doses:
  - Start 10 to 14 days prior to smoking cessation and continue for at least 12 weeks.
  - Efficacy similar to bupropion, but side effects more common; pregnancy Category D
  - The antidepressants bupropion and nortriptyline aid long-term smoking cessation (4)[A].
- Clonidine: 0.1 mg PO BID or 0.1 mg/day transdermal patch weekly (1):
  - Side effects: hypotension, bradycardia, depression, fatigue; pregnancy Category C

ADDITIONAL THERAPIES

- Electronic cigarettes: low grade of evidence (5)[A]
- Pharmacotherapy and behavior support increase success compared with minimal intervention or usual care (4)[A].
- Naltrexone: no evidence

COMPLEMENTARY & ALTERNATIVE MEDICINE

Acupuncture, aversive therapy, and hypnosis have not been proven to enhance long-term smoking cessation.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Follow up 3 to 7 days after scheduled quit date and at least monthly for 3 months thereafter.
- Refraining from tobacco products for first 2 weeks is critical to long-term abstinence.
- Encourage patients who relapse to try again.

Patient Monitoring

- Short-term withdrawal symptoms include dysphoria, depressed mood, irritability, anxiety, insomnia, increased appetite, and poor concentration.
- Longer term risks of smoking cessation include weight gain (4 to 5 kg on average) and depression.
- Quitting also is associated with exacerbations of ulcerative colitis and worsening of cognitive function in patients with schizophrenia.
- Nicotine withdrawal syndrome: dysphoric or depressed mood, insomnia, irritability, frustration, or anger; anxiety, difficulty concentrating, restlessness, and increased appetite or weight gain
- Lung cancer risk by smoking status: heavy smokers 1.00, light smokers 9.44 (0.35 to 0.56), ex-smokers 0.17 (0.13 to 0.23), never smoker 0.09 (0.06 to 0.13); adjusted hazard ratio (95% CI)

DIET

Healthy eating for limiting weight gain

PATIENT EDUCATION

1-800-QUIT-NOW

PROGNOSIS

- Measurable cardiovascular benefits of smoking cessation begin as early as 24 hours after quitting and continue to mount until the risk is reduced to that of nonsmokers by 5 to 15 years.
- People who quit smoking after a heart attack or cardiac surgery reduce their risk of death by 1/3.
- Relapse rates initially >60% but decrease to 2–4% per year after completing 2 years of abstinence.

COMPLICATIONS

- Disability and premature death due to heart attack, stroke, cancer, COPD
- Smoking more than doubles the risk of coronary artery disease and doubles the risk of stroke.
- Smokers are 12 to 22 times more likely than nonsmokers to die from lung cancer.

SEE ALSO

Nicotine Addiction; Substance Use Disorders

CODES

ICD10

- F17.210 Nicotine dependence, cigarettes, uncomplicated
- F17.213 Nicotine dependence, cigarettes, with withdrawal
- F17.211 Nicotine dependence, cigarettes, in remission

CLINICAL PEARLS

- Every patient who uses tobacco should be offered smoking cessation.
- Use the 5 As: ask, advise, assess, assist, and arrange.
- Depression with suicidal ideations is a contraindication to use varenicline.

- Even brief advice to quit has been shown to increase quit rates.

TOURETTE SYNDROME

Ravin V. Patel, MD • Dustin Creech, MD

BASICS

DESCRIPTION

- Tourette syndrome (TS) is a movement disorder most commonly seen in school-age children. A childhood-onset neurobehavioral disorder characterized by the presence of multiple motor and at least one phonic tic (see "Physical Exam").
  - Tics are sudden, brief, repetitive, stereotyped motor movements (motor tics) or sounds (phonic tics) produced by moving air through the nose, mouth, or throat.
  - Tics tend to occur in bouts.
  - Tics can be simple or complex.
    - Motor tics precede vocal tics.
    - Simple tics precede complex tics.
  - Tics often are preceded by sensory symptoms, especially a compulsion to move.
  - Patients are able to suppress their tics, but voluntary suppression is associated with an inner tension that results in more forceful tics when suppression ceases.
  - System(s) affected: nervous

EPIDEMIOLOGY

Incidence

- The onset occurs before 18 years of age.
- Predominant age
  - Average age of onset: 7 years (3 to 8 years)
  - Tic severity is greatest at ages 7 to 12 years.
    - 96% present by age 11 years
  - Of children with TS, 50% will experience complete resolution of symptoms by age 18 years (based on self-reporting).

- Predominant sex: male > female (3:1)
- Predominant race/ethnicity: clinically heterogeneous disorder, but non-Hispanic whites (2:1) compared with Hispanics and/or blacks

Prevalence

0.77% overall in children

- 1.06% in boys
- 0.25% in girls

ETIOLOGY AND PATHOPHYSIOLOGY

Abnormalities of dopamine neurotransmission and receptor hypersensitivity, most likely in the ventral striatum, play a primary role in the pathophysiology.

- Abnormality of basal ganglia development
- Thought to result from a complex interaction between social, environmental, and multiple genetic abnormalities.
- Mechanism is uncertain; may involve dysfunction of basal ganglia–thalamocortical circuits, likely involving decreased inhibitory output from the basal ganglia, which results in an imbalance of inhibition and excitation in the motor cortex
- Controversial pediatric autoimmune neuropsychiatric disorder association with *Streptococcus* (PANDAS)
  - TS/OCD cases linked to immunologic response to previous group A β-hemolytic streptococcal infection (GABHS)
  - Thought to be linked to 10% of all TS cases
  - Five criteria
    - Presence of tic disorder and/or OCD
    - Prepubertal onset of neuropsychosis
    - History of sudden onset of symptoms and/or episodic course with abrupt symptom exacerbation, interspersed with periods of partial/complete remission
    - Evidence of a temporal association between onset/exacerbation of symptoms and a prior streptococcal infection
    - Adventitious movements during symptom exacerbation (e.g., motor hyperactivity)

Genetics

- Predisposition: frequent familial history of tic disorders and OCD
- Precise pattern of transmission and genetic origin unknown. Recent studies suggest polygenic inheritance with evidence for a locus on chromosome 17q; sequence variants in *SLITRK1* gene on chromosome 13q also are associated with TS.
- Higher concordance in monozygotic compared with dizygotic twins; wide range of phenotypes

RISK FACTORS

- Risk of TS among relatives: 9.8–15%
- First-degree relatives of individuals with TS have a 10- to 100-fold increased risk of developing TS.
- Low birth weight, maternal stress during pregnancy, severe nausea and vomiting in 1st trimester

COMMONLY ASSOCIATED CONDITIONS

- OCD (28–67%)
- ADHD (50–60%)
- Conduct disorder
- Depression/anxiety including phobias, panic attacks, and stuttering
- Learning disabilities (23%)
- Impairments of visual perception, sleep disorders, restless leg syndrome, and migraine headaches

DIAGNOSIS

HISTORY

Diagnosis of TS is based on history and clinical presentation (i.e., observation of tics with/without presence of coexisting disorders). Identify comorbid conditions.

PHYSICAL EXAM

- Typically, the physical exam is normal.
- Motor and vocal tics are the clinical hallmarks.

- Tics fluctuate in type, frequency, and anatomic distribution over time.
- Multiple motor tics include facial grimacing, blinking, head/neck jerking, tongue protruding, sniffing, touching, and burping.
- Vocal tics include grunts, snorts, throat clearing, barking, yelling, hiccupping, sucking, and coughing.
- Tics are exacerbated by anticipation, emotional upset, anxiety, or fatigue.
- Tics subside when patient is concentrating/absorbed in activities.
- Motor and vocal tics may persist during all stages of sleep, especially light sleep.
- Blink-reflex abnormalities may be observed.
- No known clinical measures reliably predict children who will continue to express tics in adulthood; severity of tics in late childhood is associated with future tic severity.
- *Diagnostic and Statistical Manual of Mental Disorders* (5th ed.; *DSM-5*) criteria (1)[C]:
  - A. Both multiple motor and one or more vocal tics have been present at some time during the illness, although not necessarily concurrently.
  - B. The tics may wax and wane in frequency but have persisted for more than 1 year since first tic onset.
  - C. Onset is before age 18 years.
  - D. The disturbance is not attributable to the physiologic effects of a substance (e.g., cocaine) or another medical condition (e.g., Huntington disease, postviral encephalitis).

DIFFERENTIAL DIAGNOSIS

- Chorea/Huntington disease
- Myoclonus
- Seizure
- Ischemic or hemorrhagic stroke
- Essential tremor
- Posttraumatic/head injury
- Headache
- Dementia
- Wilson disease
- Sydenham chorea

- Multiple sclerosis
- Postviral encephalitis
- Toxin exposure (e.g., carbon monoxide, cocaine)
- Drug effects (e.g., dopamine agonists, fluoroquinolones)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- No definitive lab tests diagnose TS. Based on clinical features, particularly the presence of multiple motor and vocal tics.
- Thyroid-stimulating hormone (TSH) should be measured because of association of tics with hyperthyroidism.
- No imaging studies diagnose TS
- EEG shows nonspecific abnormalities; useful only to differentiate tics from epilepsy.

Test Interpretation

- Smaller caudate volumes in patients with TS
- Striatal dopaminergic terminals are increased, as is striatal dopamine transporter (DAT) density.

TREATMENT

GENERAL MEASURES

- Treatment assessment
  - Yale Global Tic Severity Score
  - Tourette-Syndrome Severity Scale
  - Global Assessment of Functioning Scale
  - Gilles de la Tourette Syndrome-Quality of Life Scale
- A detailed history is crucial to management, because tics and comorbidities are interrelated. Goal of treatment should be to improve social functioning, self-esteem, and quality of life.
- Educate that tics are neither voluntary nor psychiatric.
- Many patients require no treatment; patient should play an active role in treatment decisions.

- Educate patient, family, teachers, and friends to identify and address psychosocial stressors and environmental triggers.
- No cure for tics: Treatment is purely symptomatic, and multimodal treatment usually is indicated.
- Neurologic and psychiatric evaluation may be useful for other primary disorders and comorbid conditions (especially ADHD, OCD, and depression).
- TS clusters with several comorbid conditions; each disorder must be evaluated for associated functional impairment because patients often are more disabled by their psychiatric conditions than by the tics; choice of initial treatment depends largely on worst symptoms (tics, obsessions, or impulsivity).
- Nonpharmacologic therapy—reassurance and environmental modification, identification and treatment of trigger, and cognitive behavior therapy
- When pharmacotherapy is employed, monotherapy is preferred to polytherapy.

MEDICATION

First Line

- Atypical antipsychotics
  - Risperidone: now recommended for standard therapy (2)[A]
    - Initiate 0.25 BID; titrate to 0.25 to 6 mg/day
    - As effective as haloperidol and pimozide for tics with fewer side effects
    - Effective against comorbidities such as OCD
    - Side effects may limit use: sedation, weight gain, and fatigue.
- α_2-Adrenergic receptor agonists (2)[B]
  - Historically first-line agents due to favorable side-effect profile, but suboptimal efficacy in limited clinical trials
  - Side effects: sedation and hypotension common
    - Initiate therapy gradually and taper when discontinuing to avoid cardiac adverse events.
  - Clonidine 0.1 to 0.3 mg/day given BID–TID
    - Maximum dose: 0.5 mg/day
    - 25–50% of patients report at least some reduction in tics.
  - Guanfacine 1 to 3 mg/day given daily or BID
    - Less sedating and longer duration of action compared with clonidine

- Improves motor/vocal tics by 30% in some studies; no better than placebo in others

Second Line

- Neuroleptics
  - Typical antipsychotics
    - High risk for extrapyramidal symptoms (EPS)
    - Haloperidol: initiate 0.5 mg/day and titrate 0.5 mg/week up to 1 to 4 mg at bedtime (3)[B]
      - FDA-approved for treating tics
      - Considered last option of typical antipsychotics due to lower efficacy and increased side effects compared to similar medications
    - Pimozide: initiate 0.5 mg/day and titrate 0.5 mg/week up to 1 to 4 mg at bedtime (4)[A]
      - FDA-approved for treating tics
      - Risk of cardiac toxicity (prolonged Q–T interval and arrhythmias); must be given under ECG monitoring; long-term use may induce sedation, weight gain, depression, pseudoparkinsonism, and akathisia.
      - Found to work better in long-term control of tics versus acute exacerbations
    - Fluphenazine: 2.5 to 10 mg/day
      - Effective but less favored due to side effects
  - Atypical antipsychotics (3)[C]
    - Olanzapine: initiate 2.5 to 5.0 mg/day; titrate up to 20 mg/day
      - Equally effective as haloperidol and pimozide
      - May cause metabolic disturbances and weight gain
    - Quetiapine: initiate 100 to 150 mg/day; titrate to 100 to 600 mg/day
      - Well tolerated but limited data exists
    - Ziprasidone: 5 to 40 mg/day
    - Aripiprazole: initiate 2 mg/day; titrate up to 20 or 30 mg/day
      - Few studies but favorable side-effect profile
- Alternative treatments
  - Topiramate: 25 to 200 mg/day (2)[A]; promising data but not sufficient efficacy so far to recommend as first or second line

- Tetrabenazine
- Baclofen

- Treatment of ADHD in patients with tics (5)[A]
  - Stimulants
    - Comorbid tic disorder is not a serious contraindication, as previously held; exacerbation of tics is neither clinically significant nor common.
    - Methylphenidate: 2.5 to 30 mg/day
    - Dextroamphetamine: 5 to 30 mg/day
  - α_2-Adrenergic agonists
    - Guanfacine
    - Clonidine
      - The combination of methylphenidate and clonidine has shown superior efficacy in treating both ADHD and tic symptoms compared to monotherapy with either agent in one trial.
  - Other medications
    - Atomoxetine
    - Desipramine

- Treatment of OCD in patients with tics (6)[B]
  - SSRIs
    - First-line treatment of OCD; can be used in TS as well
    - Side effects include nausea, insomnia, sexual dysfunction, headache, and agitation.
    - Comorbid tic disorder not a contraindication; exacerbation of tics neither clinically significant nor common.
    - Black box warning for suicidality with SSRIs
    - Fluoxetine: 10 to 80 mg/day
    - Fluvoxamine: 50 to 300 mg/day
    - Sertraline: 50 to 200 mg/day
  - Tricyclic antidepressants
    - Clomipramine: 25 to 200 mg/day
      - Can be used in patients refractory to SSRIs or to augment SSRIs in partial responders
      - Side effects: weight gain, dry mouth, lowered seizure threshold, and constipation; ECG changes, including Q–T prolongation and

tachycardia

ADDITIONAL THERAPIES

- Botulinum toxin injections in severe cases or where chronic medication therapy is not preferred.
- Habit-reversal training provides a viable tic suppression treatment: Works equally for motor and vocal tics.

SURGERY/OTHER PROCEDURES

Thalamic ablation and deep brain stimulation have been used experimentally (7) [C].

COMPLEMENTARY & ALTERNATIVE MEDICINE

Nonpharmacologic therapy

- Reassurance and environmental modification
- Identification and treatment of triggers
- Behavioral therapy: awareness/assertiveness training, relaxation therapy, habit-reversal therapy, and self-monitoring has shown to significantly decrease tic severity.
- Hypnotherapy
- Biofeedback
- Acupuncture
- Cannabinoids: insufficient evidence to recommend; small trials show small positive effects in some parameters (8)[A].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Observe for associated psychiatric disorders.

PATIENT EDUCATION

- Reassurance that many patients with tics do not need medication; often education and/or therapy is all that is required.
- National Tourette Syndrome Association: http://www.tsa-usa.org

PROGNOSIS

- Symptoms will fluctuate throughout illness.
- Tic severity typically stabilizes by age 25 years.
- 60–75% of young adults show some improvement in symptoms.
- 10–40% of patients will exhibit full remission.

CODES

ICD10

F95.2 Tourette’s disorder

CLINICAL PEARLS

- TS is diagnosed by history and witnessing tics; have parent video patient’s tics if not present on exam in your office.
- Nearly 50% of children with tics also have ADHD. Stimulants may be used as first-line treatment for ADHD (tics are not a contraindication, as previously believed).

TOXOPLASMOSIS

Jonathan MacClements, MD, FAAFP

BASICS

- *Toxoplasma gondii* is an obligate intracellular protozoan parasite.
- Most common latent protozoan infection
- Clinically significant disease typically manifests only in pregnancy or in an immunocompromised patient.

DESCRIPTION

- Acute self-limited infection in immunocompetent
- Acute symptomatic or reactivated latent infection in immunocompromised persons
- Congenital toxoplasmosis (acute primary infection during pregnancy)
- Ocular toxoplasmosis

Pediatric Considerations

- The earlier fetal infection occurs, the more severe.
- Risk of perinatal death is 5% if infected in 1st trimester.

Pregnancy Considerations

- Pregnant immunocompromised and HIV-infected women should undergo serologic testing.
- Seronegative pregnant women should receive preventive counseling.
- Serologic testing during pregnancy remains controversial.

EPIDEMIOLOGY

Incidence

- Prevalence of congenital toxoplasmosis in the United States: 10 to 100/100,000 live births
- Predominant sex: male > female

Prevalence

- Present in every country. Seropositivity rates range from <10% to >90% (1)

[A].

- In the United States, 11% of individuals aged 6 to 49 years are seropositive. Age-adjusted prevalence in the United States is 22.5%.
- Seroprevalence among women in the United States is 15%.

ETIOLOGY AND PATHOPHYSIOLOGY

Transmission to humans

- Ingestion of raw or undercooked meat, food, or water containing tissue cysts or oocytes; usually from soil contaminated with feline feces
- Transplacental passage from infected mother to fetus; risk of transmission is 30% on average.
- Blood product transfusion and solid-organ transplantation
- Ingested *T. gondii* oocysts enter host's gastrointestinal tract where bradyzoites/tachyzoites are released, penetrate contiguous cells, replicate and are transported to susceptible tissues where clinical disease manifests.

Genetics

Human leukocyte antigen (HLA) DQ3 is a genetic marker of susceptibility in AIDS.

RISK FACTORS

- Immunocompromised states, including HIV infection with CD4 cell count <100/μL
- Primary infection during pregnancy; risk of fetal transmission increases with gestational age at seroconversion. Transmission in the 1st trimester is associated with more severe consequences.
- Chronically infected pregnant women who are immunocompromised have an increased risk of transmitting congenital toxoplasmosis.

GENERAL PREVENTION

Prevention is important in seronegative pregnant women and immunodeficient patients.

- Avoid eating undercooked meat: Cook to 152°F (66°C) or freeze for 24 hours at ≤−12°C.
- Avoid drinking unfiltered water.
- Wash produce thoroughly.

- Strict hand hygiene after touching soil
- Wear gloves and wash hands after handling raw meat or cat litter.
- Avoid shellfish (*Toxoplasma* cysts).

COMMONLY ASSOCIATED CONDITIONS

- Chorioretinitis; self-limiting, febrile lymphadenopathy; mononucleosis-like illness
- An unclear association exists between schizophrenia and several infectious agents including *T. gondii*.

DIAGNOSIS

HISTORY

- Congenital toxoplasmosis
  - Clinical presentation varies widely; 80% of patients are asymptomatic at birth.
  - Classic triad (*uncommon*)*:* chorioretinitis, hydrocephalus, cerebral calcifications
  - Manifestations may include prematurity, intrauterine growth retardation (IUGR).
  - Jaundice, rash accompanying a mononucleosis-like illness
  - Mental retardation, seizures, visual defects, spasticity, sensorineural hearing loss
- Ocular toxoplasmosis
  - Chorioretinitis: focal necrotizing retinitis
  - Yellowish-white elevated cotton patch
  - Congenital disease usually bilateral; acquired is more often unilateral.
  - Symptoms include blurred vision, scotoma, pain, and photophobia.
- Acute toxoplasmosis (immunocompetent host)
  - ~90% of patients are asymptomatic.
  - Most common manifestation is bilateral, symmetric, nontender cervical lymphadenopathy.
  - Constitutional symptoms such as fever, chills, and sweats are usually mild.
  - Headaches, myalgias, pharyngitis, hepatosplenomegaly, and diffuse

nonpruritic maculopapular rash may occur.
  - Pregnant women are often asymptomatic.
  - Most common site is CNS with toxoplasmic encephalitis.
  - Headache; focal neurologic deficits and seizures
  - Fever usually present
  - Extracerebral toxoplasmosis: pneumonitis; chorioretinitis; rarely: GI system, liver, musculoskeletal system, heart, bone marrow, bladder, and orchitis

PHYSICAL EXAM

- In adults: fever, lymphadenopathy, nonpruritic rash
- In newborns: hydrocephalus, neurologic abnormalities, hepatosplenomegaly, chorioretinitis, microcephaly, mental retardation

DIFFERENTIAL DIAGNOSIS

Syphilis, lymphoma, progressive multifocal leukoencephalopathy, cryptococcal meningitis, congenital TORCH infections, *Listeria* infection, tuberculosis (TB), erythroblastosis fetalis

DIAGNOSTIC TESTS & INTERPRETATION

- CBC: atypical lymphocytosis, anemia, thrombocytopenia
- Serology interpretation
  - In acute infection, IgM antibodies appear within the 1st week.
  - Diagnosis can be made if initial test demonstrates positive IgM and negative IgG, with both tests being positive 2 weeks later.
  - If follow-up IgG remains negative 2 to 4 weeks later but IgM is still positive, it is likely a false positive.
  - Negative IgG rules out prior infection (IgG remains detectable for life).
- Types of serologic tests
  - ELISA: most commonly used
  - Sabin-Feldman dye test: Gold standard against which all other serologic assays are compared.
  - IFA test: more available in commercial labs
  - ISAGA: widely available commercially; more sensitive and specific than IFA for detecting IgM

  - Avidity testing: confirmatory test to establish whether positive IgM/IgG reflects recent or chronic infection
- PCR: *T. gondii* DNA amplification in blood or amniotic fluid; used for diagnosis of fetal infection
- Culture (rarely necessary): Organism can be isolated either by cell culture or by mouse inoculation.

Initial Tests (lab, imaging)

- Diagnosis of primary infection is typically based on history and confirmed by serology.
- Serum *Toxoplasma*-specific IgG and IgM are first step.
- According to the result of IgM test, determine IgG avidity.
- Diagnosis of maternal infection and congenital toxoplasmosis
  - Pregnant women who have mononucleosis-like illness but negative heterophile test should be tested for toxoplasmosis.
  - Maternal infection accurately diagnosed when based on two blood samples at least 2 weeks apart showing seroconversion
  - High avidity of IgG during 1st trimester argues against maternal primary infection.
  - Real-time PCR analysis for *T. gondii* in amniotic fluid predicts fetal infection and helps guide appropriate treatment and surveillance.
  - Fetal ultrasound is useful for prognosis.
  - Routine screening for toxoplasmosis is not recommended.
- Diagnosis of congenital toxoplasmosis after birth
  - Serology requires several serum samples for IgM and IgA antibodies.
  - Sampling of the cord or peripheral blood should be done within the first 2 weeks.
  - Ophthalmologic, auditory, and neurologic examinations; lumbar puncture; and head CT should be performed.
- Diagnosis of toxoplasmic encephalitis
  - Serology for IgG
  - Imaging: MRI is more sensitive than CT scan for identification of characteristic ring-enhancing brain lesions.
- MRI: for identifying multiple ring-enhancing brain lesion in AIDS patients with cerebral toxoplasmosis

- SPECT and PET scans: can help distinguish toxoplasmosis from CNS lymphoma

Diagnostic Procedures/Other

- Lymph node biopsy
- Brain biopsy in CNS disease
- Amniocentesis with PCR (risk of false negatives and false positives)
- Placental isolation of *Toxoplasma* is diagnostic.

Test Interpretation

- Confirmatory, meningocerebritis ± abscesses with necrosis, Giemsa
- Lymph node histology shows triad of:
  - Reactive follicular hyperplasia
  - Irregular clusters of epithelioid histiocytes on and blurring margins of germinal centers
  - Distension of sinuses with monocytoid cells
- Sensitivity of triad 62.5%, specificity 91.3%

TREATMENT

GENERAL MEASURES

Immunocompetent patients usually require no treatment.

MEDICATION

First Line

ALERT

Important: All pyrimethamine-containing regimens should include leucovorin (folinic acid 10 to 25 mg/day PO) during and 1 week after completion of pyrimethamine to prevent drug-induced hematologic toxicity (2)[A].

- Treatment in immunocompromised hosts
  - Initial regimen of choice is pyrimethamine 200 mg loading dose PO, followed by 50 mg/day plus sulfadiazine 4 to 6 g/day PO in 4 divided doses; for those intolerant or allergic to sulfadiazine, clindamycin 600 to 1,200 mg IV or 450 mg PO QID can be used instead.

- Alternative regimens for patients intolerant to sulfadiazine and clindamycin include the following:
  - Pyrimethamine: 200 mg loading dose PO, followed by 50 mg/day plus azithromycin 900 to 1,200 mg PO once daily
  - Pyrimethamine: 200 mg loading dose PO, then 50 mg/day plus atovaquone 1,500 mg PO BID
  - Sulfadiazine: 1,000 to 1,500 mg QID plus atovaquone 1,500 mg BID
  - Trimethoprim-sulfamethoxazole: 10/50 mg/kg/day PO or IV divided BID (for 30 days) may be a cost-effective alternative.
- Duration of therapy: typically 6 weeks, lower doses for secondary prophylaxis (2)[A]
- Use adjunctive steroids should in patients with signs of increased intracranial pressure.
- Anticonvulsants, if there is a history of seizures

• Prophylaxis in immunocompromised patients
- Primary prophylaxis: indicated for patients with HIV infection and CD4 count <100 cells/μL who are *T. gondii* IgG–positive
  - Trimethoprim-sulfamethoxazole-DS: 1 tablet PO daily. Alternative for sulfa allergy is dapsone 50 mg/day PO *plus* pyrimethamine 50 mg PO weekly *plus* leucovorin 25 mg PO weekly *or* atovaquone 1,500 mg PO daily.
- Secondary prophylaxis: Following 6 weeks of therapy, administer lower doses of drugs:
  - Sulfadiazine 2 to 4 g/day in two to four divided doses *plus* pyrimethamine 25 to 50 mg/day is the first choice.
  - Alternative regimens include clindamycin 600 mg PO q8h *plus* pyrimethamine 25 to 50 mg/day PO *or* atovaquone 750 mg PO BID to QID ± pyrimethamine 25 mg PO daily.

• Pregnant women (3)[A]
- There is a lack of evidence on whether antenatal treatment reduces congenital transmission; however, prenatal treatment is usually offered.
- <18 weeks' gestation: Spiramycin 1 g PO q8h without food until delivery if amniotic fluid PCR is negative. Does not treat infection in the fetus
- >18 weeks' gestation: Pyrimethamine and sulfadiazine should be

considered only if fetal infection is documented by positive amniotic fluid PCR (pyrimethamine is teratogenic):
    - Pyrimethamine: 50 mg PO q12h for 2 days, then 50 mg/day plus sulfadiazine 75 mg/kg PO × 1 dose, then 50 mg/kg q12h (max 4 g/day)
- Treat infected newborns regardless of clinical manifestations:
  – Pyrimethamine 2 mg/kg/day (max 50 mg) for 2 days; then 1 mg/kg/day (max 25 mg) for 2 to 6 month; then 1 mg/kg (max 25 mg) on Monday, Wednesday, and Friday; sulfadiazine 100 mg/kg/day divided BID; and leucovorin 10 mg three times per week during pyrimethamine and 1 week after discontinuation
- Immunocompetent nonpregnant patients generally do not require treatment unless symptoms are severe or prolonged; 1 of 2 regimens can be used:
  – Pyrimethamine: 100 mg loading dose PO, followed by 25 to 50 mg/day *plus* sulfadiazine 2 to 4 g/day in four divided doses
  – Pyrimethamine: 100 mg loading dose PO, followed by 25 to 50 mg/day *plus* clindamycin 300 mg PO QID

Second Line

- Clindamycin: 900 to 1,200 mg TID IV used for ocular and CNS toxoplasmosis alone and in combination with pyrimethamine; as effective as the sulfadiazine-pyrimethamine with fewer adverse effects
- Corticosteroids (prednisone 1 to 2 mg/kg/day) are added for macular chorioretinitis or CNS infection.
- Alternatives: atovaquone (Mepron), azithromycin (Zithromax), clarithromycin (Biaxin), or dapsone *plus* pyrimethamine and leucovorin
- Trimethoprim-sulfamethoxazole appears to be equivalent to pyrimethamine-sulfadiazine in AIDS patients with CNS disease.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Precautions

- Monitor for bone marrow, renal, or liver toxicity.

- Good hydration: Sulfadiazine is poorly soluble and may crystallize in the urine.
- Watch for antibiotic-associated diarrhea.
- Sulfonamides may alter phenytoin and warfarin levels or interfere with oral hypoglycemic agents.

PATIENT EDUCATION

- http://www.aafp.org/afp/2003/0515/p2145.html
- http://familydoctor.org/familydoctor/en/diseases-conditions/toxoplasmosis.html

PROGNOSIS

- Immunodeficient patients often relapse if treatment or suppression therapy is stopped.
- Treatment may prevent the development of untoward sequelae in infants with congenital toxoplasmosis.

CODES

ICD10

- B58.9 Toxoplasmosis, unspecified
- P37.1 Congenital toxoplasmosis
- B58.2 Toxoplasma meningoencephalitis

CLINICAL PEARLS

- Toxoplasmosis is often asymptomatic in immunocompetent patients, who often don’t need treatment for clinical disease.
- Primary prevention is important, particularly for pregnant women and immunodeficient patients.
- The most common manifestation of acute toxoplasmosis in immunocompetent host is bilateral, symmetric, nontender cervical lymphadenopathy.
- Universal screening for congenital toxoplasmosis is not currently recommended.

TRACHEITIS, BACTERIAL

Mary Cataletto, MD, FAAP, FCCP

BASICS

DESCRIPTION

- Acute, potentially life-threatening infraglottic bacterial infection following a primary viral infection, usually parainfluenzae or influenza viruses
  - Direct laryngoscopy reveals marked subglottic edema and thick mucopurulent secretions, sometimes causing pseudomembranes.
- System(s) affected: pulmonary
- Synonym(s): laryngotracheobronchitis; pseudomembranous croup; bacterial croup

EPIDEMIOLOGY

Incidence

- Estimated incidence: 4 to 8 per 1,000,000 (1)
- First cases described prior to 1950; resurgence of cases has been noted since 1979.
- Peak incidence in children: fall and winter
- Mean age: 5 years (1)
- Infections in adolescents and adults have been reported.
- Predominant sex: male > female (2:1)
- Accounts for 5–14% of upper airway obstruction in children requiring critical care services

Prevalence

- Rare illness
- Most common potentially life-threatening upper airway infection in children
- Methicillin-resistant *Staphylococcus aureus* (MSRA) may contribute to changing epidemiology and virulence.

ETIOLOGY AND PATHOPHYSIOLOGY

- *Staphylococcus aureus* (most common pediatric cause): Consider MRSA.

- *Haemophilus influenzae* type B
- *Streptococcus pyogenes* group A
- *Streptococcus pneumoniae*
- *Moraxella catarrhalis* (associated with higher intubation rate; more frequent in younger children)
- Often polymicrobial

Genetics

No known genetic predisposition

RISK FACTORS

- Periods of increased seasonal activity of respiratory viruses
- Reports following adenoidectomy, with chronic tracheal aspiration, with evidence of other concurrent infections, including sinusitis, otitis, pneumonia, or pharyngitis

GENERAL PREVENTION

- Standard precautions, with scrupulous attention to hand washing, especially when caring for tracheostomy patients
- Vaccination against viruses that may predispose to bacterial tracheitis

COMMONLY ASSOCIATED CONDITIONS

- Consider anatomic abnormalities or foreign body as well as recent pharyngeal or laryngeal surgery.
- Predisposing: Down syndrome, immunodeficiency, subglottic hemangioma, tracheoesophageal fistula repair, tracheobronchomalacia
- Viral coinfection may occur.

DIAGNOSIS

- May present with fever and systemic toxicity or as more localized disease
- Careful history and physical exam are the best methods to distinguish bacterial tracheitis from croup and other rare causes of upper airway obstruction.

HISTORY

- Prodromal upper respiratory tract symptoms
- Gradual progression of mild upper airway symptoms over 1 hour to 6 days to acute, febrile phase of rapid respiratory decompensation
- No drooling
- No response to aerosolized epinephrine and/or systemic corticosteroids (1)

PHYSICAL EXAM

FEVER >38°C (100.4°F)

- Toxic appearance
- Variable degree of respiratory distress (2)
  - Tachypnea
  - Inspiratory stridor (2)
- Voice and cry usually normal
- Drooling uncommon

DIFFERENTIAL DIAGNOSIS

- Severe croup (viral)
- Spasmodic croup
- Diphtheria in nonvaccinated patients
- Retropharyngeal abscess
- Epiglottitis
- Pneumonia
- Foreign body aspiration

DIAGNOSTIC TESTS & INTERPRETATION

- Routine laboratory studies are not required to make the diagnosis.
- Radiographs are neither definitive nor diagnostic.
- Tracheal endoscopy provides a definitive diagnosis (1,3)[C].

Initial Tests (lab, imaging)

- Bacterial cultures of tracheal secretions are required for culture isolates and sensitivities.
- Rapid antigen or polymerase chain reaction (PCR)–based testing for respiratory viruses may be helpful.
- Routine laboratory studies may not be helpful.
- Blood cultures rarely positive

- CBC results may vary.
  - WBC count may show marked leukocytosis or may be normal.
  - Increased band cell count
- Radiographs may be normal, but exudates may mimic the findings in foreign body aspiration.
- Pneumonic infiltrates are common.
- Anteroposterior (AP) and lateral neck x-rays show subglottic and tracheal narrowing (i.e., steeple sign on AP film) with haziness and radiopaque linear or particulate densities (crusts).
- In patients with risk of acute respiratory obstruction, either do not obtain x-rays or monitor carefully.

Follow-Up Tests & Special Considerations

Follow chest film if suspect pneumonia.

Diagnostic Procedures/Other

- Direct laryngoscopy and tracheoscopy is diagnostic and demonstrates
  - Normal supraglottic structures
  - Marked subglottic erythema and edema
  - Ulcerations
  - Epithelial sloughing
  - Copious mucopurulent secretions ± plaques or pseudomembranes
- Obtain Gram stain and aerobic, anaerobic, and viral cultures of tracheal secretions during the procedure.

Test Interpretation

- Tracheal biopsy is rarely indicated but may be considered in immunodeficient child or child with ulcerative colitis.
- Diffuse inflammation of larynx, trachea, and bronchi
- Mucopurulent exudate; microabscesses may be present.
- Semiadherent membranes (containing numerous neutrophils and cellular debris) may be identified within the trachea.

TREATMENT

- Treat as potentially life-threatening airway emergency.
- Children with suspected or actual bacterial tracheitis should be cared for in a pediatric ICU (1)[C].
- Assess and monitor respiratory status; supplemental oxygen may be required.
- Airway protection and support, as necessary (at least 50% require intubation; some studies report up to 100%)
- Ventilatory support may be required.
- Suctioning
- Different clinical course in previously healthy children compared with those with artificial airway

MEDICATION

- Empiric therapy should cover the most common pathogens until sensitivities are available: antistaphylococcal agent (vancomycin or clindamycin) and a 3rd-generation cephalosporin (e.g., ceftriaxone or cefotaxime) (1,3)[C].
- In the case of technology-dependent children with tracheostomy, make initial antibiotic choices based on previous tracheal culture.
- Narrow regimen when pathogens and sensitivities available (1,3)[C]
- Contraindications: Refer to the manufacturer's literature for each drug.
- Precautions: Refer to the manufacturer's literature for each drug. Avoid aminoglycosides in patients with previous hearing loss.
- Significant possible interactions: Refer to the manufacturer's literature for each drug.

ISSUES FOR REFERRAL

All children with suspected or actual bacterial tracheitis should be cared for in a pediatric ICU by a pediatric critical care team that may include the following subspecialists: pediatric intensivist, infectious disease specialist, pulmonologist, and/or otolaryngologist.

ADDITIONAL THERAPIES

- At present, evidence is lacking to establish the effect of heliox inhalation in the treatment of croup in children.
- For technology-dependent children with artificial airway:
  - Initial antibiotic choices should cover most recent tracheal aspirate isolates

and then be refined according to culture and sensitivity results.
  - Adjunctive aerosol therapy may be helpful, particularly when multidrug-resistant organisms are present.

SURGERY/OTHER PROCEDURES

- Tracheostomy is usually not necessary.
- Therapeutic bronchoscopy may be necessary to facilitate removal of inspissated secretions.
- Tracheal membranes may require removal.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Aggressive supportive care and airway protection are paramount.
- Initial treatment of choice for bacterial tracheitis is broad-spectrum antibiotic coverage.
- Children with tracheitis and artificial airways present unique challenges: Tracheoscopy is important in establishing diagnosis in this population.
- Be vigilant for possible MRSA.

Pediatric Considerations

- True pediatric emergency
- Admission to ICU
- Maintain airway: often difficult due to copious secretions
  - Endotracheal or nasotracheal intubation usually needed, especially in infants and children <4 years of age
  - Much less likely to need intubation if child >8 years of age
  - Advantage of intubation is the ability to clear trachea and bronchi of secretions and pseudomembranes.
- Vigorous pulmonary toilet to clear airway of secretions
- Hydration, humidification, antibiotics
- Admission Criteria/Initial Stabilization
  - Suspected or confirmed diagnosis of tracheitis
  - Respiratory distress
  - Artificial airway
- Nursing

  - Provide calm, quiet environment for child once endoscopy and cultures are done.
  - Airway monitoring
  - Frequent suctioning
  - Monitor fluid balance.
  - Establish and maintain open lines of communication with child and parents.
- Discharge when no longer in need of acute care

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Children with artificial airways will require ongoing follow-up.

DIET

Varies with clinical situation

PATIENT EDUCATION

Keep immunizations up to date.

PROGNOSIS

- Intubation generally 3 to 11 days
- Usually requires 3 to 7 days of hospitalization
- With effective early recognition and management, complete recovery can be expected.
- Cardiopulmonary arrest and death have occurred.

COMPLICATIONS

- Cardiopulmonary arrest
- Hypotension
- Acute respiratory distress syndrome (ARDS)
- Pneumonia
- Formation of pseudomembranes

Croup (Laryngotracheobronchitis); Epiglottitis

CODES

ICD10

- J04.10 Acute tracheitis without obstruction
- J04.11 Acute tracheitis with obstruction
- J05.0 Acute obstructive laryngitis [croup]

CLINICAL PEARLS

- Bacterial tracheitis is an acute, potentially life-threatening, infraglottic bacterial infection following a primary viral infection that accounts for 5–14%

of upper airway obstructions in children requiring critical care services.

- Children with suspected or actual bacterial tracheitis should be cared for in a pediatric ICU.
- Endoscopy provides a definitive diagnosis (2).
- Initial treatment of choice for bacterial tracheitis is broad-spectrum antibiotic coverage, aggressive airway protection, and supportive care (2).

TRANSIENT ISCHEMIC ATTACK (TIA)

Samuel E. Mathis, MD • Randolph Taylor, III, MD

BASICS

DESCRIPTION

- A transient episode of neurologic dysfunction due to focal brain, retinal, or spinal cord ischemia without acute infarction
- Most important predictor of stroke: 7–40% of patients with stroke report previous TIA.
- Synonym(s): ministroke

EPIDEMIOLOGY

- 200,000 to 500,000 new TIA cases reported each year
  - 83 cases/100,000 people/year in the United States
  - 400 to 800 cases/100,000 persons aged 50 to 59 years
- Prevalence of TIA in general population: ~2.3%
- Predominant age: risk increases >60 years; highest in 7th and 8th decades
- Predominant sex: male > female (3:1)
- Predominant race/ethnicity: African Americans > Hispanics > Caucasians. The difference in African Americans is exaggerated at younger ages.

ETIOLOGY AND PATHOPHYSIOLOGY

Temporary reduction/cessation of cerebral blood flow adversely affecting neuronal function

- Carotid/vertebral atherosclerotic disease
  - Artery-to-artery thromboembolism
  - Low-flow ischemia
- Small, deep vessel disease associated with HTN
  - Lacunar infarcts
- Cardiac diseases
  - 1–6% of patients with MI develop stroke.
- Embolism secondary to the following:
  - Valvular (mitral valve) pathology

  - Mural hypokinesias/akinesias with thrombosis (acute anterior MI/congestive cardiomyopathies)
  - Cardiac arrhythmia (atrial fibrillation accounts for 5–20% incidence)
- Hypercoagulable states
  - Antiphospholipid antibodies
  - Increased estrogen (e.g., oral contraceptives)
  - Pregnancy and parturition
- Arteritis
  - Noninfectious necrotizing vasculitis
  - Drugs
  - Irradiation
  - Local trauma
- Sympathomimetic drugs (e.g., cocaine)
- Other causes: spontaneous and posttraumatic (e.g., chiropractic manipulation) arterial dissection
- Fibromuscular dysplasia

Genetics

Inheritance is polygenic, with tendency to clustering of risk factors within families.

RISK FACTORS

- Hypertension (HTN)
- Cardiac diseases (A-fib, MI, valvular disease)
- Diabetes
- Hyperlipidemia
- Atherosclerotic disease (carotid/vertebral stenosis)
- Cigarette smoking
- Thrombophilias

GENERAL PREVENTION

- Lifestyle changes: smoking cessation, diet modification, weight loss, regular aerobic exercise, and limited alcohol intake
- Strict control of medical risk factors: *diabetes* (glycemic control), *HTN* (thiazide and/or ACE/ARB), *hyperlipidemia* (statins), anticoagulation when

high risk of cardioembolism (e.g., atrial fibrillation, mechanical valves)

ALERT
10–20% of patients with TIA have CVA within 90 days; 25–50% of those occur within the first 48 hours.

Geriatric Considerations

- Older patients have a higher mortality rate than younger patients—highest in 7th and 8th decades.
- Atrial fibrillation is a frequent cause among the elderly.

Pediatric Considerations

- Congenital heart disease is a common cause among pediatric patients.
- Other causes include the following:
  - Metabolic: homocystinuria, Fabry disease
  - Central nervous system (CNS) infection
  - Clotting disorders
  - Marfan syndrome
  - Moyamoya disease
  - Sickle cell disease

Pregnancy Considerations

- Preeclampsia, eclampsia, and HELLP
- TTP and hemolytic uremic syndrome
- Postpartum angiopathy
- Cerebral venous thrombosis
- Hypercoagulable states related to pregnancy

COMMONLY ASSOCIATED CONDITIONS

- Atrial fibrillation
- Uncontrolled HTN
- Carotid stenosis
- TIA Mimics
  - Some disease processes mimic TIA presentation
  - Seizures, migraines, metabolic disturbances, syncope
  - Gradual onset with nonspecific symptoms (headache, memory loss)

DIAGNOSIS

HISTORY

- Obtain witness accounts with emphasis on symptom onset, progression, and recovery.
- Carotid circulation (hemispheric): monocular visual loss, hemiplegia, hemianesthesia, neglect, aphasia, visual field defects (amaurosis fugax); less often, headaches, seizures, amnesia, confusion
- Vertebrobasilar (brain stem/cerebellar): bilateral visual obscuration, diplopia, vertigo, ataxia, facial paresis, Horner syndrome, dysphagia, dysarthria; also headache, nausea, vomiting, and ataxia
- Past medical history, baseline functional status
- ABCD2 score: predicts risk of CVA within 48 hours (1)[A]
  - Score of 0 to 1: 0%; 2 to 3: 1.3%; 4 to 5: 4.1%; 6 to 7: 8.1%
    - **A**ge >65 years: 1 point
    - **B**P 140/90 mm Hg: 1 point
    - **C**linical presentation
      - Unilateral weakness: 2 points
      - Speech impaired without weakness: 1 point
    - **D**uration >60 minutes: 2 points
    - **D**uration 10 to 59 minutes: 1 point
    - **D**iabetes: 1 point

PHYSICAL EXAM

- Vital signs, oxygen saturation
- Thorough neurologic and cardiac exams

DIFFERENTIAL DIAGNOSIS

- Evolving stroke
- Migraine (hemiplegic)
- Focal seizure (Todd paralysis)
- Hypoglycemia
- Bell palsy
- Neoplasm of brain
- Subarachnoid hemorrhage

- Intoxication
- Electrolyte abnormalities
- Head trauma
- Central nervous system infection
- Multiple sclerosis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Neuroimaging within 24 hours of symptom onset
- MRI, including diffusion-weighted imaging, is the preferred brain diagnostic modality; if not available, then noncontrast head CT (2)[B]
- Noninvasive imaging of the cervicocephalic vessels should be performed routinely as part of the evaluation of suspected TIA (2)[A].
- Initial assessment of the extracranial vasculature may involve carotid US/TCD, MRA, or CTA depending on the availability and expertise and characteristics of the patient (2)[B].
- Routine blood tests (CBC, chemistry, PT/PTT, UPT, and fasting lipid panel) are reasonable in evaluation of patient with TIA (2)[B].

Follow-Up Tests & Special Considerations

- If only noninvasive testing is performed prior to CEA, it is reasonable to pursue two concordant noninvasive findings; otherwise, catheter angiography should be considered (2)[B].
- Echo is reasonable in evaluation of patients with suspected TIA especially when no other cause is noted (2)[B].
- TEE is useful in identifying PFO, aortic arch atherosclerosis, and valvular disease and is reasonable when this will alter management (2)[B].
- Prolonged cardiac monitoring is useful in patients with an unclear etiology after initial brain imaging and ECG (2)[B].
- EEG: if seizure suspected
- Consider a sleep study due to the high prevalence of sleep apnea among TIA patients; treatment with CPAP has shown to improve patient outcomes (3)[B].

TREATMENT

GENERAL MEASURES

- TIA is a neurologic emergency. Immediate medical attention should be sought within 24 hours of symptom onset due to increased stroke risk.
- Current evidence suggests that patients with high-risk TIAs require rapid referral and 24-hour admission (ABCD2 score ≥3 g).
- Acute phase
  - Inpatient for high-risk individuals
  - Outpatient investigations may be considered based on patient's stroke risk, arrangement of follow-up, and social circumstances.
- Antiplatelet therapy to prevent recurrence or future CVA
- Treatment/control of underlying associated conditions

MEDICATION

- For patients with TIA, the use of antiplatelet agents rather than oral anticoagulation is recommended to reduce risk of recurrent stroke and other cardiovascular events, with the exception of cardioembolic etiologies (2)[A].
- *Uncertain* if switching agent in patients who have additional ischemic attacks while on antiplatelet therapy is beneficial (4)[C]

First Line

- Enteric-coated aspirin: 160 to 325 mg/day in the acute phase (5)[A] followed by long-term antiplatelet therapy for noncardioembolic TIA and anticoagulation for cardioembolic etiology
- Antiplatelet therapy
  - Aspirin 50 to 325 mg/day (4)[A]
    - Contraindications: active peptic ulcer disease and hypersensitivity to ASA or NSAIDs
    - Precautions: may aggravate preexisting PUD; or worsen symptoms of asthma
    - Significant possible interactions: may potentiate effects of anticoagulants and sulfonylurea analogues
  - ER dipyridamole–ASA (Aggrenox): 25/200 mg BID (4,6)[B]
  - Combined therapy with dipyridamole and ASA is better than ASA alone (5,7)[A].
  - More expensive than ASA alone and may have more side effects

- Clopidogrel 75 mg/day (4)[B]
  - Can be used in patients who are allergic to ASA (4)[B]
  - Precautions: Thrombotic thrombocytopenic purpura (TTP) can occur and increases risk of bleeding when combined with aspirin.
  - May be very slightly more effective than aspirin alone (5)[B]; more expensive and more side effects than aspirin

- Combined aspirin and clopidogrel therapy has been demonstrated to reduce the incidence of subsequent stroke by 21% without increased risk of bleeding when used for a duration of 1 month or less immediately following TIA or CVA (6)[A].

- Anticoagulation therapy
  - Direct thrombin inhibitor:
    - Dabigatran (Pradaxa)
    - Idarucizumab (Praxbind) reversal agent
  - Factor Xa inhibitors
    - Apixaban (Eliquis)
    - Rivaroxaban (Xarelto)
    - Edoxaban (Savaysa)
      - Noninferior to warfarin in nonvalvular A-fib
      - Precautions: avoid in CKD (CrCl <30 mL/min)
      - Expensive but no INR needed
      - Not reversible
  - Warfarin (INR-adjusted dose) (4)[A]
    - Contraindications: intolerance/allergy, active liver disease, active bleeding, pregnancy
    - Significant possible interactions: antibiotics, antiepileptics, antifungals, and many others
  - ASA 325 mg/day or ASA 81 mg/day and clopidogrel 75 mg/day (4)[A]
    - Patients who cannot take anticoagulation for reasons other than bleeding risk

Second Line

Ticlopidine (Ticlid): 250 mg PO BID

- For patients who cannot tolerate other agents

- Contraindications: hypersensitivity, presence of hematopoietic/hemostatic disorders, conditions associated with bleeding, severe liver dysfunction
- Precautions: neutropenia (0.8% severe), which is reversible with cessation of the drug. Monitor blood counts every 2 weeks for first 3 months. TTP can occur.
- Significant possible interactions: Digoxin plasma levels decreased 15%; theophylline half-life increased from 8.6 to 12.2 hours.

ISSUES FOR REFERRAL

- Neurology for ongoing workup and treatment
- Cardiology if cardiac cause suspected
- Vascular surgery if carotid endarterectomy appropriate

ADDITIONAL THERAPIES

- Secondary prevention of TIA should be initiated; venous thromboembolism (VTE) prophylaxis
- Patients with TIA or ischemic stroke should be started on a statin.
- BP should be reduced after 24 hours. Thiazides, ACE inhibitors, and ARBs have shown to be of benefit. β-Blockers have not shown benefit in reducing recurrence or stroke.
- Patients with DM or pre-DM should be advised to follow ADA guidelines to maintain tight glycemic control (3)[A].

SURGERY/OTHER PROCEDURES

- Consider carotid endarterectomy in patients with a high degree of carotid artery stenosis ≥70%.
- When carotid endarterectomy is indicated for patients with TIA, surgery within 2 weeks is reasonable if there are no contraindications to early revascularization.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Symptoms <72 hours and the following:

- ABCD2 score of >3
- ABCD2 score of 0 to 3 and uncertainty that dx workup can be completed within 2 days as outpatient. Alternatively: If urgent imaging not available

through ED or urgent neurology follow-up not available, admit ABCD2 score ≥3 with evidence of focal ischemia.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Outpatient follow-up with neuro support every 3 months for 1st year then annually
- Close attention to recurrent or subsequent CVA

DIET

- DASH diet or as appropriate for underlying medical problems
- Physical activity
  - Any level of physical activity is beneficial, but at least 30 minutes of moderate-intensity physical activity daily is preferred.

PROGNOSIS

- The risk of stroke on the ipsilateral side within 90 days and cumulative thereafter is 10–20%.
- Frequency increases with the addition of multiple risk factors and severity of carotid stenosis.
- Patients with larger artery occlusion or cardioembolic etiology are at increased risk of recurrence.
- The major cause of death in the first 5 years is cardiac disease.

COMPLICATIONS

- Stroke
- Functional impairment

Defects

CODES

ICD10

- G45.9 Transient cerebral ischemic attack, unspecified
- G45.1 Carotid artery syndrome (hemispheric)
- G45.0 Vertebro-basilar artery syndrome

CLINICAL PEARLS

- Stress smoking cessation, exercise, weight loss, limited ETOH intake, and control of HTN, hyperlipidemia, and diabetes
- Antiplatelet therapy (e.g., aspirin, clopidogrel, or aspirin-dipyridamole) should be initiated.
- Warfarin should be initiated in patients with atrial fibrillation or cardioembolic risk factors.

TRANSIENT STRESS CARDIOMYOPATHY

Timothy P. Fitzgibbons, MD, PhD • Gerard P. Aurigemma, MD

BASICS

DESCRIPTION

- Transient stress cardiomyopathy (TSC) is a unique cause of reversible left ventricle (LV) dysfunction with a presentation indistinguishable from the acute coronary syndromes (ACS), particularly ST-segment elevation myocardial infarction (MI) (1).
- Typically, the patient is a postmenopausal woman who presents with acute chest pain or dyspnea after an identifiable "trigger" (i.e., an acute emotional or physiologic stressor).
- First reported by authors from Japan, TSC was known initially as the *takotsubo syndrome* because the typical LV morphology (i.e., apical ballooning) resembled that of a Japanese octopus trap or *takotsubo* (2)[B].
- Presenting clinical features include the following:
  - Chest symptoms and/or dyspnea
  - ECG changes, including ST-segment elevations or diffuse T-wave inversions
  - Mild elevation in cardiac biomarkers (creatine kinase [CK], troponin)
  - Transient wall motion abnormalities that may involve the base, midportion, and/or lateral walls of the LV.
  - The apex of the right ventricle (RV) may be affected in up to 25% of cases (3)[B].
- Clinical features may vary on a case-by-case basis, and formal diagnostic criteria have not been established.
- Authors from the Mayo Clinic have proposed that 3 of the 4 following criteria establish the diagnosis (1)[A]:
  - Transient akinesis or dyskinesis of the LV apical and midventricular segments with regional wall motion abnormalities extending beyond a single epicardial vascular distribution

  - Absence of obstructive coronary artery disease (CAD) or angiographic evidence of acute plaque rupture
  - New ECG abnormalities, either ST-segment elevation or T-wave inversion
  - Absence of
    - Recent significant head trauma
    - Intracranial bleeding
    - Pheochromocytoma
    - Obstructive epicardial CAD
    - Myocarditis
    - Hypertrophic cardiomyopathy
- Synonym(s): takotsubo cardiomyopathy; apical ballooning syndrome; stress cardiomyopathy; broken heart syndrome; ampulla cardiomyopathy

EPIDEMIOLOGY

Incidence

- TSC accounts for a small percentage (1–3%) of ACS.
- In a recent prospective evaluation of patients admitted to the ICU, as many as 28% had apical ballooning, often in association with sepsis.
- Predominant sex: 82–100% of cases occur in women.
- Predominant age: Mean age of patients is 62 to 75 years.

Prevalence

2.2% of patients presenting to a referral hospital with ST-segment MIs were found to have TSC.

ETIOLOGY AND PATHOPHYSIOLOGY

- The exact pathophysiology is not known.
- A perturbation in the brain-heart axis, originating in the insular cortex, may be the inciting event (4).
- Subsequent overwhelming activation of the sympathetic nervous system initiates a cascade of events, including the following:
  - Catecholamine-induced LV dysfunction: “biased agonism” of epinephrine for β_2-adrenergic receptors, located predominantly at the cardiac apex (5)
  - Endothelial dysfunction and vasospasm
  - Cellular metabolic injury

- Myocardial norepinephrine release
- Calcium overload
- Contraction band necrosis

Genetics

No genetic associations have been described to date.

RISK FACTORS

- Female sex
- Postmenopausal state
- Emotional stress (i.e., argument, death of family member)
- Physiologic stress (i.e., acute medical illness)
- Chronic neurologic or psychiatric disease (4)

COMMONLY ASSOCIATED CONDITIONS

Death from TSC is rare, and most cases resolve rapidly, within 2 to 3 days. Reported complications include:

- Left-sided heart failure
- Pulmonary edema
- Cardiogenic shock and hemodynamic compromise
- Dynamic LV outflow tract gradient complicated by hypotension
- Mitral regurgitation
- Ventricular arrhythmias
- LV thrombus formation
- LV free wall rupture
- Death (rare, 0–8%)

DIAGNOSIS

Because TSC often is indistinguishable from an ACS, it should be treated initially as such:

- Activate emergency medical services or report to emergency department.
- Oxygen, IV access, and ECG monitoring
- Urgent cardiology consultation

HISTORY

- In 2/3 of patients, there is exposure to a “trigger event.”
  - Emotional stress: argument, death of family member, divorce, public speaking, and so forth
  - Physiologic stress: acute medical condition such as head trauma, asthma attack, seizure, and so forth
- In 1/3 of patients, there is no identifiable trigger (4).
- Acute onset of dyspnea or chest pain
- Palpitations
- Syncope

PHYSICAL EXAM

Exam may be unremarkable or may include any of the following:

- Tachypnea
- Tachycardia
- Hypotension
- Jugular venous distension
- Bibasilar rales
- S_3 gallop
- Systolic ejection murmur due to dynamic LV outflow tract gradient
- Holosystolic murmur of mitral regurgitation

DIFFERENTIAL DIAGNOSIS

- Acute ST-segment elevation MI
- Pulmonary embolism
- Myopericarditis
- Pheochromocytoma
- Hypertrophic cardiomyopathy
- Subarachnoid hemorrhage or stroke

DIAGNOSTIC TESTS & INTERPRETATION

- ECG should be done urgently and may show the following:
  - Diffuse ST-segment elevations
  - Diffuse and often dramatic T-wave inversions
  - QTc interval prolongation (6)[B]
  - Q waves

- Laboratory tests typically reveal a mild elevation in cardiac biomarkers such as
  - CK (rarely >500 U/mL)
  - Troponin I
  - B-type natriuretic peptide (BNP)
  - Markers of high filling pressures (e.g., BNP) tend to be higher than markers of necrosis (e.g., CK, troponin).
  - TSC can be distinguished from AMI with 95% specificity using a BNP/TnT ratio ≥1,272 (sensitivity 52%) (7)[B].
- Chest radiograph
  - Cardiomegaly
  - Pulmonary edema
- Echocardiogram
  - Reduced LV systolic function
  - Abnormal diastolic function, including evidence of increased filling pressures
  - Regional wall motion abnormalities in one of the following patterns:
    - Classic or "takotsubo-type" ballooning of the apex with a hypercontractile base
    - "Reverse takotsubo": apical hypercontractility with basal akinesis
    - "Midventricular" akinesis with apical and basal hypercontractility
    - Focal or localized akinesis of an isolated segment
  - Dynamic intracavitary LV gradient
  - Mitral regurgitation
  - Variable involvement of the RV
- Cardiac MRI
  - Reduced LV function
  - Wall motion abnormalities as described for transthoracic echocardiography
  - Absence of delayed hyperenhancement with gadolinium

Diagnostic Procedures/Other

- Because ST-segment elevation MI is the diagnosis of exclusion, patients typically are referred for urgent cardiac catheterization.
- Coronary angiography

  - Nonocclusive CAD
  - Rarely, epicardial coronary spasm
  - Endothelial dysfunction as measured by fractional flow reserve or TIMI frame counts
- Left-sided heart catheterization: increased LV end-diastolic pressure to a similar degree as AMI (8)[B]
- Ventriculography: wall motion abnormalities as described for transthoracic echocardiography
- Right-sided heart catheterization
  - Increased pulmonary capillary wedge pressure
  - Secondary pulmonary hypertension
  - Increased right ventricular filling pressures
  - Reduced cardiac output or cardiogenic shock (cardiac index <2 and mean arterial pressure [MAP] <60 mm Hg)

Test Interpretation

Characteristic pathologic findings of involved myocardium have not been described.

TREATMENT

- Activation of emergency medical services
- Advanced cardiac life support therapies as needed
- Oxygen
- IV access
- ECG monitoring

MEDICATION

After diagnostic cardiac catheterization, empirical treatment goals are as follows:

- Management of hypotension: differentiation between cardiogenic shock and dynamic LV cavity gradient
- Management of increased filling pressures and congestive states
- Attenuation of sympathetic drive

First Line

- There are no evidence-based treatment recommendations for TSC.
- Although β-blockers are of theoretical benefit, their use has not been associated with improved outcomes in observational cohorts (4)[B].
- If there is evidence of left ventricular systolic dysfunction or pulmonary edema, consider the following:
  - Furosemide: 20 to 40 mg IV/PO BID as needed to reduce LV filling pressures and dyspnea (9)
  - ACE inhibitors or angiotensin receptor blockers: Lisinopril 10 to 40 mg/day PO or equivalent or valsartan 80 to 160 mg PO BID have been associated with improved outcomes in observational cohorts (4)[B].

Second Line

Short-term anticoagulation should be considered in patients with severely reduced LV function to prevent LV thrombus formation. Unfractionated heparin 80 U/kg IV bolus followed by 18 U/kg/hr IV or Lovenox 1 mg/kg SC BID.

ISSUES FOR REFERRAL

All patients with TSC generally should be comanaged with cardiology while inpatient and referred to cardiology as an outpatient.

ADDITIONAL THERAPIES

- Urgent cardiology consultation and consideration of cardiac catheterization
- Hypotension may require the following:
  - Vasopressors (e.g., dopamine or Levophed) if there is no LV outflow tract gradient (9)[C]
  - Phenylephrine and IV fluids to increase afterload in the presence of an LV outflow tract gradient (9)[C]
  - Cardiogenic shock that is not due to an LV outflow tract gradient may require placement of an intra-aortic balloon pump.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Admission criteria/initial stabilization
  - 12-lead ECG
  - Chest radiograph
  - Laboratory testing

  - Echocardiography
  - Patients with TSC usually are admitted for observation because the differential diagnosis includes ACS.
- Normal saline infusion to support BP, if necessary, and no evidence of heart failure
- Discharge criteria generally considered after exclusion of ACS and resolution of
  - Congestive state
  - Hypotension
  - Profound impairments of systolic function

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Impairments in systolic function typically resolve in 2 to 3 days but may last as long as 1 month.
- Patients should follow up with cardiology and serial echocardiography to document improved LV function.

PROGNOSIS

- Prognosis is excellent. Inpatient mortality is rare and ranges from 0% to 8%.
- Recurrence is rare; it also has been reported in 0–8% of patients.

Algorithm: Chest Pain/Acute Coronary Syndrome

CODES

ICD10

I51.81 Takotsubo syndrome

CLINICAL PEARLS

- TSC is a cause of reversible LV dysfunction with a clinical presentation indistinguishable from the ACS, particularly ST-segment elevation MI.
- Echocardiography may strongly suggest the diagnosis.
- Treatment is supportive and should include diuretics and ACE inhibitors in

patients with CHF.

TRICHOMONIASIS

Michael Arnold, MD, CDR, MC • Joshua R. Beer, DO

BASICS

DESCRIPTION

- Sexually transmitted urogenital infection caused by a pear-shaped, parasitic protozoan
- Causes vaginitis/urethritis in women, nongonococcal urethritis in men
- In pregnancy, increases risk of preterm labor, preterm premature rupture of membranes, small for gestational age infant, and possibly stillbirth
- Synonym(s): trich; trichomonal urethritis

EPIDEMIOLOGY

Incidence

- Affects >120 million women worldwide. The most common curable sexually transmitted infection (STI) worldwide (1).
- Estimated 1.1 million new cases annually in the United States
- 10–25% of vaginal infections
- 1–17% of cases of NGU in males; reported prevalence among men without urethritis ranges from 0% to 8%
- Predominant age: middle-aged adults
  - Rare until onset of sexual activity
  - Common in postmenopausal women; age is not protective and long-term carriage is possible.
- Women have higher prevalence (1.5 to 4.4 times more than men) and are more commonly symptomatic (2).

Pediatric Considerations

Rare in prepubertal children; diagnosis should raise concern of sexual abuse.

Prevalence

- 3.1% of all U.S. women age 25 to 49 years; 1.5% of U.S. women age 15 to 24 years

- Racial disparity demonstrated
  - 1.3% of white, non-Hispanic women
  - 1.8% of Mexican American women
  - 13.3% of black, non-Hispanic women (2)

ETIOLOGY AND PATHOPHYSIOLOGY

- *Trichomonas vaginalis*: a pear-shaped, flagellated, parasitic protozoan
- Grows best at 35–37°C in anaerobic conditions at pH of 5.5 to 6.0
- STI, but nonsexual transmission is possible because organism can survive several hours in moist environment.

Genetics

No known genetic considerations

RISK FACTORS

- Multiple sexual partners
- Unprotected intercourse
- Lower socioeconomic status
- Other STIs
- Untreated partner with previous infection
- Use of douching or feminine powders

GENERAL PREVENTION

- Use of male or female condoms
- Limiting numbers of sexual partners
- Male circumcision may be protective (3)[B].

COMMONLY ASSOCIATED CONDITIONS

- Other STIs, including HIV
- Bacterial vaginosis

DIAGNOSIS

HISTORY

- Women
  - Yellow-green, malodorous vaginal discharge

  - Vulvovaginal pruritus
  - Dysuria
  - 70–85% are symptomatic.
- Men
  - Dysuria
  - Urethral discharge
  - 80% are asymptomatic.

PHYSICAL EXAM

- Women
  - Vaginal erythema
  - Yellow-green, frothy, malodorous vaginal discharge
  - Cervical petechiae (strawberry cervix; seen in ~10% of patients)
- Men: penile discharge, spontaneous and with expression

DIFFERENTIAL DIAGNOSIS

- Women (other vaginitides)
  - Bacterial vaginosis
  - Vaginal candidiasis
  - Chlamydial infection
  - Gonorrheal infection
- Men (other urethritides)
  - Chlamydial infection
  - Gonorrheal infection

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Wet mounts of vaginal or urethral discharge: direct visualization of motile trichomonads. Most common diagnostic method since inexpensive and available
  - Sensitivity: 60–70%; declines rapidly within 1 hour from collection
  - Specificity: 99.8%
- Culture: sensitivity: >95%, specificity >99%; takes 4 to 7 days for growth
- Nucleic acid amplification test (NAAT)
  - Gold standard for diagnosis (4)

  - Sensitivity and specificity 95–99%
  - FDA approved for vaginal, endocervical, or female urine specimens
  - Results in 1 hour
  - Limited clinical availability
- Antigen detection
  - ELISA and direct fluorescent antibody tests: sensitivity of 80–90%
  - Limited clinical availability

Follow-Up Tests & Special Considerations

Detection on cervical Papanicolaou smear

- Treat since highly specific (97–99%)
- Not effective trichomonas screening test given sensitivity as low as 60%

Diagnostic Procedures/Other

Detection on self-obtained sample with DNA probe assay with specificity >98%

TREATMENT

- Symptomatic individuals require treatment.
- Sexual partners should be treated presumptively.
- Patients should abstain from sexual intercourse during treatment and until they are asymptomatic.

GENERAL MEASURES

The nitroimidazole class is only known effective antimicrobial treatment. If metronidazole resistance is suspected, use tinidazole (5)[A].

MEDICATION

First Line

- Metronidazole: 2 g PO, 1 dose (6)[A]
  - FDA pregnancy risk Category B
  - Cure rate: 84–98%
- Tinidazole: 2 g PO, 1 dose (6)[A]
  - FDA pregnancy risk Category C
  - Abstain from breastfeeding during treatment and for 3 days after the dose.

  - More expensive
  - Reaches higher levels in genitourinary tract
  - Cure rate: 92–100%

Second Line

- Metronidazole: 500 mg PO BID for 7 days
  - Only if still symptomatic after initial treatment
  - Considered first line in HIV-positive individuals
- Can dose with metronidazole or tinidazole 2 g daily for 7 days if infection persists
- May consider IV dosing of metronidazole based on case report that demonstrated cure after multiple failed oral regimens

Pregnancy Considerations

Metronidazole is effective for trichomoniasis infection during pregnancy but may increase the risk of preterm and low-birth-weight babies.

- Studies showed risk in patients receiving four times the standard dosing.
- Trichomoniasis is also associated with prematurity.

ISSUES FOR REFERRAL

- Multidrug-resistant organism
- Patient allergy to metronidazole: Desensitization to metronidazole is recommended.

ADDITIONAL THERAPIES

- Limited clinical trials assessing effectiveness of alternative therapies (4)
- Intravaginal metronidazole gel is not effective.
- Suggested alternative therapies based on small number of case reports
  - Paromomycin 6.25% cream
  - Povidone-iodine douche
  - Boric acid intravaginally
  - Furazolidone intravaginally

COMPLEMENTARY & ALTERNATIVE MEDICINE

See “Additional Therapies.”

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- If symptoms persist after initial treatment, repeat wet mount or other testing.
- Retest women for *T. vaginalis* recommended within 3 months of treatment. Data insufficient for retesting men (6)[A]
- HIV-positive patients should be screened for trichomonas at time of HIV diagnosis and at least annually (6)[A].

DIET

Abstain from alcohol during treatment and for 24 hours following last dose of metronidazole or 48 to 72 hours following last dose of tinidazole due to disulfiram-like reaction.

PATIENT EDUCATION

Educate about the sexually transmitted aspect.

- Advise patient to notify sexual partner to be treated.
- Discuss STI prevention—condom use can prevent recurrence.
- Abstain from intercourse while undergoing treatment; use condoms if abstention is not feasible.
- Avoid alcohol during treatment with metronidazole or tinidazole.

PROGNOSIS

- Excellent
- Usually eliminated after one course of antibiotics

COMPLICATIONS

Pregnancy Considerations

Linked to low birth weight, preterm premature rupture of membranes, and preterm birth

CODES

ICD10

- A59.9 Trichomoniasis, unspecified
- A59.03 Trichomonal cystitis and urethritis
- A59.01 Trichomonal vulvovaginitis

CLINICAL PEARLS

- Both partners need to be treated for trichomoniasis.
- Retest women within 3 months of treatment.
- Avoid alcohol during treatment with standard agents.
- Treatment does not reduce risk of adverse pregnancy outcomes.
- Male circumcision may be protective.
- Annual screening recommended for HIV-positive patients.
- Not a nationally notifiable condition

TRIGEMINAL NEURALGIA

Noah M. Rosenberg, MD

BASICS

DESCRIPTION

- A painful disorder of the sensory nucleus of the trigeminal nerve (cranial nerve [CN] V) that produces episodic, paroxysmal, severe, lancinating facial pain lasting seconds to minutes in the distribution of ≥1 divisions of the nerve
- Often precipitated by stimulation of well-defined, ipsilateral trigger zones: usually perioral, perinasal, and, occasionally, intraoral (e.g., by washing, shaving)
- System(s) affected: nervous
- Synonym(s): tic douloureux; Fothergill neuralgia; trifacial neuralgia; prosopalgia

EPIDEMIOLOGY

Incidence

- Women: 5.9/100,000/year
- Men: 3.4/100,000/year
- >70 years of age: ~25.6/100,000/year
- Predominant age:
  - >50 years; incidence increases with age
  - Rare: <35 years of age (consider another primary disease; see "Etiology and Pathophysiology")
- Predominant sex: female > male (~2:1)

Prevalence

16/100,000

Pediatric Considerations

Unusual during childhood

Pregnancy Considerations

Teratogenicity limits therapy for 1st and 2nd trimesters.

ETIOLOGY AND PATHOPHYSIOLOGY

- Demyelination around the compression site seems to be the mechanism by which compression of nerves leads to symptoms.
- Demyelinated lesions may set up an ectopic impulse generation causing erratic responses: hyperexcitability of damaged nerves and transmission of action potentials along adjacent, undamaged, unstimulated sensory fibers
- Compression of trigeminal nerve by anomalous arteries or veins of posterior fossa, compressing trigeminal root
- Etiologic classification:
  - Idiopathic (classic)
  - Secondary: cerebellopontine angle tumors (e.g., meningioma); tumors of CN V (e.g., neuroma, vascular malformations), trauma, demyelinating disease (e.g., multiple sclerosis [MS])

RISK FACTORS

Unknown

COMMONLY ASSOCIATED CONDITIONS

- Sjögren syndrome; rheumatoid arthritis
- Chronic meningitis
- Acute polyneuropathy
- MS
- Hemifacial spasm
- Charcot-Marie-Tooth neuropathy
- Glossopharyngeal neuralgia

DIAGNOSIS

HISTORY

Paroxysms of pain in the distribution of the trigeminal nerve

PHYSICAL EXAM

All exam findings typically are negative due to the paroxysmal nature of the disorder.

DIFFERENTIAL DIAGNOSIS

- Other forms of neuralgia usually have sensory loss. Presence of sensory loss nearly excludes the diagnosis of TN (if younger patient, frequently MS).
- Neoplasia in cerebellopontine angle
- Vascular malformation of brain stem
- Demyelinating lesion (MS is diagnosed in 2–4% of patients with trigeminal neuralgia [TN]).
- Vascular insult
- Migraine, cluster headache
- Giant cell arteritis
- Postherpetic neuralgia
- Chronic meningitis
- Acute polyneuropathy
- Atypical odontalgia
- SUNCT syndrome (short-lasting, unilateral, neuralgiform pain with conjunctival injection, and tearing)

DIAGNOSTIC TESTS & INTERPRETATION

- The International Headache Society diagnostic criteria for classic TN are as follows:
  - Paroxysmal attacks of pain lasting from a fraction of 1 second to 2 minutes, affecting ≥1 divisions of the trigeminal nerve
  - Pain has at least an intense, sharp, superficial, or stabbing characteristic, or is precipitated from trigger areas or by trigger factors.
  - Attacks are stereotyped in the individual patient.
  - No clinically evident neurologic deficit found
  - Not attributed to another disorder
- Secondary TN is characterized by pain that is indistinguishable from classic TN but is caused by a demonstrable structural lesion other than vascular compression.
  - Indicated in all first-time-presenting patients to rule out secondary causes
- MRI versus CT scan: MRI, with and without contrast, offers more detailed imaging and is preferred, if not contraindicated.
- Routine head imaging identifies structural causes in up to 15% of patients.
- No positive findings are significantly correlated with diagnosis.

Test Interpretation

- Trigeminal nerve: inflammatory changes, demyelination, and degenerative changes
- Trigeminal ganglion: hypermyelination and microneuromata

TREATMENT

GENERAL MEASURES

- Outpatient
- Drug treatment is first line.
- Invasive procedures are reserved for patients who cannot tolerate, fail to respond to, or relapse after chronic drug treatment.
- Avoid stimulation (e.g., air, heat, cold) of trigger zones, including lips, cheeks, and gums.

MEDICATION

First Line

- Carbamazepine (Tegretol) (1)[A]: Start at 100 to 200 mg BID; effective dose usually 200 mg QID; max dose 1,200 mg/day:
  - 70–90% of patients respond initially.
  - By 3 years, 30% are no longer helped (number needed to treat [NNT] = 1.7) (1)[A]
  - Most common side effect: sedation
- Contraindications: concurrent use of monoamine oxidase inhibitors (MAOIs)
- Precautions: caution in the presence of liver disease
- Significant possible medication interactions: macrolide antibiotics, oral anticoagulants, anticonvulsants, tricyclics, oral contraceptives, steroids, digitalis, isoniazid, MAOIs, methyprylon, nabilone, nizatidine, other H_2 blockers, phenytoin, propoxyphene, benzodiazepines, and calcium channel blockers
- Oxcarbazepine (Trileptal): Start at 150 to 300 mg BID; effective dose usually 375 mg BID; max dose 1,200 mg/day:
  - Efficacy similar to carbamazepine
  - Faster, with less drowsiness and fewer drug interactions than

carbamazepine
  - May cause hyponatremia
  - Most common side effect: sedation

Second Line

- Antiepileptic drugs: Insufficient evidence from randomized, controlled trials to show significant benefit from antiepileptic drugs in TN (2)[A].
- Phenytoin (Dilantin): 300 to 400 mg/day (synergistic with carbamazepine):
  - Potent P450 inducer (enhanced metabolism of many drugs)
  - Various CNS side effects (sedation, ataxia)
- Baclofen (Lioresal): 10 to 80 mg/day; start at 5 to 10 mg TID with food (as an adjunct to phenytoin or carbamazepine); side effects: drowsiness, weakness, nausea, vomiting
- Gabapentin (Neurontin): Start at 100 mg TID or 300 mg at bedtime; can increase dose up to 300 to 600 mg TID–QID. Can be used as monotherapy or in combination with other medications.
- Lamotrigine: Titrate up to 200 mg BID over weeks; side effect: 10% experience rash
- Antidepressants, including amitriptyline, fluoxetine, trazodone:
  - Used especially with anticonvulsants
  - Particularly effective for atypical forms of TN
- Clonazepam (Klonopin) frequently causes drowsiness and ataxia.
- Sumatriptan (Imitrex) 3 mg SC reduces acute symptoms and may be helpful after failure of conventional medical therapy.
- Capsaicin cream topically
- Botulinum toxin injection into zygomatic arch
- Valproic acid (Depakene, Depakote)

ISSUES FOR REFERRAL

Initial treatment failure or positive findings on imaging studies

ADDITIONAL THERAPIES

- Radiotherapy
- Stereotactic radiosurgery, such as gamma knife radiosurgery, has been shown to be effective after drug failure:

  - Produces lesions with focused gamma knife radiation
  - Therapy aimed at the proximal trigeminal root
  - Minimal clinically effective dose: 70 Gy
  - ~60–80% of patients achieve complete relief within 1 year; by 3 years, ~30–40% maintain complete relief (3)[B].
  - Most common side effect: sensory disturbance (facial numbness)
  - Failure rates are higher in patients with past TN-related invasive procedures.

SURGERY/OTHER PROCEDURES

- Microvascular decompression of CN V at its entrance to (or exit from) brain stem:
  - 98% of patients achieve initial pain relief; by 20 months, 86% maintain complete relief (NNT = 2) (4)[B].
  - Surgical mortality across studies was 0.3–0.4%.
  - Most common side effect: transient facial numbness and diplopia, headache, nausea, vomiting
  - Pain relief after procedure strongly correlates with the type of TN pain: Type 1 (shocklike pain) results in better outcomes than type 2 (aching pain between paroxysms).
- Peripheral nerve ablation (multiple methods):
  - Higher rates of failure and facial numbness than decompression surgery
  - Radiofrequency thermocoagulation
  - Neurectomy
  - Cryotherapy: high relapse rate
  - Partial sensory rhizotomy
- 4% tetracaine dissolved in 0.5% bupivacaine nerve block (only a few case reports to date; ropivacaine)
- Alcohol block or glycerol injection into trigeminal cistern: unpredictable side effects (dysesthesia and anesthesia dolorosa); temporary relief
- Peripheral block or section of CN V proximal to Gasserian ganglion
- Balloon compression of Gasserian ganglion
- Evidence supporting destructive procedures for benign pain conditions remains limited (5)[A].

COMPLEMENTARY & ALTERNATIVE MEDICINE

Acupuncture, moxibustion (herb): weak evidence for efficacy (6)[B]

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Regular outpatient follow-up to monitor symptoms and therapeutic failure

Patient Monitoring

- Carbamazepine and/or phenytoin serum levels
- If carbamazepine is prescribed: CBC and platelets at baseline, then weekly for a month, then monthly for 4 months, then every 6 to 12 months if dose is stable (regimens for monitoring vary)
- Reduce drugs after 4 to 6 weeks to determine whether condition is in remission; resume at previous dose if pain recurs. Withdraw drugs slowly after several months, again to check for remission or if lower dose of drugs can be tolerated.

DIET

No special diet

PATIENT EDUCATION

- Instruct patient regarding medication dosage and side effects, risk-to-benefit ratios of surgery, or radiation therapy.
- Support organizations:
  - The Facial Pain Association (formerly the Trigeminal Neuralgia Association): www.fpa-support.org
  - Living with Trigeminal Neuralgia: www.livingwithtn.org

PROGNOSIS

- 50–60% eventually fail pharmacologic treatment.
- After having microvascular decompression surgery, most patients wish they had undergone the procedure sooner.
- Of those, relapse is seen in ~50% of stereotactic radiosurgeries and ~27% of surgical microvascular decompressions.

COMPLICATIONS

- Mental and physical sluggishness; dizziness with carbamazepine
- Paresthesias and corneal reflex loss with stereotactic radiosurgery
- Surgical mortality and morbidity associated with microvascular decompression

2008;71(15):1183–1190.

CODES

ICD10

- G50.0 Trigeminal neuralgia
- B02.22 Postherpetic trigeminal neuralgia

CLINICAL PEARLS

- Patients with TN typically have a normal physical exam.
- The long-term efficacy of pharmacotherapy for TN is 40–50%.
- If pharmacotherapy fails, stereotactic radiosurgery or surgical microvascular decompression often is successful.

TRIGGER FINGER (DIGITAL STENOSING TENOSYNOVITIS)

Alan M. Ehrlich, MD • Robert A. Yood, MD

BASICS

DESCRIPTION

A clicking, snapping, or locking of a finger/thumb with extension movement (after flexion) ± associated pain

EPIDEMIOLOGY

Incidence

- Adult population: 28/100,000/year
  - Rare in children
- 4 times increased risk in diabetics (1)[B].
- Predominant age
  - Childhood form typically involves thumb.
  - Adult form typically presents in the 5th and 6th decades of life and involves thumb/digits.
- Predominant sex
  - Children: female = male
  - Adults: female > male (6:1)

Prevalence

Lifetime prevalence in the general population is 2.6%.

Pediatric Considerations

- The thumb is more commonly involved in children.
- Surgery is often more complicated for children with a trigger finger (as opposed to a trigger thumb).
- Release of the A1 pulley alone is often insufficient, other procedures may be necessary.

ETIOLOGY AND PATHOPHYSIOLOGY

- Narrowing around the A1 pulley from inflammation, protein deposition, or thickening of the tendon itself. Prolonged inflammation leads to fibrocartilaginous metaplasia of the tendon sheath.
- If the flexor tendon become nodular, the triggering phenomenon is worse because the nodule has difficulty passing under the A1 pulley.
- Because intrinsic flexor muscles are stronger than extensors, the finger can stick in the flexed position.
- No clear association with repetitive movements

RISK FACTORS

- Diabetes mellitus
- Rheumatoid arthritis
- Hypothyroidism
- Mucopolysaccharide disorders
- Amyloidosis

GENERAL PREVENTION

Most cases are idiopathic, and no known prevention exists. No clear association with repetitive movements

COMMONLY ASSOCIATED CONDITIONS

- De Quervain tenosynovitis
- Carpal tunnel syndrome
- Dupuytren contracture
- Diabetes mellitus
- Rheumatoid arthritis
- Hypothyroidism
- Amyloidosis

DIAGNOSIS

Diagnosis is based on clinical presentation.

HISTORY

Clicking, snapping, or locking of a digit while attempting to extend; with or without associated pain

PHYSICAL EXAM

- A palpable nodule may be present.
- Snapping/locking may be present but neither is necessary for the diagnosis.
- Tenderness to palpation is variable.

DIAGNOSTIC TESTS & INTERPRETATION

Test Interpretation

- Thickening of the A1 pulley with fibrocartilaginous metaplasia
- Thickening/nodule formation of flexor tendon

TREATMENT

- Splinting the metacarpophalangeal (MCP) joint at 10 to 15 degrees of flexion for 6 weeks with the distal joints free to move:
  - Splinting is more effective for fingers than thumbs (70% vs. 50%).
  - Splinting is less effective with severe symptoms, symptoms >6 months, or if multiple digits are involved (1)[B].
- Injection of long-acting corticosteroid may provide symptom relief. Subsequent injections are less likely to help.
- Surgery often successful for patients unresponsive to splinting/corticosteroid injections.

GENERAL MEASURES

Attempt splinting/steroid injection prior to surgery. Splinting may be more effective for preventing recurrence than as initial treatment (2)[B].

MEDICATION

First Line

- Steroid injection of the tendon sheath/surrounding SC tissue has 57–90% success rate.
- Injection in surrounding tissues is as efficacious as injecting into the tendon sheath (1,3)[B]. Injection into the palmar surface at the midproximal phalanx is associated with less pain than injection of tendon sheath at MCP joint (4)[B].
- Injection using ultrasound guidance does not improve success rate compared

to standard injection technique (5)[A]. Corticosteroid injection has higher success rate than splinting (2)[B].

Second Line

- Oral NSAIDs may reduce pain and discomfort but have not been shown to alter underlying disease. NSAIDs do not reduce symptoms of snapping/locking.
- Injection with diclofenac may be an alternative to corticosteroid for patients with diabetes mellitus if increase in blood sugar is a concern (6)[A].
- Corticosteroids are more effective than diclofenac during the first 3 weeks postinjection. Efficacy is similar to other modalities by 3 months postinjection (6)[B].
- In one randomized trial, hyaluronic acid (HA) injections were as effective as corticosteroid injections. The optimal frequency, dosage, and molecular weight of HA injections has yet to be adequately studied.

ISSUES FOR REFERRAL

Refer to a hand surgeon for release if the patient is not responding to splinting and/or steroid injections.

ADDITIONAL THERAPIES

Physiotherapy is helpful, particularly in children.

SURGERY/OTHER PROCEDURES

- Surgical release can be done as an open procedure or percutaneously.
- No apparent differences in success or rates of complications between surgical approaches (6)[A].
- Surgery has a lower rate of recurrence than corticosteroid injection (6)[A].
- Most hand surgeons prefer open release because of concern about nerve injury.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Day surgery for trigger finger release
- Discharge criteria: absence of complications

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Follow up is needed only if symptoms persist or if complications develop after surgery.
- Splinting of the affected digit to minimize flexion/extension of the MCP joint helps symptom resolution (1)[B],(7)[C].

PROGNOSIS

Prognosis is excellent with conservative treatment or surgical intervention. Recurrence following corticosteroid injection is more likely for patients with type 1 diabetes mellitus, younger patients, involvement of multiple digits, and patients with a history of other upper extremity tendinopathies (8)[B].

COMPLICATIONS

- Complications from surgery include infection, bleeding, digital nerve injury, persistent pain, and loss of range of motion of the affected finger. The rate of major complications is low (3%). The rate of minor complications (including loss of range of motion) is higher (up to 28%).
- Injury to the A2 pulley may result in bowstringing, (bulging of the flexor tendon in the palm with flexion). This can be painful.
- Diabetic patients may have increased blood sugar levels for up to 5 days following steroid injection.

CODES

ICD10

- M65.30 Trigger finger, unspecified finger
- M65.319 Trigger thumb, unspecified thumb
- M65.329 Trigger finger, unspecified index finger

CLINICAL PEARLS

- Trigger finger is caused by narrowing of the A1 flexor tendon pulley.
- Splinting the MCP joint at 10 to 15 degrees flexion for 6 weeks is the preferred initial conservative treatment.
- Splinting is more effective for fingers as opposed to thumbs (70% vs. 50%). Splinting is less effective with severe symptoms, longstanding symptoms (>6 months), or if multiple digits are involved.
- Long-acting corticosteroid injections are effective for treatment of trigger finger.
- Open and percutaneous surgical release has high success rates for patients not responsive to splinting or injections.

TROCHANTERIC BURSITIS (GREATER TROCHANTERIC PAIN SYNDROME)

David W. Kruse, MD • Joann Y. Chang, MD

BASICS

Trochanteric bursitis is the historical term referring to lateral hip pain and tenderness over the greater trochanter. Because many patients lack an inflammatory process within the trochanteric bursa, this condition has been more recently referred to as *greater trochanteric pain syndrome* (GTPS) (1).

DESCRIPTION

- Bursae are fluid-filled sacs found primarily at tendon attachment sites with bony protuberances:
  - Multiple bursae are in the area of the greater trochanter of the femur.
  - These bursae are associated with the tendons of the gluteus muscles, iliotibial band (ITB), and tensor fasciae latae.
  - The subgluteus maximus bursa is implicated most commonly in lateral hip pain (1).
- Other structures of the lateral hip include the following:
  - ITB, tensor fasciae latae, gluteus maximus tendon, gluteus medius tendon, gluteus minimus tendon, quadratus femoris muscle, vastus lateralis tendon, piriformis tendon
- *Bursitis* refers to bursal inflammation.
- *Tendinopathy* refers to any abnormality of a tendon, inflammatory or degenerative. *Enthesopathy* refers to abnormalities of the zones of attachment of ligaments and tendons to bones.

EPIDEMIOLOGY

Incidence

- 1.8/1,000 persons/year
- Peak incidence in 4th to 6th decades

Prevalence

- Predominant sex: female > male
- More common in running and contact athletes
  - Football, rugby, soccer

ETIOLOGY AND PATHOPHYSIOLOGY

- Acute: abnormal gait or poor muscle flexibility and strength imbalances lead to bursal friction and secondary inflammation
  - Tendon overuse and inflammation
  - Direct trauma from contact or frequently lying with body weight on hip can cause an inflammatory response (“hip pointer”) as well.
- Chronic
  - Fibrosis and thickening of bursal sac due to chronic inflammatory process
  - Tendinopathy due to chronic overuse and degeneration: gluteus medius and minimus most commonly involved (1,2)

Genetics

No known genetic factors

RISK FACTORS

Multiple factors have been implicated (1,3):

- Female gender
- Obesity
- Tight hip musculature (including ITB)
- Direct trauma
- Total hip arthroplasty
- Abnormal gait or pelvic architecture
  - Leg length discrepancy
  - Sacroiliac (SI) joint dysfunction
  - Knee or hip osteoarthritis
  - Abnormal foot mechanics (e.g., pes planus, overpronation)
  - Neuromuscular disorder: Trendelenburg gait

GENERAL PREVENTION

- Maintain ITB, hip, and lower back flexibility and strength.
- Avoid direct trauma (use of appropriate padding in contact sports).
- Avoid prolonged running on banked or crowned surfaces.

- Wear appropriate shoes.
- Appropriate bedding and sleeping surface
- Maintain appropriate body weight loss.

COMMONLY ASSOCIATED CONDITIONS

- Biomechanical factors (1)
  - Tight ITBs, leg length discrepancy, SI joint dysfunction, pes planus
  - Width of greater trochanters greater than width of iliac wings (4)[B]
- Other associated pathology (1):
  - Low back pain
  - Knee and hip osteoarthritis
  - Obesity

DIAGNOSIS

HISTORY

General history (1)

- Pain localized to the lateral hip or buttock
- Pain may radiate to groin or lateral thigh (pseudoradiculopathy).
- Pain exacerbated by:
  - Prolonged walking or standing
  - Rising after prolonged sitting
  - Sitting with legs crossed
  - Lying on affected side
- Other historical features:
  - Direct trauma to affected hip
  - Chronic low back pain
  - Chronic leg/knee/ankle/hip pain
  - Recent increase in running distance or intensity
  - Change in running surfaces

PHYSICAL EXAM

- Observe gait.
- Point tenderness with direct palpation over the lateral hip is characteristic of GTPS (1)[B].

- Other exam features have lower sensitivity (1)[B]:
  - Pain with extremes of passive rotation, abduction, or adduction
  - Pain with resisted hip abduction and external or internal rotation
  - Trendelenburg sign
- Other tests to rule out associated conditions:
  - Patrick-FABERE (flexion, abduction, external rotation, extension) test for SI joint dysfunction
  - Ober test for ITB pathology
  - Flexion and extension of hip for osteoarthritis
  - Leg length measurement
  - Foot inspection for pes planus or overpronation
  - Lower extremity neurologic assessment for lumbar radiculopathy or neuromuscular disorders
  - Hip lag sign (5)

DIFFERENTIAL DIAGNOSIS

- ITB syndrome
- Piriformis syndrome
- Osteoarthritis or avascular necrosis of the hip
- Lumbosacral osteoarthritis/disc disease with nerve root compression
- Fracture or contusion of the hip or pelvis—particularly in setting of trauma
- Stress reaction/fracture of femoral neck—particularly in female runners
- Septic bursitis/arthritis

DIAGNOSTIC TESTS & INTERPRETATION

No routine lab testing is recommended.

Initial Tests (lab, imaging)

- Diagnosis can be made by history and exam (6).
- If imaging is ordered:
  - US can aid in diagnosis and guide aspiration and/or injection.
  - Anteroposterior and frog-leg views of affected hip to rule out specific bony pathology (OA, stress fracture, etc).
  - Consider lumbar spine radiographs if back pain is thought to be a contributing factor.

- MRI is image of choice in recalcitrant pain or to formally exclude stress fracture.

Follow-Up Tests & Special Considerations

- If there is a concern for a septic bursitis, then aspiration or incision and drainage may be necessary.
- Advanced imaging rarely necessary; detection of abnormalities on MRI is a poor predictor of GTPS (7)[B].

TREATMENT

GENERAL MEASURES

- Physical therapy to address underlying dysfunction and rebuild atrophic muscle
- Correct pelvic/hip instability.
- Correct lower limb biomechanics.
- Low-impact conditioning and aquatic therapy
- Gait training
- Weight loss (if applicable)
- Minimize aggravating activities such as prolonged walking or standing.
- Avoid lying on affected side.
- Runners
  - May need to decrease distance and/or intensity of runs during treatment. Some need to stop running. Amount of time is case specific but may range from 2 to 4 weeks.
  - Avoid banked tracks or roads with excessive tilt.

MEDICATION

First Line

- NSAIDs (1)[B]: Treat for 2 to 4 weeks.
  - Naproxen: 500 mg PO BID
  - Ibuprofen: 800 mg PO TID
- Corticosteroid injection is effective for pain relief (8)[C] and can be considered first-line therapy for selected cases:

  - Dexamethasone: 4 mg/mL or
  - Kenalog: 40 mg/m, useL 1 to 2 mL
  - Consider adding a local anesthetic (short- and/or long-acting) for more immediate pain relief.
  - Can be repeated with similar effect if original treatment showed a strong response
  - Goal is pain relief (9)[A].

ISSUES FOR REFERRAL

- Septic bursitis
- Recalcitrant bursitis

ADDITIONAL THERAPIES

- Ice
- Low-energy shock wave therapy has been shown to be superior to other nonoperative modalities (8)[A].
- Focus on achieving flexibility of hip musculature, particularly the ITB.
- Address contributing factors:
  - Low back flexibility
  - If leg length discrepancy, consider heel lift.
  - If pes planus or overpronation, consider arch supports or custom orthotics.

SURGERY/OTHER PROCEDURES

- Surgery rare but effective in refractory cases (10)[A]
- If surgery is indicated, potential options include:
  - Arthroscopic bursectomy
  - ITB release
  - Gluteus medius tendon repair

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Acupuncture
- Prolotherapy
- Growth factor injection techniques
- Platelet-rich plasma injection

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

4 weeks posttreatment, sooner if significant worsening

PATIENT EDUCATION

- Maintain hip musculature flexibility, including ITB.
- Correct issues that may cause abnormal gait:
  - Low back pain
  - Knee pain
  - Leg length discrepancy (heel lift)
  - Foot mechanics (orthotics)
- Gradual return to physical activity

PROGNOSIS

Depends on chronicity and recurrence, with more acute cases having an excellent prognosis

COMPLICATIONS

Bursal thickening and fibrosis

CODES

ICD10

- M70.60 Trochanteric bursitis, unspecified hip
- M70.62 Trochanteric bursitis, left hip

- M70.61 Trochanteric bursitis, right hip

CLINICAL PEARLS

- Patients with GTPS often present with an inability to lie on the affected side.
- Femoral neck stress fractures are a do-not-miss diagnosis, particularly in young female runners.
- Corticosteroid injection helps as an initial therapy, particularly for pain relief to allow for aggressive physical therapy.
- Physical therapy is treatment mainstay for correcting biomechanical imbalances and restoring proper function.

TUBERCULOSIS

Swati Avashia, MD, FAAP, FACP, ABIHM

BASICS

DESCRIPTION

- Active tuberculosis (TB)
  - Occurs from primary infection or reactivation of latent infection
  - Affects 10% of infected individuals without preventive therapy
  - Risk increases with immunosuppression: Highest risk is in the first 2 years after infection.
  - Well-described forms: pulmonary (85% of cases), miliary (disseminated), meningeal, abdominal
- Usually acquired by inhalation of airborne bacilli from an individual with active TB. Bacilli multiply in alveoli and spread via macrophages, lymphatics, and blood. Three possible outcomes:
  - Eradication: Tissue hypersensitivity halts infection within 10 weeks.
  - Primary TB
  - Latent TB (See "Tuberculosis, Latent [LTBI].")

Pediatric Considerations

- In children, there is a faster rate of progression to disease, the risk of progression to disease is higher, and severe disease is more common.
- Most children with pulmonary TB are asymptomatic.
- Treatment of pediatric TB should involve four drugs and be directly observed (directly observed therapy [DOT]).

EPIDEMIOLOGY

Incidence

- Worldwide (2014): 9.6 million: 133 cases/100,000 population; highest incidence in Asia and Africa (1)
- United States (2014): 9,421 (3.0/100,000). Incidence in foreign-born persons was 13 times that of U.S.-born persons (2).

Prevalence

Worldwide (2014): 174 cases/100,000 population

Mortality

Worldwide (2014): 1.5 million deaths due to TB

ETIOLOGY AND PATHOPHYSIOLOGY

- *Mycobacterium tuberculosis*, *Mycobacterium bovis*, or *Mycobacterium africanum* are causative organisms.
- Cell-mediated response by activated T lymphocytes and macrophages forms a granuloma that limits bacillary replication. Destruction of the macrophages produces early "solid necrosis." In 2 to 3 weeks, "caseous necrosis" develops and latent tuberculosis infection (LTBI) ensues. In the immunocompetent, granuloma undergoes "fibrosis" and calcification. In immunocompromised patients, primary progressive TB develops.

RISK FACTORS

- For infection: homeless, ethnic minorities, close quarters (correctional facilities, nursing homes, barracks), close contact with infected person, living in areas with high incidence of active TB, health care workers; medically underserved, low income substance abuse
- For development of disease once infected: HIV; lymphoma; silicosis; diabetes mellitus; chronic renal failure; cancer of head, neck, or lung; children <5 years of age; malnutrition; systemic corticosteroids, immunosuppressive drugs; IV drug abuse, alcohol abuse, cigarette smokers; <2 years since infection with *M. tuberculosis*; history of gastrectomy or jejunal bypass; <90% of ideal body weight

GENERAL PREVENTION

- Screen for and treat LTBI. Report active TB to health department; test and treat all close contacts.
- Bacillus Calmette-Guérin (BCG) vaccine: Live attenuated *M. bovis* prevents 50% of pulmonary disease and 80% of meningitis and miliary disease in children. Use is more common in endemic countries. In the United States, consider BCG for high-risk children with negative PPD and HIV tests or for health workers at risk for drug-resistant infection.

COMMONLY ASSOCIATED CONDITIONS

Immunosuppression; HIV-coinfection; malignancy

DIAGNOSIS

HISTORY

- Known exposure to individual with active TB
- Immunosuppression
- Tobacco use; recreational drug use
- Signs and symptoms
  - General: fever, night sweats, weight loss, malaise, painless lymph node swelling
  - Pulmonary TB: cough, hemoptysis
  - Abdominal TB: presents acutely as surgical abdomen; chronic abdominal TB varies in presentation, vague abdominal symptoms, abdominal mass, "doughy" abdomen.
  - Meningitis: See "Tuberculosis, CNS."
  - Miliary: See "Tuberculosis, Miliary."

PHYSICAL EXAM

- Often entirely normal. Specific findings depend on organs involved: adenopathy, rales, or hepatosplenomegaly.
- Late findings: renal, bone, or CNS disease

DIFFERENTIAL DIAGNOSIS

- Pulmonary TB: pneumonia (bacterial fungal, atypical), malignancy, tularemia, actinomycosis
- Extrapulmonary TB: syphilis, cat-scratch disease, leishmaniasis, leprosy; rheumatoid disease; erythema nodosum, erythema induratum, syphilis, other mycobacterial infections

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests

To determine immune response to mycobacterium

- Tuberculin skin test (TST) (e.g., PPD): 5 U (0.1 mL) intermediate-strength

intradermal injection into volar forearm. Measure induration at 48 to 72 hours:
  - PPD positive if induration
    - >5 mm and HIV infection, recent TB contact, immunosuppressed, disease on x-ray
    - >10 mm and age <4 years or other risk factors
    - >15 mm and age >4 years and no risk factors
    - Two-step test if no recent PPD, age >55 years, nursing home resident, prison inmate, or health care worker. Second test 1 to 3 weeks after initial test; interpret as usual.
  - Context of PPD results:
    - False positive: BCG (unreliable, should not affect decision to treat)
    - False negative: HIV, steroids, gastrectomy, alcoholism, renal failure, sarcoidosis, malnutrition, hematologic or lymphoreticular disorder, very recent exposure
    - If positive once, no need to repeat.
    - No need for control with *Candida*/other
- Interferon-γ release assays (IGRAs) measure interferon release after stimulation in vitro by *M. tuberculosis* antigens (3)[A]:
  - Lack of cross-reaction with BCG and most nontuberculous mycobacteria
    - IGRA preferred for testing persons who have had BCG (vaccine or for cancer therapy) and for groups with low rates of returning to have TST's interpreted (e.g., homeless persons and drug abusers) (3)[A].
    - TST is still preferred if age <5 years (4)[A].
    - Either TST or IGRA may be used as periodic screening for persons in high-risk occupations and for recent contacts of persons with known or suspected active TB (3)[A].
    - Cotesting with TST and IGRA may be indicated when the initial test is negative but the risk for poor prognosis is increased (e.g., HIV-infected persons or children <5 years old) (3)[A].

Initial Tests-Active TB (lab, imaging)

- Three consecutive sputums (8 to 24 hours apart with at least one early morning sample) for acid-fast bacilli (AFB) stain and culture by aerosol induction, gastric aspirate (children), or bronchoalveolar lavage

- Positive AFB: Treat immediately. Culture and sensitivity ultimately guide treatment.
- Chest radiograph
  - Primary TB: infiltrate with or without effusion, atelectasis, or adenopathy. Ghon lesion: calcified tuberculous caseating granuloma (tuberculoma); if associated with calcified ipsilateral hilar lymph node, then Ghon (or Ranke) complex.
  - Recrudescent TB: cavitary lesions and upper lobe disease with hilar adenopathy
  - HIV: atypical findings with primary infection, right upper lobe atelectasis
- CT chest: good sensitivity, tree-in-bud (centrilobular nodules with branching linear opacities)

Follow-Up Tests & Special Considerations

- Baseline CBC, creatinine, AST, ALT, bilirubin, alkaline phosphatase, visual acuity, and red–green color discrimination (regimens involving ethambutol)
- Diabetes screen if risk factors present
- HIV: If positive, get baseline CD4 count.
- Check hepatitis B and C if injection drug users, Africa or Asia born, HIV infected or otherwise high risk.
- Extrapulmonary: urine, CSF, bone marrow, and liver biopsy for culture as indicated
- Nonspecific findings: anemia, thrombocytosis, SIADH, hypergammaglobulinemia, monocytosis, sterile pyuria

Diagnostic Procedures/Other

- Culture: takes several weeks for definitive results
- Xpert MTB/RIF: The World Health Organization endorses use for diagnosis of pulmonary TB and detection of rifampicin resistance in adults and children presumed to have MDR-TB, HIV-associated TB, or TB meningitis (5)[A]. Results in 2 hours (6).

TREATMENT

GENERAL MEASURES

- If clinical suspicion, treat immediately. Prescribing physician is responsible for treatment completion.
- Respiratory and droplet precautions
- Not infectious if favorable clinical response after 2 to 3 weeks of therapy and three negative AFB smears

MEDICATION

Use ideal body weight for dosing. DOT recommended for all but required for children, institutionalized patients, nonadherent patients, and nondaily regimens.

First Line

- LTBI (7)[A]
  - Isoniazid (INH) for 9 months at 5 mg/kg/day (max of 300 mg) *or* 15 mg/kg (max of 900 mg) 2 times per week *or*
  - INH 15 mg/kg + rifapentine 300 to 900 mg weekly for 12 weeks by DOT for patients age ≥12 years
- Active TB infection (8)[A]
  - Regimen 1 (preferred)
    - Initial phase:
      - INH 5 mg/kg, rifampin (RIF) 10 mg/kg (max 600 mg), pyrazinamide (PZA) 15 to 30 mg/kg, and ethambutol (EMB) 15 to 20 mg/kg daily for 8 weeks *or*
      - INH/RIF/PZA/EMB 5 days/week for 8 weeks
    - Continuation phase:
      - INH/RIF daily for 18 weeks; or, if DOT, INH/RIF 5 days/week for 18 weeks
  - Regimen 2 (preferred when more frequent DOT in continuation phase is difficult to achieve)
    - Initial phase:
      - INH/RIF/PZA/EMB daily for 8 weeks *or*
      - INH/RIF/PZA/EMB 5 days/week for 8 weeks
    - Continuation phase:
      - INH/RIF 3 times per week for 18 weeks
  - Regimen 3 (use with caution if HIV infected or with cavitary disease. Missed doses can lead to treatment failure, relapse, and acquired drug

resistance)
    - Initial phase: INH/RIF/PZA/EMB 3 times per week for 8 weeks
    - Continuation phase: INH/RIF 3 times per week for 18 week
- Regimen 4 (do not use if HIV positive, smear positive, or cavitary disease)
    - Initial phase: INH/RIF/PZA/EMB daily for 14 doses and then twice a week for 12 doses
    - Continuation phase: INH/RIF twice a week for 18 weeks

Pregnancy Considerations

- Treat TB in pregnancy with INH, RIF, and EMB; add pyridoxine 25 mg/day.
- Streptomycin: ototoxic and nephrotoxic; do not use in pregnancy. Pyrazinamide is not used in pregnant women in the United States.
- Congenital infection: from maternal miliary or endometrial TB. PPD, CXR, lumbar puncture, and culture placenta. Treat promptly if suspected.
- Breastfeeding: OK while taking TB drugs; supplement with pyridoxine 25 mg/day.

Pediatric Considerations

- Children on medication may attend school.
- Ethambutol can be used in infants and children (8)

ALERT

- Maximum drug doses: RIF 600 mg all regimens, PZA 2,000 mg/day or 4,000 mg 2 times per week, EMB, 600 mg/day or 4,000 mg 2 times per week
- If patient does not receive PZA during entire first 2 months, extend treatment to 9 months.
- *M. bovis* is resistant to PZA; must be treated 9 months
- Continue EMB until organism susceptibility to INH plus RIF is determined (7)[A].

Second Line

Fluoroquinolones and injectable aminoglycosides. Use when MDR is suspected or patient intolerance.

ISSUES FOR REFERRAL

ALERT

Notify public health authorities for all cases of active TB. Consult infectious disease specialist for cases of drug-resistant TB and for cases involving HIV-positive patients on antiretroviral therapy.

ADDITIONAL THERAPIES

- Pyridoxine: 50 mg should be given to all persons at risk for INH-neuropathy: pregnant women, breastfeeding infants, HIV positive, diabetes, alcoholism, malnutrition, chronic renal failure, or advanced age (8)[A].
- Steroids: recommended for TB meningitis (8)[A]. Not routinely recommended for TB pericarditis (8)[B], but may be used for those at highest risk of inflammatory complications.

SURGERY/OTHER PROCEDURES

For extrapulmonary complications (spinal cord compression, bowel obstruction, constrictive pericarditis)

COMPLEMENTARY & ALTERNATIVE MEDICINE

Vitamin D deficiency may increase susceptibility to TB and development of active TB (9)[C]. There is conflicting evidence regarding the utility of vitamin D supplementation in TB treatment.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Negative pressure isolation with personal respirators and droplet precautions
  - Three consecutive negative sputum AFB smears are necessary for release from isolation.
- Once TB has been excluded or the patient has demonstrated response to therapy and is not an infectious risk, arrange outpatient follow-up with a provider comfortable managing TB and coordinate case management with local public health authorities.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Monthly sputum for AFB smear and culture until 2 consecutive cultures are negative. Must confirm this prior to starting continuation phase.
- Monthly visits to assess treatment adherence and adverse medication effects; CXR after 2 months of treatment
- For HIV positive: CD4 count, CBC, and liver enzymes q3mo
- Liver enzymes monthly if chronic liver disease, alcohol use, pregnant, or postpartum. Temporarily halt medications if asymptomatic and enzymes ≥5 times normal or if symptomatic and enzymes ≥3 times normal.
- Visual acuity and red–green color monthly if on ethambutol >2 months or doses >20 mg/kg/day
- If culture-positive after 2 months of therapy, reassess drug sensitivity, initiate DOT, coordinate care with public health authorities, and consider infectious disease consultation (if not already involved).

PATIENT EDUCATION

- Emphasize medication adherence.
- Screen and treat close contacts.
- Alert patient that health authorities must be notified.
- http://www.cdc.gov/tb/publications/factsheets/general/tb.htm

PROGNOSIS

Few complications and full resolution of infection if medications are taken for full course as prescribed.

COMPLICATIONS

- Cavitary lesions can become secondarily infected.
- Risk for drug resistance increases with HIV positive, treatment nonadherence, or residence in area with high incidence of resistance.
- MDR-TB: resistance to INH and rifampicin
- XDR-TB: resistant to fluoroquinolones (9% of MDR)

- Algorithm: Weight Loss, Unintentional

CODES

ICD10

- A15.9 Respiratory tuberculosis unspecified

- A15.0 Tuberculosis of lung
- A19.9 Miliary tuberculosis, unspecified

CLINICAL PEARLS

- TB is fully curable when diagnosed and treated appropriately.
- Children and elderly patients exhibit fewer classic clinical features of TB.
- Involve public health authorities early in the diagnostic and treatment process for suspected cases of TB.
- DOT is preferred.

TUBERCULOSIS, LATENT (LTBI)

Kay A. Bauman, MD, MPH

BASICS

DESCRIPTION

- Latent tuberculosis infection (LTBI) is an asymptomatic, noninfectious condition following exposure to an active case of tuberculosis. It is usually detected by a positive skin test (i.e., purified protein derivative [PPD]) or a positive interferon-γ release assay (IGRA) test. In LTBI, acid-fast bacilli smear and culture are negative, and chest x-ray (CXR) does not suggest active TB.
- Active TB occurs in 5–10% of infected individuals who have not received preventive therapy. Chance of active TB increases with immunosuppression and is highest for all individuals within 2 years of infection; 85% of the cases are pulmonary, which spreads person-to-person via an aerosol route.
- The majority (66% in 2015) of active TB cases in the United States occur in foreign-born persons. Most are as the result of reactivation of LTBI (1). Active TB cases continue to decline but at a slower rate than in previous years.
- LTBI treatment is a key component of the TB elimination strategy of the United States.

ALERT

After 20 years of annual decreases in the number active TB cases in the United States, the incidence has recently plateaued. Identification and treatment LTBI is crucial to reverse this phenomenon. Test for LTBI (PPD or IGRA) and treat latent infection in high-risk populations.

EPIDEMIOLOGY

- TB is the leading cause of infectious disease mortality worldwide.
- High-risk groups include immigrants from Asia, Latin America, Africa, and the Pacific basin; homeless persons; persons with a history of drug use or history of incarceration; HIV-infected individuals; and health care workers.
- Also at high risk are those who are newly exposed (particularly children). In

2015, there were 9,563 new cases of TB in the United States (1).

- In 2015, Asians had the highest active TB case rate of all groups, 28 times the rate in whites. The rate of TB in non-Hispanic blacks is 7 times higher than for whites (1).
- Of active TB cases in 2015 in ethnic minorities, 95% of Asian cases, 75% of Hispanic cases, 42% of black cases, and 21% of white cases were foreign born (1), highlighting the need to screen foreign-born persons for LTBI and treat those with positive screening tests.
- In 2015, 57% of foreign-born persons with TB came from five countries: Mexico (20%), Philippines (13%), India (9%), Vietnam (8%), and China (7%) (1).
- In 2015, 6% of active TB cases in the United States were in HIV-positive individuals. It is the leading cause of death in persons living with HIV (1).

Prevalence

- 4% of the U.S. population has LTBI (~11 million).
- 1/3 of the world's population is estimated to harbor latent TB.

ETIOLOGY AND PATHOPHYSIOLOGY

Mycobacterium tuberculosis, *Mycobacterium bovis*, and *Mycobacterium africanum*

RISK FACTORS

- HIV infection, immunosuppression
- Immigrants (from Asia, Latin America, Pacific Islands, Africa, or areas with high rates of TB), including migrant workers
- Close contact with infected individual
- Institutionalization (e.g., prison, nursing home)
- Use of illicit drugs
- Lower socioeconomic or homeless status
- Health care workers
- Chronic medical disease such as diabetes mellitus (DM), end-stage renal disease, cancer, or silicosis; organ transplant (immunosuppression)
- Persons with fibrotic changes on CXR consistent with previous TB infection
- Recent TB skin test (tuberculin skin test [TST]) converters

- Laboratory personnel working with mycobacteria

GENERAL PREVENTION

Screen for LTBI and treat individuals with positive tests.

COMMONLY ASSOCIATED CONDITIONS

- HIV infection (see "Initial Tests (lab, imaging)")
- Immunosuppression

DIAGNOSIS

HISTORY

LTBI: Assess risk. History of immigration from a high-risk area including those with temporary visas for school or work (Note: TB screening for this type of visa is not required, unlike regulations for those seeking permanent residence in the United States.) (2), history of IV drug use and/or drug treatment, HIV, homelessness, recent incarceration, immunosuppression

PHYSICAL EXAM

No active signs of infection on exam in patients with LTBI

DIFFERENTIAL DIAGNOSIS

Fungal infections; atypical mycobacteria or *Nocardia*

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- CXR to rule out active TB
- No others routinely recommended
- In higher risk patients: liver profile, hepatitis C virus (HCV), and hepatitis B virus (HBV) screening
- HIV test recommended to assess risk for active TB in men who have sex with men or persons with a history of IV drug use
- CT scan of the chest has good sensitivity (rarely needed).

Diagnostic Procedures/Other

- TST: PPD: 5 U (0.1 mL) intermediate-strength intradermal volar forearm.

Measure induration at 48 to 72 hours:

- Positive if induration is
  - >5 mm and patient has HIV infection (or suspected), is immunosuppressed, had recent close TB contact, or has clinical evidence of active or old disease on CXR
  - >10 mm and patient age <4 years or has other risk factors noted earlier
  - >15 mm and patient age >4 years and has no risk factors
- Negative if induration <5 mm on initial test and, if indicated, on second test
- Use the two-step test (administer a second intradermal test 1 to 3 weeks after initial test; measure and interpret as usual) if patient has had no recent PPD and is age >55 years or is a nursing home resident, prison inmate, or health care worker.
- Preferred for children <5 years

- The interferon γ-release assays (IGRA) QuantiFERON-TB and QuantiFERON-TB GOLD; T-SPOT measure the release of interferon by sensitized lymphocytes when exposed to antigens of *M. tuberculosis*. It is unaffected by prior BCG vaccination, requires only one visit, and has improved sensitivity and specificity but is costly (3).
- Special considerations
  - Steroids: false-negative skin test
  - Measles vaccine: may suppress tuberculin activity; simultaneous PPD and measles vaccine recommended; if not simultaneous, defer PPD for 4 to 6 weeks after measles vaccine.
  - The multiple-puncture tine test is not recommended.
  - Do not use history of BCG vaccination to ignore a positive PPD in adults and forego treatment.
  - Disorders that may alter results and give a false-negative skin test:
    - Recent viral infection
    - New (<10 weeks) infection
    - Severe malnutrition; HIV; anergy
    - Age <6 months
    - Overwhelming TB

TREATMENT

GENERAL MEASURES

- Must exclude active TB
- Treatment for LTBI is critical for the control and elimination of TB disease in the United States. LTBI treatment decreases the risk of active TB and decreases risks of potential spread to others.
- Treat LTBI at any age if patient has HIV, has had close TB contact, is a recent converter (<2 years), is an IV drug user, has an abnormal CXR, has a high-risk medical condition, or is in another high-risk group.
- Directly observed therapy (DOT) is recommended if patient adherence is not assured.
  - Use isoniazid (INH) (for 9 months).
  - Acceptable alternative: INH for 6 months
  - Use INH 900 mg and rifapentine 900 mg weekly for 12 weeks.
- Treat LTBI during pregnancy if patient has recent infection or is HIV positive (use INH with pyridoxine and monitor liver enzymes); otherwise, treatment may be postponed until after delivery.
- Consult with public health or infectious disease specialist for suspected INH resistance in HIV patients.
- *Note*: Because of side effects, rifampin and pyrazinamide are less often recommended for LTBI treatment.
- Exclusions: cirrhosis, active hepatitis, history of excessive alcohol consumption

MEDICATION

- INH alone
  - INH-scored tablets: 100 mg, 300 mg, or syrup 10 mg/Ml
    - Daily: adult 300 mg; pediatric 10 to 15 mg/kg (maximum 300 mg)
    - Twice weekly: adult 900 mg; pediatric 20 to 30 mg/kg (maximum 900 mg)
    - Treatment for 9 months; typical completion rates of ≤60%
    - Precautions
      - Follow liver function if the patient has history of alcoholism, HBV,

HCV, or other liver dysfunction or new signs of liver injury.
        - INH: Peripheral neuritis and hypersensitivity are possible. Consider pyridoxine.
- INH and rifapentine
  - Patients >12 years: rifapentine, a rifampin-like drug can be used to treat LTBI. 900 mg weekly (if patient >50 kg) and INH, 15 to 25 mg/kg weekly (rounded to nearest 50 or 100 mg; 900 mg max) for 12 weeks given as direct observation therapy. This new and shorter treatment has increased rates of completion compared with 9 months of INH (82% compared with 69% in one trial), slightly more adverse effects (4.9% vs. 3.7%), and is more costly (4).
    - Contraindications to INH/rifapentine: HIV patients receiving antiretroviral therapy, pregnancy. Rifapentine may cause hyperuricemia and hematuria (4).
- Alternative: rifampin alone
  - Adults 600 mg/day for 4 months; children 10 to 20 mg/kg/day for 6 months (max 600 mg/day). Fewer data exist for efficacy of this regimen but can be considered for contacts of INH-resistant TB or patient with INH contraindications. In one study, the 4-month course increased compliance from 62.6% with INH to 71.6% with rifampin (5).

ADDITIONAL THERAPIES

Pediatric Considerations

- Follow public health recommendations for assessing and treating newborns.
- If mother or household contact has LTBI, skin test all household contacts, and treat all positive PPD.
- If contact has abnormal CXR, separate infant until infectious status is known; if not contagious, monitor infant PPD (6).
- If mother has disease and is possibly contagious, evaluate infant for congenital TB and test for HIV; separate newborn until mother is noninfectious (6).
- Treat suspected congenital TB.
- If no congenital disease, start INH and repeat PPD after 3 to 4 months. If positive, reassess infant and finish 9 months of INH. If PPD is negative and source is noninfectious, stop INH and monitor infant (6).

- BCG vaccine, live-attenuated *M. bovis*: used more commonly in developing countries in children to prevent complications of TB

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Geriatric Considerations

- Before entering a chronic care facility, patients should have a PPD using two-step protocols.
- INH side effects are more pronounced.
- Discharge criteria
  - Activity, as tolerated
  - No isolation required

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- During preventive therapy for LTBI: monthly visits to assess adherence and monitor for hepatitis and neuropathy; if stable, can monitor less frequently
- If patient remains asymptomatic, no need to repeat CXR.
- Check liver enzymes if patient is symptomatic, is HIV positive, has chronic liver disease, uses alcohol, or is pregnant or postpartum and modify drugs as needed.

DIET

Regular. Consider pyridoxine, 10 to 50 mg/day.

PROGNOSIS

- Generally, there are few complications, and treatment is effective if medications are taken as prescribed.
- Retreatment is not necessary.

COMPLICATIONS

Recrudescent TB

SEE ALSO

Tuberculosis; Tuberculosis, Miliary

CODES

ICD10

R76.11 Nonspecific reaction to skin test w/o active tuberculosis

CLINICAL PEARLS

- An estimated 4% of the U.S. population has LTBI. Treatment of LTBI is crucial to the control and elimination of TB disease in the United States.
- Screen foreign-born persons for latent TB and treat those who are positive.
- Screen household contacts of PPD-positive patients.
- History of BCG vaccination, especially >10 years before PPD testing, should not be considered as the cause of a positive PPD. The interferon-γ blood test is unaffected by prior BCG vaccination.
- Treat all HIV-positive patients with LTBI prophylactically.

TYPHOID FEVER

Douglas W. MacPherson, MD, MSc—CTM, FRCPC

BASICS

- A common enteric bacterial disease transmitted by ingestion of contaminated food or water
- Most cases in the United States are imported from endemic areas of South or Southeast Asia and Latin America.

DESCRIPTION

- Typhoid fever is an acute systemic illness in humans caused by *Salmonella typhi*.
  - Classic example of enteric fever caused by *Salmonella* bacterium
- Enteric fevers due to *Salmonella paratyphi* can present in a manner similar to classic typhoid fever.
- Typhoid is endemic in developing nations with poor sanitation. Most cases in North America and other developed nations are acquired after travel to disease-endemic areas.
- Travelers visiting family or friends may be at greater risk of typhoid.
- Mode of transmission is fecal–oral through ingestion of contaminated food (commonly poultry or milk) or water.
- Incubation period varies from 7 to 21 days.
- System(s) affected: gastrointestinal; pulmonary; skin/exocrine
- Synonym(s): typhoid; typhus abdominalis; enteric fever; nervous fever; slow fever

Geriatric Considerations

Disease is more serious in the elderly.

Pediatric Considerations

Disease is more serious in infants but may be milder in children.

EPIDEMIOLOGY

Although typhoid outbreaks have been described in the United States, most cases

are reported in international travelers returning from endemic transmission areas.

- Predominant age: all ages
- Predominant sex: male = female

Incidence

In the United States, 300 to 500 new cases per year

ETIOLOGY AND PATHOPHYSIOLOGY

- Historically, typhoid fever (untreated) occurs in several week-long stages.
- The initial infection is transmitted via the fecal–oral route, with resultant bacteremia and sepsis. Involvement of the bowel wall (Peyer patch) rarely may be associated with bleeding from the bowel or bowel perforation.
- The first stage involves fluctuations in temperature with relative bradycardia (Faget sign). Other symptoms include headache, cough, malaise, epistaxis, and abdominal pain.
- The second stage involves higher fever (with persistent relative bradycardia). Mental status changes are possible (agitation—"nervous fever"). Rose spots appear on the chest and abdomen. In some patients, abdominal pain is common as is constipation or diarrhea (with characteristic malodorous "pea soup" appearance).
- The third week is when most complications occur due to intestinal hemorrhage or encephalitis.
- The final week is characterized by defervescence and recovery.
- A chronic carrier state may occur with *S. typhi* shedding in the stools. Potential person-to-person transmission may occur. In a chronic carrier state, *S. typhi* resides in the biliary tract and gallbladder. Chronic suppressive antimicrobials may clear the carrier state. In extreme cases, cholecystectomy has been performed as an attempt to clear carriage of *S. typhi*.

RISK FACTORS

Consider in patients presenting with fever after tropical travel or exposure to a chronic carrier.

GENERAL PREVENTION

- Food and water precautions help prevent all enteric infections, including typhoid fever.

- Avoid tap water, salad/raw vegetables, unpeeled fruits, and dairy products in tropical travel.
- Avoid undercooked poultry or poultry products left unrefrigerated for prolonged periods.
- Wash hands before and after food preparation.
- For high-risk travel to an endemic area, consider vaccination against typhoid (1)[A].
  - Parenteral ViCPS or capsular polysaccharide typhoid vaccine (Typhim Vi) *or*
  - Ty21a or live oral typhoid vaccine (Vivotif Berna), particularly if traveler will be at prolonged risk (>4 weeks)
- Consider vaccination for workers exposed to *S. typhi* or those with household or intimate exposure to a carrier of *S. typhi*.
- Occupational health and safety precautions, including screening of domestic and commercial food handlers, may be considered in some situations.

DIAGNOSIS

Assess the clinical presentation and exposure history, including travel and known exposures to chronic *S. typhi* carriers.

HISTORY

- Travel history to an endemic region and exposure to contaminated food or water
- Exposure to a chronic *S. typhi* carrier
- Fever, headache
- Malaise
- Abdominal discomfort/bloating/constipation
- Diarrhea (less common)
- Dry cough
- Confusion/lethargy

PHYSICAL EXAM

- Fever
- Relative bradycardia

- Cervical adenopathy
- Conjunctivitis
- Rose spot (transient erythematous maculopapular rash in anterior thorax or upper abdomen)
- Splenomegaly
- Hepatomegaly

DIFFERENTIAL DIAGNOSIS

- Malaria
- "Enteric fever–like" syndrome caused by *Yersinia enterocolitica*, pseudotuberculosis, and *Campylobacter* spp.
- Enteric fever caused by nontyphoid *Salmonella* spp.
- Infectious hepatitis
- Dengue
- Atypical pneumonia
- Infectious mononucleosis
- Subacute bacterial endocarditis
- Tuberculosis
- Brucellosis
- Q fever
- Toxoplasmosis
- Typhus
- Viral infections: Epstein-Barr virus (EBV), cytomegalovirus (CMV), viral hemorrhagic agents

DIAGNOSTIC TESTS & INTERPRETATION

Due to the rarity of enteric fevers/typhoid syndromes in the United States, a high level of clinical suspicion is required.

- Definitive diagnosis is by culture of *S. typhi* from blood or other sterile body fluid.
- Isolation of *S. typhi* in sputum, urine, or stool leads to a presumptive diagnosis.
- Serology is nonspecific and typically not useful.
- If there are multiple negative blood cultures or in patients with prior antibiotic therapy, diagnostic yield is better with bone marrow culture.

- Anemia, leukopenia (neutropenia), thrombocytopenia, or evidence of disseminated intravascular coagulopathy. Elevated liver enzymes are common.
- Have a high clinical suspicion for intestinal perforation, or consider serial plain abdominal films looking for evidence of perforation in ill patients complaining of persistent abdominal tenderness.

Diagnostic Procedures/Other

- Bone marrow aspirate for culture of *S. typhi* is more sensitive than blood cultures but rarely indicated as a primary investigation.
- Bone marrow aspiration may be done for evaluation of a fever of unknown origin.

Test Interpretation

Classically, pathology of the bowel shows mononuclear proliferation involving lymphoid tissue of intestinal tract, especially Peyer patches of the terminal ileum.

TREATMENT

- Treatment of typhoid disease and chronic carrier states must be determined on an individual basis. Factors to be considered include age, public health and occupational health risk (e.g., food handler, chronic care facilities, medical personnel), intolerance to antibiotics, and evidence of biliary tract disease.
- Awareness of emerging drug-resistant *S. typhi* strains and the epidemiology of the patient's exposure help direct primary therapy. Knowledge of local resistance patterns for presumptive treatment or laboratory sensitivity also guide therapy. Fluoroquinolone-resistant *S. typhi* is common in Asia.

GENERAL MEASURES

- Fluid and electrolyte support
- Strict isolation of patient's linen, stool, and urine
- Consider serial plain abdominal films for evidence of perforation, usually in the 3rd to 4th week of illness.
- For hemorrhage: blood transfusion and management of shock

MEDICATION

First Line

- Chloramphenicol: pediatric 50 mg/kg/day PO QID for 2 weeks; adult dose 2 to 3 g per day PO divided q6h for 2 weeks *or*
- Ampicillin: pediatric 100 mg/kg/day (max 2 g) QID PO for 2 weeks; adults 500 mg q6h for 2 weeks *or*
- Ciprofloxacin: 500 mg PO BID for 2 weeks, *indicated in multiple-drug-resistant typhoid*
  - Has been used safely in children; WHO recommends as first line in areas with drug resistance to older first-line antibiotics.
  - Fluoroquinolones may prevent clinical relapse better than chloramphenicol (2)[A].
- Ceftriaxone: pediatric 100 mg/kg/day for 2 weeks; adult dose: 1 to 2 g IV once daily for 2 weeks *or*
- Azithromycin: pediatric 10 to 20 mg/kg (max 1 g) PO daily for 5 to 7 days; adult dose: 1 g PO once followed by 500 mg PO daily for 5 to 7 days
- Chronic carrier state
  - Ampicillin: 4 to 5 g/day plus probenecid 2 g/day QID for 6 weeks (for patients with normal gallbladder function and no evidence of cholelithiasis)
  - Ciprofloxacin: 500 mg PO BID for 4 to 6 weeks is also efficacious. Chloramphenicol resistance has been reported in Mexico, South America, Central America, Southeast Asia, India, Pakistan, Middle East, and Africa.
- Contraindications: Refer to manufacturer's profile.
- Precautions: Rarely, Jarisch-Herxheimer reaction appears after antimicrobial therapy.
- Significant possible interactions: Refer to manufacturer's profile for each drug.

Second Line

- Trimethoprim–sulfamethoxazole one double-strength tablet twice a day for 10 days (Note: Drug resistance is common, local resistance patterns and expert knowledge should guide choice of treatment agent.)
- Furazolidone: 7.5 mg/kg/day PO for 10 days; in uncomplicated multidrug-resistant typhoid; safe in children; efficacy >85% cure

Pregnancy Considerations

Ciprofloxacin therapy is relatively contraindicated in children and in pregnant patients.

ISSUES FOR REFERRAL

Complications of sepsis, bowel perforation

SURGERY/OTHER PROCEDURES

- Complications: bowel perforation
- Cholecystectomy may be warranted in carriers with cholelithiasis, relapse after therapy, or intolerance to antimicrobial therapy.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Inpatient if acutely ill
- Outpatient for less ill patient or for carrier
- Observe enteric precautions.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Bed rest initially, then activity as tolerated

Patient Monitoring

See "General Measures."

DIET

NPO if abdominal symptoms are severe. With improvement, begin normal low-residue diet, with high-calorie supplementation if malnourished.

PATIENT EDUCATION

- Discuss chronic carrier state and its complications.
- For family members, travelers, or workers at risk, educate about food/water hygiene and provide vaccination.
- Educate patients that the typhoid vaccines do not protect against *S. paratyphi* infection.
- Typhoid vaccines protect 50–80% of recipients (not 100%) with diminishing

effectiveness over 2 to 4 years.
- CDC patient handout: http://www.cdc.gov/vaccines/hcp/vis/vis-statements/typhoid.html

PROGNOSIS

Overall prognosis is good with therapy, <2% mortality rate, 15% relapse rate with some antibiotic treatments, and 3% bowel perforation.

COMPLICATIONS

- Intestinal hemorrhage and perforation in distal ileum
- Patients (up to 3%) may become chronic carriers-persistent stool excretor of *S. typhi* for >1 year.
- Seeding of the biliary tract may become a focus for relapse of typhoid fever: most common in females and older patients (>50 years of age)
- Osteomyelitis is more common in patients with sickle cell anemia, systemic lupus erythematosus, and hematologic neoplasms, as well as in immunosuppressed hosts.
- Endovascular infection in the elderly and in patients with a history of bypass operation or aneurysm
- Rarely, endocarditis or meningitis

CODES

ICD10

- A01.00 Typhoid fever, unspecified
- Z22.0 Carrier of typhoid
- A01.03 Typhoid pneumonia

CLINICAL PEARLS

- Consider typhoid (along with malaria, dengue, and other travel-associated infections) in febrile travelers returning from endemic areas such as Latin America, sub-Saharan Africa, or South Asia.
- Routine blood cultures detect *S. typhi* but may be negative if antibiotics are administered prior to testing.
- A history or documentation of vaccination against *S. typhi* does not exclude the diagnosis of typhoid fever.

TYPHUS FEVERS

Douglas W. MacPherson, MD, MSc—CTM, FRCPC

BASICS

Typhus is an infectious disease syndrome caused by several rickettsial bacterial organisms resulting in acute, chronic, and recurrent disease (1)[C].

DESCRIPTION

- Acute infection caused by three species of *Rickettsia*
  - Epidemic typhus: human-to-human transmission by body louse; primarily in setting of refugee camps, war, famine, and disaster. Recurrent disease occurs years after initial infection and can be a source of human outbreak. Flying squirrels are a reservoir.
  - Endemic (murine) typhus: spread to humans by rat flea bite
  - Scrub typhus: infection and infestation of chiggers and of rodents to humans by the chigger; primarily in Asia and western Pacific areas
- System(s) affected: endocrine/metabolic; hematologic/lymphatic/immunologic; pulmonary; skin/exocrine
- Synonym(s): louse-borne typhus; Brill-Zinsser disease; murine typhus

EPIDEMIOLOGY

- Epidemic and endemic typhus: rare in the United States (outside of South Texas)
- Scrub typhus: travelers returning from endemic areas only (rare)

Incidence

Endemic typhus: <100 cases annually, primarily in states around the Gulf of Mexico, especially South Texas; underreporting suspected

ETIOLOGY AND PATHOPHYSIOLOGY

- Epidemic typhus by *Rickettsia prowazekii*
- Endemic typhus by *Rickettsia typhi*
- Scrub typhus by *Rickettsia tsutsugamushi*

RISK FACTORS

- Vector exposure
- Travel to endemic countries

Geriatric Considerations

Elderly may have more severe disease.

GENERAL PREVENTION

Vector control:

- Scrub typhus: Wear protective clothing and use insect repellents.
- Endemic typhus: Practice ectoparasite and rodent control.
- Epidemic typhus: delousing and cleaning of clothing; vaccine for those at high risk of exposure (typhus vaccine production has been discontinued in the United States)

DIAGNOSIS

Typhus syndromes are rare in the United States. A high level of clinical suspicion is necessary.

HISTORY

Travel or other risk exposure

- Fever, chills
- Intractable headache
- Myalgias, malaise
- Cough, rash, ocular pain

PHYSICAL EXAM

- General
  - Fever
  - Relative bradycardia (scrub typhus)
- Epidemic typhus
  - Incubation period ~1 week
  - Macular or maculopapular rash beginning on trunk ~5th day of illness
  - Nonproductive cough
  - Pulmonary infiltrates

- Endemic typhus
  - Incubation period 1 to 2 weeks
  - Macular or maculopapular rash beginning on trunk 3rd to 5th day of illness
- Scrub typhus
  - Incubation period 1 to 3 weeks
  - Eschar at bite site
  - Regional lymphadenopathy
  - Generalized lymphadenopathy
  - Splenomegaly
  - Macular or maculopapular rash beginning on trunk approximately 5th day of illness
  - Relative bradycardia early in disease
  - Ocular pain
  - Conjunctival injection

DIFFERENTIAL DIAGNOSIS

- Other rickettsial disease: Rocky Mountain spotted fever; ehrlichiosis; Mediterranean spotted fever (boutonneuse fever) (*Rickettsia conorii*)
- Bacterial meningitis; meningococcemia
- Measles, rubella
- Toxoplasmosis
- Leptospirosis
- Typhoid fever
- Dengue, malaria
- Relapsing fever
- Secondary syphilis
- Viral syndromes: mononucleosis, acute retroviral syndrome

DIAGNOSTIC TESTS & INTERPRETATION

- Specific serologies with rising antibody titer
- If suspected, isolate *Rickettsia* in qualified laboratory to minimize the risk of laboratory-acquired infection.
- CDC Rickettsial Zoonoses Branch 404-639-1075.

Initial Tests (lab, imaging)

- CBC often normal
- Weil-Felix serologic reaction may be positive; test value hampered by low sensitivity and nonspecificity; epidemic and endemic typhus, 4-fold titer rise or titer >1/320 to OX-19; scrub typhus, 4-fold rise in titer to OX-K
- Hyponatremia in severe cases
- Hypoalbuminemia in severe cases
- Recent antibiotic exposure may alter lab results.

Test Interpretation

Diffuse vasculitis on skin biopsy

TREATMENT

Initiate treatment based on epidemiologic risk and clinical presentation.

GENERAL MEASURES

- Skin and mouth care
- Supportive care for the severely ill, directed at complications

MEDICATION

First Line

- Begin treatment when diagnosis is likely and continue until clinically improved and the patient is afebrile for at least 48 hours; usual course is 5 to 7 days.
- Children ≥8 years of age and adults
  - Doxycycline IV/PO: adults 100 mg q12h, children ≤45 kg: 5 mg/kg/day divided twice daily (max of 200 mg/day); >45 kg: adult dosing
  - Children ≤8 years of age: Risk of dental staining from tetracyclines is minimal with short courses of therapy.
  - Tetracycline: 25 mg/kg PO initially, then 25 mg/kg/day in equally divided doses q6h
- Children ≤8 years of age, pregnant women, or if typhoid fever is suspected
  - Chloramphenicol: 50 mg/kg PO initially, then 50 mg/kg/day in equally divided doses q6h
  - If severely ill, chloramphenicol sodium succinate: 20 mg/kg IV initially,

infused over 30 to 45 minutes, then 50 mg/kg/day infused in equally divided doses q6h until orally tolerable
  - Azithromycin, fluoroquinolones, and rifampin may be alternatives depending on the clinical scenario.
- Precautions: Refer to the manufacturer's profile for each drug.
- Significant possible interactions: Refer to the manufacturer's profile for each drug.

Second Line

- Doxycycline: single oral dose of 100 or 200 mg orally for those in refugee camps, victims of disasters, or in the presence of limited medical services
- Isolated reports indicate that erythromycin and ciprofloxacin are effective.
- Azithromycin 1,000 mg orally once a day for 3-day course is effective for scrub typhus; better tolerated than doxycycline but more expensive
- Rifampin may be effective in areas where scrub typhus responds poorly to standard antirickettsial drugs.

ISSUES FOR REFERRAL

Infectious disease consultation is recommended. Contact CDC and local public health authorities.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Outpatient care unless severely ill
- Severely ill or constitutionally unstable (e.g., shock)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Admit severely ill patients.
- If treated as an outpatient, ensure regular follow-up to assess clinical improvement and resolution.

DIET

As tolerated

PATIENT EDUCATION

Travel advice (minimize exposure risks, vector avoidance, vaccination as appropriate)

PROGNOSIS

- Recovery is expected with prompt treatment.
- Relapses may follow treatment, especially if initiated within 48 hours of onset (this is *not* an indication to delay treatment). Treat relapses the same as primary disease.
- Without treatment, the mortality rate of typhus is 40–60% for epidemic, 1–2% for endemic, and up to 30% for scrub disease.
- Mortality is higher among the elderly.

COMPLICATIONS

Organ-specific complications (particularly in the second week of illness): azotemia, meningoencephalitis, seizures, delirium, coma, myocardial failure, hyponatremia, hypoalbuminemia, hypovolemia, shock, and death

CODES

ICD10

- A75.9 Typhus fever, unspecified
- A75.0 Epidemic louse-borne typhus fever d/t Rickettsia prowazekii
- A75.2 Typhus fever due to Rickettsia typhi

CLINICAL PEARLS

- Consider typhus (along with malaria and dengue) in febrile travelers returning from endemic areas.
- Rickettsial infections typically present within 2 to 14 days. Febrile illnesses presenting with onset >18 days after travel are unlikely to be rickettsial.
- Routine blood cultures do not detect *Rickettsia*.
- Prior vaccination does not exclude the diagnosis of typhus.

ULCER, APHTHOUS

Jay A. Brieler, MD • Mattie M. White, MD

BASICS

DESCRIPTION

- Self-limited, painful ulcerations of the nonkeratinized oral mucosa, which are often recurrent (1)
- Synonyms: canker sores; aphthae; aphthous stomatitis
  - Comes from *aphth* meaning “ulcer” in Greek; first used by Hippocrates between 460 and 370 BC to categorize oral disease.
- Categorization
  - Minor (simple) aphthous ulcers (2)
    - Usually <10 mm in diameter
    - Self-limited, healing within 4 to 14 days
    - Rarely affect the roof of the mouth
    - Nonscarring
  - Major (complex) aphthous ulcers (2)
    - Usually >10 mm in diameter
    - Can affect the roof of the mouth
    - May take weeks to months to heal
    - Generally more painful than minor aphthous ulcers
    - May cause scarring
  - Herpetiform ulcers (2)
    - Usually 2 to 3 mm in diameter, may coalesce to form larger ulcerations
    - Unrelated to viral-caused herpetic stomatitis
    - Occur in small clusters numbering 10s to 100s, lasting 1 to 4 weeks
    - Generally more painful than minor aphthous ulcers
    - May cause scarring

EPIDEMIOLOGY

- Most frequent chronic disease of the oral cavity, affecting 5–25% of the population (3)
- More common in patients between 10 and 40 years of age, women,

Caucasians, nonsmokers, and those of higher socioeconomic status (3)
- Less frequent with advancing age (1)
- Minor aphthous ulcers
  - Most common: 70–85% of all aphthae
- Major aphthous ulcers
  - 10–15% of all aphthae
- Herpetiform
  - Least common: 5–10% of all aphthae

Prevalence

Lifetime prevalence of 5–60% (3)

ETIOLOGY AND PATHOPHYSIOLOGY

Likely multifactorial; association with stress-induced rise in salivary cortisol, multiple HLA antigens, cell-mediated immunity; exact etiology unknown (1)

RISK FACTORS

- Genetic factors: 40% of patients with recurrent aphthous stomatitis (RAS) have a family history. Most genetic associations with HLA antigen subtypes (1)
- Local trauma: sharp teeth, dental treatments, or mucosal injury secondary to toothbrushing
- Sodium lauryl sulfate-containing toothpaste
- Increased stress and anxiety
- Nutritional deficiencies: iron, zinc, vitamin B complex, and folate (4)[B].
- Homocysteinemia (4)[B]
- Immunodeficiency
- Recent cessation of tobacco use
- Food sensitivity: to benzoic acid/cinnamaldehyde
- Medications
  - NSAIDs
  - β-Blockers
  - Alendronate
  - Methotrexate
  - ACE inhibitors (1)

- Neutropenia
- Anemia
- Endocrine alterations (i.e., menstrual cycle) (2)
- *Helicobacter pylori* infection
- Epstein-Barr virus (1)

DIAGNOSIS

Diagnosis is made by history and clinical presentation. Lab work is rarely helpful to diagnose aphthous ulcers (2)[A].

HISTORY

- May experience prodrome of burning sensation of oral mucosa 2 to 48 hours prior to appearance of ulcers.
- Patients typically complain of oral ulcerations, which are painful and exacerbated by movement of the mouth. Exacerbation may also be reported with certain foods (hot, spicy, acidic, or carbonated foods or drinks) (2).
- Ask about ulcerative lesions of other anatomic areas, family history, or prior history of aphthous ulcers (2).

PHYSICAL EXAM

- Round or ovoid ulcerations generally <10 mm in size. Covered with a grayish-white pseudomembrane surrounded by an erythematous halo (3)[A]
- Ulcers are typically found in the buccal or lip mucosa, ventral tongue, soft palate, or oral vestibule. Rarely on the roof of the mouth or lips
- Evaluate for signs of secondary infection: elevated temperature, increased surrounding edema, or pus drainage

DIFFERENTIAL DIAGNOSIS

- Oral trauma
  - Biting
  - Dentures
- Infection
  - Herpes virus (herpetic stomatitis): vesicular lesions on keratinized tissue (dorsal tongue, vermillion border). Generally not present on mucosa (5)[C]

  - HIV: Ulcerations have lengthened healing time and tend to be more painful (5)[C].
- Mucocutaneous disease; especially if chronic or nonhealing
  - Lichen planus
  - Pemphigus
- Malignancy: Investigate and closely monitor nonhealing lesions, especially those with leukoplakia or ipsilateral cervical lymphadenopathy.
- Important to evaluate for underlying systemic disease, causing aphthous-like ulcerations
  - Particularly in adults with their first episode or lesions elsewhere (3)[A]
  - Behçet syndrome: autoimmune systemic vasculitis usually involving mucous membranes
    - Genital and oral ulceration
    - Uveitis
  - Reiter syndrome: reactive arthritis, preceded by infection, usually of the genital tract (2)[A]
    - Uveitis
    - Urethritis
    - HLA-B27–associated arthritis
  - Sweet syndrome: acute neutrophilic dermatitis (5)[C]
    - Fever, sudden onset
    - Erythematous skin plaques/papules, well-demarcated
    - Leukocytosis
    - 50% of patients have an associated malignancy
    - Most often in middle-aged females
  - Inflammatory bowel disease (IBD): Crohn disease, ulcerative colitis
    - 20–50% of patients with Crohn disease experience recurrent oral ulcers (5)[A].
    - Bloody or persistent diarrhea
    - Weight loss
  - PFAPA syndrome (1)[C]
    - Periodic fevers, aphthous ulcers, pharyngitis, and adenitis
    - Tonsillectomy may be curative.
  - Cyclic neutropenia (1)[C]

- Recurrent fevers associated with infections, occasionally occurring intraorally.
- Begins in childhood

– Systemic lupus erythematosus (SLE): autoimmune vascular collagen disease
- Oral lesions have great variability, including recurrent ulceration.

– Gluten-sensitive enteropathy (celiac disease)
- Weight loss and signs of malabsorption
- Bloating and diarrhea

DIAGNOSTIC TESTS & INTERPRETATION

May consider complete blood count, zinc, folic acid, ferritin, vitamin B_1, B_2, B_6, and B_{12} to evaluate for systemic causes in severe or recurrent cases (1)[A]

Follow-Up Tests & Special Considerations

- HIV is associated with increased amount of ulcers and increased healing time.
- Biopsy and viral cultures for nonhealing ulcers or atypical presentations
- Rheumatologic serology if underlying systemic disease is suspected.

TREATMENT

GENERAL MEASURES

- Management is symptomatic. Goal is to reduce inflammation and relieve pain.
- Avoid potentially irritating food or drink:
  – Spicy, acidic, hot
  – Carbonated beverages
  – Abrasive/hard foods (i.e., chips, nuts, etc.)
- Behavior modification to reduce dental trauma with toothbrush or bruxism

MEDICATION

In general, the goals of treatment depend on the extent of ulceration and frequency of outbreaks.

First Line

- Topical corticosteroids (to improve healing time and symptoms) (2)[A]

- Adverse effects: may increase risk of oral candidiasis (more likely with higher potency formulations)
- Topical steroid preparations
  - Triamcinolone 0.1% dental paste
    - Apply sparingly to ulcers three times daily for up to 2 weeks or until ulcer resolution.
  - Fluocinonide 0.05% gel or ointment
    - Apply sparingly to ulcer four times daily for up to 2 weeks or until ulcer resolution.
  - Dexamethasone 5 mg/5 mL elixir
    - Rinse for 3 minutes and spit four times daily until ulcer resolution.

- Topical anesthetics (to reduce symptoms only) (2)[A]
  - Adverse effects: may cause initial stinging
  - Preparations
    - Lidocaine 2% gel
      - Apply four times daily or prior to eating as needed for pain, for up to 2 weeks or until ulcer resolution.
- Antimicrobial mouth rinses (improve healing time, decrease pain, and may prevent recurrence)
  - Preparations
    - Chlorhexidine aqueous mouthwash 0.12% or 0.2%
      - Use four times daily for up to several months.
      - May cause superficial tooth staining
- Topical immunomodulators (improves healing time, reduces symptoms, and prevents recurrence when used in prodromic phase) (2)[A]
  - Adverse effects: may cause stinging sensation
  - Preparation
    - Amlexanox 5% oral paste
      - Apply to ulcers four times daily for up to 2 weeks or until ulcer resolution.

Second Line

- Systemic corticosteroids—rescue therapy in acute, severe, recurrent outbreaks (2,3)[A]

  - Prednisone 0.75 mg/kg/day, tapered by 0.25 mg/kg/day every 2 weeks (1) [A]
- Colchicine, pentoxifylline, thalidomide, and dapsone have been used with variable success but should be used with caution due to side effects (2,3)[A].

ISSUES FOR REFERRAL

Otolaryngology or dental referral if lesions have not resolved as expected.

ADDITIONAL THERAPIES

- Vitamin B_{12} supplementation appeared to decrease burden of outbreaks and recurrence, independent of preexisting deficiency in one small study. Multivitamins have not been shown to be effective (1)[B].
- *H. pylori* eradication has been associated with lower number of aphthous lesions (1)[B].

SURGERY/OTHER PROCEDURES

Chemical cautery with silver nitrate (reduces ulcer pain but not healing time)
Ozone application is an emerging therapy that decreases pain and improves healing time in small studies.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Some small cohort studies show clinical improvement with minimal side effects of several herbal and alternative treatments (3)[A].
- *Glycyrrhiza* (licorice)
- *Myrtus communis* (myrtle)
- Bee propolis (3)[A]

CODES

ICD10

K12.0 Recurrent oral aphthae

CLINICAL PEARLS

- Aphthous ulcers are the most common chronic disease of the oral cavity.
- Most cases are mild, self-limited episodes.
- Appropriate treatment should be aimed at symptom control and promotion of healing.
- Nonhealing ulcers, extra-oral involvement, and sudden onset in adulthood require additional workup.

ULCERATIVE COLITIS

George Clement, MD • Elise Leisinger, DO

BASICS

DESCRIPTION

- Chronic relapsing and remitting inflammatory disease of the bowel causing recurrent episodes of diarrhea that is often bloody and accompanied by abdominal pain, incontinence, fever, and weight loss
- Marked by inflammatory colonic mucosal changes
- Colonic involvement is universal, but may be accompanied by large joint arthritis, ocular inflammation, skin lesions, biliary disease, liver disease, thromboembolic disease, and (rarely) pulmonary complications

EPIDEMIOLOGY

Incidence

- North America: 19.2 per 100,000 person-years (1)
- Europe: 24.3 per 100,000 person-years (1)
- Asia and Middle East: 6.3 per 100,000 person-years (1)

Prevalence

- North America: 249 per 100,000 persons (1)
- Europe: 505 per 100,000 persons (1)

Pregnancy Considerations

- Increased risk of preterm delivery and small for gestational age birth
- 30% with inactive disease relapse in pregnancy
- Management with gastroenterologist and/or maternal–fetal medicine specialist/obstetrician is recommended.

ETIOLOGY AND PATHOPHYSIOLOGY

- Idiopathic; hypothesized association with autoimmune dysfunction, genetic predisposition, diet, and colonic microbiome
- Almost universally involves terminal colon, >95% of patients have rectal involvement, 50% have disease limited to rectum and sigmoid; 20% have

pancolitis.

Genetics

Moderate heritability. Specific genetic markers have not been identified.

RISK FACTORS

- Age: variable, peak incidence among ages 15 to 40 years
- First-degree relative with ulcerative colitis (UC)
- Theorized risk factors include disruption of colonic microbiome by diet or infection; dietary factors (Western diet in particular), antibiotic use, lack of breastfeeding in infant, obesity, and NSAID use.

GENERAL PREVENTION

No known preventive measures

Pediatric Considerations

- Breastfeeding may protect against pediatric inflammatory bowel disease (IBD).
- UC more likely pancolonic at onset and shorter time from diagnosis to colectomy (median 11.1 years)

COMMONLY ASSOCIATED CONDITIONS

- Arthritis: large joint, sacroiliitis, ankylosing spondylitis
- Pyoderma gangrenosum (rare)
- Erythema nodosum (common)
- Aphthous ulcers
- Episcleritis and uveitis (rare)
- Autoimmune liver disease (rare)
- Fatty liver (common)
- Liver cirrhosis (rare)
- Primary sclerosing cholangitis (rare)
- Bile duct carcinoma (rare)
- Thromboembolic disease (rare)
- Colon cancer (rare)
- Anemia (rare)
- Pulmonary diseases (very rare)

DIAGNOSIS

HISTORY

- Frequent diarrhea, may be bloody or include mucus
- Frequent, small bowel movements, associated with tenesmus, colicky abdominal pain, urgency, and fecal incontinence
- Onset is gradual and progressive over weeks.
- Episodes are sometimes accompanied by fever, weight loss, fatigue, and anemia.
- Predominant age of onset: 15 to 40 years; smaller peak in ages 50 to 80 years

PHYSICAL EXAM

- Often normal
- Abdominal tenderness
- Presence of blood on rectal exam
- In severe disease: fever, hypotension, tachycardia, pallor, loss of subcutaneous fat, muscle atrophy, peripheral edema

DIFFERENTIAL DIAGNOSIS

- Crohn disease
- Infectious colitis: bacterial, parasitic, or viral (cytomegalovirus [CMV])
- Diverticular colitis
- Diversion colitis in patients with prior bowel surgery
- Medication-induced colitis
- Radiation colitis
- Graft versus host disease
- Celiac disease

DIAGNOSTIC TESTS & INTERPRETATION

- Stool examination to rule out infectious cause.
- Sigmoidoscopy or colonoscopy with biopsy to confirm colitis.

Initial Tests (lab, imaging)

- CBC: leukocytosis and anemia support diagnosis
- BMP: urea and electrolyte abnormalities; hypokalemia supports diagnosis
- LFTs: liver function abnormalities; low albumin indicates severe disease (2)

- ESR or CRP elevation supports diagnosis and can help define severity (2)
- Ferritin and transferrin if anemic to determine iron deficiency versus chronic disease
- Vitamin B_{12} and folate levels
- Fecal calprotectin: indicates colonic inflammation (3)
- Stool studies to rule out infectious cause: *Clostridium difficile* toxin (four samples), stool cultures, shiga toxin, ova and parasite microscopy, Giardia antigen
- STI testing to rule out proctitis, particularly in MSM: chlamydia, gonorrhea, HSV, syphilis (3)
- Perinuclear antineutrophil cytoplasmic antibody (pANCA) and anti-Saccharomyces *cerevisiae* antibodies (ASCA) are commonly present in patients with UC, but testing for these is not currently recommended for diagnosis (3).
- Abdominal x-ray to exclude dangerous colonic dilation and assess disease severity (3)

Diagnostic Procedures/Other

- Colonoscopy with at least two biopsies from each of five sites along the entire colon is an initial diagnostic step (3).
- Complete colonoscopy in severe UC may be contraindicated due to risk of perforation or precipitation of toxic megacolon (3).

Test Interpretation

- Endoscopic findings that support UC include mucosal engorgement with vascular markings, mucosal erythema, and mucosal granularity. Affected areas will extend proximally and continuously.
- Histologic findings that support UC include mucosal separation, distortion, and atrophy of the crypts, chronic inflammatory cells in lamina propria, lymphocytes and plasma cells in crypt bases (4)[C]
- If only rectal biopsy, villous mucosal architecture and Paneth cells metaplasia support UC (4)[C]
- Mild ileal inflammation (“backwash ileitis”) may be present in UC (4)[C].

TREATMENT

Treatment strategies are determined by functional status, degree of colonic involvement, course of illness, frequency of relapses, extraintestinal manifestations, response to prior treatments, and side effect profile.

MEDICATION

First Line

- Proctitis/distal colitis with mild or moderate severity: 5-ASA (e.g., mesalamine 1g/day) suppository; 5-ASA foam enemas are an alternative but less effective (5)[C].
- Left-sided UC with mild to moderate severity: topical 5-ASA (e.g., Mesalamine 1 g/day) PLUS >2 g/day oral mesalamine (5)[C]
- Left-sided severe UC: hospital admission and systemic steroids (e.g., prednisone 40 to 60 mg/day) in addition to mesalamine/5-ASA (5)[C]
- Extensive UC of mild to moderate severity: oral sulfasalazine titrated up to 4 to 6 g/day OR a combination of topical and oral 5-ASA (above) (5)[C]
- Severe UC: necessitates hospitalization for intensive treatment and surveillance for complications; IV steroids (methylprednisolone 60 mg/day or hydrocortisone 400 mg/day) with or without 2 to 6 g/day oral mesalamine (5) [C]

Second Line

- Proctitis/distal colitis with mild to moderate severity: first-line therapy PLUS 2 to 6 g/day oral mesalamine. Topical corticosteroids (budesonide 2 to 8 mg/day or hydrocortisone 100 mg/day) may be added (5)[C].
- Left-sided UC with mild to moderate severity: first-line therapy PLUS topical corticosteroids (budesonide 2 to 8 mg/day or hydrocortisone 100 mg/day) may be added. Persistent rectal bleeding despite this regimen can be treated with systemic prednisone at 40 to 60 g/day with a prolonged taper (5)[C].
- Left-sided severe UC: first-line therapy PLUS prednisone at 40 to 60 g/day and long taper; if refractory, azathioprine 2.5 mg/kg/day OR 6-mercaptopurine (1.5 mg/kg/day) for induction and maintenance (5)[C]
- Severe UC: TNF-α-blocker IFX (adalimumab, Infliximab, golimumab) combined with methotrexate or thiopurine. Patients with severe UC will often

need timely colectomy (5)[C].

- Infliximab adult dose: 5 mg/kg IV at weeks 0, 2, and 6 for induction and then maintenance of 5 mg/kg IV is given every 8 weeks.
- Adalimumab: dose: 160 mg SC (given as four injections on day one or two injections daily over 2 consecutive days; limit injections to 40 mg per injection); 2nd dose 2 weeks later: 80 mg, and maintenance: 40 mg every other week (6)[C]
- Other second-line therapies, particularly in refractory disease, include CsA 4 mg/kg/day and tacrolimus 0.1 to 0.2 mg/kg/day PO or 0.01 to 0.02 mg/kg/day IV. Trough concentrations with tacrolimus should be 10 to 15 ng/mL.
- TNF-α-blockers can help maintain remission in steroid-dependent patients with severe UC.
- Immunosuppressive therapy increases risk of opportunistic infections. Chronic steroid use can cause adrenal suppression gastrointestinal bleeding, heart disease, osteoporosis, thinning of skin, and compromised vascular wall integrity. Infusion of biologics carries the risk of anaphylactic reactions during treatment.

Pediatric Considerations

Pediatric growth and development can be affected due to malabsorption.

SURGERY/OTHER PROCEDURES

- Surgery is indicated for medically refractory disease (particularly with high-dose steroids).
- Emergent surgery (typically total or subtotal abdominal colectomy with end ileostomy) for massive hemorrhage, perforation, and toxic dilatation
- Total colectomy with ileostomy is *curative*.
- Total proctocolectomy with ileal pouch anal anastomosis (IPAA) is the most common surgery and an appropriate alternative to ileostomy. Common complications include pouchitis (50%) and need for reoperation in up to 30% (4)[C].

COMPLEMENTARY & ALTERNATIVE MEDICINE

- There is ongoing research into the role of probiotics, dietary changes, and fecal microbiota transplant as treatment for UC. The current evidence is

insufficient to support the efficacy of any particular alternative therapy for achieving or maintaining remission.
- Tobacco cessation is associated with 65% reduction in relapse (3)[C].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Admission for UC or its complications warrants gastroenterology consultation.
- Severe UC may require emergent surgical intervention. Consultation with surgery is indicated.
- Imaging studies help assess disease activity and colon size.
- Initiate IV corticosteroids and rule out infectious etiologies (*C. difficile*, CMV, shigella/amoeba)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Regular surveillance colonoscopy in patients with prolonged (8 to 10 years) active disease (4)
- Initiate annual surveillance immediately in patients with primary sclerosing cholangitis.
- Annual LFTs and cholangiography for cholestasis
- Annual BUN/creatinine for patients on long-term mesalamine

Pediatric Considerations

Cumulative risk of cancer increases with duration of disease-ensure regular surveillance

DIET

- NPO during acute exacerbations
- There are otherwise no specific dietary recommendations. Dietary research is ongoing.

PATIENT EDUCATION

Crohn and Colitis Foundation of America (CCFA): http://www.ccfa.org/

PROGNOSIS

- Chronic disease with variable severity and rate of recurrence
- Variable; mortality for initial attack is ~5%; 75–85% experience relapse; up to 20% require colectomy.
- Colon cancer risk is the single most important factor affecting long-term prognosis.
- Left-sided colitis and ulcerative proctitis have favorable prognoses with probable normal lifespan.

Geriatric Considerations

- Increased mortality if first presentation occurs after 60 years of age.
- Consider lower medication dosages and slower titration due to risks of polypharmacy.

COMPLICATIONS

- Perforation: Treat toxic megacolon with prompt surgery. Limit colonoscopies in severe disease.
- Obstruction
- Anemia
- Fulminant colitis
- Toxic megacolon
- Liver disease
- Stricture formation
- Osteoporosis
- Colorectal cancer

SEE ALSO

Algorithm: Hematemesis (Bleeding, Upper Gastrointestinal)

CODES

ICD10

- K51.90 Ulcerative colitis, unspecified, without complications
- K51.919 Ulcerative colitis, unspecified with unspecified complications
- K51.80 Other ulcerative colitis without complications

CLINICAL PEARLS

- Diffuse, uninterrupted colonic mucosal inflammation
- Hallmark symptom is bloody diarrhea.
- Annual or biannual surveillance colonoscopy after 8 to 10 years of colitis due to increased risk of colorectal cancer.

URETHRITIS

Patrick L. McCurdy, PA-C, MS, MBA • Matthew E. Bryant, MD

BASICS

DESCRIPTION

- Inflammation of the urethra
- Common manifestation of sexually transmitted infection
- Frequently associated with dysuria, pruritus, and/or urethral discharge; classified as gonococcal (caused by *Neisseria gonorrhoeae*) and nongonococcal (caused by other bacteria, or less commonly autoimmune disorders [Reiter syndrome], trauma, or chemical irritation)

EPIDEMIOLOGY

Incidence

- In 2014, there were >350,000 reported cases of gonorrhea, with a rate of 110.7 cases per 100,000 population (5.1% increase since 2013) (1).
- In 2014, there were >1.4 million reported cases of *Chlamydia trachomatis* infection, or 456.1 cases per 100,000 population (2.8% increase since 2013) (1).
- Rate of chlamydial infection in U.S. women was more than twice that of men, reflecting higher rates of screening (1).
- Highest incidences of gonorrhea and chlamydia among young men and women, ages 15 to 24 years (1)
- Chlamydial infections are 10 times more likely in young adult women than gonococcal infections (1).

ETIOLOGY AND PATHOPHYSIOLOGY

- Most common cause is infection via sexual transmission of *N. gonorrhoeae*, a gram-negative diplococcus.
- *N. gonorrhoeae* interacts with nonciliated epithelial cells → cellular invasion → inflammation, neutrophil production, bacterial cell phagocytosis (2)
- Sexually transmitted *C. trachomatis* infection is the most common cause of

nongonococcal urethritis.

- Other established pathogens:
  - *Mycoplasma genitalium*
  - *Trichomonas vaginalis*
  - *Ureaplasma urealyticum*
  - Herpes simplex virus (rare)
  - Adenovirus (rare)
- Noninfectious causes (generally rare)
  - Chemical irritants (i.e., soaps, shampoos, douches, spermicides)
  - Foreign bodies
  - Urethral instrumentation

RISK FACTORS

- Age 15 to 24 years
- New sex partner
- One or more sex partner(s)
- History of or coexisting STI
- Sex partner with concurrent partner(s)
- Inconsistent condom use outside of a mutually monogamous relationship
- Exchanging sex for money or drugs
- Member of population with increased prevalence of infection, including incarcerated populations, military recruits, black and Latino persons

GENERAL PREVENTION

- Use of male condoms, female condoms, or cervical diaphragms
- Abstinence or reduction in the number of sex partners
- Behavioral counseling

COMMONLY ASSOCIATED CONDITIONS

ALERT

Annual chlamydia and gonorrhea screening is recommended for all sexually active women <25 years, women >25 years with risk factors, and all men who have sex with men (3).

DIAGNOSIS

- Chief complaint
  - Urethral discharge (mucopurulent suggestive of *N. gonorrhoeae*)
  - Dysuria
  - Erythema of the urethral meatus
  - Symptom onset 2 to 8 days following exposure
- History
  - Sexual history, including condom use, number of partners, sexual behaviors
  - Previous STIs
  - Substance abuse
  - Recent travel
  - Symptoms indicative of complications or additional sites of infection (i.e., men: testicular pain and swelling, anal itching, rectal pain or bleeding; women: lower abdominal pain, dyspareunia, irregular vaginal bleeding)
- Male GU exam (possible findings)
  - Urethral discharge
  - Meatal erythema
  - Testicular tenderness
  - Palpate scrotum to check for epididymitis or orchitis.
  - Assess for ulcers.
  - Assess for inguinal lymphadenopathy.
- Female GU exam (possible findings)
  - Vaginal discharge
  - Endocervical discharge, hyperemia, and/or friability

Pediatric Considerations

Pediatric infections with gonorrhea and chlamydia after the neonatal period strongly suggest sexual contact. If indicated, investigations should be initiated promptly (3).

DIFFERENTIAL DIAGNOSIS

- Other genitourinary tract diseases
  - Cystitis/urinary tract infection
  - Epididymitis

  - Prostatitis
  - PID
  - Pyelonephritis
- Vaginal atrophy, especially in postmenopausal women
- Stevens-Johnson syndrome
- Reiter syndrome: uveitis, urethritis, arthritis
- Wegener granulomatosis

DIAGNOSTIC TESTS & INTERPRETATION

ALERT

Health care providers are required to report all gonorrhea and chlamydia infections in accordance with local and state requirements.

Initial Tests (lab, imaging)

- Gram-stain diagnosis of urethritis if: urethral secretions with ≥2 WBC per oil immersion field, mucopurulent or purulent discharge, or first void urine sediment with ≥10 WBC per high-power field (hpf) (3)
- Gonorrhea
  - Nucleic acid amplification test (NAAT): in men: first void urine preferred (90–100% sensitivity, 97–100% specificity for gonorrhea); in women: vaginal swab preferred (patient or clinician collected), end cervical swab acceptable, first void urine may detect 10% fewer infections (3)[A]
  - Culture: traditional gold standard—most commonly used in cases of suspected treatment resistance (3)
- Chlamydia
  - NAAT: in men: first catch urine equal to urethral swab (85–95% sensitivity, 93–99% specificity); in women: vaginal swab preferred (patient or clinician collected), end cervical swab acceptable, first void urine may detect 10% fewer infections (3)[A]
  - Tissue cultures: traditional gold standard, but currently NOT recommended (3)
- If concern for trichomonas: NAAT (urine, urethral, vaginal, or endocervical swab), wet mount, or culture
- There is no FDA-approved diagnostic test available for *M. genitalium*, an

emerging pathogen with a greater prevalence than gonorrhea in many populations (4).

ALERT

Due to the similarity in clinical symptoms and high rates of coinfection, cotesting for gonorrhea and chlamydia infection is recommended. In addition, given that risk factors for gonorrhea and chlamydia indicate risks for other STIs, screening for HIV, RPR, Hepatitis C, and Hepatitis B may also be indicated.

Follow-Up Tests & Special Considerations

- Test of cure (TOC) for chlamydia and gonorrhea is recommended in pregnant women or when treatment noncompliance is suspected (3).
- Repeat testing in 3 months recommended due to rates of reinfection (3)
- HIV infection: Persons with HIV infection should receive the same treatment as patients without HIV infection (3).

Diagnostic Procedures/Other

Urethrocystoscopy for cases with suspected foreign body, intraurethral warts, urethral stricture

Test Interpretation

Urethral strictures (untreated gonorrhea), intraurethral lesions (venereal warts, congenital anomalies), PID, or tubo-ovarian abscesses are possible.

TREATMENT

GENERAL MEASURES

- Most cases can be treated in the outpatient setting.
- Single-dose regimens with direct observation preferred (3)

MEDICATION

First Line

- Gonorrhea
  - Ceftriaxone 250 mg IM plus either: azithromycin 1 g PO × 1 dose (preferred) *OR* doxycycline 100 mg PO BID for 7 days (if azithromycin

allergy) (3)[A]
  - For children ≤45 kg: ceftriaxone 25 to 50 mg/kg (max 125 mg) IM × 1 dose. For children >45 kg: Use adult dosing.
- Chlamydia
  - Azithromycin: 1 g PO × 1 dose OR
  - Doxycycline: 100 mg PO BID for 7 days (3)[A]
  - Alternative regimens (all for 7 days): erythromycin base 500 mg PO QID, erythromycin ethylsuccinate 800 mg PO QID, levofloxacin 500 mg daily, *OR* ofloxacin 300 mg PO BID
- Trichomonas
  - Metronidazole: 2 g PO × 1 dose
- Recurrent and resistant urethritis
  - Metronidazole: 2 mg PO single dose *OR* tinidazole 2 g PO single dose plus azithromycin 1 g PO × 1 dose
- Contraindications: sensitivity to any of the indicated medications
- Precautions: Patients taking tetracyclines may have increased photosensitivity.
- Significant possible interactions
  - Tetracyclines should not be taken with milk products or antacids.
  - Oral contraceptives may be rendered less effective by oral antibiotics. Patients and partners should use a back-up method of birth control for the remainder of the cycle.

Pregnancy Considerations

Chlamydia: All pregnant women <25 years and older women at increased risk should be screened for chlamydia at their first prenatal visit and again in the 3rd trimester. Women with chlamydia infections should be treated, have a documented TOC 3 to 4 weeks after treatment, and retested in 3 months (3).

- Gonorrhea: All pregnant women <25 years and older women at increased risk should be screened for gonorrhea at their first prenatal visit and again in the 3rd trimester. Women with gonorrhea infections should be treated and be retested in 3 months (3).
- Tetracyclines and quinolones are contraindicated.
- Avoid erythromycin estolate because of an increased risk of cholestatic jaundice.

- Single-dose therapy is recommended.

Second Line

- Gonorrhea: If ceftriaxone is not an option, cefixime 400 mg PO × 1 dose plus either: azithromycin 1 g PO × 1 dose OR doxycycline 100 mg PO BID for 7 days (if azithromycin allergy); followed by a TOC in 1 week (3).
- Chlamydia alternative regimens (all for 7 days): erythromycin base 500 mg PO QID, erythromycin ethylsuccinate 800 mg PO QID, levofloxacin 500 mg daily, OR ofloxacin 300 mg PO BID (3)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Sexual activity should be avoided for 7 days following administration of single-dose therapy or until completion of multiday regimen.
- All sexual partners who came in contact with the patient within 60 days should be referred for evaluation, testing, and presumptive treatment (3).
- Expedited partner therapy (EPT) is an acceptable alternative. EPT—the practice of treating the diagnosed patient's sex partner(s) for chlamydia or gonorrhea by providing medications or prescriptions to the patient to provide to the partner(s) without clinical evaluation (3).

Patient Monitoring

- Instruct patients to return if symptoms persist or recur after completing treatment.
- TOC in 3 to 4 weeks in pregnant women suspected of nonadherence, reinfection, persistent symptoms
- Screen for reinfection in all patients at 3 months.

DIET

Avoid alcohol when taking metronidazole.

PATIENT EDUCATION

- Behavioral counseling interventions are recommended. Evidence of benefit increase with intensity of intervention (5).

- Successful approaches include basic information about STIs and transmission, assess risk for transmission, include training skills (i.e., condom use, communication about safe sex, problem solving, goal setting) (5).

PROGNOSIS

If the diagnosis is firmly established, appropriate medications are prescribed and the patient is compliant with treatment; relief of symptoms occurs within days and the problem will resolve without sequela.

COMPLICATIONS

- Stricture formation
- Epididymitis
- Prostatitis
- PID in women
- Disseminated gonococcal infection
- Gonococcal meningitis
- Gonococcal endocarditis
- Perinatal transmission (chlamydial conjunctivitis, chlamydial pneumonia, ophthalmia neonatorum)
- Reiter syndrome

CODES

ICD10

- N34.2 Other urethritis
- A56.01 Chlamydial cystitis and urethritis
- A54.01 Gonococcal cystitis and urethritis, unspecified

CLINICAL PEARLS

- Inflammation of the urethra, frequently associated with dysuria, pruritus, and/or urethral discharge
- Common manifestation of STI
- Classified as gonococcal (caused by *N. gonorrhoeae*) and nongonococcal
- NAAT preferred method of diagnosis for men and women
- Single-dose regimens with direct observation preferred
- In cases of gonorrhea or chlamydia infection, in person or EPT recommended for all partners of patients within the last 60 days
- Given that risk factors for gonorrhea and chlamydia indicate risk for other

STIs, screening for HIV, RPR, hepatitis C, and hepatitis B may also be indicated.

- Repeat testing for gonorrhea and chlamydia in 3 months recommended due to rates of reinfection.
- Special considerations in pediatric and pregnant populations
- Treatment in persons with HIV infection is the same as in patients without HIV infection.
- Health care providers are required to report all gonorrhea and chlamydia infections in accordance with local and state requirements.

URINARY TRACT INFECTION (UTI) IN FEMALES

Akhil Das, MD, FACS

BASICS

DESCRIPTION

- Urinary tract infection (UTI) is the presence of pathogenic microorganisms within the urinary tract with concomitant symptoms.
- This topic refers primarily to infectious cystitis; other complicated UTIs, such as pyelonephritis, are discussed elsewhere.
- Uncomplicated UTI: occurs in patients who have a normal, unobstructed urinary tract, who have no history of recent instrumentation, and whose symptoms are confined to the lower urinary tract. Uncomplicated UTIs are most common in young, sexually active women.
- Complicated UTI: an infection of the lower or upper urinary tract in the presence of an anatomic abnormality, a functional abnormality, or a urinary catheter
- Recurrent UTI: symptomatic UTIs that follow resolution of an earlier episode, usually after appropriate treatment
  - No single definition of the frequency of recurrent UTI exists, but a pragmatic definition is ≥3 infections per year.
  - Most recurrences are thought to represent reinfection rather than relapse.
  - No evidence indicates that recurrent UTIs lead to health problems such as hypertension or renal disease in the absence of anatomic or functional abnormalities of the urinary tract (1)[A].
- System(s) affected: renal/urologic
- Synonym(s): cystitis; infectious cystitis

EPIDEMIOLOGY

Incidence

- Accounts for 8 million doctor visits and 1 million emergency room visits and contributes to >100,000 hospital admissions each year

- 11% of women have UTIs in any given year.
- Predominant age: young adults and older
- Predominant sex: female > male

Prevalence

- >50% of females have at least one UTI in their lifetime.
- One in four women has recurrent UTIs.

ETIOLOGY AND PATHOPHYSIOLOGY

- Bacteria and subsequent infection in the urinary tract arise chiefly via ascending bacterial movement and propagation (1).
- Pathogenic organisms (*Escherichia coli*) possess adherence factors and toxins that allow initiation and propagation of genitourinary infections:
  - Type 1 and *P. pili* (pyelonephritis-associated pili)
  - Lipopolysaccharide
- Most UTIs are caused by bacteria originating from bowel flora:
  - *E. coli* is the causative organism in 80% of cases of uncomplicated cystitis.
  - *Staphylococcus saprophyticus* accounts for 15% of infections.
  - Enterobacteriaceae (i.e., *Klebsiella*, *Proteus*, *Enterobacter*, and *Pseudomonas*) also contribute.
- *Candida* is associated with nosocomial UTI (2).

Genetics

Women with human leukocyte antigen 3 (HLA-3) and nonsecretor Lewis antigen have an increased bacterial adherence, which may lead to an increased risk in UTI.

RISK FACTORS

- Previous UTI
- Diabetes mellitus (DM)
- Pregnancy
- Sexual activity
- Use of spermicides or diaphragm
- Underlying abnormalities of the urinary tract such as tumors, calculi, strictures, incomplete bladder emptying, urinary incontinence, neurogenic bladder

- Catheterization
- Recent antibiotic use
- Poor hygiene
- Estrogen deficiency
- Inadequate fluid intake

GENERAL PREVENTION

- Maintain good hydration.
- Women with frequent or intercourse-related UTI should empty bladder immediately before and following intercourse; consider postcoital antibiotic.
- Avoid feminine hygiene sprays and douches.
- Wipe urethra from front to back.
- Cranberry juice (not cranberry juice cocktail) consumption may prevent recurrent infections.

COMMONLY ASSOCIATED CONDITIONS

See "Risk Factors."

Geriatric Considerations

- Elderly patients are more likely to have underlying urinary tract abnormality.
- Acute UTI may be associated with incontinence or mental status changes in the elderly.

DIAGNOSIS

HISTORY

Note: Any or all may be present:

- Burning during urination
- Pain during urination (dysuria)
- Urgency (sensation of need to urinate often)
- Frequency
- Sensation of incomplete bladder emptying
- Blood in urine
- Lower abdominal pain or cramping
- Offensive odor of urine

- Nocturia
- Sudden onset of urinary incontinence
- Dyspareunia

PHYSICAL EXAM

- Suprapubic tenderness
- Urethral and/or vaginal tenderness
- Fever or costovertebral angle tenderness indicates upper UTI.

DIFFERENTIAL DIAGNOSIS

- Vaginitis
- Asymptomatic bacteriuria
- STDs causing urethritis or pyuria
- Hematuria from causes other than infection (e.g., neoplasia, calculi)
- Interstitial cystitis
- Psychological dysfunction

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- No lab testing is necessary in women with high likelihood of lower UTI based on classic symptoms. Negative dipstick in the presence of high pretest probability does NOT rule out UTI.
- Urinalysis
  - Pyuria (>10 neutrophils/high-power field [HPF])
  - Bacteriuria (any amount on unspun urine, or 10 bacteria/HPF on centrifuged urine)
  - Hematuria (>5 RBCs/HPF)
- Dipstick urinalysis
  - Leukocyte esterase (75–96% sensitivity, 94–98% specificity, when >100,000 colony-forming units [CFU])
  - Nitrite tests are useful with nitrite-reducing organisms (e.g., enterococci, *S. saprophyticus*, *Acinetobacter*).
- Urine culture: only indicated if diagnosis is unclear or patient has recurrent infections and resistance is suspected. It is neither cost-effective nor usually helpful for lower tract, uncomplicated UTI.

  - Presence of 100,000 CFU/mL of organism indicates infection.
  - Identification of a single organism at lower CFU per milliliter likely also represents infection in the presence of appropriate symptoms.
  - Suspect a contaminated specimen when culture shows multiple types of bacteria.
- Imaging studies are often not required in most cases of UTI.

Follow-Up Tests & Special Considerations

- In nonpregnant, premenopausal women with symptoms of UTI, positive urinalysis, and no risks for complicated infection, empirical treatment may be given without obtaining a urine culture.
- Imaging may be indicated for UTIs in men, infants, immunocompromised patients, febrile infection, signs or symptoms of obstruction, failure to respond to appropriate therapy, and in patients with recurrent infections.
- CT scan and MRI provide the most complete anatomic data in adults.

Pediatric Considerations

For infants and children, obtain US; if ureteral dilatation is detected, obtain either voiding cystourethrogram or isotope cystogram to evaluate for reflux.

Diagnostic Procedures/Other

- Urethral catheterization may be necessary to obtain a urine specimen from children and adults if the voided urine is suspected of being contaminated.
- Suprapubic bladder aspiration or urethral catheterization techniques can be used to obtain specimens from infants.
- Cystourethroscopy can be used for patients with recurrent UTIs and previous anti-incontinence surgery or hematuria (3)[A].

TREATMENT

GENERAL MEASURES

- Maintain good hydration.
- Maintain good hygiene.
- 1/4 of women with uncomplicated UTI experience a second UTI within 6 months and 1/2 at some time during their lifetime.

- Many women with uncomplicated UTI clear symptoms without treatment.

MEDICATION

First Line

- The urinary tract topical analgesic phenazopyridine 100 to 200 mg TID produces rapid relief of symptoms and should be offered to patients with more than minor discomfort; it is available over the counter. This medication is not a substitute for definitive treatment. This medication also may alter urinalysis but not the urine culture.
- Uncomplicated UTI (adolescents and adults who are nonpregnant, nondiabetic, afebrile, immunocompetent, and without genitourinary anatomic abnormalities)
  - Trimethoprim-sulfamethoxazole (TMP-SMX; Bactrim): 160/800 mg PO BID for 3 days, best where resistance of *E. coli* strains <20%
  - 5-day course of nitrofurantoin should be used in patients with allergy to TMP-SMX and in areas where *E. coli* resistance to TMP-SMX >20% (3) [A].
  - Fosfomycin (Monurol): 3 g PO single dose (expensive)
- Lower UTI in pregnancy
  - Nitrofurantoin (Macrobid): 100 mg PO BID for 7 days
  - Cephalexin (Keflex): 500 mg PO BID for 7 days
- Postcoital UTI: single-dose TMP-SMX or cephalexin may reduce frequency of UTI in sexually active women.
- Complicated UTI (pregnancy, diabetes, febrile, immunocompromised patient, recurrent UTIs): Extend course to 7 to 10 days of treatment with antibiotic chosen based on culture results; may begin with fluoroquinolone, TMP-SMX, or cephalosporin while awaiting results (avoid using nitrofurantoin for complicated UTI)
  - Fluoroquinolones are not safe during pregnancy and are usually avoided in treatment of children.
  - FDA Black Box warning (2016) on fluoroquinolones due to disabling and potentially permanent side effects
  - TMP-SMX use in pregnancy is not desirable (especially in 3rd trimester) but is appropriate in some circumstances (3)[A].

Second Line

- Uncomplicated UTI
  - β-Lactams (amoxicillin/clavulanate, cefdinir, cefpodoxime proxetil) for 3 to 7 days
- Chronic UTIs
  - Women with recurrent symptomatic UTIs can be treated with continuous or postcoital prophylactic antibiotics. Treatment duration guided by the severity of patient symptoms and by physician and patient preference: Consider 6 months of therapy, followed by observation for reinfection after discontinuing prophylaxis.
    - Continuous antimicrobial prophylaxis involves daily administration of low-dose TMP-SMX 40/200 mg or nitrofurantoin 50 to 100 mg, among others.
- Another treatment option is self-started antibiotics.

Pediatric Considerations

Long-term antibiotics appear to reduce the risk of recurrent symptomatic UTI in susceptible children, but the benefit is small and must be considered together with the increased risk of microbial resistance.

ISSUES FOR REFERRAL

Men with uncomplicated UTI and most other patients with complicated UTI should be referred to a urologist for evaluation.

Pediatric Considerations

UTI in children, especially <1 year of age, should prompt workup for urinary tract anomalies.

SURGERY/OTHER PROCEDURES

- Urinary tract obstruction with urosepsis requires urgent drainage of the obstructed system.
- Patients with emphysematous pyelonephritis or pyonephrosis may need immediate surgical intervention.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Preliminary studies indicate that *Vaccinium macrocarpon* (cranberry) juice

may help to prevent and treat UTIs by inhibiting bacterial adherence to the bladder epithelium.
- Cranberry juice may decrease the number of symptomatic UTIs over a 1-year period, particularly for women with recurrent UTIs. The optimal dosage or method of administration (e.g., juice, tablets, or capsules) is still unclear.
- Complementary therapies appear to be an attractive alternative for prevention of UTIs; however, there is a lack of head-to-head trials to support its use.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Inpatient evaluation is reserved for patients with complicated or upper tract UTIs. Majority of UTIs are managed in an outpatient setting.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- First or rare UTI: Young or middle-aged, nonpregnant adult females require no follow-up if UTI is clinically cured after 3-day therapy.
- If symptoms persist after 2 to 3 days of therapy, obtain culture/sensitivity and change antibiotic accordingly.

Pregnancy Considerations

- UTI during pregnancy always requires culture/sensitivity and usually requires a 7- to 14-day treatment.
- Following the treatment of acute infection, pregnant women warrant surveillance urine cultures every trimester. They may receive prophylactic antibiotics for the remainder of pregnancy for recurrent or upper tract disease.

PATIENT EDUCATION

- Although no controlled studies support this intervention, postcoital voiding is commonly advised.
- FamilyDoctor Web site: http://familydoctor.org/familydoctor/en/diseases-conditions/urinary-tract-infections.html

PROGNOSIS

Symptoms resolve within 2 to 3 days of antibiotic treatment in almost all patients.

COMPLICATIONS

- Pyelonephritis or sepsis
- Renal abscess
- Acute urinary outlet obstruction

Pregnancy Considerations

Pregnant females, infants, and young children with cystitis are at higher risk of pyelonephritis.

Algorithm: Dysuria

CODES

ICD10

- N39.0 Urinary tract infection, site not specified
- N30.90 Cystitis, unspecified without hematuria
- N30.91 Cystitis, unspecified with hematuria

CLINICAL PEARLS

- Uncomplicated UTIs cause significant short-term morbidity but generally do not cause renal damage.
- Culture is generally not indicated for women with symptoms of uncomplicated UTI.
- Treatment of uncomplicated UTIs reduces morbidity, but the risk of recurrence stays the same.
- Uncomplicated UTIs should be treated for 3 days (TMP-SMX) or 5 days (nitrofurantoin). All pregnant women with bacteriuria should be treated.
- Health care professionals should avoid treating women with asymptomatic bacteruria.
- Fluoroquinolones should be reserved for complicated UTI.

URINARY TRACT INFECTION (UTI) IN MALES

Amy L. Wiser, MD

BASICS

DESCRIPTION

- Cystitis is an infection of the lower urinary tract, usually resulting from a single gram-negative enteric bacteria. (See also "Prostatitis," "Pyelonephritis," and "Urethritis.")
- System(s) affected: renal/urologic
- Synonym(s): urinary tract infection (UTI); cystitis
- Conventional consideration of UTI in male newborn, infant, and elderly men is complicated, with associated functional/structural mechanisms.
- In otherwise healthy males ages 15 to 50 years, UTI is uncommon and considered uncomplicated.

EPIDEMIOLOGY

Incidence

- Approximately 20% of UTIs occur in men (1).
- Predominant age: increases with age
- Uncommon in men <50 years of age
- 6 to 8 infections/10,000 men aged 21 to 50 years (2)

Prevalence

Lifetime prevalence approximately 14% (1)

ETIOLOGY AND PATHOPHYSIOLOGY

- *Escherichia coli* (majority of infections)
- *Klebsiella*
- *Enterobacter*
- *Enterococcus*
- *Proteus*
- *Serratia*
- *Citrobacter*

- *Providencia*
- *Streptococcus faecalis* and *Staphylococcus* sp.
- *Pseudomonas* and *Morganella* (more common in elderly and catheterized patients)
- Pathogenesis—bacterial entry into urinary tract via ascension or bladder instrumentation

Genetics

Not applicable

RISK FACTORS

- Age
- Obesity (3)
- History of prior UTI
- Outlet obstruction
  - Benign prostatic hypertrophy (BPH)—incidence of 33% of men with UTIs (4)
  - Urethral stricture
  - Calculi
- Cognitive impairment
- Fecal incontinence
- Urinary incontinence
- Anal intercourse
- Recent urologic surgery
- Infection of the prostate/kidney
- Urinary tract instrumentation, catheterization
- Immunocompromised host
- Diabetes
- Bladder diverticula
- Neurogenic bladder
- Institutionalization
- Uncircumcised
- Engaging in sex with an infected female partner or in anal intercourse (2)

GENERAL PREVENTION

- Prompt treatment of predisposing factors
- Use a catheter only when necessary; if needed, use aseptic technique and closed system and remove as soon as possible.
- Currently, cranberry products are not recommended for preventing UTIs in men (5).

COMMONLY ASSOCIATED CONDITIONS

- Acute bacterial pyelonephritis
- Chronic bacterial pyelonephritis
- Urethritis
- Prostatitis
- Prostatic hypertrophy
- Prostate cancer

Geriatric Considerations

Bacteriuria is common among the elderly; may be related to functional status and usually is transient. Of men older than 65 years of age, 5–10% have asymptomatic bacteriuria (ASB). If ASB is noted, no treatment is needed (6,7).

Pediatric Considerations

Can be associated with obstruction to normal flow of urine, such as vesicoureteral reflux. Unique diagnostic criteria and evaluation recommendations exist (see below) (8).

DIAGNOSIS

HISTORY

- Urinary frequency
- Urinary urgency
- Dysuria
- Hesitancy
- Slow urinary stream
- Dribbling of urine
- Nocturia
- Suprapubic discomfort or perineal pain

- Low back pain
- Hematuria
- Systemic symptoms (chills, fever) or flank pain, nausea, vomiting present with concomitant pyelonephritis or prostatitis (9).

PHYSICAL EXAM

- Suprapubic tenderness
- Costovertebral angle (CVA) tenderness and/or fever may be present with concomitant pyelonephritis/prostatitis/epididymitis.
- Perform genital examination.
- Consider digital rectal exam, including palpation of the prostate gland, to rule out bacterial prostatitis.

DIFFERENTIAL DIAGNOSIS

- Anatomic/functional pathology of the urinary tract
- Urethritis/STIs
- Infections in other sites of the genitourinary tract (e.g., epididymis, prostatitis). More than 90% of men with febrile UTI have concomitant prostate infection (9).

DIAGNOSTIC TESTS & INTERPRETATION

- Urine dipstick/manual microscopy of clean catch midstream void showing the following:
  - Pyuria (>10 WBCs)
  - Bacteriuria
  - Positive leukocyte esterase (in males: sensitivity, 78%; specificity, 59%; positive predictive value [PPV], 71%; negative predictive value [NPV], 67%)
  - Positive nitrite (in males: sensitivity, 47%; specificity, 98%; PPV, 96%; NPV, 59%)
  - In general, leukocyte esterase is more sensitive, and nitrite is more specific in detecting UTI (10).
- Automated microscopy/flow cytometry that measures cell counts and bacterial counts can be used to improve screening characteristics (sensitivity, 92%; specificity, 55%; PPV, 47%; NPV, 97%). The high NPV of these screening

tests allows for more judicious use of urine culture (11).

- Urine culture: >100,000 colony-forming units (CFU; $>10^5$ CFU) of bacteria/mL of urine confirm diagnosis.
- Lower counts, such as $>10^3$ CFU, also may be indicative of infection, especially in the presence of pyuria.
- Diagnosis in infants and children <24 months made on the basis of both pyuria and 50,000 CFU on culture.
- Renal and bladder ultrasound recommended in infants and young children after first confirmed UTI.

Follow-Up Tests & Special Considerations

- Consider assessing for risk factors for STIs, as chlamydial/gonococcal urethritis can mimic a UTI. If risk factors are present, use urine nucleic acid amplification tests to identify gonococcal and *Chlamydia* infections and treat as necessary.
- Further urologic evaluation is warranted to rule out other disorders in men with recurrent UTI, febrile UTI, or pyelonephritis. This may include the following:
  - Ultrasound
  - Cystoscopy
  - Urodynamics
  - IV pyelography
- Value of a urologic evaluation in a single uncomplicated UTI has not been determined (9).
- Antibiotics prior to culture or phenazopyridine prior to urine dipstick can alter results.
- Blood cultures are not routine; perform if concern for sepsis or bacteremia

Test Interpretation

Depends on site of infection

TREATMENT

GENERAL MEASURES

- Hydration

- Analgesia, if required
- Patient with indwelling catheters
  - If asymptomatic bacterial colonization, no need to treat (sterilization of urine is not possible, and resistant organisms may take up residence).
  - If symptomatic of acute infection, institute treatment.

MEDICATION

First Line

- Acute, uncomplicated cystitis
  - Treat empirically; strongly consider if nitrite positive, using local resistance patterns or based on culture and sensitivity results for 7 days (9)[B]. For empirical therapy, a fluoroquinolone or trimethoprim-sulfamethoxazole DS usually used to treat the most likely pathogens (9).
- Complicated, febrile, or recurrent infection
  - Prescribe a minimum of 2 weeks antibiotics based on antimicrobial sensitivities with repeat urine check after the treatment. In men with febrile UTI or pyelonephritis, prostatic involvement also has to be considered. Treatment of concomitant prostatitis requires antimicrobials with good prostatic tissue and fluid penetration (fluoroquinolones) (9)[B].

Second Line

According to culture and sensitivity results and patient's history

ISSUES FOR REFERRAL

Further urologic evaluation and referral are warranted to rule out other disorders in men with recurrent UTI, febrile UTI, or pyelonephritis.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Inability to tolerate oral medications
- Acute renal failure
- Suspected sepsis

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Close follow-up until clinically well

DIET

Encourage adequate fluid intake.

PATIENT EDUCATION

For patient education materials about this topic that have been reviewed favorably, contact the National Kidney Foundation, 30 E. 33rd Street, Suite 1100, New York, NY 10016; 212-889-2210.

PROGNOSIS

Clearing of infections with appropriate antibiotic treatment

COMPLICATIONS

- Pyelonephritis
- Ascending infection
- Recurrent infection
- Prostatitis

CODES

ICD10

- N39.0 Urinary tract infection, site not specified
- N30.90 Cystitis, unspecified without hematuria
- N30.91 Cystitis, unspecified with hematuria

CLINICAL PEARLS

- Cystitis is an infection of the lower urinary tract, usually resulting from a single gram-negative enteric bacteria.
- Risk factors/causes: age, history of UTI, obesity, BPH, cognitive impairment, fecal incontinence, urinary incontinence, anal intercourse, recent urologic surgery, catheterization, infection of the prostate/kidney, urinary tract instrumentation, immunocompromised host, diabetes, neurogenic bladder, outlet obstruction, sex with infected female partner
- Evaluation: urinalysis, urine culture, STI testing (e.g., gonorrhea, *Chlamydia* by culture/DNA probe)
- Treat empirically with fluoroquinolones or trimethoprim-sulfamethoxazole DS for 7 days.

UROLITHIASIS

Phillip Fournier, MD

BASICS

DESCRIPTION

- Stone formation within the urinary tract: Urinary crystals bind to form a nidus which grows to form a calculus (stone).
- Range of symptoms: asymptomatic to obstructive; febrile morbidity if result of infection

EPIDEMIOLOGY

- The worldwide epidemiology differs according to both geographic area (higher prevalence in hot, arid, or dry climates) and socioeconomic conditions (dietary intake and lifestyle). Radiolucent stones and stones secondary to infection are less influenced by environmental conditions.
- Vesical calculosis (bladder stones) due to malnutrition during early life is frequent in Middle East and Asian countries.
- Incidence in industrialized countries seems to be increasing, probably due to improved diagnostics as well as to increasingly rich diets.
- Increased incidence in patients with surgically induced absorption issues, such as Crohn disease and gastric bypass surgery (1)[B]

Incidence

- In industrialized countries: 100 to 200/100,000/year (2)
- Predominant age: Mean age is 40 to 60 years.
- Predominant sex: male > female (~2:1) (3)

ETIOLOGY AND PATHOPHYSIOLOGY

- Supersaturation and dehydration lead to high salt content in urine which congregates.
- Stasis of urine
  - Renal malformation (e.g., horseshoe kidney, ureteropelvic junction obstruction)

  - Incomplete bladder emptying (e.g., neurogenic bladder, prostate enlargement, multiple sclerosis)
- Crystals may form in pure solutions (homogeneous) or on existing surfaces, such as other crystals or cellular debris (heterogeneous).
- Balance of promoters and inhibitors: organic (Tamm-Horsfall protein, glycosaminoglycan, uropontin, nephrocalcin) and inorganic (citrate, pyrophosphate)
- Calcium oxalate and/or phosphate stones (80%)
  - Hypercalciuria
    - Absorptive hypercalciuria: increased jejunal calcium absorption
    - Renal leak: increased calcium excretion from renal proximal tubule
    - Resorptive hypercalciuria: mild hyperparathyroidism
  - Hypercalcemia
    - Hyperparathyroidism
    - Sarcoidosis
    - Malignancy
    - Immobilization
    - Paget disease
- Hyperoxaluria
  - Enteric hyperoxaluria
    - Intestinal malabsorptive state associated with irritable bowel disease, celiac sprue, or intestinal resection
    - Bile salt malabsorption leads to formation of calcium soaps.
  - Primary hyperoxaluria: autosomal recessive, types I and II
  - Dietary hyperoxaluria: overindulgence in oxalate-rich food
- Hyperuricosuria
  - Seen in 10% of calcium stone formers
  - Caused by increased dietary purine intake, systemic acidosis, myeloproliferative diseases, gout, chemotherapy, Lesch-Nyhan syndrome
  - Thiazides, probenecid
- Hypocitraturia
  - Caused by acidosis: renal tubular acidosis, malabsorption, thiazides, enalapril, excessive dietary protein
- Uric acid stones (10–15%): hyperuricemia causes as discussed earlier

- Struvite stones (5–10%): infected urine with urease-producing organisms (most commonly *Proteus* sp.)
- Cystine stones (<1%): autosomal recessive disorder of renal tubular reabsorption of cystine
- Bladder stones: seen with chronic bladder catheterization and some medications (indinavir)
- In children: usually due to malnutrition

Genetics

- Up to 20% of patients have a family history. However, spouses of those who form stones have higher calcium excretion rates than controls, suggesting strong dietary–environmental factors.
- Autosomal dominant: idiopathic hypercalciuria
- Autosomal recessive
  - Cystinuria, Lesch-Nyhan syndrome, hyperoxaluria types I and II
  - Ehlers-Danlos syndrome, Marfan syndrome, Wilson disease, familial renal tubular acidosis

RISK FACTORS

- White > African American in regions with both populations
- Family history
- Previous history of nephrolithiasis
- Diet rich in protein, refined carbohydrates, and sodium, carbonated drinks
- Occupations associated with a sedentary lifestyle or with a hot, dry workplace
- Incidence rates peak during summer secondary to dehydration.
- Obesity
- Surgically/medically induced malabsorption (Crohn disease, gastric bypass, celiac)

GENERAL PREVENTION

- Hydration (4)[A]
- Decrease salt and meat intake.
- Avoid oxalate-rich foods.

Pediatric Considerations

Rare: more common in men with low socioeconomic status

Pregnancy Considerations

- Pregnant women have the same incidence of renal colic as do nonpregnant women.
- Most symptomatic stones occur during the 2nd and 3rd trimesters, heralded by symptoms of flank pain/hematuria.
- Most common differential diagnosis is physiologic hydronephrosis of pregnancy. Use ultrasound to avoid irradiation. Noncontrast-enhanced CT scan also is diagnostic.
- Treatment goals
  - Control pain and avoid infection and preserve renal function until birth or stone passage.
  - 30% require intervention, such as stent placement.

DIAGNOSIS

HISTORY

- Pain
  - Renal colic: acute onset of severe groin and/or flank pain
  - Distal stones may present with referred pain in labia, penile meatus, or testis.
- Microscopic/gross hematuria occurs in 95% of patients.
- Nonspecific symptoms of nausea, vomiting, tachycardia, diaphoresis
- Low-grade fever without signs of infection
- Infectious origin: associated with high-grade fevers require more urgent treatment (see the following text)
- Frequency and dysuria especially occur with stones at the vesicoureteric junction (VUJ).
- Asymptomatic: nonobstructing stones within the renal calyces

PHYSICAL EXAM

Tender costovertebral angle with palpation/percussion and/or iliac fossa

DIFFERENTIAL DIAGNOSIS

- Appendicitis
- Ruptured aortic aneurysm

- Musculoskeletal strain
- Pyelonephritis (upper UTI)
- Pyonephrosis (obstructed upper UTI; emergency)
- Perinephric abscess
- Ectopic pregnancy
- Salpingitis

DIAGNOSTIC TESTS & INTERPRETATION

- Urinalysis for RBCs, leukocytes, nitrates, pH (acidic urine <5.5 is associated with uric acid stones; alkaline >7 with struvite stones)
- Midstream urine for microscopy, culture, and sensitivity
- Blood: urea, creatinine, electrolytes, calcium, and urate; consider CBC.
- Parathyroid hormone only if calcium is elevated
- Stone analysis if/when stone passed

Initial Tests (lab, imaging)

- Noncontrast-enhanced helical CT scan of the abdomen and pelvis has replaced IV pyelogram as the investigation of choice (5)[A].
  - Stone is found most commonly at levels of ureteric luminal narrowing: pelviureteric junction, pelvic brim, and VUJ.
  - Acute obstruction: Proximal ureter and renal pelvis are dilated to the level of obstruction, and perinephric stranding is possible on imaging.
- Renal ultrasound may be as effective with lower radiation at diagnosis as well as identifying obstruction (6)[B].
- X-ray of kidneys, ureter, and bladder to determine if stone is radiopaque or lucent
  - Calcium oxalate/phosphate stones are radiopaque.
  - Uric acid stones are radiolucent.
  - Staghorn calculi (that fill the shape of the renal calyces) are usually struvite and opaque.
  - Cystine stones are faintly opaque (ground-glass appearance).
- Ultrasound has low sensitivity and specificity but is often the first choice for pregnant women.

TREATMENT

GENERAL MEASURES

- 75% of patients are successfully treated conservatively and pass the stone spontaneously.
- Stones that do not pass usually require surgical intervention.
- 30–50% of patients will have recurrent stones.
- Increased fluid intake; eliminate carbonated drinks.

MEDICATION

- Medical expulsive therapy: α_1-antagonists (e.g., tamsulosin) and calcium channel blockers (e.g., nifedipine) improve likelihood of spontaneous stone passage with a number needed to treat (NNT) of ~5 (7).
- Category C in pregnancy
- Adequate pain control can be achieved with NSAIDs.

ISSUES FOR REFERRAL

- Urgent referral of patients with UTI/sepsis or acute renal failure/solitary kidney
- Early referral of pregnant patients, large stones (>8 mm), chronic renal failure, children
- Refer patients if no passage at 2 to 4 weeks or poorly controlled pain.

ADDITIONAL THERAPIES

- Uric acid stone dissolution therapy
  - Alkalinize urine with potassium citrate; keep pH >6.5.
  - Allopurinol 100 to 300 mg/day PO (for those who continue to form stones despite alkalinization of urine)
- Cystine stone dissolution/prevention
  - Alkalinize urine with potassium citrate; keep pH >6.5.
  - Chelating agents: captopril, α-mercapto propionylglycine, D-penicillamine
- Consider altering medications that increase risk of stone formation: probenecid, loop diuretics, salicylic acid, salbutamol, indinavir, triamterene, acetazolamide.
- Vitamin D supplementation has not been proven to induce stone formation.

- Treat hypercalciuria with thiazides on an acute basis only.
- Treat hypocitraturia with potassium citrate and high-citrate juices (e.g., orange, lemon).
- Treat enteric hyperoxaluria with oral calcium/magnesium, cholestyramine, and potassium citrate.

SURGERY/OTHER PROCEDURES

- Immediate relief of obstruction is required for patients with the following conditions:
  - Sepsis
  - Renal failure (obstructed solitary kidney, bilateral obstruction)
  - Uncontrolled pain, despite adequate analgesia
- Emergency surgery for obstruction
  - Placement of a retrograde stent (i.e., endoscopic surgery, usually requires an anesthetic)
  - Radiologic placement of a percutaneous nephrostomy tube
- Elective surgery for stone treatment
  - Extracorporeal shock wave lithotripsy
  - Ureteroscopy with basket extraction/lithotripsy (laser/pneumatic)
  - Percutaneous nephrolithotomy
- Open surgery is uncommon.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Analgesia
  - Combination of NSAIDs (ketorolac 30 to 60 mg) and oral opiate
  - Parenteral opioid if vomiting or if preceding fails to control pain (morphine 5 to 10 mg IV or IM q4h)
  - Antiemetic if required or prophylactically with parenteral narcotics
- Septic patients with urosepsis or pyonephrosis may require IV antibiotics (once blood and urine cultures are taken), IV fluids, and, in severe cases, cardiorespiratory support in intensive care during recovery.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Patients with ureteric stones who are being treated conservatively should be followed until imaging is clear or stone is visibly passed.
  - Strain urine and send stone for composition.
  - Tamsulosin and nifedipine in selected patients to speed passage
  - Present to the hospital if pain worsens/signs of infection.
  - If pain management is suboptimal or stone does not progress or pass within 2 to 4 weeks, patient should be referred to a urologist and imaging should be repeated.
- Patients with recurrent stone formation should have follow-up with a urologist for metabolic workup: 24-hour urine for volume, pH, creatinine, calcium, cystine, phosphate, oxalate, uric acid, and magnesium.

DIET

ALERT

- Increased fluid intake for life cannot be overemphasized for decreasing recurrence. Encourage intake of 2 to 3 L/day; advise patient to have clear urine rather than yellow.
- Decrease or eliminate carbonated drinks.
- Patients who form calcium stones should minimize high-oxalate foods such as green leafy vegetables, rhubarb, peanuts, chocolates, and beer.
- Decrease protein and salt intake.
- Lowering calcium intake is inadvisable and may even increase urine calcium excretion.
- Increase phytate-rich foods such as natural dietary bran, legumes and beans, whole cereal (8).
- Avoid excessive vitamin C and/or vitamin D.

PROGNOSIS

- Spontaneous stone passage depends on stone location (proximal vs. distal) and stone size (<5 mm, 90% pass; >8 mm, 10% pass).
- Stone recurrence: 50% of patients at 10 years

URTICARIA

Irina Pechenko, MD • Katie L. Westerfield, DO

BASICS

DESCRIPTION

- A cutaneous lesion involving edema of the epidermis and/or dermis presenting with acute onset and pruritis, returning to normal skin appearance within 24 hours
- Pathophysiology is primarily mast cell degranulation and subsequent histamine release.
- Angioedema may occur with urticaria although angioedema is characterized by sudden pronounced erythematous edema of the lower dermis and subcutis; may take up to 72 hours to remit.
- Pruritus and burning are more commonly associated with urticaria; pain more often with angioedema.
  - Spontaneous urticaria: acute: persists <6 weeks
- Specific extrinsic triggers drugs, foods, infections, envenomation, allergens, and autoimmune
- Underlying etiology may be difficult to pinpoint.
  - Chronic spontaneous urticaria: persists >6 weeks with >2 episodes/week off-treatment
- Recurrent acute urticaria: if symptoms occur <2 times a week.
- For those with chronic urticaria, 40% have concurrent angioedema.
- Chronic infection, pseudoallergy, malignancy including mastocytosis, autoimmunity (especially thyroid), and medications may underlie the remaining 20% (1).
- Inducible urticaria
  - Dermatographism: “skin writing” or the appearance of linear wheals at the site of any type of irritation. This is the most common physical urticaria.
  - Cold urticaria: Wheals occur within minutes of rewarming after cold exposure; 95% idiopathic but can be due to infections (mononucleosis, HIV), neoplasia, or autoimmune diseases.

  - Delayed pressure urticaria: Urticaria occurs 0.5 to 12 hours after pressure to skin (e.g., from elastic or shoes), may be pruritic and/or painful, and may not subside for several days.
  - Solar urticaria: from sunlight exposure, usually UV; onset in minutes; subsides within 2 hours
  - Heat urticaria: from direct contact with warm objects or air; rare
  - Vibratory urticaria/angioedema: very rare; secondary to vibrations (e.g., motorcycle)
  - Cholinergic urticaria: due to brief increase of core body temperature from exercise, baths, or emotional stress; small pin-sized (5 to 10 mm) wheals surrounded by an erythema but also can have larger wheals. This is the second most common form.
  - Adrenergic urticaria: also caused by stress; extremely rare; vasoconstricted, blanched skin around pink wheals as opposed to cholinergic's erythematous surrounding
  - Contact urticaria: wheals at sites where chemical substances contact the skin, may be either IgE-dependent (e.g., latex) or IgE-independent (e.g., stinging nettle)
  - Aquagenic and solar urticaria: small wheals after contact with water of any temperature or UV light, respectively; rare
- System(s) affected: integumentary
- Synonym(s): hives; wheals

EPIDEMIOLOGY

Incidence

- Equally distributed across all ages: female > male (2:1 in chronic urticaria)
- In 20% of patients, chronic urticaria lasts >10 years (1).

Prevalence

- 5–25% of the population
- Of people with urticaria, 40% have no angioedema, 40% have urticaria and angioedema, and 20% have angioedema with no urticaria.
- Up to 3% of the population has chronic idiopathic urticaria.

ETIOLOGY AND PATHOPHYSIOLOGY

- Mast cell degranulation with release of inflammatory reactants, which leads to vascular leakage, inflammatory cell extravasation, and dermal (angioedema) and/or epidermal (wheals/hives) edema
- Histamine, cytokines, leukotrienes, and proteases are main active substances released.
- Spontaneous acute urticaria
  - Bacterial infections: strep throat, sinusitis, otitis, urinary tract
  - Viral infections: rhinovirus, rotavirus, hepatitis B, mononucleosis, herpes
  - Foods: peanuts, tree nuts, seafood, milk, soy, fish, wheat, and eggs; tend to be IgE-mediated; pseudoallergenic foods such as strawberries, tomatoes, preservatives, and coloring agents contain histamine.
  - Drugs: IgE-mediated (e.g., penicillin and other antibiotics), direct mast cell stimulation (e.g., aspirin, NSAIDs, opiates)
  - Inhalant, contact, ingestion, or occupational exposure (e.g., latex, cosmetics)
  - Parasitic infection; insect bite/sting
  - Transfusion reaction
- Spontaneous chronic urticaria
  - Chronic subclinical allergic rhinitis, eczema, and other atopic disorders
  - Chronic indolent infections: *Helicobacter pylori*, fungal, parasitic (*Anisakis simplex*, strongyloidiasis), and chronic viral infections (hepatitis)
  - Collagen vascular disease (cutaneous vasculitis, serum sickness, lupus)
  - Thyroid autoimmunity, especially Hashimoto
  - Hormonal: pregnancy and progesterone
  - Autoimmune antibodies to the IgE receptor α chain on mast cells and to the IgE antibody
  - Chronic medications (e.g., NSAIDs, hormones, ACE inhibitors). NSAID sensitivity demonstrated almost in half of adults with chronic urticaria and presents with a worsening of symptoms 4 hours after ingestion (2)[A].
  - Malignancy
  - Physical stimuli (cold, heat, vibration, pressure) in physical urticaria

Genetics

No consistent pattern known: Chronic urticaria has increased frequency of HLA-

DR4 and HLA-D8Q MHC II alleles.

DIAGNOSIS

HISTORY

Fast onset; resolves in <24 to 48 hours, pruritis

PHYSICAL EXAM

- Single/multiple raised, polymorphic indurated plaques with central pallor and edema with an erythematous flare
- Evaluate for underlying conditions including thyroid abnormalities (nodules), bacterial, viral, or fungal infection (e.g., fever).

DIFFERENTIAL DIAGNOSIS

- Anaphylaxis (may present with urticaria)
- Morbilliform or fixed drug eruptions
- Erythema multiforme
- Systemic lupus erythematous (SLE), vasculitis, and polyarteritis
- Angioedema without urticaria
- Urticaria pigmentosa/systemic mastocytosis
- Bullous pemphigoid (urticarial stage)
- Arthropod bite
- Atopic/contact dermatitis
- Viral exanthem

DIAGNOSTIC TESTS & INTERPRETATION

- Directed by clinical suspicion of underlying cause:
  - Allergy skin tests and radioallergosorbent test (RAST) for inhaled allergens, insects, drugs, or foods
  - Infection: Consider pharyngeal culture, LFTs, mononucleosis test, urinalysis in appropriate setting.
- Chronic urticaria (idiopathic or spontaneous CIU/CSU) (3): Extensive lab testing is not indicated and has not proven to improve outcome nor is it cost-effective. Limit lab testing according to clinical history and indication. Skin or IgE testing should be limited to specific history of provoking allergen (4)[C].

  - CBC, ESR, and CRP is recommended by most guidelines.
  - Thyroid function tests, LFTs, and urinalysis are recommended by several guidelines.
  - Consider allergy skin tests and RAST for inhaled allergens, insects, drugs, or foods; total IgE level.
  - Autoimmune: ESR, ANA, RF, complement (e.g., CH50, C3, C4), cryoglobulins in urticarial vasculitis
  - Tests for *H. pylori* (e.g., antibodies) in dyspeptic patients. Consider stool for ova and parasites in at-risk individuals.
  - Autologous serum skin testing: injection of serum under skin to test for presence of IgE receptor–activating antibodies
  - Consider malignancy workup, including serum protein electrophoresis and immunofixation in the proper setting.
- Use the Urticaria Activity Score (UAS7) for assessing CSU.
- Recently was developed Urticaria Control Test (UCT)
  - The tool to assess disease control in patients with chronic urticaria (spontaneous and inducible) (5)[A].

Diagnostic Procedures/Other

- Food and drug reactions: elimination of (or challenges with) suspected agents
- Physical and special forms of urticaria: challenge tests:
  - Dermatographism: Stroke skin lightly with rounded object and observe for surrounding urticaria.
  - Cold urticaria: ice cube test: Place ice cube on skin for 5 minutes; observe for 10 to 15 minutes.
  - Cholinergic: Exercise to the point of sweating/partial immersion in 42°C bath for 10 minutes.
  - Solar: exposure to different wavelengths of light
  - Delayed pressure: Apply 5-lb sandbag to back for 20 minutes; observe 6 hours later.
  - Aquagenic: Apply water at various temperatures.
  - Vibratory: Apply vibration 4 to 5 minutes with a lab mixing device; observe.
- Skin biopsy with lesions lasting >24 hours

TREATMENT

ISSUES FOR REFERRAL

Referral to an allergist, immunologist, or dermatologist for recalcitrant cases

MEDICATION

First Line

- 2nd-generation antihistamine (H_1) blockers are the first-line treatment of any urticaria in which avoidance of stimulus is impossible or not feasible (6,7)[A]:
  - Fexofenadine (Allegra): 180 mg/day
  - Loratadine (Claritin): 10 mg/day, increasing to 30 mg/day if needed; only medication studied for safe use in pregnancy
  - Desloratadine (Clarinex): 5 mg/day (8)[A]
  - Cetirizine (Zyrtec): 10 mg/day, increasing to 30 mg per day if needed
  - Levocetirizine (Xyzal): 5 mg/day; requires weight-based dosing in children (8)[A]
  - Rupatadine: novel H_1 antagonist with antiplatelet-activating factor activity
- 1st-generation antihistamines (H_1; for patients with sleep disturbed by itching):
  - Older children and adults: hydroxyzine or diphenhydramine 25 to 50 mg q6h
  - Children <6 years of age: diphenhydramine 12.5 mg q6–8h (5 mg/kg/day) or hydroxyzine (10 mg/5 mL) 2 mg/kg/day divided q6–8h
- Precautions and notes: Drowsiness and dry mouth and eyes in 1st-generation H_1 blockers (elderly)

Second Line

Doubling the typical 2nd-generation H_1 blocker dosages should be attempted before adding 1st-generation H_1 or H_2 blockers (6,7,8)[A].

- H_2-specific antihistamines (beneficial as adjuvants): cimetidine, ranitidine, nizatidine, famotidine

Third Line

- Corticosteroids: prednisolone 20 to 50 mg/day for max of 10 days; best used

only for exacerbations; avoid chronic use (6,7)[C].

- Doxepin: tricyclic antidepressant with strong H_1- and H_2-blocking properties; 10 to 30 mg at bedtime; sedation limits usefulness (6)[C].
- Leukotriene antagonists (montelukast, zileuton, and zafirlukast): safe and worth trying in chronic, unresponsive cases; useful alone but best used in addition to antihistamines; limited data on use in treating acute urticaria (2) [A]
- Refractory symptoms
  - Omalizumab: anti-IgE; effective, expensive. 150 to 300 mg SQ q2–4wk. Restricted to allergists and those who can manage acute anaphylaxis (3,6,9,11)[A], significantly reduce the urticarial symptoms of CIU/CSU at 12 weeks. The best effects is reached with omalizumab dose 300 mg (3) [A]. Omalizumab is currently the only licensed treatment for H_1-antihistamine-refractory chronic spontaneous urticaria, has a favorable risk/benefit ratio, and was well tolerated in clinical studies (2).
  - Cyclosporine: well-studied, effective (2.5 to 5 mg/kg/day); best used in combination with antihistamines; significant renal side effects (6,7)[C]
  - Methotrexate: antifolate; proven useful in recalcitrant cases; GI upset most common complaint; long-term requires LFT monitoring
  - UV therapy decreases number of mast cells; has shown promise in the treatment of mastocytosis-induced urticaria (7)[C].
- Adding Vitamin D 4,000 U/day for 12 weeks may decrease the symptoms and USS score (10)[C].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Educating patient on use of EpiPen as pathophysiology similar. If the airway is threatened, immediate consult to evaluate for laryngeal edema and need for airway access.

ONGOING CARE

PROGNOSIS

Resolution of acute symptoms: 70% <72 hours. chronic urticaria: 35%

symptom-free in a year; another 30% will see symptom reduction

CODES

ICD10

- L50.9 Urticaria, unspecified
- L50.1 Idiopathic urticaria
- L50.8 Other urticaria

CLINICAL PEARLS

- “Chronic urticaria” with <2 episodes/week should be approached as acute.
- Antihistamines are the best studied and most efficacious therapy but may require higher-than-normal doses for efficacy.
- Lesions lasting >24 hours should be evaluated for urticarial vasculitis.

UTERINE AND PELVIC ORGAN PROLAPSE

Maryse A. Pedoussaut, MD • John Delzell, Jr., MD, MSPH • Suzanne Minor, MD, FAAFP

BASICS

DESCRIPTION

- Symptomatic descent of one or more of (1,2)
  - The anterior vaginal wall (bladder or cystocele)
  - The posterior vaginal wall (rectum or rectocele)
  - The apex of the vagina (uterine cervix descent and prolapse)
  - The vault (cuff) after hysterectomy (vault prolapse)
- Prolapses above or to the hymen are not symptomatic (2).
- Associated symptoms (2)
  - Feeling of vaginal or pelvic pressure
  - Heaviness
  - Bulging
  - Bowel or bladder symptoms
- Cost associated with treatment is more than $1 billion annually (~200,000 surgeries/year) (2).

EPIDEMIOLOGY

Incidence

Pelvic organ prolapse (POP) is common but not always symptomatic. It does not always progress with time. In a 3-year prospective cohort study of 249 women, prolapse increased by at least 2 cm in 11% and regressed by 2 cm in 3% (2).

Prevalence

- A national survey of 7,924 women (over 20 years of age) found a prevalence of 25% for one or more pelvic floor disorders (including urinary incontinence, fecal incontinence, and POP). Prevalence of POP was 2.9% (3).
- The prevalence of lower urinary tract symptoms is as high as 50% in parous women. 11% of all women have surgery for POP or lower urinary tract symptoms by 80 years old (4).

- 3–6% of women who present for gynecologic care have a prolapse beyond hymen (2).

ETIOLOGY AND PATHOPHYSIOLOGY

- Insidious process begins long before symptoms develop.
- There is a complex interaction between the pelvic floor musculature, connective tissue, and the vaginal wall, which provides support from the perineum to the sacrum (2). Integrity of levator ani is essential to this support system by providing a platform on which the pelvic organs rest (2).
- Symptomatic women typically have multiple defects, including laxity of supporting tissue and damage to the levator ani (2).
- Half of anterior prolapse can be attributed to apical descent of the vagina (2).

RISK FACTORS

- Vaginal childbirth (2): Women who have delivered two children vaginally have a relative risk of 8.4 and every additional child (up to five deliveries) increases the risk of prolapse by 10–20% (2).
- Age: Every 10 years of age increases the risk of prolapse by 40% (2). POP will become more prevalent, as the elderly population is expected to double by 2030 (5).
- Obesity: BMI >25 may increase the risk of developing prolapse (2).
- Constipation: independent risk factor in a survey of more than 2,000 women (2)
- Race: White and Hispanic women may be at higher risk than black or Asian women (2).
- Occupation (heavy lifting): variable support in the literature (2)
- Hysterectomy: variable support in the literature (2)
- Obstetric factors (operative delivery, infant weight, length of pushing in second stage of labor): variable support in the literature (2)

GENERAL PREVENTION

There is some evidence that pelvic floor muscle training (“Kegel exercises”) may decrease the risk of symptomatic POP (6)[B]. Weight loss and proper management of conditions that cause increase in intra-abdominal pressure may help prevent the problem.

COMMONLY ASSOCIATED CONDITIONS

- Urinary incontinence
- Other urinary symptoms (4)
  - Urgency
  - Frequency

DIAGNOSIS

HISTORY

- Less than half of women discuss symptoms with PCP. Only 10–12% seek medical attention. Barriers include embarrassment, social stigma, ability to cope, belief that POP is part of the aging process, belief that treatment options are limited, and fear of surgery (4).
- Common symptoms include the following:
  - Feeling a bulge in vagina
  - Something “falling out” of vagina
  - Pelvic pressure
  - Difficulty with voiding or defecation
  - Urgency
  - Frequency
  - Incontinence (urinary or fecal)
  - Constipation
- Document the presence, duration, and severity of urinary, bowel, or prolapse symptom. Assess impact on sexual function and quality of life with validated questionnaires (PISQ 9 OR 12) (1,7).
- Assess past medical history.
  - Gravity and parity/obstetric history
  - History of ascites
  - Chronic constipation
  - Document physical impairment (mobility, dexterity, or visual acuity), as this may affect management (1).
  - Document the patient’s desire, goals, and expectation (1).

PHYSICAL EXAM

- Abdominal examination to document any distention or masses
- Complete pelvic and rectal examination. Have patient cough or strain, particularly in an upright (standing) position while examining the distal vagina.
- The GOLD STANDARD is to measure vaginal descent using the Pelvic Organ Prolapse Quantification (POPQ) scale, which is a scale that describes the prolapse in relationship to the vaginal hymen (2). The validated simplified version has four measurements with classification in four stages. Patient is supine with the head of the bed at 45 degrees, performing Valsalva.
  - Stage 1: prolapse in which the distal point is superior or equal to 1 cm above hymen
  - Stage 2: prolapse in which the distal point is between 1 cm above and 1 cm below hymen
  - Stage 3: prolapse in which the distal point is superior or equal to 1 cm below the hymen, but some vaginal mucosa is not everted
  - Stage 4: complete vaginal vault eversion ("procidentia"). Entire vaginal mucosa everted (2)
- A split speculum can be used to observe anterior, posterior, and apical parts of the vagina successively.
- Patient should be standing for maximum descent (2).

DIFFERENTIAL DIAGNOSIS

- Rectal prolapse
- Hemorrhoids
- Bartholin cyst
- Cervical elongation

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Urinalysis if symptomatic POP (1)
- Renal function (serum creatinine) if urinary incontinence and probability of renal impairment (1)
- Imaging: not routinely recommended (1)

Follow-Up Tests & Special Considerations

- Postvoid residual if patient has urinary incontinence

- Urodynamic testing prior to invasive treatment or after treatment failure to plan further therapy (1)
- Imaging of upper urinary tract if hematuria or back pain (1)
- Cystoscopy recommended if patient has hematuria, pain, or discomfort suggesting bladder lesion (1)
- Colonoscopy or sigmoidoscopy if patient has fecal incontinence (1)
- Colonoscopy, air contrast barium enema, and/or computed tomography if change in bowel habits or rectal bleeding (1)

TREATMENT

GENERAL MEASURES

- Treatment should take into account type and severity of symptoms, patient's age, other comorbid conditions, sexual function, infertility, and risk of recurrence.
- Treatment for asymptomatic patients:
  - Stage 1 or 2: clinical observation (2)
  - Stage 3 or 4: regular follow-up and evaluation (every 6 to 12 months) (2)
- Treatment is indicated when there is urinary/bowel obstruction or hydronephrosis regardless of the degree of prolapse (2).
- A vaginal pessary should be considered in all women presenting with symptomatic prolapse (8)[B].
  - There are more than 13 types of silicone devices that may be inserted into the vagina to support the pelvic organs.
  - The most commonly used pessaries are the ring pessary and Gellhorn (8).
  - They may prevent prolapse progression and may prove to be an appropriate prevention strategy in the future because the surgical failure rate is around 30% (2).
  - Most women can be successfully fitted with a pessary (8)[B].
  - Satisfaction rate for patients using pessaries is very high (8)[B].
- Complications may be seen with neglected pessaries, such as erosions, abrasions, ulcerations, and vaginal bleeding. Minor complications such as vaginal discharge and odor can be treated without discontinuing pessary use (8)[B]. Vaginal erosion can be treated by removal of pessary and optional

vaginal estrogen supplementation.

MEDICATION

First Line

- Treatment of vaginal atrophy with topical estrogens may be beneficial for symptomatic POP (9)[B] if there are no contraindications. Suggested to use in conjunction with pelvic floor muscle training (9)
- Vaginal creams
  - Estradiol cream 0.01% (Estrace)
  - Conjugated estrogens 0.625 mg/day (Premarin)
- Vaginal tablet
  - Estradiol 10 μg (Vagifem)
- Vaginal ring
  - Estradiol 2 mg (Estring)

ISSUES FOR REFERRAL

Referral when pessary or surgery is necessary

ADDITIONAL THERAPIES

Pelvic floor muscle training: may reduce the symptoms of POP (1). Pelvic floor muscle training does not affect the degree of prolapse, only the symptoms (1).

SURGERY/OTHER PROCEDURES

- Reconstructive procedures are done with the goal of restoration of vaginal anatomy.
- Reconstructive surgery is associated with a high rate of failure (1 in 3 lifetime risk of repeat surgery). New procedures, using surgical mesh and graft material, have higher success rates but limited follow-up or comparative data (2).
- Abdominal procedures such as sacral colpopexy using graft material have a higher success rate but a longer operating time, longer time to return to normal activity levels, and an increased cost (10)[B]. There may be resulting problems with sexual function and bladder/bowel complaints (2).

ONGOING CARE

PATIENT EDUCATION

- Patients should be educated about pessary complications and possible symptoms of POP if they are still asymptomatic.
- Limit caffeine product and bladder irritants if urinary symptoms.
- Using insoluble fibers may help patients with bowel complaints such as constipation.

COMPLICATIONS

- There is a risk of vaginal mesh extrusion, erosions, dyspareunia, and pelvic pain after surgical repair (11).
- Delays in diagnosis (4)[B]
  - 61% reported POP symptoms to a physician.
  - 65.9% blamed themselves for the delay (fear of surgery, embarrassment).
  - 1/3 of women blame their physician for the delay in diagnosis.

CODES

ICD10

- N81.9 Female genital prolapse, unspecified
- N81.10 Cystocele, unspecified
- N99.3 Prolapse of vaginal vault after hysterectomy

CLINICAL PEARLS

- Many women do not discuss POP with their doctor—ask routinely.
- Vaginal pessary should be considered in all patients with symptomatic prolapse.
- Traditional surgical treatment has a high long-term failure rate (1 in 3).

UTERINE MYOMAS

Jessica M. Schechtman, DO • Michael P. Hopkins, MD, MEd

BASICS

DESCRIPTION

- Uterine leiomyomas are well-circumscribed, pseudoencapsulated, benign monoclonal tumors composed mainly of smooth muscle with varying amounts of fibrous connective tissue (1,2).
- Three major subtypes
  - Subserous: common; external; may become pedunculated
  - Intramural: common; within myometrium; may cause marked uterine enlargement
  - Submucous: ~5% of all cases; internal, evoking abnormal uterine bleeding and infection; occasionally protruding from cervix
- Rare locations: broad, round, and uterosacral ligaments
- System affected: reproductive
- Synonym(s): fibroids; myoma; fibromyoma; myofibroma; fibroleiomyoma

EPIDEMIOLOGY

Incidence

- Cumulative incidence up to 80%
  - 60% in African American women by age 35 years; 80% by age 50 years
  - 40% in Caucasian women by age 35 years; 70% by age 50 years (1,3,4)
- Incidence increases with each decade during reproductive years.
- Rarely seen in premenarchal females
- Predominant sex: females only

ETIOLOGY AND PATHOPHYSIOLOGY

- Enlargement of benign smooth muscle tumors that may lead to symptoms affecting the reproductive, GI, or genitourinary system
- Complex multifactorial process involving transition from normal myocyte to abnormal cells and then to visibly evident tumor (monoclonal expansion)

- Hormones (1): Increases in estrogen and progesterone are correlated with myoma formation (i.e., rarely seen before menarche). Estrogen receptors in myomas bind more estradiol than normal myometrium (2).
- Growth factors (1)
  - Increased smooth muscle proliferation (transforming growth factor β [TGF-β], basic fibroblast growth factor [bFGF])
  - Increase DNA synthesis (epidermal growth factor [EGF], platelet-derived growth factor [PDGF], activin, myostatin)
  - Stimulate synthesis of extracellular matrix (TGF-β)
  - Promote mitogenesis (TGF-β, EGF, insulin-like growth factor [IGF], prolactin)
  - Promote angiogenesis (bFGF, vascular endothelial growth factor [VEGF])
- Vasoconstrictive hypoxia (1): proposed, but not confirmed, mechanism of myometrial injury during menstruation

Genetics

- A variety of somatic chromosomal rearrangements have been described in 40% of uterine myomas.
  - Mutations in the gene encoding mediator complex subunit 12 (MED12) on the X chromosome were found in 70% of myomas in one study (3).
- Higher levels of aromatase and therefore estrogen have been found in myomas in African American women (3).

RISK FACTORS

- African American heritage
  - 2.9 times greater risk than Caucasian women; occur at a younger age, are more numerous, larger, and more symptomatic (1,4)
- Early menarche (<10 years)
- Oral contraceptive use before 16 years old (4)
- Nulliparous
- Hypertension
- Familial predisposition
  - 2.5 times more likely in women with a first-degree relative with myomas (1)

- Obesity
  - Risk increases by 21% with each 10 kg of weight gain (1).
- Alcohol
- Risk decreased by: parity, progesterone only contraceptives, diet (fruits, veggies, low fat dairy) (4)

COMMONLY ASSOCIATED CONDITIONS

Endometrial and breast cancer also associated with high, unopposed estrogen stimulation

DIAGNOSIS

HISTORY

- Usually asymptomatic; 30% present with abnormal symptoms—usually enlarged uterus or heavy bleeding (2,4).
- Symptoms include the following:
  - Abnormal uterine bleeding: usually heavy/prolonged menses
  - Pain: infrequent; usually associated with torsion of pedunculated myoma, degeneration, or cervical dilation by submucous myoma near cervical os
  - Pressure on bladder: suprapubic discomfort, urinary frequency/obstruction
  - Pressure on rectosigmoid: may cause low back pain, constipation
  - Infertility: rare, estimated 1–2.5% (2); usually from submucous myoma distorting the uterine cavity or interference with implantation

ALERT

Rapid growth, particularly in perimenopausal/postmenopausal patients; may indicate sarcoma. Extremely rare, 0.1–0.3% of cases (2)

PHYSICAL EXAM

- Usually incidental finding on abdominal and pelvic exam
- Firm, smooth nodules/masses arising from uterus
- Masses are mobile without tenderness.

DIFFERENTIAL DIAGNOSIS

- Intrauterine pregnancy
- Cancer, including ovarian, uterine, or leiomyosarcoma

- Cecal/sigmoid tumor
- Appendiceal abscess
- Diverticulitis
- Pelvic kidney
- Urachal cyst

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Pregnancy test
- Hemoglobin
- Pelvic ultrasound: standard confirmatory test; shows characteristic hypoechoic appearance (4,5)
- Saline infusion hysterosonography: helps to distinguish submucosal myomas
- Hysterosalpingogram: evaluates the contour of the endometrial cavity (5)
- CT scan or MRI: provides info on degeneration and special relationships (4); may help to differentiate complex cases or used when uterine artery embolization is planned (5)[B]

Follow-Up Tests & Special Considerations

Consider cancer antigen 125 (CA-125): may be slightly elevated in some cases of uterine myoma but generally more useful in differentiating myomas from various gynecologic adenocarcinomas

- IV pyelogram: if suspect ureteral distortion (5)
- Barium enema

Diagnostic Procedures/Other

- Fractional dilation and curettage: aids in ruling out cervical/uterine carcinomas when clinically suspicious
- Hysteroscopy: helps to diagnose submucosal/intracavitary myomas
- Laparoscopy: useful in complex cases and to rule out other pelvic diseases/disorders

Test Interpretation

- Myomas are usually multiple and vary in size and location; have been reported up to 100 lb
- Gross pathology: firm tumors with characteristic whorl-like trabeculated

appearance; a thin pseudocapsular layer is present.
- Microscopic: bundles of smooth muscle mixed with varying amounts of connective tissue elements running in different directions
- Cellular variant has a preponderance of muscle cells. Mitoses are rare.
- May undergo various types of degeneration
  – Hyaline degeneration: very common
  – Calcification: late result of circulatory impairment to myomas
  – Infection and suppuration: most common with submucosal myomas
  – Necrosis: most common with pedunculated myomas secondary to torsion

TREATMENT

- Treatment must be individualized and based on symptoms, fertility desires, and time until menopause.
- Medical therapy may be of benefit.
- Patients with minimal symptoms may be treated with iron preparations and analgesics.
- Conservative management of asymptomatic myomas
  – Pelvic exams and ultrasounds at ≥3-month intervals if size remains stable
  – Substantial regression usually occurs after menopause.
- Surgical options should be considered if symptomatic or worrisome myomas are unresponsive to conservative/medical management.

GENERAL MEASURES

Patients not desiring pharmacologic therapy or surgery may consider the following:

- Uterine artery embolization: averages 50% shrinkage of myomas (6)[A]; painful and may cause ovarian failure (1–2%), amenorrhea, postembolization syndrome, or other complications; shorter hospital stay and quicker recovery but no difference in satisfaction compared with hysterectomy (2,4)[B]; high reintervention rate (15–32% by 2 years) compared to hysterectomy/myomectomy (7% by 2 years) (6)
- MR-guided focused ultrasound (MRgFUS): noninvasive, ultrasound transducer passes through abdominal wall and causes coagulative necrosis of

fibroid; up to 98% reduction in myoma volume and symptoms. Not appropriate for some types of myomas (2)[B]. Efficacy may be comparable with other hysterectomy-sparing procedures (7)[B]. Fertility has been shown to be preserved (4)[A] although risks and outcomes data is limited (4).

MEDICATION

- Progestins may reduce overall uterine size (5)[B].
  - Norethindrone 10 mg/day
  - Medroxyprogesterone 200 mg IM monthly
  - Levonorgestrel intrauterine device (2)[B]
- Combination oral contraceptives: may help prevent development of new fibroids and control bleeding
  - Contraindications: history of thromboembolic events
- Gonadotropin-releasing hormone agonists
  - Nafarelin (nasal spray), goserelin acetate, and leuprolide
  - Induces abrupt artificial menopause; may reduce myoma symptoms dramatically; induces atrophy of myomas by up to 40% in 2 to 3 months (5)[B]
  - May be valuable as preoperative adjunct to myomectomy/hysterectomy by allowing recovery of anemia, donation of autologous blood, and possibly converting abdominal to vaginal hysterectomy (4,5,8)[B]
  - Not recommended for use >6 months because of osteoporosis risk
  - Following discontinuation, myomas return within 60 days to pretherapy size.
- Antiprogesterones
  - Mifepristone
    - Shown to have similar reduction in myoma size as gonadotropin-releasing hormone agonists (7)[B]
    - Decreases heavy bleeding and increases quality of life (9)[A]
  - Selective progesterone receptor modulator (SPRM)
    - Ulipristal acetate: may be as effective as gonadotropin-releasing hormones with fewer side effects (4)[B]

ISSUES FOR REFERRAL

- Medical therapy may be initiated by a primary care physician/gynecologist

after adequate pelvic examination.

- Surgical considerations may be pursued with gynecologic consultation.
- Uterine embolization may be discussed with an interventional radiologist.

SURGERY/OTHER PROCEDURES

- Surgical management is indicated in the following situations (5)[B]:
  - Excessive uterine size or excessive rate of growth (except during pregnancy)
  - Submucosal myomas when associated with hypermenorrhea
  - Pedunculated myomas that are painful or undergo torsion, necrosis, and hemorrhage.
  - If a myoma causes symptoms from pressure on bladder/rectum
  - If differentiation from ovarian mass is not possible
  - If associated pelvic disease is present (endometriosis, pelvic inflammatory disease)
  - If infertility/habitual abortion is likely due to the anatomic location of the myoma
- Surgical procedures
  - Preliminary pelvic examination, Pap smear, and endometrial biopsy should be performed to rule out malignant/premalignant conditions.
  - Hysterectomy: may be performed vaginally, laparoscopically, robotically, or by laparotomy
    - Effective in relieving symptoms and improving quality of life (4,7)[B]
    - Similar fertility and live birth rates between laparoscopic and abdominal myomectomy (2)[B]
    - FDA discourages the use of laparoscopic power morcellation during hysterectomy or myomectomy for uterine fibroids given the risk of spreading an occult malignancy and all patient should be counseled preoperatively of risk (4).
  - Abdominal, laparoscopic, robotic, or hysteroscopic myomectomy may be performed in younger women who want to maintain fertility (5,10)[B].
  - Hysteroscopic/laparoscopic cautery/laser myoma resection can be performed in selected patients.
  - Endometrial ablation: for small submucosal myomas

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Usually outpatient
- Inpatient for some surgical procedures

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Pelvic examination and ultrasound: every 2 to 3 months for newly diagnosed symptomatic/excessively large myomas
- Hemoglobin and hematocrit: if uterine bleeding is excessive
- Once uterine size and symptoms stabilize, monitor every 6 to 12 months although no high quality evidence exists (4).

DIET

No restrictions

PATIENT EDUCATION

- Society of Interventional Radiology: http://sirweb.org/patients/uterine-fibroids/
- U.S. Department of Health and Human Services: http://www.womenshealth.gov/publications/our-publications/fact-sheet/uterine-fibroids.html?from=AtoZ
- American Congress of Obstetricians and Gynecologists: http://www.acog.org

PROGNOSIS

- Resection of submucosal fibroids has been associated with increased fertility (7)[B].
- At least 10% of myomas recur after myomectomy; however, only 25% require further treatment (4,7)[B].

COMPLICATIONS

- May mask other gynecologic malignancies (e.g., uterine sarcoma, ovarian cancer)

- Degenerating fibroids may cause pain and bleeding.
- May rarely prolapse through the cervix

Pregnancy Considerations

- Rapid growth of fibroids is common.
- Pregnant women may need additional fetal testing if placenta is located over or near fibroid.
- Complications during pregnancy: abortion, premature labor, 2nd-trimester rapid growth leading to degeneration/pain, 3rd-trimester fetal malpresentation, and dystocia during labor and delivery
- Cesarean section is recommended if the endometrial cavity was entered during myomectomy due to increased risk of uterine rupture.

Geriatric Considerations

In postmenopausal patients with newly diagnosed uterine myoma/enlarging uterine myomas have a high suspicion of uterine sarcoma/other gynecologic malignancy.

CODES

ICD10

- D25.9 Leiomyoma of uterus, unspecified
- D25.2 Subserosal leiomyoma of uterus
- D25.1 Intramural leiomyoma of uterus

CLINICAL PEARLS

- Uterine myomas are benign smooth muscle tumors composed mainly of fibrous connective tissue.
- Usually incidental finding on pelvic exam or ultrasound but may cause pelvic pain and pressure, abnormal uterine bleeding, and/or infertility
- Management ranges from conservative to medical to surgical.

UVEITIS

Shailendra K. Saxena, MD, PhD • Mikayla L. Spangler, PharmD • Laura K. Klug, PharmD

BASICS

DESCRIPTION

- A nonspecific term used to describe any intraocular inflammatory disorder
- Symptoms vary depending on depth of involvement and associated conditions.
- The uvea is the middle layer of the eye between the sclera and retina. The anterior part of the uvea includes the iris and ciliary body. The posterior part of the uvea is the choroid.
  - Anterior uveitis: refers to ocular inflammation limited to the iris (iritis) alone or iris and ciliary body (iridocyclitis)
  - Intermediate uveitis: refers to inflammation of the structures just posterior to the lens (pars planitis or peripheral uveitis)
  - Posterior uveitis: refers to inflammation of the choroid (choroiditis), retina (retinitis), or vitreous near the optic nerve and macula
- System(s) affected: nervous
- Synonym(s): iritis; iridocyclitis; choroiditis; retinochoroiditis; chorioretinitis; anterior uveitis; posterior uveitis; pars planitis; panuveitis. Synonyms are anatomic descriptions of the focus of the uveal inflammation.

Geriatric Considerations

The inflammatory response to systemic disease may be suppressed.

Pediatric Considerations

- Infection should be the primary consideration.
- Allergies and psychological factors (depression, stress) may serve as a trigger.
- Trauma is also a common cause in this population.

Pregnancy Considerations

May be of importance in the selection of medications

EPIDEMIOLOGY

- Predominant age: all ages
- Predominant sex: male = female, except for human leukocyte antigen B27 (HLA-B27) anterior uveitis: male > female, autoimmune etiology: female > male

Incidence

- Overall prevalence is 38 to 714 cases/100,000 annual incidence.
- Anterior uveitis is the most common.

Prevalence

Iritis is 4 times more prevalent than posterior uveitis.

ETIOLOGY AND PATHOPHYSIOLOGY

- Infectious: may result from viral, bacterial, parasitic, or fungal etiologies
- Suspected immune-mediated: possible autoimmune or immune-complex–mediated mechanism postulated in association with systemic (especially rheumatologic) disorders
  - Autoimmune uveitis (AIU) patients should be referred to an ophthalmologist for local treatment.
- Isolated eye disease
- Idiopathic (~25%)
- Some medications may cause uveitis. The most causative medications include rifabutin, bisphosphonates, sulfonamides, metipranolol, topical corticosteroids, brimonidine, prostaglandin analogs, anti–vascular endothelial growth factor (VEGF) agents, bacillus Calmette-Guérin (BCG) vaccination, and systemic and intraocular cidofovir.
- Masquerade syndromes: diseases such as malignancies that may be mistaken for primary inflammation of the eye

Genetics

- No specific pattern for uveitis in general
- Iritis: 50–70% are HLA-B27–positive.
- Predisposing gene for posterior uveitis associated with Behçet disease may include HLA-B51.

RISK FACTORS

- No specific risk factors
- Higher incidence is seen with specific associated conditions.

COMMONLY ASSOCIATED CONDITIONS

- Viral infections: herpes simplex, herpes zoster, HIV, cytomegalovirus, congenital Zika virus
- Bacterial infections: brucellosis, leprosy, leptospirosis, Lyme disease, propionibacterium infection, syphilis, tuberculosis (TB), Whipple disease
- Parasitic infections: acanthamebiasis, cysticercosis, onchocerciasis, toxocariasis, toxoplasmosis
- Fungal infections: aspergillosis, blastomycosis, candidiasis, coccidioidomycosis, cryptococcosis, histoplasmosis, sporotrichosis
- Suspected immune-mediated: ankylosing spondylitis, Behçet disease, Crohn disease, drug or hypersensitivity reaction, interstitial nephritis, juvenile rheumatoid arthritis, Kawasaki disease, multiple sclerosis, psoriatic arthritis, Reiter syndrome, relapsing polychondritis, sarcoidosis, Sjögren syndrome, systemic lupus erythematosus, ulcerative colitis, vasculitis, vitiligo, Vogt-Koyanagi (Harada) syndrome
- Isolated eye disease: acute multifocal placoid pigmentary epitheliopathy, acute retinal necrosis, bird-shot choroidopathy, Fuchs heterochromatic cyclitis, glaucomatocyclitic crisis, lens-induced uveitis, multifocal choroiditis, pars planitis, serpiginous choroiditis, sympathetic ophthalmia, trauma
- Masquerade syndromes: leukemia, lymphoma, retinitis pigmentosa, retinoblastoma

DIAGNOSIS

HISTORY

- Decreased visual acuity
- Pain, photophobia, blurring of vision (1)[C]
  - Usually acute
- Anterior uveitis (~80% of patients with uveitis) (1)[C]
  - Generally acute in onset
  - Deep eye pain

  - Photophobia (consensual)
- Intermediate and posterior uveitis (2)
  - Unresolving floaters
  - Generally insidious in onset
  - More commonly bilateral

PHYSICAL EXAM

Slit-lamp exam and indirect ophthalmoscopy are necessary for precise diagnosis (1)[C].

- Anterior uveitis (~80% of patients with uveitis)
  - Conjunctival vessel dilation
  - Perilimbal (circumcorneal) dilation of episcleral and scleral vessels (ciliary flush)
  - Small pupillary size of affected eye
  - Hypopyon or hyphema (WBCs or RBCs pooled in the anterior chamber)
  - Frequently unilateral (95% of HLA-B27–associated cases); if first occurrence and otherwise asymptomatic, no further diagnostic testing is needed (1)[C].
  - Bilateral involvement and systemic symptoms (fever, fatigue, abdominal pain) may be associated with interstitial nephritis (1)[C].
  - Systemic disease is most likely to be associated with anterior uveitis (in one study, 53% of patients were found to have systemic disease) (1)[C].
- Intermediate and posterior uveitis
  - More commonly bilateral
  - Posterior inflammation will generally cause minimal pain or redness unless associated with an iritis.

DIFFERENTIAL DIAGNOSIS

- Acute angle-closure glaucoma
- Conjunctivitis
- Episcleritis
- Keratitis
- Scleritis

DIAGNOSTIC TESTS & INTERPRETATION

No specific test for the diagnosis of uveitis. Tests for etiologic factors or associated conditions should be based on history and physical exam (1)[C].

Initial Tests (lab, imaging)

- CBC, BUN, creatinine (interstitial nephritis) (1)[C]
- HLA-B27 typing (ankylosing spondylitis, Reiter syndrome) (1)[C]
- Antinuclear antibody, ESR (systemic lupus erythematosus, Sjögren syndrome) (1)[C]
- Venereal disease research laboratory (VDRL) test, fluorescent titer antibody (syphilis) (1)[C]
- Fluorescent treponemal antibody absorption (FTA-ABS) or microhemagglutination assay for antibodies to *Treponema pallidum* (MHA-TP) (1)[C]
- Purified protein derivative (PPD) tuberculin skin test (TB) (1)[C]
- Lyme serology (Lyme disease) (1)[C]
- Disorders that may alter lab results: immunodeficiency
- Chest x-ray (sarcoidosis, histoplasmosis, TB, lymphoma) (1)[C]
- Sacroiliac radiograph (ankylosing spondylitis) (1)[C]

Diagnostic Procedures/Other

Slit-lamp exam (1)[C]

TEST INTERPRETATION

- Keratic precipitates
- Inflammatory cells in anterior chamber or vitreous
- Synechiae (fibrous tissue scarring between iris and lens)
- Macular edema
- Perivasculitis of retinal vessels

TREATMENT

GENERAL MEASURES

- Outpatient care with urgent ophthalmologic consultation
- Medical therapy is best initiated following full ophthalmologic evaluation.
- Treatment of underlying cause, if identified

- Anti-inflammatory therapy

MEDICATION

First Line

- The treatment depends on the etiology, location, and severity of the inflammation.
- Prednisolone acetate 1% ophthalmic suspension: 2 drops to the affected eye q1h initially, tapering to once a day with improvement
  - Contraindications
    - Hypersensitivity to the medication or component of the preparation
    - Topical corticosteroid therapy is contraindicated in uveitis secondary to infectious etiologies, unless used in conjunction with appropriate anti-infectious agents.
  - Precautions
    - Topical corticosteroids may increase intraocular pressure, increase susceptibility to infections, impair corneal or scleral wound healing, or cause corneal epithelial toxicity or crystalline keratopathy. Prolonged use may cause cataract formation and exacerbate existing herpetic keratitis, which may masquerade as iritis.
  - Significant possible interactions
- Systemic corticosteroids are useful for maintenance therapy for patients with noninfectious uveitis. These should always be used with other immunosuppressive medications for steroid-sparing effects; prednisone 5 to 10 mg daily (3,4)[B].
- Cycloplegic agents may be used to dilate the eye and relieve pain. Agents include scopolamine hydrobromide 0.25% (Isopto Hyoscine) or atropine 1% 1 to 2 drops up to QID or homatropine hydrobromide (Isopto) 2% or 5% 1 to 2 drops BID or as often as q3h if necessary (1)[C].
  - Contraindications
    - Cycloplegia is contraindicated in patients known to have, or be predisposed to, glaucoma.
  - Precautions
    - Use extreme caution in infants, young children, and elderly because of increased susceptibility to systemic effects.

Second Line

- Anti-inflammatory: prednisolone sodium phosphate 1%, dexamethasone sodium phosphate 0.1%, dexamethasone suspension, rimexolone 1% (Vexol), and loteprednol etabonate 0.5% (Lotemax), difluprednate (Durezol) 0.05% (1,4)[C]
  - Rimexolone 1% (Vexol) may be equally effective as prednisolone acetate 1% for short-term treatment of anterior uveitis (1)[C].
  - Loteprednol etabonate (Lotemax) may not be as effective as prednisolone acetate 1% but may be less likely to increase intraocular pressure in cases of acute anterior uveitis.
- Periocular corticosteroids may be injected with triamcinolone acetonide being most commonly used; 40 mg/1 mL (5)[C].
- Intravitreous corticosteroid deposits may also be used for long-term maintenance. Fluocinolone acetonide (Retisert) 590 μg released >30 months, dexamethasone (Ozurdex) 0.7 mg released slowly >3 to 6 months (4,5)[B].
  - Retisert has caused all patients to develop cataracts and significant increases in intraocular pressure in about 2/3 of patients, whereas Ozurdex had only 1/4 of patients require medication for increased intraocular pressure and 15% develop cataracts (5)[C].
- Intravitreal corticosteroid injections are used only in severe cases of recurrence; triamcinolone acetonide 4 to 20 mg/0.1 mL, dexamethasone phosphate 0.4 mg/0.1 mL, dexamethasone implant (Ozurdex)
  - Ozurdex has a longer effect than triamcinolone acetonide.
- Immunosuppressive agents including antimetabolites (methotrexate, azathioprine, and mycophenolate mofetil), T-cell inhibitors (cyclosporine, tacrolimus, and sirolimus), and alkylating agents (cyclophosphamide, chlorambucil) may be employed in cases resistant to initial treatment but close monitoring is required (4,5)[C].
- Although biologic therapy has been used for refractory uveitis, the sparsity of randomized clinical trials as well as high cost and adverse effect potential of these agents limit their use (3,4)[C].
- Systemic and ophthalmic preparations of NSAIDs may provide some symptom relief (1)[C].

ISSUES FOR REFERRAL

Caution should be used when using empiric treatment; referral to an ophthalmologist is recommended in most cases.

SURGERY/OTHER PROCEDURES

Various surgical procedures may be used therapeutically for visual rehabilitation, diagnostically, or to manage complications associated with uveitis (6).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Complete history and physical to evaluate for associated systemic disease
- Ophthalmologic follow-up as recommended by consultant

PATIENT EDUCATION

- Instruct on proper method for instilling eye drops.
- Wear dark glasses if photophobia is a problem.

PROGNOSIS

- Depends on the presence of causal diseases or associated conditions
- Uveitis resulting from infections (systemic or local) tends to resolve with eradication of the underlying infection.
- Uveitis associated with seronegative arthropathies tends to be acute (lasting <3 months) and frequently recurrent.

COMPLICATIONS

- Cycloplegia: paralysis of the ciliary muscle of the eye, resulting in a loss of accommodation
- Loss of vision as a result of the following:
  - Keratic precipitate deposition on the corneal or lens surfaces (1)
  - Increased intraocular pressure, acute angle-closure glaucoma (1)
  - Formation of synechiae
  - Cataract formation (1)
  - Vasculitis with vascular occlusion, retinal infarction

- Macular edema (1)
- Optic nerve damage

SEE ALSO

Conjunctivitis, Acute; Glaucoma, Primary Closed-Angle; Scleritis

CODES

ICD10

- H20.9 Unspecified iridocyclitis
- H30.90 Unspecified chorioretinal inflammation, unspecified eye
- H20.019 Primary iridocyclitis, unspecified eye

CLINICAL PEARLS

- Symptoms vary depending on depth of involvement and associated conditions but should be suspected when eye pain is associated with visual changes.
- Severe or unresponsive uveitis may require therapy, including periocular injection of corticosteroids, sustained-release corticosteroid implants, systemic corticosteroids, cytotoxic agents, immunosuppressive agents, immunomodulatory agents, or tumor necrosis factor inhibitors.

VAGINAL ADENOSIS

Maeve K. Hopkins, MA, MD • Michael P. Hopkins, MD, MEd

BASICS

DESCRIPTION

- The normal vagina is lined with squamous epithelium. Adenosis is characterized by the presence of columnar epithelium or glandular tissue in the wall of the vagina.
- Around week 15 of embryologic development, the müllerian system, which forms the upper 2/3 of the vagina, fuses with the invaginating cloaca or urogenital sinus to form the lower 1/3 of the vagina. Squamous metaplasia from the cloacal region then produces squamous epithelium within the vagina (1).
- Adenosis occurs when this squamous epithelium fails to epithelialize the vagina completely.
- Three main types of adenosis epithelium described
  - Endocervical
  - Endometrial
  - Tubal
- System(s) affected: reproductive

Geriatric Considerations

- Adenosis is a disorder of the young female. By menopause, the vagina and cervix should be completely epithelialized.
- The presence of glandular epithelium in the postmenopausal patient is an indication for excision and close evaluation for the possibility of a well-differentiated adenocarcinoma.

Pregnancy Considerations

Pregnancy produces a wide eversion of the transformation zone of the cervix. This occasionally will become so widely everted that it will extend onto the vaginal fornices, leading to the impression of adenosis. This will resolve after

the pregnancy is completed.

EPIDEMIOLOGY

Incidence

- Although the cumulative incidence of vaginal adenosis is unknown, the incidence of cloacal malformations is 1/20,000 to 1/25,000 live births.
- Although spontaneous vaginal adenosis appears to be fairly common (10% of adult women), it is mostly an insignificant coincidental finding. Widespread symptomatic involvement is rare (2).

Prevalence

- In the United States, adenosis is relatively common; affecting 10–20% of young females studied. As maturation progresses with puberty, epithelialization occurs.
- Predominant age
  - Age <1 month: 15%
  - Prepubertal: typically absent
  - Age 13 to 25 years: 13%
  - Age >25 years: decreasing prevalence, uncommon beyond age 30 years (2)

ETIOLOGY AND PATHOPHYSIOLOGY

- In most young females, the etiology is incomplete squamous metaplasia or epithelialization. This occurs as a natural phenomenon and resolves with age.
- Described as congenital or acquired (2)
  - Congenital: proliferation of the remnant müllerian epithelium in the vagina due to exposure to diethylstilbestrol (DES) in utero (DES daughters)
  - Transformation-related protein 63 (TRP63/p63) marks the cell fate decision of müllerian duct epithelium to become squamous epithelium in the cervix and vagina. DES disrupts the TRP63 expression and induces adenosis lesions (3). It has also been suggested that DES induces vaginal adenosis by inhibiting the BMP4/Activin A-regulated vaginal cell fate decision through a downregulation of RUNX1 (4).
  - Acquired: trauma and inflammation causing spontaneous de novo changes or changes in an acquired lesion in the vaginal epithelium
  - Additional reports have documented adenosis occurring subsequent to

sulfonamide-induced Stevens–Johnson syndrome and after treatment of vaginal condylomas with 5-fluorouracil (5).

RISK FACTORS

Adenosis of the vagina/cervix may arise in up to 90% of DES daughters, and there is a 40-fold increased risk of the subsequent development of clear cell adenocarcinoma (6).

GENERAL PREVENTION

None: last DES exposure in the 1970s

COMMONLY ASSOCIATED CONDITIONS

DES exposure

- Adenosis from DES exposure should lead to an evaluation of other DES-related abnormalities.
- Müllerian tract anomalies associated with DES exposure include cervical hood, cervical ridge, shortened cervix, incompetent cervix, and T-shaped uterine cavity.
- Patients with known DES exposure should have their reproductive tract evaluated prior to conception.
- Most patients with adenosis have not been DES-exposed and do not require evaluation of the reproductive system.
- DES is a synthetic, nonsteroidal estrogen that was used to prevent spontaneous abortions or premature deliveries from 1938 to 1971 (6). An estimated 5 million women were prescribed DES during this period (3).
- The FDA issued a drug bulletin in 1971 advising physicians to stop prescribing DES to pregnant women because of its link to vaginal clear cell adenocarcinoma in DES daughters (6).

DIAGNOSIS

HISTORY

- Maternal DES exposure
- Complaints of
  - Profuse mucoid vaginal discharge from the glandular epithelium

- Pruritus
- Pain/soreness of the vaginal introitus
- Postcoital bleeding
- Dyspareunia

PHYSICAL EXAM

On pelvic exam, adenosis appearance is varied: patchy or diffuse red stippling, granularity or nodularity, single or multiple cysts, erosions, ulcers, or warty protuberances that may even extend to the vulva.

DIFFERENTIAL DIAGNOSIS

- Erosive lichen planus
- Fixed drug eruption
- Erythema multiforme
- Bullous skin disease
- Adenocarcinoma
  - A thorough evaluation for adenocarcinoma of the vagina arising in adenosis should be done.
  - A biopsy may be necessary to ensure that the process represents only benign adenosis.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

Four-quadrant Pap smear should be used liberally to isolate quadrants of the vagina that may contain abnormalities. No imaging is indicated, unless diagnosed with underlying malignancy.

Follow-Up Tests & Special Considerations

Pap smear can be followed by colposcopy and biopsy.

Diagnostic Procedures/Other

Colposcopy should be used to outline areas of adenosis to ensure that no malignancy is present.

Test Interpretation

- Biopsy will show benign glandular epithelium.
- Biopsies in the areas of ongoing squamous metaplasia are typical (7).

TREATMENT

GENERAL MEASURES

- Unless malignancy is present, conservative treatment is indicated.
- In most young females with this condition, it will resolve with expectant management (2).
- Treatment is warranted in women with severe subjective symptoms that impair the quality of life (8).
- For patients with focal lesions and no history of DES exposure, simple excision appears to be an effective modality of treatment (5)

ISSUES FOR REFERRAL

Malignancy found on biopsy warrants referral to gynecologic oncology specialist.

SURGERY/OTHER PROCEDURES

- Aggressive therapy, such as laser or surgical excision, is necessary if premalignant or malignant changes arise (4).
- Symptomatic treatment with carbon dioxide laser coagulation, unipolar coagulation, or, lastly, vaginal resection (2)

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Outpatient management

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

If the initial colposcopy is normal, a yearly four-quadrant Pap smear of the vagina and of the cervix is all that is necessary.

DIET

No special diet

PATIENT EDUCATION

- No limitations
- It is not necessary to avoid intercourse or placing objects in the vagina.
- The patient should be educated to keep normal guideline-recommended pelvic and Pap smear appointments. In most situations, this is benign, and expectant management is all that is necessary.
- http://www.acog.org/

PROGNOSIS

- It is expected that most patients will have squamous metaplasia and epithelialization with complete resolution of the adenosis.
- The rare patient, 1/1,000 to 1/10,000, may develop adenocarcinoma in the adenosis and will require definitive therapy as for vaginal cancer.
  - Cumulative incidence of progression of adenosis to adenocarcinoma is 1.5/1,000 for DES daughters (6).

COMPLICATIONS

- Infertility with DES association
- Adverse pregnancy outcome with DES association
- Adenocarcinoma of vagina
- Clear cell adenocarcinoma with DES association

SEE ALSO

Vaginal Malignancy

CODES

ICD10

- Q52.4 Other congenital malformations of vagina
- N89.8 Other specified noninflammatory disorders of vagina
- T38.5X5A Adverse effect of other estrogens and progestogens, initial encounter

CLINICAL PEARLS

- Adenosis is characterized by the presence of columnar epithelium or glandular

tissue in the wall of the vagina.

- Adenosis is more common among the daughters of women exposed to DES.
- Adenosis is rarely associated with an underlying vaginal malignancy.

VAGINAL BLEEDING DURING PREGNANCY

Virginia J. Van Duyne, MD

BASICS

DESCRIPTION

- Vaginal bleeding during pregnancy has many causes and ranges in severity from benign with normal pregnancy outcome to life-threatening for both infant and mother.
- Etiology can be from the vagina, cervix, uterus, fetus, or placenta. The differential diagnosis is guided by the gestational age of the fetus.

EPIDEMIOLOGY

Prevalence

- In early pregnancy: 7–25% of patients
- In late pregnancy: 0.3–2% of patients

ETIOLOGY AND PATHOPHYSIOLOGY

- Many times the cause is unknown.
- Anytime in pregnancy:
  - Cervicitis (infectious or noninfectious)
  - Vaginal or cervical trauma (including postcoital)
  - Cervical lesion or neoplasia
  - Hyperemia of cervix (increased blood flow from pregnancy)
- Early pregnancy:
  - For up to 50% of early pregnancy bleeding, no cause is ever found.
  - Ectopic pregnancy: leading cause of 1st-trimester maternal death in the United States. Risk factors: previous ectopic, trauma to fallopian tubes (tubal surgery, infection, tumor), congenital anomaly of tubes, in utero diethylstilbestrol (DES) exposure, current use of IUD, history of infertility, tobacco use
  - Spontaneous abortion: risk factors: advanced maternal age (AMA), alcohol use, tobacco use, anesthetic gas, heavy caffeine use, cocaine use, chronic maternal diseases (poorly controlled diabetes mellitus [DM], celiac disease,

autoimmune diseases such as antiphospholipid syndrome), short interconception time (3 to 6 months), current use of IUD, maternal infection (e.g., herpes simplex virus [HSV], gonorrhea, chlamydia, toxoplasmosis, listeriosis, HIV, syphilis, malaria), medications (e.g., retinoids, methotrexate, NSAIDs), multiple previous therapeutic abortions, previous spontaneous abortion, toxins (arsenic, lead, polyurethane), uterine abnormalities (congenital, adhesions, fibroids)
  - Implantation bleeding: benign, about 6 days after fertilization
  - Uterine fibroids
  - Subchorionic bleed: in late 1st trimester
  - Low-lying placenta
  - Gestational trophoblastic disease: hydatidiform mole (most common), choriocarcinoma, or placental-site trophoblastic tumors
- Late pregnancy:
  - Bloody show of labor (mucus plug)
  - Placenta previa: painless bleeding; occurs in 0.4% deliveries in the United States. Risk factors: previous history of placenta previa, previous uterine surgery (cesarean section, D&C), chronic hypertension, multiparity, multiple gestation, tobacco use, AMA
  - Placental abruption: painful bleeding; occurs in 1–2% deliveries in the United States. Risk factors: previous placental abruption, 1st-trimester bleeding, hypertension, preeclampsia, multiple gestation, tobacco, cocaine or methamphetamine use, unexplained elevated maternal α-fetoprotein, poly- or oligohydramnios, AMA, trauma to abdomen, premature rupture of membranes, thrombophilia, short umbilical cord, male fetus, chorioamnionitis, nutritional deficiency
  - Vasa previa: minimal bleeding with fetal distress; rare (1:2,500 deliveries). Risk factors: in vitro fertilization, multiple gestation, placental abnormalities (low-lying position, bilobate, succenturiate lobe, velamentous insertion of umbilical cord)
  - Placenta accreta, increta, percreta: risk factors: uterine scar (e.g., from cesarean section, endometrial ablation or D&C), current placenta previa, AMA, tobacco use, multiparity, uterine anomalies, uterine fibroids, hypertension

- Uterine rupture: vaginal bleeding, abnormal fetal heart rate, and disordered or hypertonic uterine contractions with or without pain. Risk factors: previous cesarean section (most common), trauma, use of oxytocin or prostaglandins, multiparity, external cephalic version, placental abruption, shoulder dystocia, placenta percreta, müllerian duct anomalies, history of pelvic radiation

RISK FACTORS

See specific etiologies in earlier discussion.

GENERAL PREVENTION

- Address modifiable risk factors such as domestic violence and tobacco and drug use.
- If placenta or vasa previa, nothing per vagina

DIAGNOSIS

HISTORY

- Anytime in pregnancy: quality of pregnancy dating, context (e.g., following bowel movement, during voiding, after intercourse, drug use, or trauma including domestic violence), amount of bleeding, obstetrical history, personal or family history of inherited bleeding disorders
- Early pregnancy: severe nausea/vomiting (can be associated with molar pregnancy); amount of bleeding, pelvic pain, or suprapubic cramping (e.g., spontaneous abortion, ectopic) complications in previous pregnancies (e.g., spontaneous abortion, abruption, 1st-trimester vaginal bleeding)
- Late pregnancy: contractions (labor), abdominal pain especially between contractions (abruption, uterine rupture), presence or absence of fetal movement, rupture of membranes
- See "Etiology and Pathophysiology" for additional pertinent history.

PHYSICAL EXAM

- Vital signs: When present, signs of hemodynamic instability are first tachycardia and tachypnea, then hypotension and thready pulse.
- Abdomen: uterine tenderness, fundal height (increasing fundal height may be

associated with placental abruption)

- Speculum: Visualize cervix and identify source of bleeding (from cervical os or from within vagina).
- Cervix: assess for dilation; required to assess for labor but should not be performed until placenta previa ruled out via ultrasound
- Fetal monitoring: Doppler heart tones in early pregnancy; external fetal monitoring for gestational age >26 weeks

DIFFERENTIAL DIAGNOSIS

- Hematuria (UTI, kidney stones)
- Rectal bleeding

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- CBC
- Blood type and screen; if significant hemorrhage, type and cross-match
- Quantitative β-human chorionic gonadotropin (β-hCG):
  - Prior to 12 weeks, levels can be followed serially every 2 days with following trends:
    - Doubles or at least 66% rise in 48 hours in normal pregnancy
    - Falls in spontaneous abortion
    - Extremely high in molar pregnancy
    - Rises gradually (<50% in 48 hours) or plateaus in ectopic pregnancy
- Transvaginal ultrasound should be used to confirm an intrauterine pregnancy (IUP) when the quantitative β-hCG >2,000 (1)[A].
- Other lab tests based on clinical scenario:
  - Wet mount, gonorrhea/chlamydia, Pap smear
  - Progesterone level occasionally used to determine viability in threatened abortion (<5 indicates not viable, >25 indicates viability, 5 to 25 is equivocal).
  - Bleeding time, fibrinogen, and fibrin split products: if suspect coagulopathy or abruption
  - Kleihauer-Betke: low sensitivity and specificity for abruption; helpful for dosing Rho(d) immune globulin (RhoGAM)
- Ultrasound is the preferred imaging modality.

- Early pregnancy:
  - Gestational sac seen at 5 to 6 weeks; fetal heartbeat observed by 8 to 9 weeks
  - Diagnostic of ectopic with nearly 100% sensitivity when β-hCG level 1,500 to 2,000 mIU/mL. If no IUP is present and ultrasound does not confirm ectopic pregnancy, serial quantitative β-hCG values should be followed (2)[C].
- Late pregnancy:
  - Proceed to rule out placenta previa with ultrasound, labor with serial cervical exams, and abruption with external fetal monitoring.

ALERT
Confirm fetal presentation and placental position prior to cervical exam.

TREATMENT

MEDICATION

First Line

- Treat underlying cause of bleeding, if identified.
- If mother is Rh negative, give RhoGAM to prevent autoimmunization. In late pregnancy, dose according to the amount of estimated fetomaternal hemorrhage.
- If cause of bleeding is preterm labor, consider betamethasone for fetal lung maturity if <34 weeks' gestation. Tocolytics may be used to prolong pregnancy to allow for course of steroids.
- If threatened abortion: Consider progesterone (relative risk 0.53) (3)[A].
- If mother has an inherited bleeding disorder or if bleeding is severe, consider recombinant or donor blood products.

SURGERY/OTHER PROCEDURES

- Cesarean section may be indicated for recurrent or uncontrolled bleeding with placenta or vasa previa.
- If ectopic is diagnosed, immediate surgical treatment may be needed. Some early ectopic pregnancies can be treated medically if certain criteria are met

(2)[C].

- Surgical uterine evacuation is necessary for molar pregnancy due to malignant potential (4)[C].
- Incomplete or inevitable spontaneous abortion: Management is patient centered. In the absence of infection, patient may elect expectant, medical, or surgical management. If expectant management, typically wait 2 weeks for patient to complete abortion; most complete by 9 days. If at 2 weeks abortion is not completed or medical management has failed, surgical intervention (D&C or aspiration) is generally indicated (5)[A]. May send tissue to pathology to confirm.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- In early pregnancy: based on quantity of bleeding, need for surgical treatment for ectopic pregnancy, or presence of infection in case of spontaneous abortion
- In late pregnancy, if significant bleeding and/or presence of maternal or fetal compromise
- In late pregnancy with trauma, if ≥2 contractions/10 minutes
- In late pregnancy, may discharge when bleeding has stopped; labor, previa, and abruption have been ruled out; and fetal heart tracing is normal.
- After trauma in late pregnancy, may discharge home if normal fetal heart tracing for ≥4 hours with <2 contractions/10 minutes

ONGOING CARE

Patient Monitoring

- Patient should be instructed to report any increase in the amount or frequency of bleeding and to seek immediate care if experiencing fever, abdominal pain, or sudden increased bleeding. Patient should save any tissue passed vaginally for examination.
- Frequency of outpatient follow-up as indicated based on etiology of bleeding

PATIENT EDUCATION

- American Academy of Family Physicians (AAFP): www.familydoctor.org

- American College of Obstetricians & Gynecologists (ACOG): www.acog.org

PROGNOSIS

- Prognosis depends on the etiology of vaginal bleeding, severity of bleeding, and rapidity of diagnosis.
- Maternal mortality is 31.9 deaths/100,000 ectopic pregnancies.
- 1/2 of patients with early pregnancy bleeding miscarry. If fetal heart activity (ultrasound) present in 1st-trimester bleed, <10% chance of pregnancy loss.
- Heavy bleeding in early pregnancy, particularly when accompanied by pain, is associated with higher risk of spontaneous abortion. Spotting and light episodes are not, especially if lasting only 1 to 2 days.
- Subchorionic hemorrhage has about 2- to 3-fold increased risk of spontaneous abortion. Smaller hemorrhage and presence of viable fetal heart rate confer lower risk of loss. Most resolve spontaneously.
- Women with early pregnancy bleeding have an increased risk of preterm delivery, premature rupture of membranes, manual removal of placenta, placental abruption, elective cesarean delivery, and term labor induction later in the same pregnancy. These women also have an increased risk of adverse pregnancy outcomes, including hyperbilirubinemia, congenital anomalies, NICU admission, and reduced neonatal birth weight. Finally, there is an increased risk in subsequent pregnancies of recurrence of early pregnancy bleeding.
- Bed rest has not been shown to affect the outcome of bleeding in early pregnancy but may be indicated for bleeding in late pregnancy with placenta or vasa previa or with maternal hypertension.

CODES

ICD10

- O20.9 Hemorrhage in early pregnancy, unspecified
- O46.90 Antepartum hemorrhage, unspecified, unspecified trimester
- O20.0 Threatened abortion

CLINICAL PEARLS

- Obtain blood type and screen all women presenting with vaginal bleeding in pregnancy and administer RhoGAM to all Rh-negative patients.
- For up to 50% of early pregnancy bleeding, no cause is ever found.
- Always consider ectopic pregnancy in 1st-trimester bleeding.
- Do not perform digital exam in late pregnancy bleeding until placenta has been located on ultrasound.

VAGINAL MALIGNANCY

Jay R. Patibandla, MD • Michael P. Hopkins, MD, MEd

BASICS

DESCRIPTION

- Carcinomas of the vagina are uncommon: 3% of gynecologic malignancies, 2,300 new cases annually.
- Vaginal intraepithelial neoplasia (VAIN), defined by squamous cell atypia, is classified by the depth of epithelial involvement:
  - VAIN 1: 1/3 thickness
  - VAIN 2: 2/3 thickness
  - VAIN 3 and carcinoma in situ (CIS): >2/3 with CIS, designating full-thickness neoplastic changes without invasion through the basement membrane
- Invasive malignancies: Vaginal malignancies include squamous cell carcinoma (85–90%), adenocarcinoma (5–10%), sarcoma (2–3%), and melanoma (2–3%). Clear cell carcinoma is a subtype of adenocarcinoma. Invasive squamous cell carcinoma has the potential for metastasis to the lungs and liver.
- To be classified as a vaginal malignancy, only the vagina can be involved. If the cervix or vulva is involved, then the tumor is classified as a primary cancer arising from the cervix or the vulva.
- Most vaginal malignancies are metastatic (e.g., cervix, vulva, endometrium, breast, ovary).

Pregnancy Considerations

This malignancy is not associated with pregnancy.

EPIDEMIOLOGY

Incidence

- An estimated 4,070 new cases will be diagnosed in 2015 with 910 resulting deaths (1).
- Predominant age

- CIS: mid-40 to 60 years
- Invasive squamous cell malignancy: mid-60 to 70 years
- Adenocarcinoma: any age; 50 years is the mean age. Peak incidence is between 17 and 21 years of age.
- Clear cell adenocarcinoma occurs most often in females <30 years with a history of exposure to diethylstilbestrol (DES) in utero.
- Mixed müllerian sarcomas and leiomyosarcomas in the adult population: mean age 60 years

Pediatric Considerations

Vaginal tumors are extremely rare. Rhabdomyosarcoma (botryoid and embryonal subtype) is the most common malignant neoplasm of the vagina. Less common entities are germ cell tumor and clear cell adenocarcinoma.

Prevalence

In the United States, it is one of the rarest of all gynecologic malignancies (3%).

ETIOLOGY AND PATHOPHYSIOLOGY

- Women with a history of cervical malignancy have a higher probability of developing squamous cell malignancy in the vagina even after hysterectomy.
- Human papillomavirus (HPV) is found in 80–93% of patients with vaginal CIS and 50–65% of the patients with invasive vaginal carcinoma (2,3).
- HPV-16 is the most common, found in 66% of CIS and 55% of invasive vaginal cancers.
- Smokers have a higher incidence.
- Clear cell adenocarcinoma of the vagina in young women has been associated with DES exposure. The incidence, however, is exceedingly rare, estimated at 1/1,000 to 1/10,000 exposed females.
- Metastatic lesions can involve the vagina, spreading from the other gynecologic organs.
- Although rare, renal cell carcinoma, lung adenocarcinoma, GI cancer, pancreatic adenocarcinoma, ovarian germ cell cancer, trophoblastic neoplasm, and breast cancer can all metastasize to the vagina.

Genetics

No known genetic pattern

RISK FACTORS

- Similar risk factors as cervical cancer
- Age
- African American
- Smoking
- Multiple sex partners, early age of first sexual intercourse
- History of squamous cell cancer of the cervix or vulva
- HPV infection
- Vaginal adenosis
- Vaginal irritation
- DES exposure in utero

COMMONLY ASSOCIATED CONDITIONS

Due to the field effect, patients with vaginal cancer are more likely to develop malignancy in the cervix or vulva and should be followed closely.

DIAGNOSIS

HISTORY

- Abnormal bleeding is the most common symptom.
- Postcoital bleeding can result from direct trauma to the tumor.
- Vaginal discharge
- Dyspareunia
- Urinary symptoms, including hematuria and increased frequency
- Constipation
- Pain along with symptoms and signs of hydroureter are late findings when the tumor has spread into the paravaginal tissues and extends to the pelvic sidewall.

Pediatric Considerations

In children, sarcomas can present either as a mass protruding from the vagina or as abnormal genital bleeding.

PHYSICAL EXAM

Pelvic examination

- The vagina, uterus, adnexa (fallopian tubes and ovaries), bladder, and rectum should be evaluated for unusual changes.
- Vaginal malignancies are found most commonly on the posterior wall in the upper 1/3 of the vagina.

DIFFERENTIAL DIAGNOSIS

- Premalignant changes: VAIN 1, 2, 3, and CIS
- Adequate biopsies ensure that invasive lesions are not overlooked. Invasive lesions penetrate the basement membrane and cannot be treated conservatively.
- Other malignancies, such as endometrial, cervix, bladder, or colon cancer, can invade directly into the vagina or metastasize to the vagina.
- In the childbearing years, trophoblastic disease should be considered.
  - The vagina is a common site of metastases; however, biopsy should typically be avoided because the implants are very vascular and may hemorrhage if sampled.
  - The clinical presentation is typically obvious so histopathologic confirmation before treatment is not required.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Pap smear may incidentally detect asymptomatic lesions.
- Biopsy suspicious lesions
- Chest x-ray (CXR): to evaluate for metastatic disease
- CT scan and MRI: to evaluate the liver and retroperitoneum, especially the lymph nodes in the pelvic and periaortic area
- PET scan detects primary and secondary metastatic lesions more often than CT scan.

ALERT

PET scan correlation with CT scan lesions strongly suggests malignancy.

Follow-Up Tests & Special Considerations

- Lymphoscintigraphy (sentinel lymph node mapping) as part of the pretreatment evaluation can result in a change in the radiation fields and improve comprehensive treatment planning in women with vaginal cancer.

- HPV vaccination: Implementation of prophylactic HPV vaccination could prevent ~2/3 of the intraepithelial lesions in the lower genital tract but is yet unproven.

Diagnostic Procedures/Other

- Colposcopy with directed biopsies for small lesions
- Wide excision under anesthesia of superficial disease may be necessary to ensure that invasive cancer is not present.
- Cystoscopy to rule out bladder invasion
- Proctosigmoidoscopy to rule out rectal invasion

Test Interpretation

Tumors are staged clinically:

- Stage 0: VAIN and CIS
- Stage I: carcinoma limited to the vaginal wall (26%)
- Stage II: involves the subvaginal tissues but has not extended to the pelvic wall (37%)
- Stage III: extends to the pelvic wall (24%)
- Stage IV: extends beyond the true pelvis (13%)
  - IVa: Tumor invades bladder and/or rectal mucosa and/or direct extension beyond the true pelvis.
  - IVb: spread to distant organs

TREATMENT

GENERAL MEASURES

Treatment methods for VAIN and CIS include the following:

- Wide local excision
- Partial or total vaginectomy
- Intravaginal chemotherapy with 5% fluorouracil cream
- Laser therapy
- Intracavitary radiation therapy

MEDICATION

- Imiquimod

  - In a review of the effectiveness of 5% imiquimod cream in the treatment of VAIN, the following results were reported (4)[C]:
    - 26–100% of patients had complete regression.
    - 0–60% of patients had partial regression.
    - 0–37% experienced recurrence.
- Contraindications
  - The diagnosis must be established with certainty prior to treatment.
  - If there is any doubt that a process beyond in situ disease exists, vaginectomy must be performed. These patients are often elderly, and aggressive therapy is limited by the patient's performance status and ability to tolerate radical surgery, chemotherapy, or radiation.

ISSUES FOR REFERRAL

Patients should be treated by a gynecologic oncologist and/or a radiation oncologist.

ADDITIONAL THERAPIES

- Treatment with radiotherapy depends on the stage of disease. This treatment option should be discussed with physicians experienced with this malignancy.
- It is common to use radiotherapy and chemotherapy (chemoradiation) for better cancer control.
- Early-stage primary squamous cell carcinoma treated with radiation alone has shown good results (5)[A].
- Stage III vaginal cancer may benefit from combined radiation and hyperthermia (6)[C].
- Patients with advanced squamous cell carcinoma or adenocarcinoma receive concurrent irradiation and cisplatin-based chemotherapy (7)[B].
- Neoadjuvant chemotherapy followed by radical surgery may benefit select patients (8)[C].
- In most tumor types, metastatic disease from the vagina to other sites is only minimally responsive to chemotherapy.
- With one exception, no chemotherapeutic agents have shown a survival advantage. The exception is childhood sarcomas, which have been treated with combinations of the following:
  - Vincristine

- Dactinomycin (actinomycin-D)
- Cyclophosphamide (Cytoxan)
- Cisplatin
- Etoposide (VP-16)

SURGERY/OTHER PROCEDURES

- Whenever there is a doubt as to the presence or absence of invasive disease, vaginectomy must be performed.
- Invasive lesions usually are treated by radiation therapy, but stage I lesions can be treated with radical hysterectomy or radical vaginectomy with pelvic lymph node dissection (9)[A].
- If the lesion involves the lower vagina, inguinal node dissection also must be done because cancer involving the lower vagina can metastasize to the groin region.
- Premenopausal women who desire to retain ovarian function are better candidates for radical surgery for early-stage disease, with vaginal reconstruction possible afterward.
- Patients who have not completed their family can occasionally be treated with limited resection and localized radiation to the area.
- Sarcomas are treated by radiation therapy followed by pelvic exenteration if persistent disease is present.

Pediatric Considerations

The treatment of vaginal tumors today mainly consists of neoadjuvant chemotherapy followed by local control with surgery or radiotherapy.

Geriatric Considerations

Older patients, many with a long history of smoking, are at a higher risk for malignancies requiring surgical treatments.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Patients are usually ambulatory and able to resume full activity by 6 weeks after surgery.

- Most patients are fully active while receiving chemotherapy and radiation therapy.

Patient Monitoring

- Pelvic examination and Pap smear every 3 months for 2 years, then every 6 months for the next 3 years and then yearly thereafter
- Annual CXR

PATIENT EDUCATION

- Printed patient information available from American College of Obstetricians and Gynecologists, 409 12th St., SW, Washington, DC 20024-2188; 800-762-ACOG: http://www.acog.org
- American Cancer Society: http://www.cancer.gov
- Medline Plus: http://www.nlm.nih.gov/medlineplus/vaginalcancer.html

PROGNOSIS

Stage and 5-year survival (10)

- I: 77.6%
- II: 52.2%
- III: 42.5%
- IVA: 20.5%
- IVB: 12.9%

COMPLICATIONS

- Those typically associated with major abdominal surgery or radiation therapy
- Common complications of treatment include rectovaginal or vesicovaginal fistulas, rectal/vaginal strictures, radiation cystitis, and/or proctitis.

CODES

ICD10

- C52 Malignant neoplasm of vagina
- D07.2 Carcinoma in situ of vagina
- N89.3 Dysplasia of vagina, unspecified

CLINICAL PEARLS

- Vaginal cancer is rare; 85–90% of vaginal cancers are squamous cell.
- Vaginal malignancies are found most commonly on the posterior wall in the upper 1/3 of the vagina.
- Most vaginal malignancies are metastatic (from cervix, vulva, endometrium, breast, or ovary).

VAGINITIS AND VAGINOSIS

KrisEmily McCrory, MD, FAAFP

BASICS

DESCRIPTION

- "Vaginosis" and "Vaginitis" are broad terms indicating any disease process of the vagina caused by or leading to infection, inflammation, or changes in the normal vaginal flora.
- The difference between vaginitis and vaginosis is the presence (vaginitis) or absence (vaginosis) of inflammation.
- The most common symptoms of vaginitis/vaginosis are vaginal discharge, odor, itching, burning, or pain.
- The most common causes of vaginitis/vaginosis are bacterial vaginosis (BV), vulvovaginal candidiasis (VVC), and trichomoniasis.
- Other causes of vaginitis can be stratified by age and are generally associated with postmenopausal vaginal atrophy or foreign bodies in the pediatric population.
- Lichen planus, lichen sclerosus, psoriasis, and contact/allergic dermatitis may also cause vaginitis.
- Diagnosis of vaginitis relies on thorough history, physical exam, and clinical assessment. Microscopy, cultures, DNA probes, and tissue biopsy can be helpful in confirming diagnosis.
- BV is the most common cause of vaginal discharge in reproductive-aged women. It is caused by a disturbance in the normal vaginal flora. The normally dominant hydrogen peroxide–producing lactobacilli are overwhelmed by an overgrowth of gram-negative species causing an increase in the vaginal pH, discharge, and odor.
- VVC is the second most common cause of vaginitis in reproductive-aged women. It is caused by invasion of the *Candida* organism into the superficial epithelial cells of the vagina causing mild to severe vaginal inflammation, pruritus, and discharge.

EPIDEMIOLOGY

- Vaginal symptoms are typical and common in the general population and are one of the most frequent reasons women present to their medical care providers accounting for approximately 10 million office visits each year.
- About 30% of women with complaint of vaginal discharge or irritation remain undiagnosed despite extensive testing.
- In the United States, BV continues to be the leading cause of vaginal complaints. The frequency of VVC is highest among women in their reproductive years.
- Neither vaginal candidiasis nor BV is considered to be sexually transmitted diseases.
- Vaginal trichomoniasis is a common sexually transmitted disease with 7.4 million cases diagnosed yearly in the United States.

ETIOLOGY AND PATHOPHYSIOLOGY

- BV
  - BV is caused by a change in the normal vaginal flora. Dominant lactobacilli responsible for maintaining the acidic vaginal pH are overcome by an increase of the gram-negative organisms.
  - Change in the vaginal environment leads to an increase in the pH and an overgrowth of vaginal anaerobes, causing a malodorous, clear, white, or gray discharge and a fishy odor.
  - BV is highly prevalent and associated with multiple adverse outcomes, including enhanced HIV transmission.
  - The organisms generally implicated in BV infections include:
    - *Gardnerella vaginalis*
    - *Prevotella* species
    - *Porphyromonas* species
    - *Bacteroides* species
    - *Peptostreptococcus* species
    - *Mycoplasma hominis*
    - *Ureaplasma urealyticum*
    - *Mobiluncus* species
    - *Fusobacterium* species
    - *Atopobium vaginae*
- VVC

  - VVC is caused by *Candida albicans* (80–92%) and *C. glabrata* (<10%).
  - *Candida* organisms can be identified in the lower genital tract in healthy women, and it is thought to gain access via rectal and perianal colonization and migration.
  - Symptoms occur when candidal organisms overwhelm the normal vaginal flora and invade the superficial vaginal epithelial cells, causing inflammation, pruritus, and thick vaginal discharge.
  - Complicated VVC should be considered in pregnant patients, patients with diabetes, or immunocompromising conditions. Patients who experience four or more episodes of VVC in a year or who have only budding yeast on wet mount may also be considered to have complicated VVC.
- Trichomoniasis
  - Caused by an infection via *Trichomonas vaginalis*, a flagellate protozoan. The organism infects the squamous epithelium of the vagina, as well as the urethra, and paraurethral glands. This infection is primarily transmitted during sexual intercourse.
- Other sources of vaginitis/vaginosis are usually mediated by disruption of the vaginal squamous epithelium. This disruption can lead to inflammation, pain, and discharge.
  - Other than the three most common causes of vaginitis/vaginosis, menses, sexual activity, contraception, pregnancy, foreign bodies, estrogen levels, STDs, and use of vaginal hygiene products, topical creams, or antibiotics can contribute to vaginal symptoms.

RISK FACTORS

- BV
  - Sexual activity; while BV is not considered an STD, studies show increased rates of BV in women with multiple sex partners.
  - Women who have sex with women
  - Smoking
  - Vaginal douching
  - The presence of STDs such as HSV-2 (1)
- VVC
  - Diabetes
  - Diet high in refined sugars

  - Use of broad-spectrum antibiotics.
  - Immunosuppression
  - Higher estrogen levels have been associated with increased vaginal yeast infection, explaining why it is more commonly diagnosed in reproductive-aged women and in pregnancy.
- Trichomoniasis
  - Inconsistent use of barrier contraception
  - Multiple sex partners
  - African Americans
  - Limited education and low socioeconomic status
  - Illicit drug use
  - Smoking
- Other risk factors associated with vaginitis/vaginosis:
  - Decreased estrogen
  - Smoking
  - Use of vaginal douches and creams
  - Tight fitting clothing
  - Poor hygienic practice
  - Changes in diet

GENERAL PREVENTION

- Vulvar hygiene
- Except in cases of trichomoniasis, treatment of sexual partners generally is not recommended but may be considered in recurrent cases.
- Advise patients not to douche.

COMMONLY ASSOCIATED CONDITIONS

- STDs such as gonorrhea, chlamydia, or HSV
- Vaginal intraepithelial neoplasia and cancer can present with symptoms of vaginitis.
- Desquamative inflammatory vaginitis presents with similar symptoms but most commonly occurs in postmenopausal women.

DIAGNOSIS

HISTORY

- General principles:
  - The key to diagnosis is clarification of the presenting symptoms.
  - Onset, timing, and character of the vaginal symptoms are important questions to ask.
  - Many patients will be asymptomatic, and diagnosis is made on routine physical exam and lab testing.
  - Pap smears should not be used as diagnostic tools due to low sensitivity and specificity.
  - Symptomatic patients generally complain of itching, burning, irritation, and abnormal discharge.
- BV
  - Symptomatic patients complain of abnormal vaginal discharge and a fishy odor.
  - Pain and pruritus are uncommon.
- VVC
  - Symptomatic women report itching, burning, irritation, dyspareunia, burning with urination, and a white thick discharge.
  - Odor is uncommon.
- Trichomoniasis
  - Symptomatic patients will complain of abnormal discharge, itching, burning, or postcoital bleeding.

PHYSICAL EXAM

- BV
  - Thin watery, sometimes foamy discharge. Can appear beige- or tan-colored. An amine or “fishy” smell may be present on exam.
  - The vaginal epithelium should appear normal and noninflamed.
- VVC
  - Erythema and swelling of the vulva and vaginal mucosa
  - Some patients may have vulvar excoriation and fissures.
  - If discharge is present, it is usually white, thick, and can have a cottage cheese appearance. Some women may have thin white dilute discharge. No odor is present.

- Trichomoniasis
  - Significant erythema of the vulva and vaginal mucosa
  - Greenish discharge with an amine or fishy odor
  - Discharge can also appear purulent in some patients.
  - Occasionally punctate hemorrhages can be seen on the vaginal walls and on the cervix (“strawberry cervix”).

DIFFERENTIAL DIAGNOSIS

- Physiologic discharge
- Leukorrhea of pregnancy
- STDs
- Foreign body
- Contact dermatitis
- Cervicitis
- Desquamative inflammatory vaginitis
- Urinary tract infection (UTI)
- Atrophic vaginitis
- Dermatoses: lichen sclerosus, lichen planus, seborrheic dermatitis, psoriasis

DIAGNOSTIC TESTS & INTERPRETATION

- BV
  - Symptomatic patients complain of an abnormal vaginal discharge and a fishy odor.
  - Clinical diagnosis is established with Amsel criteria. A positive diagnosis can be made if 3 out of 4 of the following criteria are present.
    - Thin, homogenous discharge
    - Vaginal pH >4.5
    - A positive amine or “Whiff” test with use of KOH solution added to discharge
    - >20% of the epithelial cells identified as “clue cells”
- Vulvovaginal candidiasis
  - Visualization of blastospores or pseudohyphae on saline or 10% KOH microscopy
  - A positive culture in a symptomatic patient
- Trichomoniasis

- Visualization of motile trichomonads on saline microscopy
- Several POC identification tests, including patient performed, are available with increased sensitivity compared to microscopy but are expensive.

TREATMENT

GENERAL MEASURES

- Avoid douching and tight fitting clothing.
- Regular use of condoms may help to prevent BV.
- Asymptomatic, pregnant women generally do not require treatment for BV.

MEDICATION

Medication recommendations based on CDC treatment guidelines (2)[A]

- BV
  - Metronidazole 500 mg orally BID for 7 days, vaginally 0.75% gel 1 applicator daily for 5 days, or clindamycin given vaginally (1 applicator = 100 mg) for 5 days. Recurrent infection may require repeated treatment (e.g., 1 week monthly for 6 months). Advise patients to avoid alcohol during treatment with oral metronidazole and for 3 days following.
- Vulvovaginal candidiasis
  - Uncomplicated infections can be treated with a one-time dose of fluconazole 150 mg tab. Topical/vaginal suppository antifungal regimens such as butoconazole, clotrimazole, miconazole, terconazole, or nystatin creams. Treatment can range from 3 to 7 days.
  - Recurrent or complicated infections may require additional oral dosing of fluconazole 150 mg tab for extended treatment and/or prophylaxis.
  - Non-albican candidiasis may require longer duration of treatment with topical or oral azoles.
  - Avoid oral azoles in pregnant women.
  - Advise patients that topical medications may weaken rubber or latex condoms.
- Trichomoniasis
  - A one-time 2-g oral dose of either tinidazole or metronidazole. Alternatively, 500-mg dose of metronidazole twice daily for 7 days.

- The patient's partner should be treated as well and counseled to abstain from sex until both patients have completed treatment and are asymptomatic.
- Test of cure is not necessary.

ISSUES FOR REFERRAL

Treating male partners does not reduce symptoms or prevent recurrence but can be considered in patients with recurrent infection.

COMPLEMENTARY & ALTERNATIVE MEDICINE

A Cochrane analysis reviewed the use of probiotics for BV and found inconclusive evidence to recommend probiotics as primary treatment or as a preventive strategy (3)[A]. Further study was recommended.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Delay sexual relations until symptoms clear/discomfort resolves.
- Use of condoms may reduce recurrence of BV.

Patient Monitoring

- No specific follow-up needed; if symptoms persist or recur within 2 months, repeat pelvic exam and culture.
- Consider suppressive therapy for recurrent infection.

PATIENT EDUCATION

American College of Obstetricians and Gynecologists (ACOG), 409 12th St., SW, Washington, DC 20024-2188; 800-762-ACOG: www.acog.org

PROGNOSIS

VVC: 80–90% of uncomplicated cases cured with appropriate treatment; 30–50% of recurrent infections return after discontinuation of maintenance therapy; there is a relatively high spontaneous remission rate of untreated symptoms as well.

COMPLICATIONS

- VVC may occur following treatment of BV.
- BV has been associated with an increased risk of acquisition and transmission of HIV.
- BV has been associated with increased risk of preterm birth, chorioamnionitis, postpartum and postabortal endometritis, and pelvic inflammatory disease.

SEE ALSO

Algorithm: Discharge, Vaginal

CODES

ICD10

- N76.0 Acute vaginitis
- B37.3 Candidiasis of vulva and vagina
- N95.2 Postmenopausal atrophic vaginitis

CLINICAL PEARLS

Clinical symptoms, signs, and microscopy have relatively poor performance compared with so-called gold standards such as culture and DNA probe assays, but these more sensitive assays can detect organisms that may not be causing symptoms.

- Most women experience relief of symptoms with therapy chosen without such gold standard tests, even when the treatment does not correspond with the underlying infection.
- Vaginal pH is underused as a diagnostic tool for evaluation of vaginitis.

VARICOSE VEINS

Joseph A. Florence, MD • Leigh D. Johnson, MD

BASICS

DESCRIPTION

- Superficial venous disease causing a permanent dilatation and tortuosity of superficial veins, usually occurring in the legs and feet; caused by systemic weakness in the vein wall and may result from congenitally incomplete valves or valves that have become incompetent
- Affects legs where reverse flow occurs when dependent
- Truncal varices involve the great and small saphenous veins; branch varicosities involve the saphenous vein tributaries.
- Categorized as the following:
  - Uncomplicated (cosmetic)
  - With local symptoms (pain confined to the varices, not diffuse)
  - With local complications (superficial thrombophlebitis, may rupture causing bleeding)
  - Complex varicose disease (diffuse limb pain, swelling, skin changes/ulcer)
- System(s) affected: cardiovascular; skin

ALERT

Ulceration of varicose veins has a high rate of infection, which can lead to sepsis.

Geriatric Considerations

- Common; usually valvular degeneration but may be secondary to chronic venous deficiency
- Elastic support hose and frequent rests with legs elevated rather than ligation and stripping

Pregnancy Considerations

- Frequent problem
- Elastic stockings are recommended for those with a history of varicosities or if

prolonged standing is involved.

EPIDEMIOLOGY

Incidence

- Predominant age: middle age
- Predominant gender: female > male (2:1)
- National Women's Health Information Center estimates that 50% of women have varicose veins.

ETIOLOGY AND PATHOPHYSIOLOGY

- Varicose veins are caused by venous insufficiency from faulty valves in ≥1 perforator veins in the lower leg, causing secondary incompetence at the saphenofemoral junction (valvular reflux).
- Valvular dysfunction causing venous reflux and subsequently venous hypertension (HTN)
- Failed valves allow blood to flow in the reverse direction (away from the heart), from deep to superficial and from proximal to distal veins.
- Deep thrombophlebitis
- Increased venous pressure from any cause
- Congenital valvular incompetence
- Trauma (consider arteriovenous fistula; listen for bruit)
- Presumed to be due to a loss in vein wall elasticity with failure of the valve leaflets
- An increase in venous filling pressure is sufficient to promote varicose remodeling of veins by augmenting wall stress and activating venous endothelial and smooth muscle cells (1).

Genetics

Autosomal dominant with incomplete penetrance

RISK FACTORS

- Increasing age
- Pregnancy, especially multiple pregnancies
- Prolonged standing
- Obesity
- History of phlebitis (postthrombotic syndrome)

- Family history
- Female sex
- Increased height
- Congenital valvular dysfunction

COMMONLY ASSOCIATED CONDITIONS

- Stasis dermatitis
- Large varicose veins may lead to skin changes and eventual stasis ulceration.

DIAGNOSIS

HISTORY

- Symptoms range from minor annoyance/cosmetic problem to a lifestyle-limiting problem.
- Localized symptoms: pain, burning, itching
- Generalized symptoms
  - Leg muscular cramp, aching
  - Leg fatigue/swelling
- Pain if varicose ulcer develops
- Symptoms often worse at the end of the day, especially after prolonged standing.
- Women are more prone to symptoms due to hormonal influences: worse during menses.
- No direct correlation with the severity of varicose veins and the severity of symptoms

PHYSICAL EXAM

- Inspect lower extremities while the patient is standing. Varicose veins in the proximal femoral ring and distal portion of the legs may not be visible when the patient is supine.
- Varicose veins are the following:
  - Dilated, tortuous, superficial veins, chiefly in the lower extremities
  - Dark purple/blue in color, raised above the surface of the skin
  - Often twisted, bulging, and can look like cords
  - Most commonly found on the posterior/medial lower extremity

- Edema of the affected limb may be present.
- Skin changes may include the following:
  - Eczema
  - Hyperpigmentation
  - Lipodermatosclerosis
- Spider veins (idiopathic telangiectases)
  - Fine intracutaneous angiectasis
  - May be extensive/unsightly
- Neurologic sensory and motor exam
- Peripheral arterial vasculature; pulses
- Musculoskeletal exam for associated rheumatologic/orthopedic issues

DIFFERENTIAL DIAGNOSIS

- Nerve root compression
- Arthritis
- Peripheral neuritis
- Telangiectasia: smaller, visible blood vessels that are permanently dilated
- Deep vein thrombosis
- Inflammatory liposclerosis

DIAGNOSTIC TESTS & INTERPRETATION

Duplex ultrasound: Noninvasive imaging duplex ultrasound will confirm the etiology, anatomy, and pathophysiology of segmental venous reflux. The severity of both symptoms and signs tends to correlate with the degree of venous reflux, which is identified by duplex ultrasound as retrograde or reversed flow of greater than 0.5 second duration (2).

Diagnostic Procedures/Other

Duplex scanning, venous Doppler study, photoplethysmography, light-reflection rheography, air plethysmography, and other vascular testing should be reserved for patients who have venous symptoms and/or large (>4 mm in diameter) vessels or large numbers of spider telangiectasia indicating venous HTN.

Test Interpretation

A clinical classification illustrating the current physical state is useful in clinical practice (1).

- 0: no visible or palpable signs of venous disease
- 1: spider veins or telangiectasias
- 2: varicose veins
- 3: edema
- 4: skin changes (pigmentation, eczema, lipodermatosclerosis, atrophie blanche)
- 5: healed ulcer
- 6: active ulcer

TREATMENT

- Conventional wisdom suggests conservative therapy (e.g., elevation, external compression, weight loss) as being helpful; while compression stockings improve the severity of varicose veins, they do not seem to improve quality of life (3)[B].
- There is insufficient, high-quality evidence to determine whether or not compression stockings are effective as the sole and initial treatment of varicose veins in people without healed or active venous ulceration, or whether any type of stocking is superior to any other type (4)[A].
- All the current modalities of endoluminal and open surgical treatment have similar short-term outcomes and risks (5)[A].
- Appropriate surgical treatment has the best long-term outcomes and evidence base (5)[A].
- Treatment of choice, however, depends on many factors, including local expertise (5)[A].
- When comparing quality of life, pain relief, and long-term relief, surgery is favored (6)[A].
- Endovenous laser ablation (EVLA); radiofrequency ablation, foam sclerotherapy, and surgical stripping for great saphenous varicose veins are all efficacious (7)[A].
- Endovenous ablation (radiofrequency and laser) is at least as effective as surgery in the treatment of great saphenous varicose veins and outcomes remain similar at 2 years (8)[A]; however, ultrasound-guided foam sclerotherapy has insufficient support from available data (7)[A].

- The ambulatory conservative hemodynamic correction of venous insufficiency method (cure conservatrice et hémodynamique de l'insuffisance veineuse en ambulatoire [CHIVA]) is a less-invasive approach based on venous hemodynamics with deliberate preservation of the superficial venous system. The CHIVA method reduces recurrence of varicose veins and produces fewer side effects than vein stripping (9)[A].

GENERAL MEASURES

Patients with unsightly varicose veins often seek treatment for cosmetic reasons.

MEDICATION

Superficial thrombophlebitis is not an infective condition and does not require antibiotic treatment.

ISSUES FOR REFERRAL

- Emergency: bleeding from a varicosity that has eroded the skin
- Urgent: varicosity that has bled and is at risk for bleeding again
- Soon: ulcer that is progressive/painful despite treatment
- Routine
  - Active/healed ulcer/progressive skin changes that may benefit from surgery
  - Recurrent superficial thrombophlebitis
  - Troublesome symptoms attributable to varicose veins or patient and provider feel that the extent, site, and size of the varicosities are having a severe impact on quality of life.

ADDITIONAL THERAPIES

- Apply elastic stockings before lowering legs from the bed.
- Activity
  - Frequent rest periods with legs elevated
  - If standing is necessary, frequently shift weight from side to side.
  - Appropriate exercise routine as part of conservative treatment
  - Walking regimen after sclerotherapy is important to help promote healing.
  - Never sit with legs hanging down.
- Physical therapy

SURGERY/OTHER PROCEDURES

- Surgery
  - Improved quality-adjusted life-years and symptoms compared to conservative management at 2 years (1)[A]
  - Surgery is indicated if there is pain, recurrent phlebitis, or skin changes/ulceration or for cosmetic improvement for severe cases.
  - Minimally invasive techniques include the following:
    - Radiofrequency ablation (RFA): compared with surgery provides a faster return to work; less pain, better short-term quality of life; less bruising and tenderness compared with endovenous laser therapy (1)[A]
    - Endovenous microwave ablation (EMA) is an effective new technique for the treatment of varicose veins and had a more satisfactory clinical outcome than high ligation and stripping (HLS) in the short term (10)[A].
    - EVLA is as effective as conventional surgery (CS) and superior to ultrasound-guided foam sclerotherapy (UGFS), according to occlusion on ultrasound duplex (11)[B].
    - Quality of life improves after treatment in all groups (EVLA, CS, UGFS), significantly (11)[B].
    - There is no significant difference between EVLA and open surgery in patients with great saphenous vein incompetence (12)[A].
- Sclerotherapy is a simple, safe, and particularly effective for smaller, early varicosities and also for residual veins after surgery (13)[C].
- Radiotherapy
  - RFA takes longer to perform but has better early outcome than CS in patients with great saphenous varicose veins.
  - Radiofrequency and laser treatments replace “stripping”; however, most varicosities still require phlebectomy/sclerotherapy.

ONGOING CARE

DIET

- No special diet
- Weight-loss diet is recommended if obesity is a problem.

PATIENT EDUCATION

- Avoid long periods of standing and crossing legs when sitting.
- Exercise (walking, running) regularly to improve leg strength and circulation.
- Maintain an appropriate weight.
- Wear elastic support stockings.
- Avoid clothing that constricts legs.
- Surgery/sclerotherapy may not prevent development of varicosities, and the procedure may need to be repeated in later years.
- National Heart, Lung and Blood Institute, Communications and Public Information Branch, National Institutes of Health, Building 31, Room 41–21, 9000 Rockville Pike, Bethesda, MD 20892; 301-496-4236. http://www.nhlbi.nih.gov/
- JAMA Patient Page| Treatment of Varicose Veins; http://jama.jamanetwork.com/article.aspx?articleid=1672241

PROGNOSIS

- Usual course: chronic
- Favorable with appropriate treatment
- Surgery has a nonsignificant reduction in the risk of varicose vein recurrence compared with liquid sclerotherapy and endoluminal interventions (6)[A].
- Increasing disease severity by venous clinical severity score (VCSS) is associated with reductions in quality of life (14)[B].

COMPLICATIONS

- Complications with sclerotherapy include hyperpigmentation, matting, local urticaria, cutaneous necrosis, microthrombi, accidental intra-arterial injection, phlebitis, deep vein thrombosis, thromboembolism, scintillating scotomas, nerve damage, and allergic reactions.
- Petechial hemorrhages
- Chronic edema
- Superimposed infection
- Varicose ulcers
- Pigmentation
- Eczema
- Recurrence after surgical treatment
- Scarring/nerve damage from stripping technique

- Neurologic complications after sclerotherapy are rare (6)[B].

CODES

ICD10

- I83.90 Asymptomatic varicose veins of unspecified lower extremity
- I83.009 Varicose veins of unsp lower extremity w ulcer of unsp site
- I83.10 Varicose veins of unsp lower extremity with inflammation

CLINICAL PEARLS

- Long-term safety and efficacy of surgery for the treatment of varicose veins is supported by low-quality evidence. Less-invasive treatments, which are associated with less periprocedural disability and pain, are supported by short-term studies (4)[A].
- Endovascular treatment of varicose veins is safe and effective and has a rapid recovery (7)[A]. Insufficient evidence exists to prefer sclerotherapy over surgery (6)[A].
- The efficacy of sclerotherapy is not significantly affected by the choice of sclerosant, dose, formulation (foam vs. liquid), local pressure dressing, or degree and length of compression (6)[A].

VASCULITIS

Irene J. Tan, MD

BASICS

DESCRIPTION

An inflammatory blood vessel disorder

- Clinical features result from the destruction of blood vessel walls with subsequent thrombosis, ischemia, bleeding, and/or aneurysm formation.
- Vasculitis consists of a large, heterogeneous group of diseases classified by the predominant size, type, and the location of involved blood vessels (1).
  - Small-vessel vasculitis
    - Microscopic polyangiitis (MPA)
    - Granulomatosis with polyangiitis (GPA, formerly Wegener granulomatosis)
    - Eosinophilic granulomatosis with polyangiitis (EGPA; formerly Churg-Strauss syndrome)
    - Antiglomerular basement membrane disease (anti-GBM)
    - Cryoglobulinemic vasculitis
    - IgA vasculitis (formerly Henoch-Schönlein purpura)
    - Hypocomplementemic urticarial vasculitis
  - Medium-vessel vasculitis
    - Polyarteritis nodosa (PAN)
    - Kawasaki disease (KD)
  - Large-vessel vasculitis
    - Takayasu arteritis (TAK)
    - Giant cell arteritis (GCA)
- Vasculitis occurs as a primary disorder or secondary to infection, a drug reaction, malignancy, or connective tissue disease.
  - Variable vessel vasculitis
    - Behçet disease
    - Cogan syndrome
  - Single-organ vasculitis

    - Cutaneous leukocytoclastic angiitis
    - Cutaneous arteritis
    - Primary CNS vasculitis
  - Vasculitis associated with systemic disease
    - Lupus vasculitis
    - Rheumatoid vasculitis
    - Sarcoid vasculitis
  - Vasculitis associated with other etiology
    - Hepatitis C–associated cryoglobulinemic vasculitis
    - Hepatitis B–associated vasculitis
    - Syphilis-associated aortitis
    - Drug-induced immune complex vasculitis
    - Drug-associated antineutrophil cytoplasmic antibodies (ANCA)–associated vasculitis
    - Cancer-associated vasculitis
- Protean features often delay definitive diagnosis.

EPIDEMIOLOGY

Highly variable, depending on the particular syndrome

- Hypersensitivity vasculitis is most commonly encountered in clinical practice.
- KD, IgA vasculitis, and dermatomyositis are more common in children.
- TAK is most prevalent in young Asian women. GPA, MPA, and EGPA are more common in middle-aged males.
- GCA occurs exclusively in those >50 years of age and is rare in the African American population.

Incidence

Annual incidence in adults (unless otherwise specified)

- IgA vasculitis: 200 to 700/1 million in children <17 years of age
- GCA: 100 to 170/1 million in Caucasians age >50 years
- KD: depends on race/age; ~200/1 million
- PAN: 2 to 33/1 million
- GPA: 4 to 15/1 million
- MPA: 1 to 24/1 million
- EGPA: 1 to 3/1 million

- TAK: 2/1 million
- Primary CNS vasculitis: 2/1 million in adults
- Hypersensitivity vasculitis: depends on drug exposure
- Viral-/retroviral-associated vasculitis: unknown; >90% of cases of cryoglobulinemic vasculitis are associated with hepatitis C.
- Connective tissue disorder–associated vasculitis: variable

ETIOLOGY AND PATHOPHYSIOLOGY

- Three major immunopathogenic mechanisms
  - Immune-complex formation: systemic lupus erythematosus (SLE), IgA vasculitis (HSP), and cryoglobulinemic vasculitis
  - ANCAs: GPA, MPA, and EGPA
  - Pathogenic T-lymphocyte response: GCA and TAK
- Pathophysiology best understood where known drug triggers have been identified (e.g., antibiotics, sulfonamides, and hydralazine)

Genetics

- Several vasculitides linked to candidate genes.
- No single gene has been found to cause vasculitis.
- Angiotensin-converting enzyme insertion/deletion polymorphism is associated with susceptibility to vasculitis, especially in Behçet disease and IgA vasculitis.

RISK FACTORS

A combination of genetic susceptibility and environmental exposure likely triggers onset.

GENERAL PREVENTION

Early identification is the key to prevent irreversible organ damage in severe forms of systemic vasculitis.

COMMONLY ASSOCIATED CONDITIONS

Hepatitis C (cryoglobulinemic vasculitis), hepatitis B (PAN), cytomegalovirus (CMV), Epstein-Barr virus (EBV), HIV (viral-/retroviral-associated vasculitis), SLE, rheumatoid arthritis (RA), Sjögren syndrome, mixed connective tissue disease (MCTD), dermatomyositis, ankylosing spondylitis, Behçet disease,

relapsing polychondritis (CTD-associated vasculitis), respiratory tract methicillin-resistant *Staphylococcus aureus* (MRSA) in GPA, levamisole adulterated cocaine, medications: propylthiouracil, methimazole, hydralazine, minocycline

DIAGNOSIS

HISTORY

- Consider age, gender, and ethnicity.
- Comprehensive medication history
- Family history of vasculitis
- Constitutional symptoms: fever, weight loss, malaise, fatigue, diminished appetite, sweats
- CNS/PNS: mononeuritis multiplex, polyneuropathy, headaches, visual loss, tinnitus, stroke, seizure, encephalopathy
- Heart/lung: myocardial infarction, cardiomyopathy, pericarditis, cough, chest pain, hemoptysis, dyspnea
- Renal: hematuria
- GI: abdominal pain, hematochezia, perforation
- Musculoskeletal: arthralgia, myalgia
- Miscellaneous: unexplained ischemic or hemorrhagic events, chronic sinusitis, and recurrent epistaxis
- Note the organs affected and estimate the size of blood vessels involved.
- Demographics, clinical features, and the predominant vessel size/organ involvement help identify specific type of vasculitis.

PHYSICAL EXAM

- Vital signs: blood pressure (hypertension) and pulse (regularity and rate)
- Skin: palpable purpura, livedo reticularis, nodules, ulcers, gangrene, nail bed capillary changes
- Neurologic: cranial nerve exam, sensorimotor exam
- Ocular exam: visual fields, scleritis, episcleritis
- Cardiopulmonary exam: rubs, murmurs, arrhythmias
- Abdominal exam: tenderness, organomegaly

DIFFERENTIAL DIAGNOSIS

- Fibromuscular dysplasia
- Embolic disease (atheroma, cholesterol emboli, atrial myxoma, mycotic aneurysm with embolization)
- Drug-induced vasospasm (cocaine, amphetamines, ergots)
- Thrombotic thrombocytopenic disorders (disseminated intravascular coagulation [DIC], thrombotic thrombocytopenic purpura [TTP], antiphospholipid syndrome, heparin- or warfarin-induced thrombosis)
- Systemic infection (infective endocarditis, fungal infections, disseminated gonococcal infection, Lyme disease, syphilis, Rocky Mountain spotted fever [RMSF], bacteremia)
- Malignancy (lymphomatoid granulomatosis, angioimmunoblastic T-cell lymphoma, intravascular lymphoma)
- Miscellaneous (Goodpasture syndrome, sarcoidosis, amyloidosis, Whipple disease, congenital coarctation of aorta)

DIAGNOSTIC TESTS & INTERPRETATION

ALERT

Renal involvement is often clinically silent. Routine serum creatinine and urinalysis with microscopy are needed to identify underlying glomerulonephritis.

- Initial tests to exclude alternate diagnosis and guide appropriate therapy
- Routine tests
  - CBC
  - Liver enzymes
  - Serum creatinine
  - Urinalysis with microscopy
- Specific serology
  - Antinuclear antibodies (ANA)
  - Rheumatoid factor (RF)
  - Rapid plasma reagin/venereal disease reaction level (RPR/VDRL)
  - RMSF titer
  - Lyme titer

  - Complement levels C3, C4
  - ANCA
  - Antiproteinase 3 antibodies (anti-PR3)
  - Antimyeloperoxidase antibodies (anti-MPO)
  - Hepatitis screen for B and C
  - Cryoglobulin
  - Anti-GBM titer
  - HIV
  - Serum and urine protein electrophoresis
- Miscellaneous
  - Drug screen
  - ESR
  - C-reactive protein
  - Creatine kinase (CK)
  - Blood culture
  - ECG
- CXR, CT scan, MRI, and arteriography may be required to delineate extent of organs involved.

Diagnostic Procedures/Other

- Electromyography with nerve conduction can document neuropathy and target nerve for biopsy.
- Biopsy of affected site confirms diagnosis (e.g., temporal artery, sural nerve, renal biopsy).
- If biopsy is not practical, angiography may be diagnostic for large- and medium-vessel vasculitides.
- Bronchoscopy may be required to differentiate pulmonary infection from potentially life-threatening hemorrhagic vasculitis in patients with hemoptysis.

Test Interpretation

Blood vessel biopsy shows immune cell infiltration into vessel wall layers with varying degrees of necrosis and granuloma formation, depending on the type.

TREATMENT

GENERAL MEASURES

- Discontinue offending drug (hypersensitivity vasculitis).
- Simple observation for mild cases of IgA vasculitis
- ANCA-associated vasculitis has 2-phase treatment: initial induction followed by maintenance (steady tapering of corticosteroids with immunosuppressants or immunomodulators)

MEDICATION

First Line

Corticosteroids are initial anti-inflammatory of choice.

Second Line

Cytotoxic medications, immunomodulatory, or biologic agents (e.g., cyclophosphamide (2)[B],(3,4)[A] methotrexate (4,5)[A], azathioprine (4,5)[A], leflunomide (4)[A], mycophenolate mofetil (2)[B],(4)[A], and rituximab (3,4)[A]) are often required in combination with corticosteroids for rapidly progressive vasculitis with significant organ involvement or inadequate response to corticosteroids.

ISSUES FOR REFERRAL

- Rheumatology referral for complicated cases where newer or more toxic treatments are required
- Nephrology referral for persistent hematuria or proteinuria, rising creatinine, or a positive ANCA titer
- Pulmonary referral for persistent pulmonary infiltrate unresponsive to antibiotic therapy or if gross hemoptysis

ADDITIONAL THERAPIES

- IVIG and aspirin for KD, but corticosteroids are contraindicated.
- Plasma exchange appears to improve recovery of patients with severe acute renal failure secondary to vasculitis and pulmonary hemorrhage (4)[A].

SURGERY/OTHER PROCEDURES

Rarely, corrective surgery is required to repair tissue damage as a result of aggressive vasculitis.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Hemoptysis, acute renal failure, intestinal ischemia, any organ-threatening symptoms or signs, and/or need for biopsy
- Initial therapy is guided by the organ system involved.
  - If pulmonary hemorrhage is present, life-saving measures may include mechanical ventilation, plasmapheresis, and immunosuppression.
  - If acute renal failure is present, attend to electrolyte and fluid balance and consider plasma exchange and immunosuppression.
  - If signs of intestinal ischemia are present, make NPO and consider plasmapheresis, immunosuppression, and parenteral nutrition.
- Discharge criteria: stabilization or resolution of potential life-threatening symptoms

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

If significant coronary artery disease is involved in KD, moderate activity restriction may be of benefit.

Patient Monitoring

Frequent clinical follow-up supported by patient self-monitoring to identify disease relapse

DIET

Alter diets for patients with renal involvement or hyperglycemia/dyslipidemia.

PROGNOSIS

Prognosis is good for patients with vasculitis and limited organ involvement. Relapsing courses, renal, intestinal, or extensive lung involvement have a poorer prognosis.

COMPLICATIONS

- Persistent organ dysfunction may be the result of the disease, medications, or inflammation/scarring in the more serious forms of vasculitis.

- Early morbidity/mortality is due to active vasculitic disease; delayed morbidity/mortality may also be secondary to complications of chronic therapy with cytotoxic medications.

CODES

ICD10

- I77.6 Arteritis, unspecified
- M31.30 Wegener’s granulomatosis without renal involvement
- M30.0 Polyarteritis nodosa

CLINICAL PEARLS

- Suspect vasculitis in patients with a petechial rash, palpable purpura, glomerulonephritis, pulmonary-renal syndrome, intestinal ischemia, or mononeuritis multiplex.
- Exclude silent renal involvement by routinely obtaining serum creatinine and urinalysis with microscopy.
- Vasculitis has “skip” lesions, which may complicate diagnostic biopsy.
- In patients with vasculitis, look for a primary underlying process such as medication, infection, thrombosis, or malignancy.

VENOUS INSUFFICIENCY ULCERS

Barbara J. Provo, MSN, RN, FNP-BC, CWON •
Theodore MacKinney, MD, MPH

BASICS

- Venous insufficiency disorders include simple spider veins, varicose veins, and leg edema.
- In the United States, 23% of adults have varicose veins, an estimated 22 million women and 11 million men.
- Venous leg ulcers are the most serious consequence of venous insufficiency.
- Venous leg ulcers are a type of chronic wound affecting up to 1% of adults in developed countries at some point during their lives.
- 500,000 people in the United States have chronic venous ulcers, with an estimated treatment cost of >$3 billion per year.

DESCRIPTION

- Full-thickness skin defect with surrounding pigmentation and dermatitis
- Most frequently located in ankle region of lower leg (“gaiter region”)
- Present for >30 days and fails to heal spontaneously
- May only have mild pain unless infected
- Other signs of chronic venous insufficiency include edema/brawny edema and chronic skin changes (i.e., hyperpigmentation and/or fibrosis).

EPIDEMIOLOGY

Up to 80% of leg ulcers are caused by venous disease; arterial disease accounts for 10–25%, which may coexist with venous disease.

Incidence

- Overall incidence of venous ulcers is 18/100,000 persons.
- Prevalent sex: women > men (20.4 vs. 14.6 per 100,000 for venous ulcer); increased with age for both sexes

Prevalence

- Seen in ~1% of adult population in industrialized countries; increased to 5%

in patients ≥80 years old
- Prevalence studies only available for Western countries
- Point prevalence underestimates the extent of the disease because ulcers often recur.
- 70% of ulcers recur within 5 years of closure.

ETIOLOGY AND PATHOPHYSIOLOGY

- In a diseased venous system, venous pressure in the deep system fails to fall with ambulation, causing venous hypertension.
- Venous hypertension comes from the following:
  - Venous obstruction
  - Incompetent venous valves in the deep or superficial system
  - Inadequate muscle contraction (e.g., arthritis, myopathies, neuropathies) so that the calf pump is ineffective
- Venous pressure transmitted to capillaries leading to venous hypertensive microangiopathy and extravasation of RBCs and proteins (especially fibrinogen)
- Increased RBC aggregation leads to reduced oxygen transport, slowed arteriolar circulation, and ischemia at the skin level, contributing to ulcers.
- Leukocytes aggregate to hypoxic areas and increase local inflammation.
- Factors promoting persistence of venous ulcers
  - Prolonged chronic inflammation
  - Bacterial infection, critical colonization

RISK FACTORS

- History of leg injury
- Obesity
- Congestive heart failure (CHF)
- History of deep venous thrombosis (DVT)
- Failure of calf muscle pump (e.g., ankle fusion, inactivity) is a strong independent predictor of poorly healing wounds.
- Previous varicose vein surgery
- Family history

GENERAL PREVENTION

- Primary prevention after symptomatic DVT: Prescribe compression hose to be used as soon as feasible for at least 2 years (≥20 to 30 mm Hg compression).
- Secondary prevention of recurrent ulceration includes compression, correction of the underlying problem, and surveillance. Circumstantial evidence from two RCTs showed those who stopped wearing compression hose were more likely to recur.
- Compression hose reduces rates of recurrence compared with no compression.
- Because most ulcers develop following some type of trauma, avoiding lower leg trauma may help to prevent ulceration.

COMMONLY ASSOCIATED CONDITIONS

Up to 50% of patients have allergic reactions to topical agents commonly used for treatment.

- Contact sensitivity was more common in patients with stasis dermatitis (62% vs. 38%).
- Avoid neomycin sulfate in particular (including triple antibiotic ointment) (1) [A].

DIAGNOSIS

A diagnosis of venous reflux or obstruction must be established by an objective test beyond the routine clinical examination of the extremity.

HISTORY

- Family history of venous insufficiency and ulcers
- Recent trauma
- Nature of pain: achy (better with leg elevation)
- Wound drainage
- Duration of wound and over-the-counter (OTC) treatments already attempted
- History of DVTs (especially factor V Leiden mutation; strongly associated with ulceration)
- History of leg edema that improves overnight
- Edema that does not improve overnight is more likely lymphedema.

PHYSICAL EXAM

- Look for evidence of venous insufficiency:
  - Pitting edema
  - Hemosiderin staining (red and brown spotty or diffuse pigment changes)
  - Stasis dermatitis
  - White skin lesions (atrophie blanche)
  - Lipodermatosclerosis ("bottle neck" narrowing in the lower leg from fibrosis and scarring)
- Look for evidence of significant lymphedema (i.e., dorsal foot or toe edema, edema that does not resolve overnight or with elevation). This may require referral for special comprehensive lymph therapy.
- Examine for palpable pulses.

ALERT

- Examine wound for the following:
  - Length, width, depth, to monitor wound healing rate
  - Presence of necrotic tissue
  - Presence of biofilms or infection: purulent material in the wound, increased amount odorous exudate, spreading cellulitis, fever, and chills
- Get initial and interim girth measurements (at ankle and midcalf) to monitor edema.
- Important to rule out poor arterial circulation:
  - Compression dressings cannot be used in patients with ankle brachial index (ABI) <0.8.

DIFFERENTIAL DIAGNOSIS

- Arterial insufficiency ulcer
- Neuropathic ulcer
- Malignancy
- Sickle cell ulcer
- Vasculitic ulcer
- Calciphylaxis
- Cryoglobulinemia
- Pyoderma gangrenosum
- Collagen vascular disease
- Leishmaniasis

- Cutaneous tuberculosis

DIAGNOSTIC TESTS & INTERPRETATION

- Consider prothrombin time (PT)/international normalization ratio (INR) and partial thromboplastin time (PTT) if patient is anticoagulated.
- Consider biopsy of leg ulcers that fail to heal or have atypical features.
- Consider factor V Leiden mutation; strongly associated with venous ulcers
- Test for diabetes as necessary with fasting glucose
- Use duplex imaging to diagnose anatomic and hemodynamic abnormalities with venous insufficiency. It will also identify any DVT present.

Diagnostic Procedures/Other

- Check ABI for evidence of arterial disease.
- An ABI <0.8 is a relative contraindication to compression therapy.
- Duplex imaging for evaluation of superficial and deep venous reflux and incompetent perforator veins
- With concomitant severe arterial insufficiency, refer to a vascular surgeon for revascularization.

Test Interpretation

Strongly consider biopsy on wounds with atypical locations, failure to heal, or any suspicion of malignancy.

TREATMENT

GENERAL MEASURES

Dressings: All wounds need some kind of a dressing underneath the compression system.

- Wound dressings: No single type of dressing has data indicating greater efficacy.
- Maintain semimoist wound environment: not excessively wet or dry.
- Wounds are often exudative until edema is decreased: Use absorptive dressings (calcium alginate or absorptive pads) (2)[B]. Both superabsorbent diapers and female protection pads are cost-effective alternatives.
- Consider using barrier ointment/cream to prevent maceration of surrounding

skin.

- If wound tends to be dry, use a hydrogel.
- A hydrocolloid dressing may be used with minimal exudate, if skin adhesive is tolerated.

MEDICATION

- Effective compression management is the cornerstone of therapy.
- Diuretics may help to reduce edema, but compression is the mainstay.
- Routine use of antibiotics for all venous ulcers is not recommended (1)[A], (3). Do not use antibiotics on noninfected wounds (3)[A].
- Levamisole, not widely available, was the only systemic antibiotic with some evidence of benefit in terms of ulcer healing versus treatment of infection (2) [B],(3).
- Evidence is insufficient for use of silver-based preparations and honey for healing wounds.
- Pentoxifylline 400 mg PO TID, in addition to local care and compression, improves cure rates. There is some response even without compression. GI side effects are common (4)[A].
- Aspirin 300 mg PO daily; effective when used with compression therapy

ISSUES FOR REFERRAL

- With prominent toe or foot edema, consider lymphedema. Refer to a certified lymphedema therapist (CLT).
- Refer to a wound clinic for complex or poorly healing ulcers.
- Refer to a vein clinic or vascular specialist for recurrent ulcers.
- Use home health nurses to help with immobile patients needing frequent wrapping/dressing changes.

ADDITIONAL THERAPIES

- Edema management: Reduce venous hypertension and improve venous return to reduce inflammation, pain, and improve healing (5)[A].
  - Compression therapy for edema management is the cornerstone of treatment for venous insufficiency with or without ulcers.
  - Short-stretch multilayer bandages are ideal for acute phase, until edema is stable, and the patient can be fitted for compression hose.

  - Long-term compression hose (fit once edema is reduced). Aim for a minimum pressure 20 to 30 mm Hg, preferably 30 to 40 mm Hg.
  - Elevation of legs to heart level for 30 minutes 3 to 4 times per day
  - Exercise to strengthen calf muscle pump is also effective.
- Infection control
  - Débride necrotic tissue.
  - Treat cellulitis (usually gram-positive bacteria) with bactericidal systemic antibiotics. Suspect local infection when there is pain or no improvement in the wound after 2 weeks of compression. Consider deep quantitative swab, after thorough cleansing, or tissue biopsy for culture.
  - Treat critical colonization with topical antimicrobials, such as cadexomer iodine (silver dressings and honey are widely used, but definitive data are lacking) (3)[B].
- For venous ulcers resistant to healing with wound care and compression, consider adding an intermittent compression pump 1 to 4 hr/day.
- Encourage exercise (e.g., activation of calf muscle pump with ankle flexion and extension) in conjunction with leg compression and elevation.
- Vacuum-assisted closure (VAC) dressings may be beneficial but no clear benefit over optimal traditional wound care.

SURGERY/OTHER PROCEDURES

- Necrotic tissue impedes healing.
  - Consider sharp débridement.
  - Other methods include enzymatic ointments (collagenase), low-frequency ultrasound, and wet-to-dry dressings.
  - Avoid using collagenase with silver dressings because silver inactivates the enzyme.
- Allografts made of synthetic skin bilayered with living keratinocytes and fibroblasts improve healing at 6 months; insufficient evidence to support use of autografts
- In patients with ulcers refractory to conservative therapy, a variety of endovenous and surgical options exist. Consultation with a vascular surgeon is recommended.
- Endovenous ablation of incompetent superficial and perforator veins has

shown to reduce the size and recurrence of ulcers in those who have failed conventional compression therapy (6)[A].

- A subset of patients with nonhealing ulcers have stenosis and obstruction of the deep venous system. Venous angioplasty and stenting is emerging as an important adjunct to compression and other medical therapy (7)[A].

COMPLEMENTARY & ALTERNATIVE MEDICINE

Chestnut seed extract (50 mg BID) is effective for venous insufficiency but not ulceration.

- Topical medicinal honey used on wounds shows no evidence of improved healing.
- Oral zinc has not been shown to be beneficial.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- For those with acute significant cellulitis
- Infected wounds requiring IV antibiotics, especially in diabetics

ONGOING CARE

- Venous insufficiency is a lifelong issue.
- After resolution of an ulcer, edema management must be maintained lifelong.

FOLLOW-UP RECOMMENDATIONS

When ulcers are nearly healed and edema is controlled, switch from compression bandages to compression hose.

- Insurance may not reimburse for compression hose unless an ulcer is present.
- Referral for hose fitting must be done just prior to the ulcer being healed for some insurances to reimburse.

Patient Monitoring

Monitor the ulcer for healing by measuring its area. Expect at least 10% reduction every 2 weeks.

DIET

- Obese patients may benefit from weight loss.

- Low-salt diets help fluid retention.

PATIENT EDUCATION

Patient education for understanding of underlying mechanism is important for long-term management.

- Develop long-term plan for edema management and instruction on compression therapy.
- Instruct the patient on topical wound therapy.
- Teach early recognition and treatment of new ulcers or cellulitis.

PROGNOSIS

- Ulcers recur frequently. Early identification and immediate treatment are essential.
- Ongoing diligence, with edema control, avoiding infections, and avoiding trauma, are important.

CODES

ICD10

- I87.2 Venous insufficiency (chronic) (peripheral)
- I83.009 Varicose veins of unsp lower extremity w ulcer of unsp site
- I89.0 Lymphedema, not elsewhere classified

CLINICAL PEARLS

- Initial diagnostic workup should include venous duplex scan and arterial evaluation.
- Refer patients with ABI <0.8 to vascular surgery specialist.
- Refer patients with recurrent or venous ulcers failing to heal with moist wound care and compression after 4 to 6 weeks, to venous specialist or wound specialist.
- Compression is essential for edema management with or without wounds.
- Treat critical colonization with topical antimicrobials (avoid neomycin).
- Make sure that the diagnosis is correct and biopsy when in doubt.

VENTRICULAR SEPTAL DEFECT

Ian D. Thomas, MD • Brent J. Barber, MD

BASICS

DESCRIPTION

- Congenital or acquired defect of the interventricular septum that allows communication of blood between the left and the right ventricles
- Other than bicuspid aortic valve, it is the most common congenital heart malformation reported in infants and children. It also occurs as a complication of acute myocardial infarction (MI).
- Severity of the defect is correlated with its size, with large defects being the most severe.
- Blood flow across the defect typically is left to right, depending on defect size and pulmonary vascular resistance (PVR).
- Prolonged left to right shunting of blood can lead to pulmonary hypertension (HTN). This may eventually lead to a reversal of flow across the defect and cyanosis (Eisenmenger complex).

Geriatric Considerations

Almost entirely associated with MI

Pediatric Considerations

Congenital defect

ALERT

- Pregnancy may exacerbate symptoms and signs of a ventricular septal defect (VSD).
- Can be tolerated during pregnancy if VSD is small
- May be associated with an increased risk of preeclampsia in women with an unrepaired VSD

EPIDEMIOLOGY

Incidence

- Congenital defect: no gender predilection, occurs in ~2/1,000 live births and

accounts for 30% of all congenital cardiac malformations
- Post-MI: Males are affected more than females.

Prevalence

In the United States:
- Congenital defect: lowered prevalence in adults due to spontaneous closure
- Post-MI: estimated to complicate 1–3%

ETIOLOGY AND PATHOPHYSIOLOGY

- Congenital
- In adults, complication of MI

Genetics

Multifactorial etiology; autosomal dominant and recessive transmissions have been reported.

RISK FACTORS

- Congenital:
  - Risk of sibling being affected: 4.2%
  - Risk of offspring being affected: 4%
  - Prematurity
- Complication of MI:
  - First MI
  - HTN
  - Most frequently within first week after MI
  - Occurs in 1–3% of MIs, most commonly after anterior MI

GENERAL PREVENTION

Avoid prenatal exposure to known risk factors (ibuprofen, marijuana, organic solvents, febrile illness). For adults, avoid risk factors for MI and obtain evaluation before pregnancy.

COMMONLY ASSOCIATED CONDITIONS

- Congenital:
  - Tetralogy of Fallot
  - Aortic valvular deformities, especially aortic insufficiency and bicuspid aortic valve

  - Down syndrome (trisomy 21), endocardial cushion defect
  - Transposition of great arteries
  - Coarctation of aorta
  - Tricuspid atresia
  - Truncus arteriosus
  - Patent ductus arteriosus
  - Atrial septal defect
  - Pulmonic stenosis
  - Subaortic stenosis
- Adult: coronary artery disease

DIAGNOSIS

HISTORY

- Presentation depends on the degree of shunting across the defect; may be completely asymptomatic with small defects
- Respiratory distress, tachypnea, tachycardia
- Diaphoresis with feeds, poor weight gain in infants

PHYSICAL EXAM

- Small defect:
  - Harsh holosystolic murmur loudest at left lower sternal border
  - Detected after PVR drops at 4 to 8 weeks of life
- Moderate defect:
  - Harsh holosystolic murmur at left lower sternal border associated with a thrill
  - Forceful apical impulse with lateral displacement
  - Increased intensity of P_2
  - Diastolic rumble at apex due to increased flow across the mitral valve
- Large defect:
  - Holosystolic murmur heard throughout the precordium with diastolic rumble at apex with precordial bulge and hyperactivity, although large defects may have little or no murmur initially
  - If congestive heart failure (CHF) exists: tachycardia, tachypnea, and

hepatomegaly
  - If pulmonary HTN exists: cyanosis with exertion
  - If Eisenmenger complex is present: cyanosis and clubbing

DIFFERENTIAL DIAGNOSIS

- Any defect with left-to-right shunt, such as patent ductus arteriosus, atrial septal defect
- Children: tetralogy of Fallot
- Adults: mitral regurgitation

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- A 12-lead ECG may suggest severity of VSD. Initially, left ventricular hypertrophy and left atrial enlargement may be evident. As pulmonary HTN develops, right ventricular hypertrophy and right atrial enlargement may be seen.
- A chest x-ray (CXR) may demonstrate increased pulmonary vascularity and/or cardiomegaly.
- A 2D echocardiogram for visualization of location and size of defect
- Color flow Doppler for direction and velocity of VSD jet; may be used to estimate right ventricular pressure

Follow-Up Tests & Special Considerations

- Weight and hematocrit check
- Cardiac catheterization performed occasionally for perioperative planning or to assess need for closure of defect

Diagnostic Procedures/Other

- Cardiac catheterization (left and right sides of heart) can confirm the diagnosis, document number of defects, quantify ratio of pulmonary blood flow to systemic blood flow (Qp/Qs), and determine PVR.
- Demonstration of an oxygen saturation step up from the right atrium to the distal pulmonary artery

Test Interpretation

- Congenital VSD (four major anatomic types)

  - Membranous (70%)
  - Muscular (20%)
  - Atrioventricular canal type (5%)
  - Supracristal (5%; higher in Asians)
- Post-MI VSD predominantly involves muscular septum.
- After surgical repair, right bundle branch block is common.

TREATMENT

- Start diuretic therapy if overload signs are present (1)[A].
- Minimize IV fluids.
- Consider ACE inhibitor and/or digoxin.
- Nasogastric feeds for neonates
- Correct anemia via iron supplementation or a possible RBC transfusion.

GENERAL MEASURES

- Appropriate health care maintenance
- Outpatient, until surgical repair is indicated
- Inpatient in setting of acute MI
- Inpatient for treatment of severe CHF

MEDICATION

First Line

- Per the 2007 American Heart Association guidelines, endocarditis antibiotic prophylaxis is not recommended for most VSDs. It is recommended for VSDs associated with complex cyanotic heart disease, during the first 6 months after surgical repair, or for residual VSDs located near the patch following surgery (2)[A]. However, recent reports suggest that patients with a left ventricle to right atrium VSD (Gerbode defect) may be at higher risk for endocarditis and thus may also need antibiotic prophylaxis (3)[C].
- Pediatric: Medications aim to control pulmonary edema, decrease work of breathing, and allow for growth:
  - Furosemide 1 to 2 mg/kg PO/IV once to twice a day
  - Spironolactone 1 to 2 mg/kg/day divided BID

- Captopril
  - Infants: Oral: 0.3–2.5 mg/kg/day divided every 8–12 hours; max 2 mg/kg/day
  - Children and adolescents: Oral: 0.3–6 mg/kg/day divided every 8–12 hours; maximum daily dose: 150 mg/day
- Digoxin: infants <2 years of age, 10 μg/kg/day PO divided BID; children, 2 to 10 years of age, 5 to 10 μg/kg/day PO divided BID; children >10 years of age, 2 to 5 μg/kg/day PO divided BID

- Adults: Digoxin and diuretics may be beneficial in some circumstances (1) [A].
- Side effects:
  - Drugs that increase systemic vascular resistance may increase left-to-right shunting and cause signs and symptoms of pulmonary overcirculation.
  - HTN

Second Line

- Surgical closure is generally indicated if the pulmonic-to-systemic flow is >2:1 or with poorly controlled pulmonary overcirculation despite maximal medical and dietary interventions.
- If an infant with a VSD has persistent pulmonary HTN or failure to grow, surgical repair generally is recommended prior to 6 months of age even if patient is otherwise asymptomatic.
- For post-MI VSDs, afterload reduction, inotropic support, intra-aortic balloon pump, and left ventricular assist device may be used to stabilize the patient prior to surgery. Surgical repair includes septal debridement and patch placement.

ISSUES FOR REFERRAL

Close follow-up of a congenital VSD is necessary until primary intracardiac repair is performed to ensure that significant pulmonary HTN does not develop.

ADDITIONAL THERAPIES

- Infant caloric requirements up to 150 kcal/kg/day or more for adequate weight gain
- Treatment of iron deficiency anemia to increase oxygen-carrying capacity

SURGERY/OTHER PROCEDURES

- Surgical correction with either a VSD patch or repair is commonly used. Postsurgical outcomes for isolated VSD are excellent. Complications are rare and include reoperation for residual VSD, extended hospital stay, arrhythmias, valve injury, depressed ventricular function, and heart block (4)[B].
- Percutaneous transcatheter device closure has become a safe and effective option for some children with small to moderate VSDs. Complications include valvular regurgitation, residual defects, and heart block. There is a greater risk of conduction abnormality with this technique compared to surgical closure. Recent studies have shown steroids may decrease this risk (5)[A].
- Perventricular device closure (hybrid technique) of some subtypes of isolated VSDs without cardiopulmonary bypass is feasible under transesophageal echocardiographic (TEE) guidance. Complications are similar to percutaneous closure (6)[A].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Failure to thrive
- Pulmonary overcirculation/CHF
- Stabilize airway
- Reduce temperature stress
- Frequent vital sign monitoring; daily weight and calorie counts
- Discharge criteria: CHF stabilization, weight gain, or successful repair

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Small VSDs without evidence of CHF or pulmonary HTN generally can be followed every 1 to 5 years after the neonatal period.
- Moderate to large VSDs require more frequent follow-up.
- Potential complications of VSDs include right ventricular outflow obstruction and aortic valve prolapse.

Patient Monitoring

- Physical growth and development monitoring
- Influenza vaccine for children >6 months of age
- Palivizumab to children <12 months of age with hemodynamically significant lesions. Children with small VSDs do not need RSV prophylaxis (7)[A].

DIET

- Low sodium in heart failure
- High calorie in failure to thrive

PATIENT EDUCATION

- No activity restriction in absence of pulmonary HTN
- Parents need support and instructions for prevention of complications until the child is ready for surgery.

PROGNOSIS

- Congenital:
  - Course is variable depending on the size of the VSD.
  - Small VSD: many will close spontaneously by age 3 years. Muscular defects are more likely to close spontaneously.
  - Large VSD: CHF or failure to thrive in infancy necessitating surgical repair.
  - 20-year cumulative survival rate after surgery for isolated VSD is 87%; 40 years is 78% (8).
  - Progressive pulmonary vascular disease and pulmonary HTN are the most feared complications of VSD caused by left-to-right shunting and may eventually lead to reversal of the shunt (Eisenmenger complex). Death usually occurs in the 4th decade of life if untreated.
- Post-MI:
  - With medical management alone, 80–90% mortality in the first 2 weeks
  - Prognosis worse with inferior MI compared with anterior MI

COMPLICATIONS

- CHF
- Aortic insufficiency
- Sudden death
- Hemoptysis

- Cerebral abscess
- Paradoxical emboli
- Cardiogenic shock
- Heart block rarely may accompany surgical closure.
- Pulmonary HTN

Down Syndrome; Acute Coronary Syndromes: NSTE-ACS (Unstable Angina and NSTEMI); Tetralogy of Fallot

CODES

ICD10

- Q21.0 Ventricular septal defect
- I23.2 Ventricular septal defect as current comp following AMI
- Q21.3 Tetralogy of Fallot

CLINICAL PEARLS

- A loud 2/6 to 3/6 low-pitched harsh holosystolic murmur at the left lower sternal border is typical.
- A diastolic rumble at the apex indicates moderate to large VSD or Qp:Qs >2:1, which likely will require surgical or percutaneous closure.
- Disappearance of the murmur could be secondary to spontaneous closure of the defect or the development of pulmonary HTN.
- Development of a new murmur of semilunar valve insufficiency should be further evaluated. Pulmonary regurgitation may occur as PVR increases, and the development of aortic regurgitation usually will require early surgery.

VERTIGO

Jeremy Raab, MD • James J. Arnold, DO, FAAFP

BASICS

DESCRIPTION

- A symptom, not a disease process. Among the potential causes are several life-threatening conditions. As such, the cause must be identified in order to determine the appropriate treatment.
- Sensation of movement ("room spinning") when no movement is actually occurring; results from peripheral or central causes or may be induced by medications/anxiety disorders
- Important to distinguish between vertigo, presyncope (patient feels like they are going to black out; vision and hearing may become obscured), disequilibrium (off balance), and light-headedness (vague, inconsistent symptoms, no rotational component)
- System(s) affected: nervous
- Synonym(s): dizziness; acute vestibular neuritis; labyrinthitis; benign paroxysmal positional vertigo (BPPV)

EPIDEMIOLOGY

Incidence

- Vertigo accounts for 54% of cases of dizziness reported in primary care; >90% of these patients are diagnosed with peripheral causes such as BPPV (1).
- Predominant sex: female = male; women are more likely to experience central causes, particularly vertiginous migraine.

Geriatric Considerations

- Elderly patients with risk factors for cerebrovascular disease (CVD) are more likely to experience central causes.
- BPPV is commonly undiagnosed in the elderly and is an important risk factor for falls.

Prevalence

- Ranges from 5% to 10% within the general population
- Lifetime prevalence for BPPV is 2.4%.

ETIOLOGY AND PATHOPHYSIOLOGY

- Dysfunction of the rotational velocity sensors of the inner ear results in asymmetric central processing. This is related to the combination of sensory disturbance of motion and malfunction of the central vestibular apparatus.
- Peripheral causes: acute labyrinthitis, acute vestibular neuritis, BPPV (posterior canal 85–95%, lateral canal 5–15%), herpes zoster oticus, cholesteatoma, Ménière disease, otosclerosis, perilymphatic fistula, superior canal dehiscence syndrome, motion sickness (1,2); BPPV, vestibular neuritis, and Ménière disease account for 93% of all vertigo (2).
- Central causes: cerebellar tumor, CVD, migraine, multiple sclerosis (1)
- Drug causes: psychotropic agents (antipsychotics, antidepressants, anxiolytics, anticonvulsants, mood stabilizers), aspirin, aminoglycosides, furosemide (diuretics), amiodarone, α-/β-blockers, nitrates, urologic medications, muscle relaxants, phosphodiesterase inhibitors (sildenafil), excessive insulin, ethanol, quinine, cocaine
- Other causes: cervical, psychological

Genetics

Family history of CVD/migraines may indicate higher risk of central causes.

RISK FACTORS

- History of migraines
- History of CVD/risk factors for CVD
- Use of ototoxic medications
- Trauma/barotrauma
- Perilymphatic fistula
- Heavy weight bearing
- Psychosocial stress/depression
- Exposure to toxins

GENERAL PREVENTION

If due to motion sickness, consider pretreatment with anticholinergics, such as scopolamine.

DIAGNOSIS

HISTORY

- Determine if true vertigo or not by asking, “When you have dizzy spells, do you feel light-headed or do you see the world spin around you?” This reliably differentiates vertigo from nonvertiginous dizziness (1,2)[C].
- Obtain other medical and medication history: recent use of ototoxic medications (e.g., aminoglycosides); history of alcohol, nicotine, and caffeine use; sexual history; history of CVD/risk factors for CVD (1,3).
- Ask about duration of symptoms (2)[C].
  - A few seconds: peripheral cause such as unilateral loss of vestibular function; late stages of Ménière disease
  - Several seconds to a few minutes: BPPV; perilymphatic fistula
  - Several minutes to 1 hour: posterior TIA; perilymphatic fistula
  - Hours: Ménière disease, migraine, acoustic neuroma
  - Days: early acute vestibular neuritis, CVA, migraine, MS
  - Weeks: psychogenic (constant symptoms without improvement)
- Provoking factors that help distinguish different causes of vertigo (2)[C]
  - Changes in head position: acute labyrinthitis, BPPV, cerebellar tumor, MS, perilymphatic fistula
  - Spontaneous episodes/no clear provoking factors: vestibular neuritis, TIA/CVA, Ménière disease, migraine, MS
  - Recent URI: vestibular neuritis
  - Stress: psychogenic causes, migraine
  - Immunosuppression: herpes zoster oticus
  - Changes in ear pressure, trauma, loud noises: perilymphatic fistula
- Symptoms that help distinguish between common causes (does not include all, see differential diagnoses) (2,3)[C]
  - Aural fullness: acoustic neuroma, Ménière disease
  - Ear/mastoid pain: acoustic neuroma, acute middle ear disease (AOM, herpes zoster oticus)
  - Facial weakness: acoustic neuroma, herpes zoster oticus
  - Focal neurologic findings: cerebellar tumor, CVD, MS
  - Headache: acoustic neuroma, migraine

- Hearing loss: Ménière disease, acoustic neuroma, otosclerosis, labyrinthitis, herpes zoster oticus, transient ischemic attack (TIA), cholesteatoma, perilymphatic fistula
- Imbalance: acute vestibular neuritis (moderate), cerebellar tumor (severe)
- Phonophobia/photophobia: migraine
- Rash: herpes zoster oticus
- Tinnitus: acute labyrinthitis, acoustic neuroma, Ménière disease

PHYSICAL EXAM

- Neurologic: cranial nerves. Consider the HINTS battery to when evaluating for a central cause (4)[C].
  - Horizontal **H**ead **I**mpulse: Rapidly bring patient's head to midline from 20 degrees. Patients with peripheral vertigo will show rapid saccades to refocus on target. In central vertigo, eyes will stay on target.
  - Direction-changing **N**ystagmus: Nystagmus typically is unidirectional. Nystagmus that changes direction with eye motion indicates a central lesion.
  - **T**est of **S**kew: Vertical eye movement during cover-uncover test indicates a central lesion. A normal test has no movement.
  - A combination of these findings is 96.8% sensitive, 98.5% specific for CVA/other central cause (HINTS positive) (4)[C].
- Balance
  - Peripheral: mild to moderate, able to walk
  - Central: severe, unable to walk
- Dix-Hallpike maneuver (2)[C]: Rapidly move the patient from seated to supine position with the head turned 45 degrees to the right. Observe for nystagmus and ask the patient if he or she is experiencing vertigo. Note: There may be 5 to 20 seconds of latency before nystagmus/vertigo begin. Wait until symptoms resolve and then return the patient to the sitting position. Always repeat on the left side.
  - The presence of extinguishing horizontal nystagmus is a positive test, consistent with peripheral causes and specifically posterior canal BPPV.
  - If induced nystagmus does not subside, consider central causes.
  - Vertical nystagmus always indicates a central cause.
  - In primary care, PPV of 83% for BPPV and NPV of 52%

  - If Dix-Hallpike is negative, check for lateral canal BPPV: With patient supine, rapidly rotate head 90 degrees. If nystagmus induced, wait for it to subside and then return to neutral. Repeat on other side. Nystagmus with this test suggests lateral canal BPPV (5)[C].
- Head and neck: tympanic membranes
  - Vesicles: herpes zoster oticus
  - Cholesteatoma
  - Infection
- Cardiovascular: orthostatic changes in BP, dehydration/autonomic dysfunction

DIFFERENTIAL DIAGNOSIS

- Acoustic neuroma
- Anxiety disorder
- Arrhythmia
- BPPV (posterior or lateral canal)
- Cerebellar degeneration, hemorrhage, or tumor
- Dehydration
- Eustachian tube dysfunction/middle ear effusion
- Hypoglycemia
- Labyrinthitis/labyrinthine concussion
- Ménière disease
- Multiple sclerosis
- Orthostatic hypotension
- Perilymphatic fistula
- Parkinson disease
- Peripheral neuropathy
- Syphilis
- Superior canal dehiscence syndrome
- Vascular ischemia
- Vertiginous migraine
- Vestibular neuritis/ototoxicity

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Labs not routinely necessary and identify a cause in <1% of patients (2)[C].

- Start MRI if a central cause is suspected to rule out stroke. CT cannot reliably see the posterior fossa and will not show changes in the early stages of an infarct. Vertigo may be the only symptom of acute stroke (4)[C].
- ENT/audiology referral if Ménière disease is suspected for electronystagmography (1,2,4)[C]
- If acoustic neuroma is suspected, either CT or MRI to evaluate internal auditory canal (1,2,4)[C]

Diagnostic Procedures/Other

Audiometry if acoustic neuroma or Ménière disease is suspected

TREATMENT

GENERAL MEASURES

Treatments depend on cause.

- BPPV: Epley maneuver (1,3,5)[A] and modified Epley maneuver (1)[B] (Epley maneuver—YouTube)
- Vestibular neuritis and labyrinthitis
  - Vestibular-suppressant medications (1)[C],(3)
  - Vestibular rehabilitation exercises (1)[B],(3)
  - No evidence to support improvement of symptoms with corticosteroid use (6)[B]
- Ménière disease (see separate topic) (1)[B],(3):
  - Low-salt diet (<1 to 2 g/day)
  - Diuretics such as hydrochlorothiazide
- Vascular ischemia: prevention of future events through BP reduction, lipid lowering, smoking cessation, antiplatelet therapy, and anticoagulation, if necessary; MRI or CT if suspected (1,4)[C],(3)
- Vertiginous migraines: dietary and lifestyle modifications, vestibular rehab, prophylactic and abortive medications (1)[B],(3)
- Psychological: SSRIs are better than benzodiazepines for anxiety-related vertigo. Use slow titration to avoid worsening symptoms (1)[B].

MEDICATION

Avoid use of medication in mild cases. Use for acute phase only (few days at most), as longer term use may impair adaptation/compensation by the brain (1). Medications not recommended for BPPV (1,3,5)[C]

- Meclizine: 12.5 to 50 mg PO q4–8h (1)
  - Dimenhydrinate: 25 to 100 mg PO, IM, or IV q4–8h (1) Precautions: prostatic hyperplasia, glaucoma
  - Adverse effects: sedation, xerostomia
  - Interactions: CNS depressants
- Prochlorperazine: 5 to 10 mg PO or IM q6–8h; 25 mg rectally q12h; 5 to 10 mg by slow IV over 2 minutes (1)
  - Contraindications: blood dyscrasias, age <2 years, hypotension
  - Precautions: acutely ill children, glaucoma, breast cancer history, impaired cardiac function, prostatic hyperplasia
  - Adverse effects: sedation, extrapyramidal effects
  - Interactions: phenothiazines, tricyclic antidepressants
- Metoclopramide: 5 to 10 mg PO q6h, 5 to 10 mg slow IV q6h (1)
  - Contraindications: concomitant use of drugs with extrapyramidal effects, seizure disorders
  - Precautions: history of depression, Parkinson disease, hypertension
  - Adverse effects: sedation, fluid retention, constipation
  - Interactions: linezolid, cyclosporine, digoxin, levodopa
- Psychiatric causes (1)
  - SSRIs for depression/anxiety (1)[B]
  - Lorazepam (Ativan) 0.5 to 2 mg orally, IM, or IV q4–8h for short-term relief of more severe anxiety
  - Diazepam (Valium) 2 to 10 mg orally or IV q4–8h for short-term relief of more severe anxiety

Geriatric Considerations

Use vestibular-suppressant medications with caution due to increased risk of falls and urinary retention.

Pregnancy Considerations

Meclizine and dimenhydrinate are pregnancy Category B.

ISSUES FOR REFERRAL

Consider referral to otolaryngologist, ENT specialist, vestibular rehabilitation therapist, or neurologist if patient requires further care.

ADDITIONAL THERAPIES

- Epley maneuver/modified Epley maneuver for BPPV to displace calcium deposits in the semicircular canals (1,3,5)[A]
  - Effective for short-term symptomatic improvement and for converting patient from positive to negative Dix-Hallpike maneuver (1)[A] and some studies suggest long-term relief (1)[C]
  - Contraindications: carotid stenosis, unstable cardiac disease, severe neck disease
- Lateral canal BPPV may respond to barbecue roll maneuvers (5)[C].
- Vestibular rehabilitation exercises: ball toss, lying-to-standing, target-change, thumb-tracking, tightrope, walking turns (1)[B]

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Balance exercises should be adhered to for symptom reduction and return to normal activities of daily living (ADLs).

Patient Monitoring

After 1 to 2 weeks, assess for the following:

- Recurrence of symptoms
- New-onset symptoms
- Medication-related adverse effects
- Relief from vestibular rehabilitation exercises

DIET

- Restricted salt intake for Ménière disease
- Dietary modifications for vertiginous migraine

PATIENT EDUCATION

- Reduce sodium intake (Ménière disease).

- Avoid triggers such as caffeine/alcohol (vertiginous migraine).

PROGNOSIS

Depends on diagnosis and response to treatment

COMPLICATIONS

- Anxiety
- Depression
- Disability
- Injuries from falls

SEE ALSO

- Ménière Disease; Motion Sickness, Vertigo, Benign Paroxysmal Positional (BPPV)
- Algorithm: Vertigo

CODES

ICD10

- R42 Dizziness and giddiness
- H81.10 Benign paroxysmal vertigo, unspecified ear
- H81.49 Vertigo of central origin, unspecified ear

CLINICAL PEARLS

- Risk factors include migraines, CVD/CVD risk factors, ototoxin exposure/meds, trauma/barotrauma, perilymphatic fistula, heavy weight bearing, psychosocial stress.
- Acute vertigo with a normal horizontal head impulse, direction-changing nystagmus, and skew deviation (HINTS positive) is highly sensitive and specific for CVA.
- Nystagmus indicates a positive Dix-Hallpike test implies a peripheral cause. If nystagmus persists, investigate a central cause.
- The Epley maneuver is recommended for the treatment of BPPV; the modified Epley can be performed at home.
- Medications are not recommended for BPPV.

VERTIGO, BENIGN PAROXYSMAL POSITIONAL (BPPV)

Chirag N. Shah, MD, FACEP • Kyung In Yoon, MD

BASICS

DESCRIPTION

- Benign paroxysmal positional vertigo (BPPV) is a mechanical disorder of the inner ear characterized by a brief period of vertigo experienced when the position of the patient's head is changed relative to gravity.
- Vertigo results from the mismatch of the perception of movement by the visual, vestibular, and proprioceptive symptoms when none exist.
- The brief period of vertigo is caused by abnormal stimulation of ≥1 of the 3 semicircular canals of the inner ear, with the posterior canal most commonly affected.
- BPPV is the single most common cause of vertigo.

EPIDEMIOLOGY

- Lifetime prevalence is 2.4%, and 1-year incidence 0.6%.
- Age of onset is most commonly between the 5th and 7th decades of life.
- Incidence of increases with each decade of life.
- Prevalent sex: female > male
- BPPV affects the quality of life of elderly patients and is associated with reduced activities of daily living scores, falls, and depression.

Prevalence

- Common
- Lifetime prevalence 2.4% with 1-year incidence 0.6%

ETIOLOGY AND PATHOPHYSIOLOGY

- In BPPV, calcite particles (otoconia) that normally weight the sensory membrane of the maculae become dislodged and settle into the semicircular canal, changing the dynamics of the canal. Reorientation of the canal relative to gravity causes the otoconia to move to the lowest part of the canal, causing

displacement of the endolymph, deflection of the cupula, and activation of the primary afferent. This results in the generation of nystagmus and the associated sensation of vertigo.

- BPPV may be idiopathic, posttraumatic, or associated with viral neurolabyrinthitis.

DIAGNOSIS

- The diagnosis is established based on history and findings on positional testing, clarified by Dix and Hallpike in 1952 (1,2)[A].
- Positional tests place the plane of the canal being tested into the plane parallel with gravity.

HISTORY

- Brief episodes of vertigo (sensation that the room is spinning) associated with
  - Rolling over in bed
  - Getting out of bed
  - Looking up (referred to as “top-shelf syndrome”)
  - Bending forward
  - Quick head movements
- Patients may also complain of light-headedness or feeling “off balance.”
- Frequently, patients complain of nausea and, if severe enough, vomiting.

PHYSICAL EXAM

- The Dix-Hallpike test (DHT) is used to diagnose BPPV (1)[A]. The test provokes the characteristic nystagmus associated with the symptoms of vertigo. For the DHT, the estimated sensitivity is 79% (95% CI 65–94) and specificity is 75% (95% CI 33–100) (3)[B].
- To perform the DHT, the patient is positioned in long-sitting on the exam table with the knees extended. The head is then rotated 45 degrees toward the side to be tested. The patient is then lowered quickly to supine with the head 30 to 40 degrees below the horizontal, over the edge of the exam table. The position is maintained for a minimum of 45 to 60 seconds.
- For each position, the clinician notes the direction of the fast phase of the nystagmus and the latency and duration of the nystagmus.

- Supportive for BPPV: latency period of <30 seconds between head movement and onset of nystagmus, nystagmus peaks then slowly resolves, duration of nystagmus is 5 to 40 seconds, nystagmus reverses direction with head positioning from the down direction to the sitting position, and repeated head positioning causes the vertiginous symptoms with nystagmus to fatigue
- Posterior canal BPPV:
  - In the head-hanging position, the otoconia move away from the ampullary organ resulting in upward ipsitorsional nystagmus.
  - The superior poles of the eyes beat up toward the forehead and rotate toward the lower most ear, the involved ear
  - On return to the seated position, the otoconia move toward the ampullary organ resulting in the nystagmus reversing direction.
  - The latency of onset of nystagmus is 1 to 45 seconds, and the duration is usually <1 minute.
  - The nystagmus fatigues (reduction in the severity of symptoms) with repeated positioning.
- Horizontal canal BPPV
  - Directional-changing positional nystagmus is observed in the test positions; the eyes will beat linear-horizontal toward the ground (geotropic nystagmus) or beat toward the sky (apogeotropic nystagmus).
  - One position may illicit a stronger nystagmus response. The side with great intensity indicates the side involved with geotropic lateral canal BPPV and the uninvolved side with apogeotropic lateral canal BPPV.
- Anterior canal BPPV
  - In the head-hanging position, the nystagmus is downbeating and torsional, with the top of the eye torting away from the lower ear.
  - Usually caused by “canal switching” from canalith repositioning procedure (CRP) maneuvers
  - No further testing is indicated unless the diagnosis is uncertain, or there are additional symptoms and signs unrelated to BPPV that warrant testing.
- Peripheral versus central vertigo
  - Onset: sudden *versus* sudden or slow
  - Severity: intense spinning *versus* less intense
  - Pattern: paroxysmal *versus* constant

  - Aggravated by movement: yes *versus* variable
  - Nausea or diaphoresis: frequent *versus* variable
  - Nystagmus: rotatory-vertical, horizontal *versus* vertical
  - Fatigue of symptoms: yes *versus* no
  - Hearing loss or tinnitus: may occur *versus* no
  - Abnormal TM: may occur *versus* no
  - CNS symptoms: No *versus* usually present
- Red flags in vertigo
  - Neurologic deficit, ipsilateral hearing loss, gait abnormality, direction changing nystagmus
- HINTS exam
  - Head Impulse Nystagmus Test of Skew
    - Head impulse test of vestibulo-ocular reflex function
      - Normally, eye movement will correct with rapid head movement so that the center of the vision remains on a target. This reflex fails in peripheral causes of vertigo.
      - Have patient fix their eyes on your nose, and move their head in the horizontal plane to the left and then to the right.
      - When the head is turned toward the normal side the vestibulo-ocular reflex remains intact and eyes are fixated on the examiner's nose
      - When the head is turned toward the affected side, the vestibulo-ocular reflex fails and the eyes make a corrective saccade to re-fixate on the examiner's nose
      - It is reassuring if the reflex is *abnormal* (due to dysfunction of the peripheral nerve).
    - Nystagmus in primary, right, and left gaze
    - Test for skew deviation "vertical dysconjugate gaze."
      - Skew deviation is a fairly specific predictor of central lesion in patients with acute vestibular syndrome.
      - The presence of skew may help identify stroke when a positive head impulse test falsely suggests a peripheral lesion.
      - Have patient look at your nose with their eyes and start by covering one eye and then rapidly move to cover the other eye, do this rapidly back and forth.

    - When each eye is uncovered, quickly look to see if the eye has movement or refixation. Horizontal is normal, vertical is not.
  - In the setting of dizziness and vertigo, HINTS substantially outperforms ABCD2 for stroke diagnosis and outperforms MRI obtained within the first 2 days after symptom onset (4)[B].

DIFFERENTIAL DIAGNOSIS

- Orthostatic hypotension and other disorders that cause low BP; symptoms usually occur when the patient stands up.
- Damage to the brainstem or cerebellum can cause positional vertigo but is accompanied by other neurologic signs and usually has a different pattern of nystagmus.
- Low spinal fluid pressure may cause positional symptoms that are better when the patient lies down.
- Migraine-associated vertigo
- Traumatic brain injury
- Brain tumors
- Brain hemorrhage or infarction
- Vestibular neuronitis

TREATMENT

- The CRP or Epley maneuver is effective in the treatment of posterior canal BPPV (1)[A]. Using a particle repositioning maneuver, the clinician moves the patient through a series of positions. With each position, the otoconia settles to the lowest part of the canal. The debris is moved around the arc of the canal into the vestibule. In randomized controlled trials, the average short-term success rate of the CRP following one treatment session is 80 ± 9% (1)[A].
- The clinician moves the patient through a series of four provoking positions:
  - Placement of the right posterior canal (involved canal) in the right head-hanging position of the DHT.
  - The head is then rotated a total of 90 degrees toward the left (uninvolved side) into 45 degrees of left head rotation.

  - Maintaining 45 degrees of left head rotation, the patient is rolled onto the left side (uninvolved side) with the head slightly elevated from the supporting surface.
  - The patient then sits up and flexes the neck 36 degrees. Each position is maintained for a minimum of 45 seconds or as long as the nystagmus lasts. The procedure is repeated three times.
- CRP is the best maneuver for posterior BPPV and should be offered to all age groups (5)[A].
- Semont maneuver is also another maneuver, less superior when performed alone (5)[A].
- Contraindications are carotid stenosis, unstable cardiac disease, and severe neck disease. If the CRP is ineffective, self-administered CRP is performed at home (1)[A]. The patient performs the CRP on the bed with the head extended over the edge of a pillow. Better outcomes are achieved with a combination of CRP with self-administered CRP (1)[A].
- CRP and Semont are ineffective for horizontal BPPV; variations of the Lempert maneuver, barbecue roll, or Gufoni maneuver are widely used treatment methods for horizontal BPPV.
- Postmaneuver activity restrictions were previously advocated but in controlled trials it did not differ in clinical outcomes (2,5)[A].

MEDICATION

- Vestibular suppressant medications are not recommended for treatment of BPPV, other than for the short-term management of vegetative symptoms (3)[A].
- Antiemetics such as ondansetron (Zofran) may be considered for prophylaxis for patients who have had severe nausea or vomiting with the DHT.
- Vestibular suppressants such as benzodiazepines and antihistamine anticholinergics such as meclizine should be avoided because they may suppress nystagmus during the DHT and treatment.

ISSUES FOR REFERRAL

Consider a referral to a specialist if BPPV is unresponsive to treatment or if the patient is diagnosed with atypical BPPV involving the anterior or lateral canal. Consider referring to a physical therapist, neurologist, or an otolaryngologist.

ADDITIONAL THERAPIES

- Brandt-Daroff exercises and habituation exercises are not as effective as self-administered CRP. At 1 week, the average success rate for the Brandt-Daroff exercise is 23–24% compared with 90% for self-administered CRP (1)[A].
- Surgical intervention is rarely indicated, except for refractory BPPV, and includes posterior canal occlusion and singular neurectomy.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

The patient should follow up within a week after treatment to ensure resolution.

PATIENT EDUCATION

A number of illustrative videos are available at www.youtube.com for education and self CRP maneuvers.

PROGNOSIS

80% cure rate with CRP maneuvers, with a 30% recurrence rate at 1 year, and 44% redevelop BPPV within 2 years.

COMPLICATIONS

During the maneuvers, a canal conversion may occur. The debris from the canal being treated may reflux into another canal.

CODES

ICD10

- H81.10 Benign paroxysmal vertigo, unspecified ear
- H81.12 Benign paroxysmal vertigo, left ear
- H81.11 Benign paroxysmal vertigo, right ear

CLINICAL PEARLS

- The diagnosis of BPPV is based on history and findings on positional testing.
- The typical presentation is reports of transient episodes of vertigo (sensation that the room is spinning) associated with a change in position of the head relative to gravity.
- BPPV may be treated effectively with particle-repositioning maneuvers in the office and at home.

- Vestibular suppressant medications and antiemetics are not recommended for treatment of BPPV, other than for the short-term management of symptoms.
- Patients should always be ambulated in to verify normal gait prior to discharge.

VINCENT STOMATITIS

Patrick J. Holland, MD, MS • Daniel V. Girzadas, Jr., MD

BASICS

DESCRIPTION

- Inflammatory oral infection of the gingiva, characterized by pain, ulcerations, and necrotizing damage to interdental papillae
- Caused by an imbalance of oral flora resulting in a predominance of invasive anaerobic bacteria: *Fusobacterium, Prevotella intermedia*, and spirochetes
- Concomitant infection with Epstein-Barr virus, herpes simplex virus, and type 1 human cytomegalovirus is common.
- Organisms invade gingiva and interdental papillae with the formation of a grey pseudomembranous exudate.
- Clinical presentation includes pain, fetid breath, gingival ulcerations, bleeding, and interdental papillary necrosis. It is differentiated from other periodontal diseases by rapid onset, pain, ulcerated gingival mucosa, and "punched out" interdental papillary necrosis.
- Synonym(s): Vincent angina; trench mouth; acute necrotizing ulcerative gingivitis

EPIDEMIOLOGY

Incidence

- Predominant age: 18 to 30 years in developed countries
- Affects both genders with similar frequency
- Malnourished children ages 3 to 14 years

Prevalence

- Prevalence is low in healthy children up to age 18 years.
- Prevalence is more common in persons aged 18 to 30 years. Prevalence increases with malnutrition, immunocompromise, poor oral hygiene, and smoking.

ETIOLOGY AND PATHOPHYSIOLOGY

- Impaired host immunologic response due to immunocompromise or malnutrition
- Disruption of normal oral flora with predominance of invasive anaerobic bacteria
- Loss of integrity and necrosis of the gingival mucosa and interdental papillae
- Increased bacterial attachment with herpesvirus active infection

RISK FACTORS

- Malnutrition
- Immunosuppression (cancer, HIV infection)
- Tobacco use
- Poor oral hygiene
- Infrequent or absent dental care
- Orthodontics
- Herpesvirus infection
- Psychological stress

GENERAL PREVENTION

- Appropriate nutrition
- Proper oral hygiene
- Regular dental care
- Prompt recognition and institution of therapy
- Management of medical problems such as cancer and HIV infection
- Stress management

COMMONLY ASSOCIATED CONDITIONS

- Seen most commonly in malnourished patients, patients undergoing cancer treatment, and patients with HIV infection
- Bacteremia
- Osteomyelitis
- Tooth loss
- Dehydration
- Noma/cancrum oris, which can be life threatening
- Aspiration pneumonia

DIAGNOSIS

HISTORY

- Acute onset of oral pain
- Gingival ulcerations
- Fetid odor of breath
- Bleeding and necrosis of interdental papillae
- Cervical adenopathy
- Fever
- Malaise
- History of immunosuppression, chemotherapy, HIV infection
- History of herpesvirus infection

PHYSICAL EXAM

- Fetid odor of breath
- Ulceration of gingival mucosa
- Inflamed, erythematous gingiva
- Necrosis of interdental papillae
- Gingival bleeding
- Formation of gray, pseudomembranous exudate
- Cervical lymphadenopathy
- Fever and malaise may be present.

DIFFERENTIAL DIAGNOSIS

- Herpes simplex virus
- Periodontitis
- Recurrent aphthous stomatitis
- Medication side effects
- Oral malignancy
- Xerostomia
- Diphtheria
- Lymphoma/leukemia
- Primary syphilis
- Ascorbic acid deficiency
- Gingivitis

- Behçet disease
- Oral mucositis
- Erosive lichen planus

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

Diagnosis is primarily based on clinical exam, but if systemic illness or invasive spread to deeper tissue or bone is suspected, the following studies should be considered:

- Aerobic and anaerobic cultures of inflamed or debrided tissue
- Group A strep rapid antigen detection assay
- Group A strep throat culture
- Blood cultures if systemic involvement
- Dental radiographs
- CT imaging of the face and neck if infection has progressed

TREATMENT

GENERAL MEASURES

Elimination of tobacco, improved nutritional status, and improved immunologic status will increase rate of healing and reduce risk of future gingival disease.

MEDICATION

Most cases are treatable on outpatient basis. Severe disease with systemic effects and/or neck involvement requires inpatient treatment.

First Line

- Chlorhexidine gluconate 0.12% 15 mL 30 sec rinse/spit QID (1)[C] *plus*
- Penicillin V potassium 250 to 500 mg QID PO for 10 days; pediatric dosing: 25 to 50 mg/kg/day div q6–8h *or*
- Metronidazole 500 mg q8h for 7 to 10 days (2)[C]; pediatric dosing: 30 mg/kg/day div q6h *or*
- Amoxicillin 500 mg TID PO for 7 days (2)[C]; pediatric dosing: 25 to 45 mg/kg/day div q12h *or*
- Amoxicillin-clavulanate 875 mg q12h for 7 to 10 days (2)[C]; pediatric

dosing: 25 to 45 mg/kg/day div q12h (based on amoxicillin component)

Second Line

- Tetracycline 250 to 500 mg QID PO for 10 days (do not use for children less than 8 years of age); pediatric dosing 25 to 50 mg/kg/day div q6h *or*
- Erythromycin 250 to 500 mg QID PO for 10 days; pediatric dosing: 30 to 50 mg/kg/day div q6–8h *or*
- Clindamycin 450 mg q8h for 7 to 10 days; pediatric dosing: 10 to 25 mg/kg/day div q6–8h

ISSUES FOR REFERRAL

Severe disease requires débridement by consultant dentist, oral surgeon, or ENT specialist.

ADDITIONAL THERAPIES

- Warm saline rinses q2h
- Sodium bicarbonate toothpaste, brush q2h
- Viscous lidocaine 2% 1 tbsp rinse/spit q6–8h
- NSAID medications q4–12h
- Opioid analgesics q4–6h (severe pain)
- Treatment of underlying immunodeficiency (if present)

SURGERY/OTHER PROCEDURES

- Débridement of inflamed/necrotic gingival tissue
- Dental extraction
- Gingival restoration

COMPLEMENTARY & ALTERNATIVE MEDICINE

Multivitamins

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Severe disease, failure of oral antibiotics, or ongoing comorbidities
- Parenteral antibiotics and/or analgesia requirement
- Inability to tolerate PO

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Close dental follow-up
- Primary care follow-up
- Specialty follow-up (if underlying immunodeficiency)

DIET

- Soft diet until healed
- Balanced nutritional diet
- Multivitamin supplementation

PATIENT EDUCATION

- Proper nutrition
- Oral hygiene
- Tobacco cessation

COMPLICATIONS

- Pain
- Malnutrition
- Gingival/ tooth loss
- Deep infection of neck
- Systemic infection

CODES

ICD10

A69.1 Other Vincent’s infections

CLINICAL PEARLS

- Immunosuppression, malnourishment, smoking, and poor oral hygiene are key risk factors for necrotizing ulcerative gingivitis.
- Diagnosis is largely clinical with patients presenting with oral pain, fetid breath, gingival ulcerations, interdental papillary necrosis, and greyish exudate on the gingival surface.
- Most patients experience rapid improvement of symptoms following appropriate treatment with chlorhexidine rinses, improved oral hygiene, and oral antibiotics.
- Smoking cessation and treatment of malnutrition or underlying illness are additional important treatment considerations.
- Severe disease requires débridement of necrotic gingival tissue.

VITAMIN B_{12} DEFICIENCY

Justin D. Chaltry, DO • Katie L. Westerfield, DO

BASICS

- Vitamin deficiency related to inadequate intake or absorption of cobalamin (vitamin B_{12})
- Cobalamin is critical for CNS myelination and normal functioning.
- Deficiency can cause a multitude of symptoms and disorders including megaloblastic anemia, bone marrow dysfunction, and diverse and potentially irreversible neuropsychiatric changes.
- Neuropsychiatric disorders are due to demyelination of cervical, thoracic dorsal, and lateral spinal cords; demyelination of white matter; and demyelination of cranial and peripheral nerves (1)[C].
- Low vitamin B_{12} level can lead to elevated methylmalonic acid (MMA) and homocysteine levels.
- Elevated MMA causes abnormality in fatty acid synthesis affecting neuronal membrane.
- Elevated homocysteine is neurotoxic through overstimulation of the *N*-methyl-D-aspartate (NMDA) receptor and toxic to vasculature through activation of coagulation system and effects on endothelium.

DESCRIPTION

Normal B_{12} absorption

- B_{12} present in animal-source foods (meat, fish, eggs, milk) and foods fortified with B_{12}
- Dietary vitamin B_{12} (cobalamin) bound to food is cleaved by acids in stomach and bound to haptocorrin (commonly known as R-factor).
- Duodenal proteases cleave B_{12} from haptocorrin.
- In duodenum, B_{12} uptake depends on binding to intrinsic factor (IF) secreted by gastric parietal cells.
- B_{12}-IF complex is absorbed by terminal ileum into portal circulation.

- Body's B_{12} stored in liver = 50–90%
  - B_{12} secreted into bile from liver recycled via enterohepatic circulation
  - Delay 5 to 10 years from onset of B_{12} deficiency to clinical symptoms due to hepatic stores and enterohepatic circulation
- Typical Western diet: 5 to 30 μg/day; however, only 1 to 5 μg/day is effectively absorbed.
  - Recommend 2.4 μg/day for adults and 2.6 μg/day during pregnancy and 2.8 μg/day during lactation (most prenatal vitamins contain B_{12}).

EPIDEMIOLOGY

Prevalence

- Endemic area: Northern Europe, including Scandinavia; more common in those of African ancestry
- Increasing recognition in breastfed-only infant populations with vitamin B12–deficient mothers
- Prevalence 5–20% in developed countries
  - 12% in elderly living in community
  - 30–40% in elderly in institutions, sick, or malnourished
  - 5% patients in tertiary reference hospitals
- Prevalence by age group
  - 20 to 39 years old: prevalence 3%
  - 40 to 59 years old: prevalence 4%
  - >70 years old: prevalence 6%

ETIOLOGY AND PATHOPHYSIOLOGY

- Decreased oral intake
  - Vegetarians and vegans: B_{12} is found in animal-source foods; however, strict vegetarians uncommonly develop deficiency because only 1 mg/day is needed, with adequate amounts present in legumes.
- Decreased intrinsic factor (IF)
  - Pernicious anemia (PA): can be associated with autoantibodies directed against gastric parietal cells and/or IF
  - Chronic atrophic gastritis: autoimmune attack on gastric parietal cells causing autoimmune gastritis and leading to decreased IF production

  - Gastrectomy: Removal of entire or part of stomach decreases amount of parietal cells.
- Decreased ileal absorption
  - Crohn disease: Terminal ileal inflammation decreases body's ability to absorb B_{12}.
  - Chronic alcoholism: decreases body's ability to absorb B_{12}
  - Ileal resection
  - Pancreatic insufficiency: Pancreatic proteases are required to cleave the vitamin B_{12}–haptocorrin bond to allow vitamin B_{12} to bind to intrinsic factor.
  - *Helicobacter pylori* infection: impairs release of B_{12} from bound proteins.
- Medications: proton pump inhibitors (PPIs), H_2 antagonists, and antacids decrease gastric acidity, inhibiting B_{12} release from dietary protein; metformin
  - Metformin usage
    - Chronic metformin usage leads to Vitamin B_{12} deficiency. Caused by calcium-dependent membrane inhibition, interfering with vitamin B_{12}–intrinsic factor absorption. Years on metformin is the only predictive factor for B_{12} deficiency.
- Hereditary (rare)
  - Imerslund-Grasbeck disease (juvenile megaloblastic anemia)
  - Congenital deficiency of transcobalamin
  - Severe methylene tetrahydrofolate reductase deficiency
  - Abnormalities of methionine synthesis
- Causes:
  - Food-cobalamin malabsorption syndrome
    - As many as 60–70% of cases
    - Primary cause in elderly
    - Pathophysiology: inability to release cobalamin from food or binding protein, especially if in the setting of hypochlorhydria
    - Seen in atrophic gastritis, long-term ingestion of antacids and biguanides, possible relationship to *H. pylori* infection
  - PA
    - 15–30% of all cases; most frequent cause of severe disease. Neurologic

disorders are common presenting complaints.
    - Common in elderly, as high as 20%, with mild atrophic gastritis, hypochlorhydria, and impaired release of dietary vitamin B_{12}
    - Autoimmune disease with destruction of gastric fundal mucosa cells via a cell-mediated process
    - Anti-gastric parietal cell antibodies: sensitivity >90%, specificity 50%; use for screening test
    - Anti-intrinsic factor antibodies: sensitivity 50%
    - Associated with other autoimmune diseases
- Insufficient dietary intake: 2% of cases; vegans or long-standing vegetarians
- Infants born to vitamin B_{12}–deficient mothers may have deficiency or develop it if breastfed exclusively.
- Intestinal causes:
    - 1% of cases; prevalence depends on risk factors, such as surgical conditions
    - Gastrectomy: due to decreased production of intrinsic factor
    - Gastric bypass: appears 1 to 9 years after surgery, prevalence 12–33%
    - Ileal resection or disease
    - Fish tapeworm
    - Severe pancreatic insufficiency
- Undetermined etiology
    - 1/10 of cases

Genetics

Imerslund-Grasbeck disease (juvenile megaloblastic anemia) caused by mutations in the amnionless (AMN) or cubilin (CUBN) genes with autosomal recessive pattern of inheritance; inadequate ileal uptake of B_{12}-IF complex and B_{12} renal protein reabsorption

GENERAL PREVENTION

Risk factors: vegan diet, age >65 years, female, chronic atrophic gastritis, Crohn disease or other ileal disorders, chronic medication use including PPI, metformin, H_2 antagonists

DIAGNOSIS

Symptoms and physical exam findings:

- Asymptomatic patients may be diagnosed by the incidental finding of anemia or an elevated mean corpuscular volume (MCV) during routine testing or evaluation of unassociated disorders.
- Hematologic
  - Frequent: macrocytosis, neutrophil hypersegmentation, spinal cord medullar megaloblastosis (blue spinal cord)
  - Rare: isolated thrombocytopenia and neutropenia, pancytopenia
  - Very rare: hemolytic anemia, thrombotic microangiopathy with schistocytes
- Neuropsychiatric
  - Frequent: sensory polyneuritis, paresthesias, positive Babinski sign, weakness, gait unsteadiness, loss of proprioception (impaired vibratory sensation, positive Romberg, ataxia, hyperreflexia)
  - Classic but uncommon: subacute combined degeneration of spinal cord associated with PA; myelin degeneration in the lateral and posterior columns; ataxia, proprioception and vibration loss, bowel and bladder incontinence, orthostatic hypotension, decreased memory, mania, delirium, psychosis, depression
- Digestive
  - Classic: Hunter glossitis, jaundice, and high lactate dehydrogenase and bilirubin
  - Possible: abdominal pain, dyspepsia, nausea, vomiting, diarrhea
  - Rare: mucocutaneous ulcers
- Other
  - Frequent: pallor, edema, jaundice
  - Under investigation: chronic vaginal and urinary infections, atrophy of vaginal mucosa, hypofertility, venous thromboembolism, angina, miscarriages
  - Commonly insidious and nonspecific; thus, delay in diagnosis is common

HISTORY

- Underlying disease associated with vitamin B_{12} deficiency

- Fatigue, anorexia
- Depression
- Falls (due to diminished proprioception)
- Loss of sensation in “stocking-glove” distribution
- Glossitis/loss of sense of taste and other subtle, nonspecific neurologic symptoms

DIAGNOSTIC TESTS & INTERPRETATION

- Measurement of vitamin B_{12}, CBC (MCV)
- Measurement of B_{12} may be low or low normal depending on institution’s cutoff value.
  - 65–95% sensitivity levels <200 pg/mL
  - May need additional tests such as MMA and homocysteine if vitamin B_{12} level is low normal (<350 pg/mL) and no evidence of anemia depending on clinical suspicion
- If high suspicion on normal B_{12} with high/normal MCV, consider testing MMA and homocysteine levels.
- MCV often increased
- Measurement of MMA
  - More sensitive and specific than homocysteine
  - Levels increased in renal failure and volume depletion
- Measurement of homocysteine
  - Levels increased in folate deficiency, renal failure, and homocystinuria
- MMA and homocysteine levels only reliable in an untreated patient, as levels fall with supplementation
- Other tests: folate and other markers of anemia (iron studies)
- MCV may be normal, decreased, or increased if vitamin B_{12} deficiency coexists with other forms of anemia, such as iron deficiency or hemolysis. Thus, RBCs may be normochromic, normocytic, or hypochromic microcytic.

ALERT

- Low levels of vitamin B_{12} are seen in folate deficiency, HIV, and multiple myeloma.
- Elevated levels of vitamin B_{12} are seen in renal disease, occult malignancy,

and alcoholic liver disease and as a result of technical error.

- Macrocytosis may be due to folate deficiency, reticulocytosis, medications, bone marrow dysplasia, and hypothyroidism or be masked by concomitant microcytic anemia.
- Serum homocysteine and MMA
  - Elevated in B_{12} deficiency secondary to decreased metabolism
  - If both are normal, B_{12} deficiency is effectively ruled out.
  - If MMA is normal and homocysteine is increased, think folate deficiency.
- PA
  - Check antibody to intrinsic factor; positive test is confirmatory for PA, but sensitivity is only 50–70%.
  - Antiparietal cell antibody positivity indicates PA.
  - For patients who are antibody positive, consider screening for autoimmune thyroid disease.

Pregnancy Considerations

- Because B_{12} crosses the placenta, pregnant women with low levels of B_{12} are at higher risk of having children with neural tube defects, congenital heart defects, developmental delay, and failure to thrive.
- Exclusively breastfed infants of mothers who are B_{12} deficient are at risk of developing B_{12} deficiency. Infants breastfed from B_{12}-deficient mothers might not show signs or symptoms until 4 to 6 months of age, which may include developmental regression, feeding difficulties, lethargy, or hypotonia.

Diagnostic Procedures/Other

- Bone marrow exam is usually unnecessary in the evaluation of B_{12} deficiency because of the inability to differentiate from folate deficiency.
- Spinal cord imaging is not standard; MRI in selected cases, especially with severe myelopathy

TREATMENT

MEDICATION

- Parenteral cyanocobalamin replacement recommended in patients with severe

neurologic symptoms: IM cyanocobalamin (2)[C]
  – 1,000 μg/day for 7 days, *then*
  – 1,000 μg weekly for 4 weeks, *then*
  – 1,000 μg monthly for life
- High-dose, daily oral cyanocobalamin at doses of 1,000 to 2,000 μg are as effective as monthly intramuscular injection and is the preferred route of initial therapy in most circumstances because it is cost-effective and convenient (3)[A]. Requires greater patient compliance. Transnasal and buccal preparations of cyanocobalamin are also available; however, further study is needed.

ALERT

Folic acid without vitamin B_{12} in patients with PA is contraindicated; it will not correct neurologic abnormalities.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Consider blood transfusion for severe anemia.
- Draw blood for hematologic parameters before transfusing.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Hematologic
  – Reticulocytosis in 1 week
  – Rise in hemoglobin beginning at 10 days; usually will return to normal in 6 to 8 weeks
  – Monitor potassium in profoundly anemic patients (hypokalemia due to potassium use).
  – Serum MMA decreases with replacement therapy.
- Neurologic: can note improvement within 3 months of treatment; however, maximum improvement noticed at 6 to 12 months. Some symptoms may be irreversible.

DIET

Meat, animal protein, and legumes unless contraindicated

CODES

ICD10

- E53.8 Deficiency of other specified B group vitamins
- D51.0 Vitamin B12 defic anemia due to intrinsic factor deficiency
- D51.3 Other dietary vitamin B12 deficiency anemia

CLINICAL PEARLS

- Consider screening for B_{12} deficiency in high-risk patients including the elderly and monitoring B_{12} levels annually if on metformin or **on chronic PPIs.**
- Correcting folate deficiency without treating with cyanocobalamin in megaloblastic anemia may correct hematologic but not neurologic disorders.
- Vitamin B_{12} deficiency can coexist with other causes of anemia, including iron deficiency or hemolysis; thus, MCV can be normal, decreased, or increased.
- For patients with PA, cyanocobalamin replacement must be lifelong.
- Patients with PA are at increased risk for other autoimmune conditions as well as gastric malignancy.

VITAMIN D DEFICIENCY

Frank J. Domino, MD • Samir Malkani, MD, MRCP—UK

BASICS

This topic covers the commonly acquired vitamin D deficiency and not type II vitamin D–resistant rickets/type I pseudovitamin D–resistant rickets (both rare autosomal recessive disorders).

DESCRIPTION

- Vitamin D is both a hormone and a vitamin.
- Cholecalciferol (D_3) is synthesized in the skin by exposure to ultraviolet B (UV-B) radiation. Ergocalciferol (D_2) and D_3 are present in foods.
- D_2 and D_3 are hydroxylated in the liver to 25 vitamin D (calcidiol), its major circulating form.
- Calcidiol is further hydroxylated in the kidney to the active metabolite 1,25 vitamin D (calcitriol).
- Hypocalcemia stimulates parathyroid hormone (PTH) to be secreted, which prompts the increased conversion of 25 vitamin D to 1,25 vitamin D.
  - 1,25 vitamin D decreases renal calcium and phosphorus excretion, increases intestinal calcium and phosphorus absorption, and increases osteoclast activity. These effects increase serum calcium.

EPIDEMIOLOGY

- Unclear in general population
- In the community, a cohort study of asymptomatic adolescents in Boston found 24.1% were deficient, with 4.6% severely deficient.
- A study of hospitalized patients in Massachusetts found 57% vitamin D–deficient (VDD).
- Women with history of osteoporosis/osteoporotic fracture have high prevalence of vitamin D deficiency.
- A cohort study in Arizona found >25% of adults were VDD; highest rates among African Americans and Hispanics

- A study of about 56,000 individuals across Europe found 13% to have vitamin D deficiency.

Pediatric Considerations

NHANES data found 70% of children did not have sufficient 25-OH vitamin D serum levels (9% deficient and 61% insufficient), which was associated with an increase in BP and decrease in high-density lipoprotein (HDL) cholesterol.

ETIOLOGY AND PATHOPHYSIOLOGY

- Insufficient dietary intake of vitamin D and/or lack of UV-B exposure (in sunlight) results in low levels of vitamin D.
  - This limits calcium absorption, causing excess PTH to be released.
- PTH stimulates osteoclast activity, which helps to normalize calcium and phosphorous, but results in osteomalacia.
- Dietary deficiency
  - Inadequate vitamin D intake
- Inadequate sunlight exposure
  - Institutionalized/hospitalized patients
- Chronic illness: liver/kidney disease
- Malabsorptive states

Genetics

Vitamin D–dependant rickets type 1 occurs due to inactivating mutation of the 1 alpha hydroxylase gene; as a result, calcidiol is autosomal recessive, not hydroxylated to calcitriol.

RISK FACTORS

- Inadequate sun exposure
- Female
- Dark skin
- Immigrant populations
- Low socioeconomic status
- Latitudes higher than 38 degrees
- Elderly
- Institutionalized
- Depression

- Medications (phenobarbital, phenytoin)
- Gastric bypass surgery/malabsorption syndromes
- Obesity

GENERAL PREVENTION

- Adequate exposure to sunlight and dietary sources of vitamin D (plants, fish); many foods are fortified with vitamin D_2 and D_3.
- Recommended minimum daily requirement from the 2010 Institute of Medicine Report is minimally 600 IU/day for those 1 to 70 years of age and 800 IU/day for those >70 years of age. Up to 4,000 IU/day is safe in healthy adults without risk of toxicity.
- Higher intake of vitamin D recommended for age >50 years
- 2005 and 2009: meta-analysis demonstrated for ages 51 to 70 years; minimally recommended supplementation is 800 IU/day to prevent nonvertebral fractures.

Pediatric Considerations

- The American Academy of Pediatrics recommends all breastfed babies receive 400 IU/day of vitamin D beginning “within the first few days of life.”
- 2016 Global Consensus Recommendations on Prevention and Management of Nutritional Rickets recommends all infants, regardless of feeding method, should begin vitamin D 400 IU within a few days of birth (1).

Pregnancy Considerations

ACOG recommends data insufficient to screen all pregnancies; only those “at risk” and states it is safe to take 1,000 to 2,000 IU/day during pregnancy (2)[B]

Geriatric Considerations

U.S. Preventive Services Task Force recommends seniors take at least 800 IU/day vitamin D to reduce risk of falls in community-dwelling older adults (3) [A].

COMMONLY ASSOCIATED CONDITIONS

- Osteomalacia, osteoporosis
- Premenstrual syndrome
- Rickets

- Celiac disease
- Gastric bypass
- Chronic renal disease
- Bacterial vaginosis in pregnant women
- Hypertension

ALERT

VDD is associated with risk of myocardial infarction (MI) and all-cause mortality (4)[A].

DIAGNOSIS

- Nonspecific musculoskeletal complaints
- Weak antigravity muscles
- Fracture with minimal trauma

HISTORY

- Senior citizens at risk of falling
- Renal disease
- GI (malabsorption) disorders
- Liver dysfunction
- Immigration from tropical to colder climates
- Dark-skinned/veiled individuals
- Housebound patients
- Women at perimenopause

PHYSICAL EXAM

- Vague neurologic signs: numbness, proximal myopathy, paresthesias, muscle cramps, laryngospasm
- Chvostek sign: contraction of the facial muscles by tapping along the facial nerve
- Trousseau phenomenon: carpal spasms and paresthesia produced by pressure on nerves and vessels of the upper arm, by inflation of a BP cuff
- Tetany, seizures

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- 25-OH vitamin D (most sensitive measure of vitamin D status)
- Vitamin D deficiency
  - <20 ng/mL
- PTH elevation: not routinely obtained unless severe deficiency
- Low-normal/low calcium and phosphorous
- Elevated alkaline phosphatase (in later disease)
- Plain radiographs: If atypical fracture, radiographs may show osteomalacia (pseudofractures/looser zones) in pelvis, femur, and fibula.
- Osteoporosis screen
  - Women ≥65 years with no risk factors
  - Women ≥60 years at risk: body weight <70 kg (best predictor)
  - Less evidence: smoking, low body mass index, family history, decreased activity, alcohol or caffeine use
  - African American women have higher bone density than Caucasians.

TREATMENT

- Treatment goals remain unclear, but current “normal” 25-OH vitamin D levels are based on suppression of PTH.
- Obesity: Treatment of VDD in obesity, especially those who are obese and depressed, improves depressive symptoms and may improve weight loss.

ALERT

All-cause mortality: Cochrane Systematic Review found vitamin D supplementation lowers all-cause mortality (5)[A].

Geriatric Considerations

In senior citizens, serum 25-OH vitamin D of 20 ng/mL resulted in improved physical performance scores; recent data suggests supplementation may not improve fracture risk and remains unclear about a true benefit.

MEDICATION

- Vitamin D sufficient (25-OH vitamin D ≥20 ng/mL)
  - Vitamin D 800 to 4,000 IU/day D_2/D_3

  - D_3 (animal derived) may be slightly more effective than D_2 (plant derived), but clinical significance is uncertain.
  - Calcium supplementation: unclear benefit and may increase some CHD risk in patients. No supplementation currently required (see below).
- Vitamin D deficiency (25-OH vitamin D <20 ng/mL)
  - D_2 50,000 IU/week for 8 to 12 weeks, followed by 800 to 2,000 IU/day of vitamin D_3
- Calcium: meta-analysis data support
  - Dietary intake of ~700 mg/day leads to best outcomes; higher doses did NOT decrease risk of osteoporotic fractures.
  - Dietary calcium may be more beneficial than calcium supplementation.
  - Supplementary calcium associated with an increased risk of MI, especially in women (6)[A], but this data remains controversial.

ISSUES FOR REFERRAL

Endocrinology if no response to treatment

ADDITIONAL THERAPIES

Aggressive calcium in ICU patients with ionized calcium <3.2 mg/dL or if symptomatic (tetany, seizures, QT prolongation, bradycardia, or hypotension or ventilated patient with decreased diaphragmatic function)

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Symptoms of severe hypocalcemia
- Malabsorption syndromes

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Follow-up of abnormal 25-OH vitamin D not required

DIET

- Cod liver oil is most potent source of vitamin D and has ~1,300 IU vitamin D/tablet/tablespoon.

- Fatty fish (tuna, salmon)
- Fortified milk (100 IU/8 oz), cereal, and foods

PROGNOSIS

- Systematic review of 63 observational studies found adequate 25-OH vitamin D levels correlate with lower rates of colon, breast, and prostate cancer.
- Cohort study found that vitamin D deficiency is correlated with increased risk of all-cause mortality.

ALERT

Meta-analysis data support supplementation of >500 IU/day lowered the risk of all-cause mortality (5,7)[A] but remains controversial.

CODES

ICD10

- E55.9 Vitamin D deficiency, unspecified
- M83.8 Other adult osteomalacia

CLINICAL PEARLS

- Risk factors for VDD: senior citizen, renal disease, GI (malabsorption) disorders, liver dysfunction, immigration from tropical to colder climates, dark-skinned/veiled individuals, housebound patients, perimenopause
- Diagnosis: 25-OH vitamin D (most sensitive measure of vitamin D status)
- Vitamin D deficiency: <20 ng/mL
- Up to 4,000 IU/day is safe in healthy adults without risk of toxicity.
- 2005 and 2009: meta-analysis demonstrated for ages 51 to 70 years; minimally recommended supplementation is 800 IU/day to prevent nonvertebral fractures.
- The American Academy of Pediatrics recommends all breast-fed babies receive 400 IU/day of vitamin D beginning within a few days of birth.

VITAMIN DEFICIENCY

Michelle E. Szczepanik, MD • Christopher D. Meyering, DO

BASICS

DESCRIPTION

- Vitamins are essential micronutrients required for normal metabolism, growth, and development.
- Deficiencies are less common in the Western world, but certain populations are at increased risk.
- Regulations mandating vitamin supplementation in food products, adequate food supply, and availability of vitamin supplements all make vitamin deficiencies in the Western world lower.
- Toxicity is rare in water-soluble vitamins; however, is possible with fat-soluble vitamins (A, D, E, K).

EPIDEMIOLOGY

Incidence

- Predominant age
  - Geriatric population, pregnant women, exclusively breastfed infants, and individuals with certain chronic disease states
- Individuals from Africa and Southeast Asia are at increased risk.
- True incidence is unknown as most vitamin deficiencies are asymptomatic.

Prevalence

- Varies by age groups, comorbid conditions, geography, and setting (i.e., urban, rural)
- The prevalence of vitamin B_{12} deficiency is around 6% in those <60 years of age but increases to around 20% after the age of 60 years (1).
- Vitamin D deficiency has become increasingly recognized and its prevalence is increased in individuals with darker skin pigmentation, obesity, low dietary intake of vitamin D, or low sunlight exposure.

ETIOLOGY AND PATHOPHYSIOLOGY

- Deficiencies usually related to disease can develop under healthy conditions and generally occur due to 1 of 5 mechanisms:
  - Reduced intake
  - Diminished absorption
  - Increased use
  - Increased demand
  - Increased excretion
- Chronic disease states: HIV, malabsorption (such as celiac sprue and short bowel syndrome), chronic liver and kidney disease, alcoholism, malignancies, pernicious anemia, and rare inborn errors of metabolism
- Bariatric surgeries: gastric bypass, gastrectomy, small or large bowel resection
- Predisposition related to certain drugs: prednisone, phenytoin, isoniazid, protease inhibitors, methotrexate, phenobarbital, alcohol, nitrous oxide, H_2 receptor antagonists, metformin, colchicine, cholestyramine, 5-fluorouracil, 6-mercaptopurine, azathioprine, chloramphenicol, proton pump inhibitors, chronically used antibiotics, penicillamine, and hydralazine
- Malnutrition, imbalanced nutrition, obesity, fad diets, extreme vegetarianism, total parenteral nutrition, bulimia/anorexia, and other eating disorders
- Dialysis
- Parasitic infestation

Genetics

- Cystic fibrosis
- Hartnup disease
- Rare genetic predisposition
  - Autoimmune disease (e.g., pernicious anemia)
  - Congenital enzyme deficiencies (e.g., biotinidase or holocarboxylase synthetase deficiency)
  - Transcobalamin II deficiency
  - Ataxia and vitamin E deficiency (AVED)
- A-β-lipoproteinemia

RISK FACTORS

Poverty, malnutrition, chronic disease states, advanced age, dietary restrictions,

bariatric surgery, and exclusively breastfed infants

GENERAL PREVENTION

- Ingesting large and varied amounts of vitamins increases risk of toxicity and drug–drug interactions.
- Antioxidant supplement use has not been shown to impact cancer incidence and, in some studies, has *increased* risk of death (2).
- Avoidance of restrictive diets decreases the likelihood of vitamin deficiency.
- In particular age groups or with certain risk factors, vitamin supplementation may be recommended.
- U.S. Preventive Services Task Force (USPSTF) recommends vitamin D supplementation in community-dwelling adults aged 65 years or older who are at increased risk for falls (3)[B].
- USPSTF recommends against low-dose supplementation with vitamin D (<400 IU) and calcium (<1,000 mg) to reduce fracture risk in noninstitutionalized populations and concluded that data on the effects of higher doses were insufficient (3).
- USPSTF recommends that all women planning or capable of pregnancy take a daily supplement containing 0.4 to 0.8 mg of folic acid (4)[A].
- USPSTF recommends against the use of beta carotene or vitamin E supplements for the prevention of cardiovascular disease or cancer (2).
- All infants should receive 400 IU/day of vitamin D beginning soon after birth whether breast or formula-fed (5).

COMMONLY ASSOCIATED CONDITIONS

Anemia, neuropathies, dermatitis, visual disturbances

DIAGNOSIS

HISTORY

- Review dietary intake (6).
- Decreased visual acuity or night blindness
- Poor wound healing or easy bruising
- Skin changes or new rash
- Neuropathy (6)

- Abnormal food cravings (pica)
- Osteomalacia or history of low-energy fracture
- Previous birth of a child with spina bifida
- Previous GI or bariatric surgery (1)
- Recurrent or persistent vomiting or diarrhea
- Prior or current medical conditions
  - Tuberculosis (TB), HIV infection, hepatitis, cancer
  - Hypermetabolic state
    - Thyrotoxicosis
    - 2nd- or 3rd-degree burns
    - Extensive or chronic wound
    - Any systemic infection
- Chronic disease requiring steroids, disease-modifying antirheumatic drugs (DMARDs), or immunosuppressants
- Malabsorptive or chronic GI disorder: celiac disease, sprue, Crohn disease, ulcerative colitis, GERD
- Parenteral or enteral nutrition via tube feeding
- Pregnancy
- Amenorrhea or infertility issues
- Medications, supplements
- Food allergies or intolerances, fad or restrictive diet

PHYSICAL EXAM

- Neurologic exam: gait, memory/cognitive impairment, reflexes, sensory or motor impairment, peripheral neuropathy (1,6)
- Oropharyngeal exam to look for glossitis, bleeding gums, hyperemic pharynx, stomatitis, cheilitis (1)
- Skin exam to look for maculosquamous dermatitis, photosensitive pigmented dermatitis, ecchymosis and/or petechiae (6)
- Visual assessment

DIFFERENTIAL DIAGNOSIS

Many conditions may mimic signs and symptoms of vitamin deficiencies.

- Diabetes mellitus (DM), thyroid disorders, hyperparathyroidism, heart failure, Alzheimer disease, multiple sclerosis, substance abuse, toxic ingestions, and

hematologic disorders/malignancies

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- No routine screening indicated.
- Test if symptomatic or history indicates at high risk. If clinical characteristics are present, consider the following:
  - 25-OH vitamin D (5)
  - Prothrombin time (PT)/partial thromboplastin time (PTT)
  - Vitamin B_{12} and folate levels (1)
  - Serum homocysteine and methylmalonic acid levels if high suspicion of vitamin B_{12} deficiency with normal serum B_{12} level (6)
  - Retinol serum level, retinol binding protein
- Ancillary tests include the following:
  - BUN, calcium, phosphorus, magnesium
  - Albumin, liver function tests
  - CBC
  - Parathyroid hormone
- Bone densitometry indicated in the following:
  - Women 65 years of age or older without previous known fractures or risk factors
  - Women <65 years old whose 10-year fracture risk is equal to that of a 65-year-old white woman without additional risk factors.
  - According to the United States fracture risk assessment tool (FRAX), the 10-year fracture risk for a 65-year-old white woman without risk factors is 9.3%.
- Give bariatric surgery patients additional consideration as they are at risk for deficiencies. Laparoscopic gastric banding is less frequently associated with vitamin deficiencies.
- Cyanocobalamin, thiamine, vitamin A
- Disease states from vitamin deficiency
  - Vitamin A (retinol): night blindness, complete blindness, xerophthalmia
  - Vitamin B_1 (thiamine)
    - Wernicke encephalopathy: acute syndrome with memory disturbance,

truncal ataxia, nystagmus, ophthalmoplegia
    - Korsakoff syndrome: anterograde and retrograde amnesia, confabulation
    - Dry beriberi: symmetric motor and sensory peripheral neuropathy, paresthesias, loss of reflexes
    - Wet beriberi: neuropathy with cardiovascular symptoms of peripheral vasodilation, high-output failure, dyspnea, and tachycardia
    - Infantile beriberi: loud piercing cry, cyanosis, tachycardia, cardiomegaly, dyspnea, vomiting, seizures
- Vitamin B_2 (riboflavin): glossitis, stomatitis, cheilitis, hyperemia of the pharyngeal mucosal membranes, normocytic-normochromic anemia
- Vitamin B_3 (niacin): pellagra: photosensitive pigmented dermatitis, dementia, and diarrhea
- Vitamin B_5 (pantothenic acid): paresthesias and dysesthesias, anemia
- Vitamin B_6 (pyridoxine): dermatitis, cheilosis, atrophic glossitis, stomatitis, neuropathy
- Vitamin B_9 (folate): megaloblastic anemia, rarely manifest neurologic symptoms
- Vitamin B_{12} (cobalamin): pernicious anemia, shuffling broad-based gait, atrophic glossitis, loss of vibration and position sense, cognitive impairment
- Vitamin C (ascorbic acid): scurvy: ecchymoses, bleeding gums, petechiae, hyperkeratosis, arthralgias, impaired wound healing
- Vitamin D (calciferol): rickets, osteomalacia
- Vitamin E: neuromuscular disorders and hemolysis
- Vitamin K: easy bruising, mucosal bleeding, melena, hematuria
- Biotin: changes in mental status, dysesthesias, nausea, maculosquamous dermatitis of the extremities

TREATMENT

MEDICATION

- Ask patients about any herbal or dietary supplements and encourage them to bring in vitamin and supplement bottles for review.
- Assess for potential adverse drug effects/reactions. Patients with alcohol

dependence should receive thiamine, folic acid, and MVI.

- Treat patients with suspected thiamine deficiency with 100 mg thiamine prior to IV fluids containing glucose to prevent precipitation of Korsakoff psychosis.
- If there is concomitant vitamin B_{12} and folate deficiency, then start vitamin B_{12} first to avoid precipitating subacute combined degeneration of the spinal cord (1).
- Consider obtaining prealbumin/albumin levels and a dietary consult for malnourished patients.
- Bariatric surgery patients will need lifelong vitamin supplementation; there are no consensus practice guidelines for supplement dosing regimens.

Geriatric Considerations

- Vitamin B_{12} deficiency exists in around 20% of the general population ≥60 years of age. Treat symptomatic or severe deficiency with an intramuscular (IM) injection of cyanocobalamin 1,000 μg/day 3 times a week for 2 weeks. If there are neurologic symptoms, then give the same dose of cyanocobalamin every other day for 3 weeks or until symptoms have resolved. To prevent recurrence or treat mild deficiency, use a regimen of oral vitamin B_{12} 1,000 μg/day or an IM injection of vitamin B_{12} 1,000 μg every month (6). Low-dose oral therapy with 50 to 150 μg/day may be considered for mild cases (1). High-dose (1,000 to 2,000 μg/day) oral treatment is as effective as monthly IM injections, but use caution in patients with malabsorption or compliance issues (1,6)[C].
- >40% of elderly in United States are vitamin D deficient. Deficiency is defined as a serum 25-OH vitamin D level of <20 ng/mL. Treatment of vitamin D deficiency is 50,000 IU of oral ergocalciferol weekly for 8 weeks (3).
- Current evidence from observational studies supports that vitamin A intake levels greater than 1500 μg/day are a risk factor for osteopenia and fractures (7).

Pediatric Considerations

- Vitamin K deficiency bleeding

  - Neonates may exhibit signs of vitamin K deficiency because they require 1 week of life to establish intestinal flora which manufactures vitamin K.
  - Condition peaks 2 to 10 days after birth: bleeding from the umbilical stump and/or circumcision site, generalized bruising, and GI hemorrhage
  - Infrequent in developed countries due to routine injection of newborns with vitamin K (1 mg)
- Vitamin D deficiency: Vitamin D supplementation (400 IU/day) is recommended in all infants starting in the first few days of life regardless of mode of feeding (5)[A].
- All children older than 12 months and adults need to meet the nutritional requirement of 600 IU/day of vitamin D either through diet or supplementation (5).
- Morbidly obese and minority children are at increased risk for vitamin D deficiency.
- In children age >6 months in developing countries, vitamin A supplementation has been shown to decrease mortality.
- Vitamin deficiency associated with developmental delay

Pregnancy Considerations

All pregnant women and women of childbearing age considering pregnancy are strongly encouraged to take a multivitamin containing at least 0.4 mg folic acid daily to prevent neural tube defects (4)[A].

ONGOING CARE

DIET

Vitamins are best utilized by the body from food intake. Supplements should be used where it is not feasible to ingest the recommended amount of a particular vitamin.

PATIENT EDUCATION

- In healthy adults, multivitamins have no value in a patient with an adequate diet and may increase risk of some cancers.
- Drug–drug interactions may occur between vitamins and some medications.

Patients should report all supplements along with medications to their health care provider.
- Risk of vitamin toxicity occurs most commonly with the fat-soluble vitamins (A, D, E, K).

PROGNOSIS

Most vitamin deficiencies are fully reversible if treated without undue delay.

COMPLICATIONS

- Vitamin toxicities
- Liver failure (vitamins A, D, E, K)
- Desquamation of skin (vitamin A)
- Neuropathy (vitamin B_6)
- Kidney stones (vitamin C, vitamin D)
- Hypercoagulability (vitamin K)
- Pseudohyperparathyroidism (vitamin D)
- Masking of pernicious anemia (folic acid)

CODES

ICD10

- E56.9 Vitamin deficiency, unspecified
- E56.0 Deficiency of vitamin E
- E55.9 Vitamin D deficiency, unspecified

CLINICAL PEARLS

- Obtain a thorough dietary history.
- Specifically ask patients about supplement use.
- Vitamin D supplementation is recommended in community-dwelling adults aged 65 years or older who are at increased risk for falls (3). All women planning or capable of pregnancy should take a daily supplement containing 0.4 to 0.8 mg of folic acid (4). All infants and children, including adolescents, should have a minimum daily intake of 400 IU of vitamin D beginning soon after birth (5).

VITILIGO

Sonia Rivera-Martinez, DO, FACOFP • Karen Sheflin, DO

BASICS

DESCRIPTION

- An acquired depigmentation of the skin, which correlates with a loss of epidermal melanocytes. There are three clinical variants, each with subtypes.
- Localized: often in childhood, rapid onset then stabilizes. Involvement of hair is common early in the course. Lacks associated autoimmune diseases.
  - Focal: few lesions, random distribution
  - Segmental: Lesions occur within a dermatome (mostly trigeminal) or may follow Blaschko lines. Lesions usually stop abruptly at the midline (1).
  - Mucosal: Only mucosal surfaces involved
- Generalized/nonsegmental (most common variant): progressive, with flares, commonly associated with autoimmunity. Common locations are acral, periorificial, and in sites sensitive to pressure/friction (Koebner phenomenon) (1).
  - Vulgaris: most common subtype; scattered macules; often symmetric, wide distribution; mostly hands, axillae, and groin
  - Acrofacial: on distal extremities and face
  - Mixed: coexistence of above
- Universal: involves >80% of the body surface area (BSA). Most likely to have family history; comorbidities are common and associated with poorest quality-of-life (QOL) scores.
- Other rare variants
  - Ponctué: discrete confetti-like macules (1)
  - Inflammatory: peripheral erythematous rim (1)
  - Trichrome: Tan zone is present between normal and depigmented skin (1).
  - Quadrichrome: as above but with marginal/perifollicular hyperpigmentation (1)
  - Blue: Dermal melanophages give blue hue, in areas affected by prior

postinflammatory hyperpigmentation (1).

- System(s) affected: skin, mucous membranes
- Synonym(s): leukoderma

EPIDEMIOLOGY

- 50% begin before age 20 years, peak in females: 1st decade; males: 5th decade. Onset earlier with positive family history; can appear as early as 6 weeks (1).
- Predominance: male = female; however, females are more likely to seek treatment (1).
- No race or socioeconomic predilection

Prevalence

~1% in the United States and Europe; 0.1–8% in the world; highest in Gujarat, India, at 8.8% (1)

ETIOLOGY AND PATHOPHYSIOLOGY

Most likely a spectrum of disorders with a common phenotype and multiple mechanisms contribute to the pathology (convergence theory).

- Genetic: see above.
- Autoimmune: humoral autoantibodies and skin-homing T cells (1)
- Neural: local or systemic dysregulation leading to excess neurotransmitters (1)
- Viral: direct melanocyte toxicity, cytomegalovirus (CMV), hepatitis C, and Epstein-Barr virus (EBV) found in lesional biopsies (1)
- Oxidative stress from elevated H_2O_2 and NO and decreased catalase and erythrocyte glutathione (1)

Genetics

- Polygenic/multifactorial inheritance
- 20% of patients report affected relative, but monozygotic twins have only 23% concordance.
- HLA haplotypes, small nucleotide polymorphisms, and specific genes are all possible contributors (1).

RISK FACTORS

- Family history of vitiligo/autoimmune disorders

- Personal history of associated conditions

COMMONLY ASSOCIATED CONDITIONS

- Most common
  - Endocrine: thyroid disease (hypo-/hyperthyroidism), hypoparathyroidism, Addison disease, insulin-dependent diabetes
  - Dermatologic: psoriasis, atopic dermatitis, alopecia areata, chronic urticaria, halo nevi, ichthyosis
  - Pernicious anemia
  - Hypoacusis, rheumatoid arthritis
  - Ocular abnormalities in up to 40%
  - Elevated antinuclear antibodies in up to 40%
  - Elevated thyroperoxidase antibodies in 50%
- Less common
  - Systemic lupus erythematosus
  - Inflammatory bowel disease
  - Melanoma (may be a sign of positive outcome of melanoma) and other skin cancers
  - Syndromes: Alezzandrini; mitochondrial encephalomyopathy, lactic acidosis, and stroke-like episodes (MELAS); Schmidt; and autoimmune polyendocrinopathy candidiasis ectodermal dysplasia (APCED)
- Age >50 years at onset should prompt investigation for associated conditions.

Pediatric Considerations

Associated with Hashimoto thyroiditis in a significant portion of children. Screening at onset and possibly annually may be beneficial.

DIAGNOSIS

HISTORY

- Inquire about recent history of sunburns, pregnancy, skin trauma, or emotional stress (1).
- Family history of premature graying, vitiligo, and autoimmune disorders
- Review of systems for related associated conditions
- Ascertain psychological impact on QOL, Dermatology Life Quality Index

(DLQI).

PHYSICAL EXAM

- Full-body skin exam with Wood lamp to accentuate lesions and distinguish depigmentation from hypopigmentation (1)
- Lesions are well-demarcated, uniform white macules and patches.
- Look for evidence of repigmentation (most commonly around hair follicles).

DIFFERENTIAL DIAGNOSIS

- Infectious: tinea versicolor, leprosy, leishmaniasis, onchocerciasis, treponematoses (pinta/syphilis)
- Postinflammatory hypopigmentation: psoriasis, atopic dermatitis, pityriasis alba, systemic lupus erythematosus, scleroderma
- Inherited hypomelanoses: piebaldism, tuberous sclerosis, Waardenburg, hypomelanosis of Ito, Vogt-Koyanagi-Harada
- Malformations: nevus anemicus, nevus depigmentosus
- Paraneoplastic: mycosis fungoides, melanoma-associated leukoderma
- Occupational and chemical induced
  - Occupational: phenolic/catechol derivatives and arsenic-containing compounds
  - Chemical: numerous, including cosmetics, cleansers, insecticides, and even medications (imatinib, potent topical corticosteroids [TCS]) (1)
- Melasma: Normal skin may be confused as vitiligo in the setting of surrounding hyperpigmentation.
- Halo nevi
- Lichen sclerosus et atrophicus
- Idiopathic guttate hypomelanosis
- Progressive-acquired macular hypomelanosis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- TSH, CBC, ANA (1)
- Consider antithyroid peroxidase, antithyroglobulin antibodies, hemoglobin, vitamin B_{12} levels if family/patient history of autoimmune disease (1).

Follow-Up Tests & Special Considerations

- Monitor for disease progression/flares.
- Monitor for symptoms of related conditions.

Diagnostic Procedures/Other

- Skin biopsy is rarely needed. Highest yield is with comparison of lesional/perilesional biopsies.
- Consider ophthalmologic and audiologic evaluation.

Test Interpretation

Few or no epidermal melanocytes. At margins, melanocytes may be larger, vacuolated, and dendritic. Early lesions show inflammation and later, degeneration, including of adnexa and nerves.

TREATMENT

The variant of vitiligo may affect response.

- If untreated, progression is the natural course for those with mucosal involvement, family history, koebnerization, and nonsegmental variants.
- Lesions that respond best are on the face, of recent onset, in darker skin type, and in younger patients.

GENERAL MEASURES

- Sunscreen to decrease sunburn and prevent accentuation of uninvolved skin
- Corrective camouflage as coverup (Cover FX, Dermablend)

MEDICATION

- Individualize therapy depending on age, extent, distribution, and rate of progression.
- Many therapies are considered “off-label” and not FDA-approved for vitiligo, although they are often considered first-line therapy.
- Corticosteroids: Mid-potency topical corticosteroids (mometasone furoate, fluticasone propionate) applied daily as monotherapy are considered first-line treatments. Do not use on face/axilla/groin; do not occlude except under close monitoring. Pediatric: as above, for children >12 years of age. Consider decreased potency. Local side effects including atrophy, telangiectasia, hypertrichosis, acneiform eruptions, and striae limit treatment; regular steroid

holidays are recommended (2). The combination of light therapy and TCS is the most effective treatment overall (3). Most efficacious on sun-exposed areas: face/neck, dark-skinned patients, newer lesion (3). Addition of tretinoin 0.025–0.05% BID is effective and can decrease potential skin atrophy (4). Systemic corticosteroids can be helpful, but dosage and safety parameters have not been fully evaluated (2,5)[A].

- Topical calcineurin inhibitors: slightly inferior to TCS as monotherapy but better side effect profile (3,6,7)[B]; can be used as adjunctive to light therapy; carries a controversial black box warning for a theoretical risk of lymphoma or skin cancer. Extensive safety profiling has not revealed any evidence for this in children or adults using topical calcineurin inhibitors. Local reactions include burning sensation, pruritus, erythema, and rare transient hyperpigmentation (3).
  - Tacrolimus 0.03% or 0.1% ointment BID (2). Pediatric: 0.03% ointment BID, for children >2 years of age (7)
  - Pimecrolimus 1% cream BID (2). Pediatric: as adults, for children >2 years of age (7)
- Topical vitamin D_3 analogs: less effective than TCS alone, but in combination with TCS or phototherapy can shorten time until, and improve stability of, repigmentation (5,7)[B].
  - Calcipotriene ointment 1 to 2 times per day. Pediatric: not defined.
  - Available as a combination formulation, betamethasone dipropionate 0.064%/calcipotriene 0.005% ointment daily, max dose of 100 g/week for 4 weeks, not for >30% BSA, and not for face/axilla/groin. Pediatric: not defined.
- Oral vitamin D_3: reported to induce repigmentation. Oral vitamin D_3 35,000 U once daily plus low-calcium diet for 6 months. Pediatric: not defined.
- Phototherapy: Narrow band UVB (NBUVB) is superior to UVA and indicated for lesions involving more than 15–20% BSA (5,7,8)[A]. Psoralen and khellin enhance the effect of light. Psoralen plus UVA (PUVA) may increase the incidence of skin cancers. Khellin may have reduced cross-linking of DNA and may be less carcinogenic; however, it is associated with increased liver toxicity (8). L-phenylalanine can be used topically and orally as a photosensitizer for natural or artificial light. Pediatric: Oral PUVA is

contraindicated.
- Laser therapy: Excimer laser (308 nm) is superior to other light therapy. Helium–neon laser works for segmental vitiligo (7)[A].
- Antioxidants: may have protective role in preventing melanocyte degradation from reactive oxygen species. Options include vitamin C, vitamin E, Vitix, *Polypodium leucotomos* extracts, and *Ginkgo biloba* (6)[B].
- Surgical therapy: See later discussion.
- New concepts: Tumor necrosis factor-α inhibitors, cyclosporine, cyclophosphamide, azathioprine, minocycline, and immunosuppressants are currently being evaluated (8).

First Line

- Recommended: avoidance of triggering factors plus TCS alone or in combination with NBUVB
- Alternatively
  - Topical calcineurin inhibitors (preferred for face, neck, axilla, and groin)
  - NBUVB
  - PUVA in adults
  - Camouflage and psychotherapy should be offered to all patients at any stage (8).

Second Line

- Recommended: photochemotherapy with psoralens or vitamin D analogues
- Alternatively
  - Topical vitamin D analogues
  - Targeted phototherapy
  - 308-nm laser in combination with topical steroids, topical calcineurin inhibitors, or vitamin D analogues
  - Oral corticosteroids (pulse therapy)
  - Surgical treatments indicated for stable 2- to 3-cm lesions, refractory to other treatments
    - Mini-punch graft (pretreat with cryotherapy/dermabrasion or posttreat with phototherapy) (9)[B]
    - Suction blister graft (9)[B]
    - Autologous melanocyte suspension transplant (6)[B]

ISSUES FOR REFERRAL

- Dermatologist: for facial/widespread vitiligo or when advanced therapy is necessary
- Ophthalmologist: for ocular symptoms or monitoring of TCS near eyes
- Endocrinologist: evaluation/management of associated conditions
- Psychologist: for severe distress
- Medical geneticist for associated conditions

ADDITIONAL THERAPIES

- Depigmentation therapy with monobenzone, hydroquinone, or Q-switched ruby laser: for extensive vitiligo recalcitrant to therapy (9)
- Pseudocatalase with addition of NBUVB (2)[B]
- Prostaglandin E for short-duration disease and localization to face and scalp (2)[B]
- Cosmetic tattooing for localized stable vitiligo

SURGERY/OTHER PROCEDURES

- Goal is to transport melanocytes from other areas of the skin. Methods include punch, blister, or split-thickness skin grafting, or transplantation of autologous melanocytes.
- Dermabrasion and curettage alone or in combination with 5-fluorouracil may induce follicular melanocyte reservoirs (7)[A].
- Patients who koebnerize or form keloids may be worse, and permanent scarring is a risk for all patients.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- *Ginkgo biloba* 60 mg PO daily may significantly improve extension and spreading of lesions (8)[B].
- *Polypodium leucotomos* may help with repigmentation with NBUVB and aid in reducing phototoxic reactions (7,8)[B].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Monitor for symptoms of related conditions.

- With topical steroids, follow at regular intervals to avoid steroid atrophy, telangiectasia, and striae distensae.

DIET

No restrictions

PATIENT EDUCATION

- Discussion of disease course, progression, and cosmesis
- Education regarding trauma/friction and Koebner phenomenon

PROGNOSIS

- Vitiligo may remain stable or slowly or rapidly progress.
- Spontaneous repigmentation is uncommon.
- Generalized vitiligo is often progressive, with flares. Focal vitiligo often has rapid onset, then stabilizes.

COMPLICATIONS

- Adverse effects of each treatment modality
- Psychiatric morbidity: depression, adjustment disorder, low self-esteem, sexual dysfunction, and embarrassment in relationships (1)
  - Different cultures may have different perceptions/social stigmas about vitiligo. Some believe it to be contagious or related to infection. Women with vitiligo may have difficulty finding a marriage partner and have low self-esteem.

CODES

ICD10

L80 Vitiligo

CLINICAL PEARLS

- Vitiligo can be a psychologically devastating skin disease.
- Screen for associated diseases, particularly if onset occurs later in life.
- Treatment should be individualized based on BSA, skin type, and patient goals.
- Dermatology consultation when extensive disease, facial involvement, and when advanced treatments are considered.

VOCAL CORD DYSFUNCTION

Daniel A. Cieslak, MD • Emily M. Culliney, MD, FAAFP

BASICS

DESCRIPTION

- Vocal cord dysfunction (VCD): a breathing disorder in which vocal cords adduct inappropriately primarily on inspiration, producing airflow obstruction that may result in dyspnea, wheezing, and stridor
- Synonym(s): paradoxical vocal fold motion (PVFM)

EPIDEMIOLOGY

Incidence

Not well defined

Prevalence

- Unknown; likely uncommon in the general population
- Most frequently diagnosed in patients evaluated for asthma and exercise-induced dyspnea
- Female predominance, 2:1 (1)
- 71% of patients are adults and 29% of patients <18 years of age. Also has been diagnosed in young children/infants (1)
- Suspect occurrence in approximately 3% of intercollegiate athletes with exercise-induced asthma (2).

ETIOLOGY AND PATHOPHYSIOLOGY

- Exact etiology is unclear—both organic and nonorganic causes have been identified.
- Possible laryngeal hyperresponsiveness to irritants, such as smoke, dust, postnasal drip, gastroesophageal reflux disease (GERD), URI, or other irritants (3)
- Noncompetitive and competitive exercises—unknown mechanism (4)
- Psychological factors such as anxiety, severe social stresses (e.g., competitive sports), history of sexual abuse (2)

Genetics

None defined

RISK FACTORS

See “Commonly Associated Conditions.”

COMMONLY ASSOCIATED CONDITIONS

- Asthma
- GERD
- Rhinosinusitis
- Psychological conditions such as posttraumatic stress disorder, anxiety, depression, and panic disorder

DIAGNOSIS

HISTORY

- Recurrent episodes of “difficulty breathing in,” wheezing, throat or chest tightness, choking sensation, stridor, panic, and agitation
- Stridulous sounds that are loudest above the throat, less audible throughout the chest wall.
- Some patients (typically elite athletes) experience inspiratory stridor that resolves spontaneously when activity ceases.
- The stridor is often mistaken for wheezing, leading to misdiagnosis of asthma or exercise-induced asthma.
- Dysphonia or aphonia is possible between attacks.
- History of multiple ED visits, possibly multiple intubations
- The symptoms tend to be relatively mild but can be prolonged and severe.
- Patients may report their asthma medications do not help their symptoms.

PHYSICAL EXAM

- Inspiratory stridor
- Cough
- Wheezing (especially if unresponsive to bronchodilators)
- Mild respiratory distress

DIFFERENTIAL DIAGNOSIS

- Asthma: primary differential diagnosis because wheezing is a big component—although VCD can coexist with asthma (1,2). The key differences between the two are the following:
  - Asthma typically has wheeze on expiration, VCD on inspiration.
  - Asthma symptoms associated with nocturnal awakenings, uncommon in VCD
  - Asthma is not typically associated with a sensation of choking.
  - Asthma symptoms usually improve with albuterol use (3).
  - VCD causes more difficulty with inspiration rather than expiration.
  - VCD is not responsive to asthma treatment (unless coexisting) (2).
- Anaphylaxis
- Foreign body
- Laryngeal angioedema
- Chronic obstructive pulmonary disease
- Epiglottitis
- Vocal cord polyps/tumor
- Vocal cord paralysis
- Croup
- Tracheal stenosis or masses
- Laryngomalacia (1)
- Neurologic cause: vagus or recurrent laryngeal nerve injury, amyotrophic lateral sclerosis (3)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Flexible laryngoscopy—gold standard (2)[C]
  - Allows for direct visualization of abnormal adduction of the vocal cords
  - May allow for diagnosis in more than half of asymptomatic patients; however, provocation tests such as methacholine (5), exercise (4), and histamine may be needed for diagnosis (4,5)[C].
- Pulmonary function testing with flow volume loop
  - Most commonly used test
  - Positive findings consist of normal expiratory volume loop with a flattened inspiratory volume loop. This is consistent with extrathoracic upper airway

obstruction (6)[C].
  - May require exercise testing for patients in whom exercise is the trigger
  - Useful for distinguishing from asthma, which may show a scooped expiratory loop
- Imaging
  - Chest radiographs to rule out other causes of dyspnea (2)
  - High-resolution CT of upper airways to evaluate for stenosis, masses (if not able to visualize trachea during laryngoscopy) (7)
- Arterial blood gases
  - Useful to rule out other causes of severe respiratory distress

TREATMENT

GENERAL MEASURES

- Short term
  - Asthma control/treatment with appropriate meds, if coexisting (3)[C]
  - Reassurance and relaxation techniques:
    - Pursing lips
    - Panting (rapid, shallow breathing)
    - Diaphragmatic breathing
    - Breathing through the nose or a straw
    - Exhaling with a hissing sound
  - Continuous positive airway pressure (CPAP)
  - Intermittent CPAP with heliox (helium-oxygen) mixture may reduce airway resistance in some patients (1,2)[C].
  - Anxiolytics if associated with anxiety attack (must confirm normal oxygen saturation prior to administration)
  - Intubation with severe symptoms (3)[C]
- Long term
  - Avoid triggers.
  - Behavioral speech/voice therapy (8)[B]
  - Treat underlying conditions.

MEDICATION

First Line

No medications are specifically helpful. Exercise-induced VCD may respond to anticholinergics in addition to speech therapy; thus, consider a trial of ipratropium if symptoms are exercise-induced (9)[C].

ISSUES FOR REFERRAL

- Diagnosis and treatment may require assistance of pulmonologist, otolaryngologist, allergist, psychiatrist, and/or psychologist.
- Speech therapy is the mainstay of long-term treatment for patients with ongoing symptoms. It helps reduce recurrence.

ONGOING CARE

PROGNOSIS

Spontaneous resolution is common.

CODES

ICD10

- J38.3 Other diseases of vocal cords
- J38.00 Paralysis of vocal cords and larynx, unspecified
- J38.1 Polyp of vocal cord and larynx

CLINICAL PEARLS

- Always consider VCD in poorly controlled asthmatics.
- A multidisciplinary approach may be required for diagnosis and treatment.
- Speech therapy is the mainstay of long-term treatment.

VON WILLEBRAND DISEASE

Juliana Perez Botero, MD • Ewa M. Wysokinska, MD • Aneel Ashrani, MD, MS

BASICS

DESCRIPTION

- von Willebrand disease (vWD) is a bleeding disorder caused by deficiency or a defect of *von Willebrand factor* (vWF) protein.
- vWF is critical to the initial stages of blood clotting, acting as a bridge for platelet adhesion; it also acts as a carrier for factor VIII (FVIII).
- vWD primarily manifests as mucocutaneous or perioperative bleeding or menorrhagia.
- vWD is an inherited condition but rarely can be acquired (1,2,3).

EPIDEMIOLOGY

Prevalence

- Prevalence of the inherited forms of vWD is 1 in 100 to 10,000 of the general population with 2:1 female-to-male ratio (1).
- Exact prevalence of the acquired forms of vWD (AvWD) is unknown but is estimated to be up to 0.1% of the general population.

Pediatric Considerations

Many cases of vWD are diagnosed in childhood, often during initial years of menstruation. vWD may be difficult to diagnose before 6 months of age.

Pregnancy Considerations

Although levels of vWF increase during pregnancy, women with vWD are more likely to experience an increased incidence of obstetric complications that manifest with bleeding.

ETIOLOGY AND PATHOPHYSIOLOGY

- vWF is a large, multimeric protein that is released from endothelial cells and is also carried within platelets in α-granules.
- vWF binds to collagen at sites of vascular injury and creates a surface for

platelet adhesion through GP1b receptor. This results in platelet plug formation.

- vWF is also a carrier for FVIII and stabilizes this factor from degradation. A deficiency in vWF may result in lower levels of FVIII.
- When vWF is deficient or dysfunctional, primary hemostasis is compromised, resulting in increased mucocutaneous and postprocedural bleeding.
- Three major categories of vWD exist
  - Type 1, the most common and mildest form, represents 60–80% of cases.
    - Mild to moderate quantitative deficiency of vWF and concordant deficiency of FVIII
    - Generally, a mild bleeding disorder
  - Type 2 caused by qualitative defect in vWF accounts for 10–30% of cases and is divided into the following multiple subtypes.
    - Type 2A is noted for loss of hemostatically active large multimers with low ristocetin cofactor/vWF activity.
    - Type 2B, noted for increased binding affinity for platelets, is associated with thrombocytopenia, low ristocetin cofactor/vWF activity, abnormal ristocetin-induced platelet aggregation (RIPA), and loss of large multimers.
    - Type 2M is noted for defective platelet or collagen binding without loss of large multimers.
    - Type 2N demonstrates defective binding to FVIII, which results in increased clearance of FVIII and hemophilia A–like picture
  - Type 3 represents 1–5% of cases.
    - Most severe form characterized by markedly decreased-to-undetectable levels of vWF and FVIII
    - Manifests as hemophilia A with hemarthroses (1,2,3,4)
- AvWD may be due to cardiovascular, hematologic, or autoimmune conditions as well as tumors and medications
- The pathophysiology of AvWD is related to the underlying cause and may result from shear-induced cleaving of vWF in cardiovascular conditions, increased adsorption of vWF by certain tumor cells or activated platelets, or presence of anti-vWF autoantibodies detected in hematologic disorders.

Genetics

- The 175-kb gene for vWF is located on short arm of chromosome 12.
- Type 1 follows an autosomal dominant inheritance pattern, with variable expressivity.
- Type 2 varies but primarily follows an autosomal dominant inheritance pattern.
- Type 3 follows an autosomal recessive inheritance pattern (4).

COMMONLY ASSOCIATED CONDITIONS

AvWD may be found in patients with hematologic disorders such as MGUS and myeloproliferative neoplasms. Commonly associated cardiovascular conditions include aortic stenosis and left ventricular assist device (LVAD) placement. AvWD is associated with gastrointestinal bleeding from arteriovenous malformations.

DIAGNOSIS

HISTORY

- Most patients with vWD have a positive family history of bleeding disorder; however, patients with mild forms of vWD and their families may be unaware of their disease. Those with acquired vWD usually have no family history of this disorder.
- The most important component of diagnosis is the hemostatic history often aided by specifically designed bleeding questionnaires.
- Common symptoms are those of mucocutaneous (recurrent epistaxis, menorrhagia, ecchymosis) or postprocedural bleeding. Hemarthroses are a rare presentation, mostly associated with types 2N and 3.

PHYSICAL EXAM

- Physical exam may be entirely normal, although there may be some ecchymoses.
- Findings suggestive of other causes of increased bleeding should be sought (liver disease, skin laxity, or telangiectasias).

DIFFERENTIAL DIAGNOSIS

- Primary hemostatic disorders: congenital thrombocytopenia or qualitative

platelet defects, coagulation factor deficiencies

- Secondary hemostatic disorders: liver disease, uremia, connective tissue disorders, coagulation factor inhibitors

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Initial tests: vWF antigen, ristocetin cofactor activity, FVIII activity, CBE, PT/INR, aPTT, platelet function analyzer assay (PFA-100), RIPA
- The specific tests for vWD include vWF antigen (vWF:Ag), vWF activity/ristocetin cofactor activity (vWF:RCo) (if available: collagen-binding activity [vWF:CB]) and FVIII activity; these tests should be ordered when suspicion for vWD is high. Additional specific tests include RIPA, vWF multimer analysis, vWF propeptide (vWFpp), and genetic testing.
- Interpretation:
  - Platelet count is often normal, except in type 2B or in AvWD when there is an underlying myeloproliferative disorder.
  - Platelet function assays via PFA-100 (i.e., collagen/epinephrine and collagen/ADP closure time) are usually prolonged but may be normal in mild disease.
  - PT/INR is normal, unless there is concurrent liver disease or warfarin (Coumadin) use.
  - Activated PTT may be prolonged if a decrease in FVIII accompanies vWD.
- Specific tests for vWD
  - vWF antigen testing is done via immunologic methods.
    - vWF antigen testing has a positive predictive value (PPV) of 33% for detecting significant FVIII deficiency and a PPV of 80% for detecting ristocetin cofactor activity abnormalities.
    - vWF antigen may be normal in type 2 vWD.
  - Ristocetin cofactor activity is a functional assessment of vWF. Ristocetin promotes binding of platelets to vWF, and this activity is disproportionately reduced compared to vWF antigen in most forms of type 2 vWD.
  - Ratio of vWF: RCo to vWF: Ag <0.5 to 0.7 may be used to differentiate type 1 from type 2 vWD.
  - Alternatively, latex particle–enhanced immunoassay may be used to

quantify vWF activity. A specific monoclonal anti-vWF antibody directed against platelet GP1b-binding site of vWF adsorbed onto the latex reagent reacts with plasma vWF proportional to the vWF activity.
  - Collagen-binding activity, another functional assessment of vW, is reduced in most forms of vWD.
  - FVIII activity may be normal or mildly decreased in most types of vWD (in 2N and type 3, levels are markedly decreased).
  - vWFpp is useful in accelerated clearance variants of vWD (type 1C).
  - vWF multimer analysis is performed by electrophoresis on agarose gel. This test differentiates patients with type 2 vWD.
  - RIPA is useful in diagnosing type 2B vWD.
  - FVIII-vWF binding assay activity is low in patients with type 2N vWD.
  - Genotype testing may also be used, especially for types 2 and 3 (1,2,3,4).

Follow-Up Tests & Special Considerations

- Unless patients have severe forms of vWD or are undergoing treatment, follow-up laboratory studies are not usually obtained.
- Patients with blood group O have 20–30% baseline lower levels of vWF antigen and ristocetin cofactor activity.
- vWF is an acute-phase reactant, so elevations may be seen in inflammatory conditions, liver disease, pregnancy (which may correct mild deficits), or with estrogen use.

TREATMENT

GENERAL MEASURES

- Most patients with type 1 vWD do not require activity restrictions.
- Patients with type 3 vWD should avoid contact sports.
- An emergency ID bracelet may be useful.

MEDICATION

First Line

- Desmopressin (DDAVP)
  - Enhances release of vWF from endothelial cells
  - Primarily effective for type 1 vWD; not to be used in type 2B

- Typically raises vWF by 2- to 3-fold from baseline levels (5)[B]
- Not effective in severe deficiencies, in types of vWD with defective vWF, or for prophylaxis prior to major procedures
- Dosed 0.3 μg/kg (max 20 mg) IV/SC; intranasal (high concentration) spray: <50 kg: 150 μg/day; >50 kg: 300 μg/day (Stimate)
- Common side effects: flushing, tachycardia, water retention, hyponatremia
- Obtain repeat testing of ristocetin cofactor activity and FVIII 1 and 4 hours after infusion to evaluate peak response and clearance of DDAVP.
- Tachyphylaxis may develop with prolonged dosing; limit use to administering DDAVP once every 24 to 48 hours for 3 to 5 days.

- vWF and FVIII concentrates
  - Plasma-derived vWF and FVIII concentrates of various purity such as Humate-P, Alphanate, Wilate, or Fandhi (not available in United States) are commercial concentrates of vWF and FVIII that are given in doses of 25 to 60 IU/kg/day based on clinical situation (6,7)[B]
    - Administration of 1 IU/kg vWF:RCo concentrate raises the plasma RCo activity by approximately 2%.
    - Dose of vWF concentrate may be adjusted for FVIII levels and ristocetin cofactor activity.
    - FVIII levels should be monitored to avoid supranormal levels and possible venous thromboembolism (VTE).
    - Contraindicated if patient develops alloantibodies to vWF
  - Recombinant vWF concentrate (Vonvendi) is approved for use in adults. It requires rFVIII with the first infusion (8)[B].
  - In patients with severe bleeding phenotype, prophylactic treatment is used.
- Cryoprecipitate
  - Cryoprecipitate contains FVIII, fibrinogen, vWF, factor XIII, and fibronectin.
  - Not considered as safe as the recombinant and virus-inactivated plasma concentrates listed above and should not be used unless those are unavailable
- Antifibrinolytics
  - Useful for mucosal bleeding
  - Contraindicated in patients with hematuria due to risk of retention of large

blood clots in the renal collecting system
  - Given as adjunct to DDAVP
  - Aminocaproic acid may be given at 50 to 70 mg/kg (max: 5 g; lower doses may be effective) q4–6h IV or PO.
  - Tranexamic acid may be given at 10 to 15 mg/kg IV or 25 mg/kg (1,300 mg) PO q8–12h.
- Recombinant FVIIa/NovoSeven
  - Used for patients who develop alloantibodies to vWF
  - Given as IV bolus of 90 μg/kg q2h or 20 μg/kg every hour until hemostasis is achieved

Second Line

- Oral contraceptives raise vWF/FVIII levels and have a role in the treatment of chronic menorrhagia.
- Platelets may be given as an adjunct to factor concentrates if hemostasis has not been achieved.
- IVIG has been useful in some patients with AvWD associated with monoclonal gammopathy (9).
- Recombinant FVIIa has been used effectively in patients with type 3 vWD.

ISSUES FOR REFERRAL

The diagnosis and management of vWD is not always straightforward; consider consultation with hematologist.

SURGERY/OTHER PROCEDURES

Valve replacement or correction may be curative for patients with AvWD associated with underlying cardiovascular conditions.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- For patients with major bleeding or those undergoing major surgical procedures, levels of ristocetin cofactor/vWF activity and FVIII need to be restored to 80 to 100 IU/dL for first 2 days and then maintained >50 IU/dL for 5 to 7 days.
- For patients undergoing minor surgical procedures, maintain FVIII levels >50 IU/dL for 5 to 7 days.

- For patients delivering or in need of epidural anesthesia, obtain FVIII levels >50 IU/dL.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patients should be seen by a hematologist prior to invasive procedures for determination of perioperative management or advice regarding delivery.

Patient Monitoring

Patients with mild disease do not require monitoring.

DIET

No dietary restrictions are recommended. However, aspirin and other NSAIDs should be avoided due to their antiplatelet effects, which can exacerbate the bleeding phenotype.

PATIENT EDUCATION

National Hemophilia Foundation: www.hemophilia.org/NHFWeb/MainPgs/MainNHF.aspx?menuid=182&contentid=47&rptname=bleeding

PROGNOSIS

Most patients with vWD have a normal life expectancy.

COMPLICATIONS

- Significant perioperative bleeding may occur.
- Patients with type 3 vWD and type 2N can have bleeding complications similar to patients with hemophilia A such as hemarthrosis and intracranial hemorrhage.
- Patients with aortic stenosis and AvWD are known to have higher rates of GI bleeding.
- Multiple transfusions may result in alloantibodies against vWF.
- VTE may result from supranormal levels of FVIII.

CODES

ICD10

D68.0 Von Willebrand's disease

CLINICAL PEARLS

- vWD varies from a minor to severe bleeding disorder; affects 1–2% of the U.S. population.
- It is important to determine the exact type of vWD (1, 2, or 3) to guide treatment.
- AvWD should be considered in patients with acquired bleeding disorder if they have underlying predisposing conditions.

VULVAR MALIGNANCY

Jay R. Patibandla, MD • Michael P. Hopkins, MD, MEd

BASICS

DESCRIPTION

- Premalignant lesions of the vulva are collectively known as vulvar intraepithelial neoplasia (VIN). Exposure to human papillomavirus (HPV) has been linked to >70% of VIN (1).
- Invasive squamous cell carcinoma is the most common malignancy involving the vulva (90% of patients); can be well, moderately, or poorly differentiated and derives from keratinized skin covering the vulva and perineum.
- Melanoma is the second most common type of vulvar malignancy (8%) and sarcoma is the third (1).
- Other invasive cell types include basal cell carcinoma, Paget disease, adenocarcinoma arising from Bartholin gland or apocrine sweat glands, adenoid cystic carcinoma, small cell carcinoma, verrucous carcinoma, and sarcomas.
- Sarcomas are usually leiomyosarcoma and probably arise at the insertion of the round ligament in the labium major; however, sarcoma can arise from any structure of the vulva, including blood vessels, skeletal muscle, and fat.
- Rarely, breast carcinoma has been reported in the vulva and is thought to arise from ectopic breast tissue.
- System(s) affected: reproductive

Geriatric Considerations

- Older patients with associated medical problems are at high risk from radical surgery. The surgery, however, is usually well tolerated.
- Patients who are not surgical candidates can be treated with combination chemotherapy and/or radiation.
- In the very elderly, palliative vulvectomy provides relief of symptoms for ulcerating symptomatic advanced disease.

EPIDEMIOLOGY

Incidence

- In 2015, 5,150 women were diagnosed with vulvar cancer and 1,080 women died from vulvar cancer in the United States (2).
- Ethnic distribution: more common in Caucasian women than in any other race
- Surveillance, epidemiology, and end result (SEER) data showed that the incidence of in situ vulvar carcinoma increased by >400% between 1973 and 2000.
- Mean age at diagnosis 65 years; in situ disease: mean age 40 years; invasive malignancy: mean age 60 years (3)

ETIOLOGY AND PATHOPHYSIOLOGY

- Patients with cervical cancer are more likely to develop vulvar cancer later in life, secondary to “field effect” phenomenon with a carcinogen involving the lower genital tract (3).
- HPV has been associated with squamous cell abnormalities of the cervix, vagina, and vulva; 55% of vulvar cancers are attributable to oncogenic HPV, predominantly HPV 16 and 33; 92% of VIN 2/3, vaginal intraepithelial neoplasia (VAIN) 2/3, and anal intraepithelial neoplasia (AIN) are attributable to HPV.
- Squamous cell carcinoma
  - The warty basaloid type, also known as bowenoid type, is related to HPV infection and occurs in younger women. Although traditionally graded in a three-level system, the International Society for the Study of Vulvovaginal Disease voted not to use a grading system for VIN in 2004. This system eliminated VIN 1 and combined VIN 2 and VIN 3. This is based on the fact that VIN 1 is not reproducible. VIN 2 and VIN 3 were combined because VIN 2 is rare and carries the same risk of progression to malignancy as VIN 3 (1).
  - The more common variant is simplex or differentiated and does not appear to be related to HPV, occurs in older age groups, and associated with lichen sclerosus and chronic venereal diseases; it is thought to carry a higher risk of progression to malignancy.
  - Melanoma, second most common histology, often identified in postmenopausal women; often pigmented but can be amelanotic, arising de

novo, often found on clitoris or labia minora (1).

- Cases not associated with HPV infection are typically associated with vulvar dystrophies, such as lichen sclerosus or squamous cell hyperplasia.
- Smoking is associated with squamous cell disease of the vulva, possibly from direct irritation of the vulva by the transfer of tars and nicotine on the patient's hands or from systemic absorption of carcinogen.

Genetics

No known genetic pattern

RISK FACTORS

- VIN or cervical intraepithelial neoplasia (CIN)
- Smoking
- Lichen sclerosus (vulvar dystrophy)
- HPV infection, condylomata or sexually transmitted diseases (STD) in the past
- Low economic status
- Autoimmune processes
- Immunodeficiency syndromes or immunosuppression
- Northern European ancestry

GENERAL PREVENTION

- HPV vaccination has the potential to decrease vulvar cancer by 60% (3–5).
- Abstinence from smoking/smoking cessation counseling (1)

COMMONLY ASSOCIATED CONDITIONS

- Patients with invasive vulvar cancer are often elderly and have associated medical conditions.
- High rate of other gynecologic malignancies

DIAGNOSIS

HISTORY

Complaints of pruritus or raised lesion in the vaginal area

PHYSICAL EXAM

- In situ disease: a small raised area associated with pruritus, single vulvar plaque, ulcer, or mass on labia majora, perineum, clitoris
- Vulvar bleeding, dysuria, enlarged lymph nodes less common symptomatology
- Invasive malignancy: an ulcerated, nonhealing area; as lesions become large, bleeding occurs with associated pain and foul-smelling discharge; enlarged inguinal lymph nodes indicative of advanced disease.

DIFFERENTIAL DIAGNOSIS

- Infectious processes can present as ulcerative lesions and include syphilis, lymphogranuloma venereum, and granuloma inguinale.
- Disorder of Bartholin gland, seborrheic keratosis, hidradenomas, lichen sclerosus, epidermal inclusion cysts
- Crohn disease can present as an ulcerative area on the vulva.
- Rarely, lesions can metastasize to the vulva.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Hypercalcemia can occur when metastatic disease is present.
- Squamous cell antigen can be elevated with invasive disease.

Follow-Up Tests & Special Considerations

- Upon examination, any suspicious lesions should be biopsied.
- Diagnosis based on histologic findings following vulvar biopsy (6)
- The vulva can be washed with 3% acetic acid to highlight areas and visualized with a colposcope, allows for visualization of acetowhite lesions and vascular lesions (6).
- For patients with new onset of pruritus, the area of pruritus should be biopsied.
- Liberal biopsies must be used to diagnose in situ disease prior to invasion and to diagnose early invasive disease.
- The patient should not be treated for presumed benign conditions of the vulva without full exam and biopsy, including Pap smear and colposcopy of cervix, vagina, and vulva.
- When symptoms persist, reexamine and rebiopsy.
- Treatment of benign condyloma of the vulva has not been shown to decrease

the eventual incidence of in situ or invasive disease of the vulva.

- CT scan to evaluate pelvic and periaortic lymph node status if tumor >2 cm or if suspicion of metastatic disease (6)[A].

Diagnostic Procedures/Other

Office vulvar biopsy is done to establish the diagnosis.

Test Interpretation

A surgical staging system is used for vulvar cancer (International Federation of Obstetrics and Gynecology Classification).

- Stage I: tumor confined to the vulva
  - Stage IA: lesions ≤2 cm in size, confined to the vulva or perineum and with stromal invasion ≤1 mm, no node metastasis
  - Stage IB: lesions >2 cm in size or with stromal invasion >1 mm, confined to the vulva or perineum, with negative nodes
- Stage II: tumor of any size with extension to adjacent perineal structures (lower 1/3 urethra, lower 1/3 vagina, anus) with negative nodes
- Stage III: tumor of any size with or without extension to adjacent perineal structures (lower 1/3 urethra, lower 1/3 vagina, anus) with positive inguinofemoral lymph nodes
  - Stage IIIA
    - With 1 lymph node metastasis (≥5 mm), or
    - 1 to 2 lymph node metastases (<5 mm)
  - Stage IIIB
    - With ≥2 lymph node metastases (≥5 mm), or
    - ≥3 lymph node metastases (<5 mm)
  - Stage IIIC: with positive nodes with extracapsular spread
- Stage IV: tumor invades other regional (upper 2/3 urethra, upper 2/3 vagina) or distant structures
  - Stage IVA: tumor invades any of the following:
    - Upper urethral and/or vaginal mucosa, bladder mucosa, rectal mucosa, or fixed to pelvic bone
    - Fixed or ulcerated inguinofemoral lymph nodes
  - Stage IVB: any distant metastasis, including pelvic lymph nodes (7)[B]

TREATMENT

GENERAL MEASURES

- Wide excision can be performed for carcinoma in situ, and any suspicious lesion should be excised for definitive diagnosis.
- Cystoscopy and sigmoidoscopy should be performed if there is a question of invasion into the urethra, bladder, or rectum.

MEDICATION

- As an adjuvant therapy, fluorouracil (Efudex) cream for in situ disease can produce occasional results but is not well tolerated because of irritation of the vulva (8)[A].
- Chemoradiotherapy with cisplatin and 5-fluorouracil (5-FU) has been successful in advanced or recurrent disease, although local morbidity is increased (8)[A].
- Contraindications: elderly patients: If chemotherapeutic agents are used, pay close attention to the patient's performance status and ability to tolerate aggressive chemotherapy.

ISSUES FOR REFERRAL

Patients may need care from a gynecologic oncologist and/or a radiation oncologist.

ADDITIONAL THERAPIES

- Preoperative radiation therapy can be used in those with advanced vulvar cancer (6)[B].
- Adjuvant radiation should be considered with tumor size >4 cm, evidence of lymphovascular invasion, positive surgical margins, or lymph node involvement.
- Preoperative chemoradiation allows for a less radical surgical procedure in patients who are not surgical candidates (8)[A].
- Postoperative radiation decreases recurrence frequency and may improve survival (8)[A].
- Radiation is contraindicated with verrucous carcinoma because it induces anaplastic transformation and increases metastases.

SURGERY/OTHER PROCEDURES

- In situ disease can be treated with wide excision or laser vaporization of the affected area. Laser vaporization is preferable in the younger patient, whereas wide excision is preferable in the elderly patient, in whom the risk of invasive disease is also higher (6)[A].
- If tumor extension within <1 cm from structures that will not be removed, preoperative radiation to prevent inadequate surgical margins prior to excision
- Inguinofemoral lymphadenectomy removal of superficial inguinal and deep femoral lymph nodes
- 1 cm tumor-free margin is required because smaller margin would increase risk of recurrence (8)[A].
- Stage IA: radical local excision without lymph node dissection
- Stage IB: radical local excision with either sentinel lymph node biopsy (SLNB) or ipsilateral inguinofemoral lymph node dissection because the risk of metastases is >8%
- Stage II: modified radical vulvectomy and/or chemoradiation and groin node dissection
- Stages III and IV: neoadjuvant chemoradiation and less radical surgery
- Pelvic exenteration after radiation provides effective therapy for advanced or recurrent malignancies involving the bladder or rectum.
- More limited surgery
  - Has been undertaken for early invasive lesions, especially in young patients, to preserve the clitoris and sexual function
  - Sentinel lymph node biopsy (SLNB) also has been advocated for early invasive lesion (stage IB or higher). It has shown to accurately diagnose groin metastases in women with early vulval cancer and unknown groin node status. This will limit the surgical morbidity associated with inguinofemoral lymphadenectomy (IFL) in those with early stage disease (9)[A].
  - Radical vulvectomy with bilateral groin node dissection through separate incisions provides better cosmetic results than en bloc technique.
  - Unilateral lymphadenectomy should be considered when lesion <2 cm, lateral lesion >2 cm from vulvar midline, or no palpable groin nodes (7)[B].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Typically inpatient for treatment
- In advanced malignancy involving the urethra and rectum, concomitant cisplatin/5-FU chemotherapy with radiation produces a significant decrease in size of the primary tumor, usually obviating the need for pelvic exenteration.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Early stage, treated with surgery alone: clinical exam of the groin nodes and vulvar area every 6 months for 2 years; then annually
- Following chemoradiation, assessment for further treatment within 6 to 12 weeks of therapy completion
- Advance stage, clinical exam of the groin nodes and vulvar area every 3 months for 2 years; then every 6 months for 3 years, and then annually (10) [B]
- Cervical and/or vaginal cytology annually
- Majority of relapses occur within 1st year.

DIET

As tolerated and according to comorbid conditions

PATIENT EDUCATION

- American College of Obstetricians and Gynecologists (ACOG), 409 12th St. SW, Washington, DC 20024-2188; (800) 762-ACOG; http://www.acog.org/
- American Cancer Society: http://www.cancer.org/

PROGNOSIS

The 5-year survival is based on stage:

- Stage I: 78.5%
- Stage II: 58.8%
- Stage III: 43.2%
- Stage IV: 13.0%

- Inguinal and/or femoral node involvement is the most important determinant of survival (11)[A].

COMPLICATIONS

- The major complications from radical vulvectomy and groin node dissection are wound breakdown, lymphedema, urinary stress incontinence, and psychosexual consequences.
- Two common complications with radical vulvectomy and bilateral groin node dissection
  - In the immediate postoperative period, ~50% of patients experience breakdown of the wound. This requires aggressive wound care by visiting nurses as often as twice a day. The wounds usually granulate and heal over a period of 6 to 10 weeks.
  - ~15–20% of patients experience some form of mild to moderate lymphedema after the groin node dissection. These patients should be instructed in the use of leg elevation and support hose. <1% of patients experience severe, debilitating lymphedema.

CODES

ICD10

- C51.9 Malignant neoplasm of vulva, unspecified
- D07.1 Carcinoma in situ of vulva
- C51.0 Malignant neoplasm of labium majus

CLINICAL PEARLS

- 60% of vulvar cancers are attributable to oncogenic HPV, and 92% of all VIN 2/3, VAIN 2/3, and AIN are attributable to HPV. Therefore, HPV vaccination has the potential to decrease vulvar cancer by 1/3.
- Biopsy all suspicious or nonhealing vulvar lesions.

VULVODYNIA

Jessica Johnson, MD, MPH • Amy L. Wiser, MD

BASICS

DESCRIPTION

- Vulvar pain lasting 3 months or more. Occurs in the absence of relevant visible findings, relevant lab abnormalities, or a clinically identifiable neurologic disorder
- Classification by ISSVD is based on whether pain is generalized or localized and whether it is provoked (by physical contact), spontaneous, or mixed.
  - Generalized: involvement of majority of the vulva; usually persistent or spontaneous pain
  - Localized: severe pain of certain vulvar areas such as the vestibule (formerly known as *vestibulodynia*), usually provoked with touch or attempted vaginal entry; thought to be the leading cause of painful intercourse among premenopausal women
    - Primary: introital dyspareunia from first episode of intercourse or first insertion of tampon or vaginal speculum
    - Secondary: introital dyspareunia developing after a period of painless intercourse, tampon use, or speculum exams

EPIDEMIOLOGY

- Most women diagnosed between age 20 and 80 years
- Nearly half of woman opt not to seek treatment (1).
- Patients are psychologically comparable with asymptomatic controls and have similar marital satisfaction.

Incidence

- Recent retrospective study estimates annual rate of new onset vulvodynia to be 1.8% (2).
- Evidence indicates lifetime cumulative incidence approaches 15%, suggesting nearly 14 million U.S. women will experience persistent vulvar discomfort at some point in their lives (3).

Prevalence

- Reports between 8.3% and 16%; non–clinical-based studies approximate a prevalence of 7% with validation by exam (1).
- Studies show Hispanics are 80% more likely to present with vulvar pain compared with Caucasians and African Americans.

ETIOLOGY AND PATHOPHYSIOLOGY

- Vulvodynia is likely to be neuropathically mediated:
  - Allodynia and hyperalgesia are thought to result from neurogenic inflammation, leading to sensitization of primary afferents by inflammatory peptides, prostaglandins, and cytokines. Impulses transmitted to the CNS, where reinforcing signals sustain pain loop
  - In recent investigations of vulvar biopsy specimens, increased neuronal proliferation and branching in vulvar tissue are evident when compared with tissue of asymptomatic women.
- Pelvic floor pathology also should be considered: In one study, the vulvodynia group showed an increase in pelvic floor hypertonicity at the superficial muscle layer, less vaginal muscle strength with contraction, and decreased relaxation of pelvic floor muscles after contraction (3).
- No cause of vulvodynia has been established. It is most likely a neuropathic pain caused by a combination of the following:
  - Recurrent vulvovaginal candidiasis or other infections
  - Immune-mediated chronic neuro-inflammatory process within vulvar tissues
  - Chemical exposure (trichloroacetic acid) or physical trauma
  - Reduced estrogen receptor expression/changes in estrogen concentration
  - CNS etiology, similar to other regional pain syndromes

RISK FACTORS

- Vulvovaginal infections, specifically candidiasis. Unclear if infection, treatment, or underlying hypersensitivity is the cause (1). Multiple infections compound this risk.
- Hormonal factors: Controversial evidence proposes increased risk with use of oral contraception pills (OCPs); early age at first use of OCPs and longer duration of use has been associated with increased risk.

- Pelvic floor dysfunction: Increased instability of pelvic floor muscles may perpetuate vulvar tissue inflammation, leading to vascular changes and histamine release.
- Comorbid interstitial cystitis and painful bladder syndrome; potentially related to common embryologic origin of structures
- Abuse: increased risk of vulvodynia if childhood had physical or sexual abuse by a primary family member; causal relationship remains unclear (3).
- Depression and anxiety (1)
- Other neuropathic disorders, including regional pain syndrome

Genetics

Proposed genetic deficiency impairing one's ability to stop the inflammatory response triggered by infection or chemicals; homozygosity of the two alleles of the IL-1 receptor antagonist occurs in 25–50% of vestibulodynia patients, compared with <10% in controls (4).

GENERAL PREVENTION

- Wear 100% cotton underwear in the daytime and no underwear to sleep.
- Avoid douching and other vulvar irritants such as perfumes, dyes, and detergents.
- Avoid abrasive activities and tight, synthetic clothing.
- Avoid panty liners.
- Clean the vulva with water only and pat area dry after bathing.
- Avoid use of hair dryers in the vulvar area.

COMMONLY ASSOCIATED CONDITIONS

Higher incidence of chronic pain syndromes associated with vulvodynia, including chronic cystitis, irritable bowel syndrome, fibromyalgia, migraines, depression, endometriosis, low back pain. Women with vulvodynia have a higher incidence of depression and anxiety both preceding and resulting from their symptoms (1).

DIAGNOSIS

- Vulvodynia is a clinical diagnosis and it should be suspected in any women

with chronic pain at the introitus and vulva (4)[B].

- Pain should be characterized using a standard measure such as the McGill Pain Questionnaire; duration and nature of the pain should be established. Use physical exam to rule out other causes of vulvovaginal pain. Negative fungal culture, along with relevant history and positive cotton swab test, confirm diagnosis.

HISTORY

Adequate sexual, social, and pain history should be taken to assess degree of symptoms. Visual pain scales and pain diaries may be helpful (5)[B]:

- Onset of vulvodynia often sudden and without precedents
- Pain often described as generalized, unprovoked.
- Quality of pain is burning, stinging, irritating, or rawness (1).
- Specifically ask about bowel and bladder habits, history of trauma or abuse, history of infections including herpes, and personal hygiene.
- Specific skin complaints may suggest alternate diagnosis; a history of allergies may suggest vulvar dermatitis.
- Assess for precipitants of vulvar pain: tight garments, bicycle riding, tampon use, prolonged sitting, perfumed or deodorant soaps, douching (1)
- Assess for complaints of dyspareunia:
  - Presence of vaginismus (involuntary vaginal muscle spasm), adequate lubrication, anorgasmia, partner problems, abuse
  - Psychosexual morbidity significantly higher in patients with vulvodynia; counseling may complement medical interventions.

PHYSICAL EXAM

- Ask patient to show where pain is localized or most painful.
- Mouth and skin exams to assess for lesions suggestive of lichen planus or lichen sclerosus
- Vaginal exam should be done to exclude other causes of vulvovaginal pain, including external inspection; palpation; and single digit, speculum, and bimanual exams:
  - The vulva may be erythematous, especially at the vestibule. Discomfort with separation of the labia minora is common.
  - Spontaneous or elicited pain at the lower 1/2 of anterior vaginal wall

suggests bladder etiology.

- Bulbocavernosus and anal wink reflexes should be checked to assess for peripheral neuropathy.

DIFFERENTIAL DIAGNOSIS

- Infections: candidiasis, herpes, human papillomavirus (HPV), bacterial vaginosis, trichomoniasis, dermatophytes
- Inflammation: lichen planus, immunobullous disorder, allergic vulvitis, lichen sclerosus, atrophic vaginitis
- Neoplasia: Paget disease, vulvar or vaginal intraepithelial neoplasia, squamous cell carcinoma
- Neurologic/muscular: herpes neuralgia, spinal nerve compression, vaginismus

DIAGNOSTIC TESTS & INTERPRETATION

- Cotton swab or Q-tip test: Vulva tested for localized areas of pain beginning at thighs and continuing medially toward vestibule using the soft end and broken sharp end of the cotton swab. Five distinct positions (2, 4, 6, 8, and 10 o'clock) surveyed using light palpation. Pain rated on a scale from 0 (none) to 10 (most severe). Posterior introitus and posterior hymenal remnants most common sites of increased sensitivity.
- Test for concurrent vaginismus: Apply pressure with a gloved finger to levator ani and obturator internus muscles to assess for tenderness, pain, or contracture.

Initial Tests (lab, imaging)

- Vaginal pH, wet mount, and yeast culture are recommended to rule out vaginitis.
- Gonorrhea and chlamydia testing done at physician's discretion
- HPV screening is unnecessary; no association has been identified between HPV and vulvodynia.

Follow-Up Tests & Special Considerations

- Varicella-zoster and herpes simplex virus should be considered if ulcers or vesicular eruptions are present.
- Consider biopsy if concerned for neoplasm or dermatophyte infection or if the patient is resistant to treatment.

Diagnostic Procedures/Other

Colposcopy can be helpful if epidermal abnormalities are present. This should be done with caution because acetic acid worsens vulvar pain.

Test Interpretation

No specific histologic features are associated with vulvodynia, although reactive squamous atypia has been observed. Biopsies are unnecessary for diagnosis. Presence of rash/altered mucosa is not consistent with vulvodynia; this requires further evaluation (5)[C].

TREATMENT

A trial of several medications for at least 3 months is usually needed.

GENERAL MEASURES

Combining treatments should be encouraged when treating women with vulvodynia (5)[C]: Various reports on use of a combination of medical treatments, psychotherapy, and dietary intervention reveal women on these combinations do significantly better compared with those who receive medication only.

MEDICATION

- Oral therapies
  - Tricyclic antidepressants (TCAs): first-line treatment for unprovoked vulvodynia (5)[B]; do not stop use abruptly; contraindicated in patients with cardiac abnormalities and those taking MAOIs; fatigue, constipation, sweating, palpitations, and weight gain are most common side effects
    - Amitriptyline, nortriptyline: most widely studied; start at 10 mg daily; dose should be titrated to pain control. Average effective dose is 60 mg daily. In one study, a 47% complete response rate was recorded (6)[B]. Nortriptyline may be preferred due to less anticholinergic adverse effects.
  - Anticonvulsant therapies:
    - Gabapentin: Started at 300 mg daily at HS and increased by 300 mg every 3 days. Maximum recommended dose is 3,600 mg daily divided into 3 doses. Dosing regimen limits popularity.

    - Topiramate and lamotrigine have been recommended if other therapies are not effective.
  - SSNRIs: not commonly used; however, have been helpful in those who cannot tolerate TCAs
    - Venlafaxine or duloxetine have also been used; evidence is limited.
  - Opioids/NSAIDs: not consistently helpful in relieving vulvar pain
- Topical therapies
  - A trial of local anesthetics may be recommended for all patients who present with vulvodynia. Use judiciously to avoid increased irritation (5) [C].
  - Lidocaine 5% ointment: for provoked vestibulodynia; application advised 15 to 20 minutes prior to intercourse. Penile numbness and possible toxicity with ingestion can occur.
    - In one study, lidocaine 5% ointment was left in vestibule overnight (average of 8 hours) for a period of 6 to 8 weeks; at follow-up, up to 76% of women reported no discomfort with intercourse (3)[C].
  - Cromolyn 4% cream: decreases mast cell degranulation in vulvar tissue; recommended application TID (1)[C]
  - Capsaicin 0.025%: decreases in discomfort and increases in frequency of intercourse with 20-minute daily application (3)[B]
  - Topical amitriptyline 2% combined with baclofen 2% is helpful in patients with comorbid vaginismus.
  - Topical corticosteroids and testosterone creams have not been shown to alleviate symptoms of vulvodynia.
  - Gabapentin 3–6% ointment (must be compounded)
  - Topical nitroglycerin may be helpful but may cause headaches.
  - Topical estrogen
- Injectable therapies
  - Triamcinolone acetonide: no more than 40 mg should be injected monthly; is best when combined with 0.25–0.5% bupivacaine
  - Submucosal methylprednisone and lidocaine: reports of up to 68% response rate with weekly injections (5)[B]
  - Interferon-α: useful in treatment of vestibulodynia. Side effects (myalgias, fever, malaise) limit its use.

– Botulinum toxin A injectable is being studied.

ISSUES FOR REFERRAL

A team approach is recommended for most effective management. Triage to psychosexual medicine, psychology, partner therapy, and pain management teams should be strongly considered (5)[B].

ADDITIONAL THERAPIES

- Cognitive-behavioral therapy (CBT): One randomized trial revealed that CBT is associated with a 30% decrease in vulvar discomfort with sexual intercourse. CBT is the recommended treatment for patients who present with dyspareunia as a main complaint (4)[B].
- Biofeedback/physical therapy: useful with concomitant vaginismus. Treats both generalized and localized vulvar pain; treatment value for unprovoked pain remains unclear. Most studies report an average of 12- to 16-week treatment time.
- Vaginal dilators
- Surface electromyography (sEMG): efficacious for pelvic floor rehabilitation. Patients are more likely to experience pain-free sexual intercourse after sEMG. Significant reductions seen on pain measures at long-term follow-up.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Acupuncture: Small studies of women with unprovoked vulvodynia who did not respond to conventional treatment reported significant decreases in pain severity with acupuncture; treatment value with provoked pain is unknown (5)[C].

SURGERY/OTHER PROCEDURES

- Surgery may be considered for patients with localized symptoms who have failed to respond to other measures. Not recommended for generalized vulvodynia (5)[B]
- 60–80% of women who undergo surgery report a significant reduction in pain symptoms; however, when surveyed, patients prefer behavioral therapies than surgical intervention.
- All patients who are considering surgical intervention should be tested and treated for vaginismus. Vestibulectomy is less successful in this subgroup.
- Surgical approaches

- Local excision: precise localization of painful areas; tissue closed in elliptical fashion
- Total vestibulectomy: Tissue is removed from Skene ducts to perineum. The vagina is then brought down to cover defect.
- Perineoplasty: vestibulectomy plus removal of perineal tissue; incision usually terminated above the anal orifice; reserved for severe cases (4)[B]

ONGOING CARE

PATIENT EDUCATION

Patients should be reassured that this condition is neither infectious, nor does it predispose to cancer (5)[C]. Emphasize self-hygiene. Encourage treatment with home remedies, including ice packs, sitz baths with baking soda, olive oil, and barrier cream to preserve moisture after bathing.

PROGNOSIS

Traditionally viewed as a chronic pain disorder, new evidence of remission has been documented; recent 2-year follow-up study revealed 1 in 10 vulvodynia patients reported remission regardless of treatment (7).

CODES

ICD10

- N94.819 Vulvodynia, unspecified
- N94.818 Other vulvodynia
- N94.810 Vulvar vestibulitis

CLINICAL PEARLS

- Vulvodynia is a clinical diagnosis; it should be suspected in any woman with chronic pain at the introitus and vulva.
- A decrease in pain may take weeks to months and may not be complete.
- No single treatment is proven in all women; improvement over time is common even without treatment.

VULVOVAGINITIS, ESTROGEN DEFICIENT

Maria De La Luz Nieto, MD

BASICS

DESCRIPTION

- Vaginal atrophy is due to decreased blood flow to vaginal epithelium, resulting in thinning of the female genital tissues.
- Estrogen deficiency affects all tissues in the female body; however, the genital tissues are especially hormone-responsive and are most affected, leading to atrophy.
- Patients with estrogen-deficient vulvovaginitis may present with urinary incontinence, vaginal burning and itching, dyspareunia, increased urinary frequency, or recurrent UTIs.
- System(s) affected: reproductive

EPIDEMIOLOGY

Incidence

- Predominant age: postmenopausal females. The average age of menopause in the United States is 51.3 years but ranges from 45 to 55 years old.
- May affect lactating women
- Predominant sex: female only
- May occur in younger women with premature ovarian failure

Prevalence

- Most postmenopausal women are affected to some degree.
- Up to 40% of postmenopausal women experience symptoms severe enough to seek treatment.

ETIOLOGY AND PATHOPHYSIOLOGY

- Decreased estrogen levels in the vagina and vulva result in decreased blood flow and decreased lubrication of vaginal and vulvar tissue.
- Vaginal and vulvar tissues become thin secondary to decreased vaginal cell maturation.

- Decreased cellular maturation results in decreased glycogen stores, which affects the normal vaginal flora and pH.
- Estrogen deficiency due to the following:
  - Menopause (surgical or natural)
  - Premature ovarian failure (chemotherapy, irradiation, autoimmune, anorexia, genetic)
  - Postpartum, lactation
  - Medications that alter hormonal concentration, such as gonadotropin-releasing hormone agonists, and antiestrogens, such as tamoxifen and danazol
  - Elevated prolactin from hypothalamic–pituitary disorders

Genetics

No known pattern

RISK FACTORS

Estrogen-deficient states

COMMONLY ASSOCIATED CONDITIONS

- Urge and stress urinary incontinence
- Pelvic organ prolapse
- Frequent UTIs
- Bacterial vaginosis or yeast infections

DIAGNOSIS

HISTORY

- All female patients should be asked about symptoms because many women are embarrassed to discuss these issues with their health care providers (1)[C].
  - Vaginal dryness
  - Dyspareunia
  - Pruritus
  - Burning
  - Pressure
  - Tenderness

  - Malodorous discharge
  - Urinary symptoms: dysuria, hematuria, frequency, infections, stress, and urge urinary incontinence
- Ask about self-treatment and products used.
- Determine exposure to irritants (e.g., soaps, feminine sprays, lotions, lubricants, constant pad use).

PHYSICAL EXAM

Evidence for the diagnosis includes the following:

- Loss of pubic hair
- Decreased vulvar and vaginal fullness
- Decreased vulvar subcuticular fat and moisture
- Pale-appearing, shiny, smooth vaginal and urethral epithelium
- Vaginal shortening, intolerance to speculum exams
- Loss of vaginal rugation
- Pelvic organ prolapse
- Shorten urethra

DIFFERENTIAL DIAGNOSIS

- Malignancy
- Dermatologic conditions of vulva and vagina:
  - Dermatitis
  - Lichen sclerosis
  - Lichen planus
- Bacterial or yeast vulvovaginitis

DIAGNOSTIC TESTS & INTERPRETATION

Because vulvovaginitis is a clinical diagnosis, labs are not always necessary, but if suspect dermatologic or oncologic condition, biopsy is recommended (2)[A].

Initial Tests (lab, imaging)

However, the following labs may be obtained as corroborative of clinical impression:

- Check follicle-stimulating hormone (FSH) and estrogen levels. FSH rises and estrogen drops with menopause.
- Evaluate for infections via wet preparation and vaginal pH (usually >5).

- Urine dip and urinalysis if suspected concomitant UTI
- Perform cytology for maturation index: Higher proportion of parabasal cells and lower proportion of intermediate and superficial cells indicate decreased maturation index.

Follow-Up Tests & Special Considerations

Drugs that may alter lab results:

- Estrogen therapy will alter the maturation index.
- Digoxin has estrogen-like properties.
- Tamoxifen may produce menopausal-type symptoms but also may act on genital tissues as a weak estrogen agonist.
- Progestins, danazol, and gonadotropin-releasing hormone agonists may produce a reversible pseudomenopause state.

Test Interpretation

- Thinning of the cornified squamous layer of both the vulva and the vagina
- Increased parabasal cells
- Compact underlying collagenous tissue

TREATMENT

GENERAL MEASURES

- Wear loose-fitting, undyed cotton underwear.
- Avoid prolonged pad use, especially scented pads.
- Avoid feminine deodorant sprays and douching.
- Use over-the-counter water-based lubricants, as needed.
- Symptomatic relief, if needed (e.g., cool baths or compresses)

MEDICATION

- Vaginal estrogen can reverse atrophic changes and help to alleviate symptoms (3)[A].
  - Vaginal cream 1 g (conjugated equine estrogens or estradiol cream): Insert via applicator each night for 14 days and then 2 to 3 times per week.
  - Vaginal estradiol 10-μg tablet: Insert via preloaded applicator each night for 14 days and then 2 to 3 times per week.

  - Estradiol-containing vaginal ring 2 mg: Insert into vagina, and replace every 3 months.
- Estrogen therapy should be used in the lowest possible dose for the shortest duration of time (4)[B].
- Long-term therapy may be necessary owing to the chronic nature of estrogen-deficient vulvovaginitis (5)[A].
- Systemic therapy typically is used as hormonal treatment of vasomotor symptoms and not for the primary treatment of estrogen-deficient vulvovaginitis.
- Contraindications
  - Breast or estrogen-dependent carcinoma
  - Undiagnosed vaginal bleeding
  - Thromboembolic disorders
  - Thrombophlebitis
  - Pregnancy
- Precautions: Any abnormal vaginal bleeding must be evaluated.
- Nonestrogen therapy: estrogen agonist/antagonist (6)[B]
  - Ospemifene (Osphena) 60-mg tablet daily
- Contraindications
  - Breast or estrogen-dependent carcinoma
  - Undiagnosed vaginal bleeding
  - Thromboembolic disorders
  - Thrombophlebitis
  - Hepatic impairment
- Precautions: Any abnormal vaginal bleeding must be evaluated, monitor for DVT and stroke.

ISSUES FOR REFERRAL

- Refer to urogynecologist for evaluation if symptomatic due to pelvic organ prolapse and/or stress and urge urinary incontinence.
- Recurrent UTIs should be referred to urogynecology and/or urology for evaluation.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Outpatient treatment

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

No restrictions

Patient Monitoring

Instruct the patient that symptoms should improve within 30 to 60 days. If they do not, reevaluate and reexamine for other causes.

DIET

No special diet

PATIENT EDUCATION

- American College of Obstetricians and Gynecologists (ACOG), 409 12th St., SW, Washington, DC 20024-2188; 800-762-ACOG: http://www.acog.org/
- Lactating postpartum women with high levels of prolactin are in a hypoestrogenic state. These women should be instructed to use lubrication for symptoms of dyspareunia and reassured that the symptoms will resolve when they are no longer breastfeeding.

PROGNOSIS

The prognosis is excellent. Most symptoms will be alleviated with vaginal estrogen replacement therapy.

COMPLICATIONS

- Recurrent UTIs may occur in women with vaginal atrophy.
- Vaginal atrophy predisposes patients to vaginal infections.

CODES

ICD10

- N95.2 Postmenopausal atrophic vaginitis
- E28.39 Other primary ovarian failure

CLINICAL PEARLS

- Estrogen-deficient vulvovaginitis affects virtually all postmenopausal women to some degree.
- This disorder is often associated with urinary incontinence, increased urinary frequency, and recurrent UTIs.
- Lab tests are generally unnecessary to make the diagnosis.
- Vaginal estrogen preparations, rather than systemic preparations, should be the first-line therapy in a woman whose primary complaint is associated with vaginal atrophy.

VULVOVAGINITIS, PREPUBESCENT

Sarah Parrott, DO

BASICS

DESCRIPTION

- Vulvitis is inflammation of the external genitals.
- Vaginitis, often associated with vaginal discharge, is inflammation involving the vaginal mucosa.
- In premenarchal girls, vulvitis is usually primary with secondary extension into the vagina.
- System(s) affected: reproductive, skin/exocrine
- Synonym(s): vaginitis; vulvitis

EPIDEMIOLOGY

Incidence

Unknown

Prevalence

Most common gynecologic problem in prepubertal girls

ETIOLOGY AND PATHOPHYSIOLOGY

- In the prepubertal child, the levels of estrogen are low.
- Due to the low levels of estrogen, the vaginal epithelium is thin, immature, and fragile.
- Absence of pubic hair and a well-developed labia as well as close proximity of the anus and vagina, make contamination more likely.
- The prepubertal child also has an absence of lactobacilli, creating a neutral to alkaline vaginal pH.
- Neutral pH, atrophic mucosa, and moist environment of the vagina increase the risk of infection.
- Most cases of pediatric vulvovaginitis are nonspecific inflammation.
- Specific infections that occur are typically respiratory, enteric, or sexually transmitted.

- Nonspecific vulvovaginitis
- Poor perineal hygiene
- Nonspecific chemical irritants (bubble baths, scented soaps, shampoos)
- Tight-fitting clothing
- Etiology
  - Bacterial: The most common bacteria are introduced from respiratory and GI tracts.
    - The most common respiratory pathogen is *Streptococcus pyogene*s (1) [B]. Vulvitis may occur in the absence of respiratory symptoms.
    - Urinary tract infections are common in children with vulvovaginitis (2) [B].
    - *Escherichia coli* is the most common fecal pathogen.
    - *Shigella* vaginitis is associated with mucopurulent bloody discharge and likewise, is not always accompanied by a history of diarrhea.
- *Enterobius vermicularis* (pinworms)
  - Very common in young children and certain populations
  - Should be considered in children with vaginal itching and irritation
  - Most common symptom is nocturnal perineal itching.
  - Foreign body
    - Presents with foul-smelling, bloody, or brown discharge from the vagina
    - Should be considered with recurrent vulvovaginitis where other causes have been eliminated
  - Other
    - With chronic vulvovaginitis, anatomic abnormalities or systemic disease should be considered:
      - Anatomic abnormalities include double vagina with fistula, ectopic ureter, and urethral prolapse.
  - Systemic disease (inflammatory diseases)
  - Other conditions, such as lichen sclerosus, vitiligo, psoriasis, and atopic dermatitis, should be considered.

Genetics

Understudied

RISK FACTORS

- Prepubertal girls are particularly susceptible due to behavioral and anatomic reasons:
  - Inadequate hand washing or perineal cleansing after urination and defecation
  - Tight-fitting clothing
  - Proximity of the vagina to the anus, lack of protective hair, and labial fat pads
  - Trauma
- Obese girls are also susceptible to nonspecific vulvovaginitis (3)[A].

GENERAL PREVENTION

- Good perineal hygiene (including wiping from front to back)
- Urination with legs spread apart and labia separated
- Avoidance of tight-fitting clothing and nonabsorbent underwear
- Avoidance of irritants such as harsh/perfumed soaps and bubble baths

ALERT

Cultures of sexually transmitted organisms in prepubertal children warrant investigations of sexual abuse.

DIAGNOSIS

HISTORY

- Irritation and erythema of vulva
- Itching
- Bleeding
- Vaginal discharge
- Unpleasant odor
- Dysuria
- Soreness

PHYSICAL EXAM

- Look for evidence of chronic illness or dermatologic disease.
- Look for trauma or other signs that may correlate with abuse.
- Inspect the genital area in the supine position:

- Excoriation of the genital area
- Inflammation (erythema, swelling) of the introitus
- Inspect the vagina and cervix in the knee–chest position or frog leg position.
- Perform rectal exam if vaginal bleeding or abdominal pain.

DIFFERENTIAL DIAGNOSIS

- Contact dermatitis
- Eczema
- Psoriasis
- Lichen sclerosus

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Culture for bacteria, fungi (yeast), or viruses (herpes)
- Urinalysis, urine culture, and urine for STI (via nucleic acid amplification test)
- Tape exam for pinworms
- Potassium hydroxide and saline smears of vaginal discharge, if present
- If an anatomic abnormality is suspected, imaging may be necessary to confirm.
- Consider consultation with a pediatric or adult gynecologist to determine the most appropriate imaging study.

Follow-Up Tests & Special Considerations

Exploration of the vagina for a foreign body may be necessary in cases of persistent, recurrent vulvitis.

Diagnostic Procedures/Other

If blood or foul-smelling discharge is present, visualization is mandatory:

- Place the child in the knee–chest position for best results. Hold the buttocks apart and slightly upward.
- Visualization of the vagina may be necessary by using a nasal speculum or infant laryngoscope.
- If available, consider referral to a provider with specific training/experience in this specialized exam.

TREATMENT

- The definitive diagnosis of bacterial vulvitis requires a culture of vulva and vaginal secretions.
- The typical colony count and bacterial mix are unknown in prepubescent girls. Antibiotic use should be directed against the species with the highest colony count.
- General hygiene should always be recommended, particularly in cases of a retained foreign body (e.g., toilet paper).
- When no cause is identified, treatment should focus on hygiene as well as minimizing soap exposure and tight-fitting clothes (1).

GENERAL MEASURES

- Appropriate health care: outpatient (except where systemic illness requires hospital care)
- Soak the vulva/perineum in a small amount of clear, warm water for 15 minutes BID.
- If smegma is present in the labial folds, clean the area gently with a mild soap.

MEDICATION

First Line

- To break the itching–scratching–infection cycle, use a low-dose topical hydrocortisone cream for a limited time.
- Estrogen deficiency with labial adhesion/agglutination: estrogen cream 0.625 mg to fused area nightly for 2 weeks
- Emollients or protective creams may offer symptomatic relief.
- Antibiotic use should be restricted to cases of bacterial infection only (4)[A].
- Specific organisms on culture
  - Group A *Streptococcus*, *S. pneumoniae*: penicillin V (Pen Vee K) 250 mg PO BID–TID for 10 days
  - *Haemophilus influenzae*: amoxicillin, 20 to 40 mg/kg/day PO divided TID for 7 days
  - *Staphylococcus aureus*: cephalexin, 25 to 50 mg/kg/day PO divided QID for 7 to 10 days *or* dicloxacillin, 25 mg/kg/day divided QID for 7 to 10 days *or* amoxicillin-clavulanate, 20 to 40 mg/kg/day PO divided BID for 7 to 10

days
  - *S. pyogenes*: amoxicillin, 50 mg/kg/day PO divided into 3 doses/day for 10 days
  - *Candida* sp.: topical nystatin (Mycostatin), miconazole, clotrimazole, or terconazole
  - *Shigella*: trimethoprim/sulfamethoxazole or ampicillin for 5 days
  - Pinworms: mebendazole, 100 mg PO, repeated in 2 weeks
  - *Chlamydia trachomatis*: ≤45 kg: erythromycin, 50 mg/kg/day QID for 14 days; ≥45 kg and <8 years old: azithromycin, 1 g PO single dose; ≥45 kg and ≥8 years old: azithromycin, 1 g PO single dose or doxycycline 100 mg BID for 7 days
  - *Neisseria gonorrhoeae*: ≤45 kg: ceftriaxone, 125 mg IM plus medication for chlamydia; >45 kg: ceftriaxone, 250 mg IM × 1 plus medication for chlamydia
  - *Trichomonas*: metronidazole, 15 mg/kg/day PO divided TID (max 250 mg TID) for 7 days
- Contraindications: allergy to proposed treatment
- Precautions: Avoid potential allergens and topical sensitizers if possible.

ISSUES FOR REFERRAL

- Suspected sexual abuse
- Suspected anatomic abnormality (except minor labial agglutination)
- Persistent, severe, or recurrent infections

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Monitor for fever, pruritus, and vaginal discharge.

DIET

- Healthy balanced diet, high in fiber to prevent constipation
- Adequate fluid intake

PATIENT EDUCATION

Hygiene

- Wipe front to back after elimination.
- Avoid bubble baths and other irritating products.
- Clean daily with mild soap and water and dry gently with soft towel or cool hair dryer.
- Apply bland ointments for skin protection, if necessary.

PROGNOSIS

Excellent

COMPLICATIONS

- If an STI is identified and not treated effectively, the patient is at risk for pelvic inflammatory disease (PID).
- Vaginismus

girl: effect of topical oestrogen. *Acta Derm Venereol*. 2009;89(2):198–199.

CODES

ICD10

- N76.0 Acute vaginitis
- N77.1 Vaginitis, vulvitis and vulvovaginitis in dis classd elswhr

CLINICAL PEARLS

- Vulvovaginitis is the most common gynecologic problem in prepubescent girls.
- The hypoestrogenic state and prepubescent anatomy may increase susceptibility to vulvar and vaginal infection.
- Treatment is typically supportive (avoid scratching, warm soaks) but may require antibiotics if a bacterial infection is suspected.
- Isolating an infection with known sexual transmission should prompt further investigation.
- Recurrent or persistent vulvitis, especially with foul-smelling discharge, should prompt a skilled exam of the vagina for a retained foreign body.
- Good perineal hygiene will limit this condition.

WARTS

Mercedes E. Gonzalez, MD, FAAD • Herbert P. Goodheart, MD

BASICS

- Warts (verrucae) are benign growths that are confined to the epidermis. All warts are caused by the human papillomavirus (HPV). Warts can appear on any area of the skin or mucous membranes. Common warts are predominantly seen in children and young adults.
- Clinically, warts are rather arbitrarily described as the following:
  - Common warts (verrucae vulgaris)
  - Plantar warts (verrucae plantaris)
  - Flat warts (verrucae plana)
  - Venereal warts (condyloma acuminatum)
  - Epidermodysplasia verruciformis is a rare, lifelong hereditary disorder characterized by chronic infection with HPV.
- System(s) affected: skin/exocrine

DESCRIPTION

- Common warts are most often found at sites subject to frequent trauma, such as the hands and feet. Because warts often vary widely in shape, size, and appearance, the various descriptive names for them generally reflect their clinical appearance, location, or both.
- For example, filiform (fingerlike) warts are threadlike, planar warts are flat, and plantar warts are located on the plantar surfaces (soles) of the feet.
- Genital warts, or condyloma acuminata, may be large and cauliflower-like, or they may consist of small papules.
- Warts on mucous membranes (mucosal papillomas), such as those in the mouth or vagina, tend to be white in color due to moisture retention.

EPIDEMIOLOGY

Incidence

- Predominant age: young adults and children

- Predominant sex: female = male

Prevalence

- ~7–10% of the U.S. population
- Common warts appear 2 times as frequently in whites as in blacks or Asians.

ETIOLOGY AND PATHOPHYSIOLOGY

- HPV is a double-stranded, circular, supercoiled DNA virus.
- The virus infects epidermal keratinocytes, stimulating cell proliferation.
- Various strains of DNA HPV: To date, >150 different subtypes have been identified.
- Common warts: HPV types 2 and 4 (most common), followed by types 1, 3, 27, 29, and 57
- Palmoplantar warts: HPV type 1 (most common), followed by types 2, 3, 4, 27, 29, and 57
- Flat warts: HPV types 3, 10, and 28
- Butcher warts: HPV type 7
- The virus is passed primarily through skin-to-skin contact or from the recently shed virus kept intact in a moist, warm environment.

RISK FACTORS

- HIV/AIDS and other immunosuppressive diseases (e.g., lymphomas)
- Immunosuppressive drugs that decrease cell-mediated immunity (e.g., prednisone, cyclosporine, and chemotherapeutic agents)
- Pregnancy
- Handling raw meat, fish, or other types of animal matter in one’s occupation (e.g., butchers)
- Previous wart infection

GENERAL PREVENTION

There is no known way to prevent warts.

DIAGNOSIS

- Most often made on clinical appearance
- Skin biopsy, if necessary

PHYSICAL EXAM

- Distribution of warts is generally asymmetric, and lesions are often clustered or may appear in a linear configuration due to scratching (autoinoculation).
- Common wart: rough-surfaced, hyperkeratotic, papillomatous, raised, skin-colored to tan papules, 5 to 10 mm in diameter; several may coalesce into a larger cluster (mosaic wart); most frequently seen on hands, knees, and elbows; usually asymptomatic but may cause cosmetic disfigurement or tenderness
- Filiform warts: These are long, slender, delicate, fingerlike growths, usually seen on the face around the lips, eyelids, or nares.
- Plantar warts often have a rough surface and appear on the plantar surface of the feet in children and young adults.
  - Can be tender and painful; extensive involvement on the sole of the foot may impair ambulation, particularly when present on a weight-bearing surface.
  - Most often seen on the metatarsal area, heels, and toes in an asymmetric distribution (pressure points)
  - Pathognomonic “black dots” (thrombosed dermal capillaries); punctate bleeding becomes more evident after paring with a no. 15 blade.
  - Both common and plantar warts generally demonstrate the following clinical findings:
    - A loss of normal skin markings (dermatoglyphics) such as finger, foot, and hand prints
    - Lesions may be solitary or multiple, or they may appear in clusters (mosaic warts).
- Flat warts: slightly elevated, flat-topped, skin-colored or tan papules, small (1 to 3 mm) in diameter
  - Commonly found on the face, arms, dorsa of hands, shins (women)
  - Sometimes exhibit a linear configuration caused by autoinoculation
  - In men, shaving spreads flat warts.
  - In women, they often occur on the shins, where leg shaving spreads lesions.
- Epidermodysplasia verruciformis (rare): Widespread flat, reddish brown pigmented papules and plaques that present in childhood with lifelong persistence on the trunk, hands, upper and lower extremities, and face are

characteristics.

DIFFERENTIAL DIAGNOSIS

- Molluscum contagiosum
- Seborrheic keratosis
- Epidermal nevus
- Acrochordon (skin tag)
- Solar keratosis and cutaneous horn
- Acquired digital fibrokeratoma
- Squamous cell carcinoma (SCC)
- Keratoacanthoma
- Subungual SCC can easily be misdiagnosed as a subungual wart or onychomycosis.
- Corns/calluses
  - Corns (clavi) are sometimes difficult to distinguish from plantar warts. Like calluses, corns are thickened areas of the skin and most commonly develop at sites subjected to repeated friction and pressure, such as the tops and the tips of toes and along the sides of the feet.
    - Corns are usually hard and circular, with a polished or central translucent core, like the kernel of corn from which they take their name.
    - Corns do not have “black dots,” and skin markings are retained except for the area of the central core.

ALERT

- A melanoma on the plantar surface of the foot can mimic a plantar wart.
- Verrucous carcinoma, a slow-growing, locally invasive, well-differentiated SCC, also may be easily mistaken for a common or plantar wart.

DIAGNOSTIC TESTS & INTERPRETATION

Diagnosis

- HPV cannot be cultured and lab testing is rarely necessary.
- Definitive HPV diagnosis can be achieved by the following:
  - Electron microscopy
  - Viral DNA identification employing Southern blot hybridization is used to identify the specific HPV type present in tissue.

- Polymerase chain reaction may be used to amplify viral DNA for testing.

Follow-Up Tests & Special Considerations

Skin biopsy if unusual presentation or if diagnosis is unclear

Test Interpretation

- Histopathologic features of common warts include digitated epidermal hyperplasia, acanthosis, papillomatosis, compact orthokeratosis, hypergranulosis, dilated tortuous capillaries within the dermal papillae, and vertical tiers of parakeratotic cells with entrapped red blood cells above the tips of the digitations.
- In the granular layer, HPV-infected cells may have coarse keratohyaline granules and vacuoles surrounding wrinkled-appearing nuclei. These koilocytic (vacuolated) cells are pathognomonic for warts.

TREATMENT

- The abundance of therapeutic modalities described below is a reflection of the fact that none of them is uniformly or even clearly effective in trials. Placebo treatment response rate is significant and quality of evidence in general is poor. Beyond topical salicylates, there is no clear evidence-based rationale for choosing one method over another (1)[A].
- The choice of method of treatment depends on the following:
  - Age of the patient
  - Cosmetic and psychological considerations
  - Relief of symptoms
  - Patient’s pain threshold
  - Type of wart
  - Location of the wart
  - Experience of the physician

GENERAL MEASURES

- There is no ideal treatment.
- In children, most warts tend to regress spontaneously.
- In many adults and immunocompromised patients, warts are often difficult to

eradicate.

- Painful, aggressive therapy should be avoided unless there is a need to eliminate the wart(s).
- For surgical procedures, especially in anxious children, pretreat with anesthetic cream such as EMLA (emulsion of lidocaine and prilocaine).

MEDICATION

First Line

- Self-administered topical therapy
  - Keratolytic (peeling) agents: The affected area(s) should be hydrated first by soaking in warm water for 5 minutes before application. Most over-the-counter agents contain salicylic acid and/or lactic acid; agents such as Duofilm, Occlusal-HP, Trans-Ver-Sal, and Mediplast.
- Office-based
  - Cantharidin 0.7%, an extract of the blister beetle that causes epidermal necrosis and blistering
  - Combination cantharidin 1%, salicylic acid 30%, and podophyllin resin 5% in flexible collodion; applied in a thin coat, occluded 4 to 6 hours, then washed off.

Second Line

Home-based

- Imiquimod 5% (Aldara) cream, a local inducer of interferon, is applied at home by the patient. It is approved for external genital and perianal warts and is used off-label and may be applied to warts under duct tape occlusion. It is applied at bedtime and washed off after 6 to 10 hours. Applied to flat warts without occlusion.
- Topical retinoids (e.g., tretinoin 0.025–0.1% cream or gel) for flat warts

Office-based

- Immunotherapy: induction of delayed type hypersensitivity with the following:
  - Diphenylcyclopropenone (DCP) (2)[B]
  - Dinitrochlorobenzene (DNCP)
  - Squaric acid dibutylester (SADBE): There is possible mutagenicity and side effects with this agent.

- Intralesional injections
  - Mumps or *Candida* antigen
  - Bleomycin: Intradermal injection is expensive and usually causes severe pain.
  - Interferon-α-2b
- Oral therapy
  - Oral high-dose cimetidine: possibly works better in children
  - Acitretin (an oral retinoid)
- Other treatments (all have all been used with varying results)
  - Dichloroacetic acid, trichloroacetic acid, podophyllin, formic acid, aminolevulinic acid in combination with blue light, 5-fluorouracil, silver nitrate, formaldehyde, levamisole, topical cidofovir (3)[B] or IV cidofovir for recalcitrant warts in the setting of HIV, and glutaraldehyde
- The quadrivalent HPV vaccine has cleared recalcitrant, chronic oral, and cutaneous warts (4)[C].

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Duct tape: Cover wart with waterproof tape (e.g., duct tape). Leave the tape on for 6 days, and then soak, pare with emery board, and leave uncovered overnight; then reapply tape cyclically for eight cycles; 85% resolved compared with 60% efficacy with cryotherapy (5)[A].
- Hyperthermia: safe and inexpensive approach; immerse affected area into 45°C water bath for 30 minutes 3 times per week
- Hypnotherapy
- Raw garlic cloves have demonstrated some antiviral activity.
- Vaccines are currently in development.

Pregnancy Considerations

The use of some topical chemical approaches may be contraindicated during pregnancy or in women who are likely to become pregnant during the treatment period.

SURGERY/OTHER PROCEDURES

- Cryotherapy with liquid nitrogen (LN_2) may be applied with a cotton swab or with a cryotherapy gun (Cryogun). Aggressive cryotherapy may be more

effective than salicylic acid (6)[A], but it is associated with increased adverse effects (blistering and scarring):
  - Best for warts on hands; also during pregnancy and breastfeeding
  - Fast; can treat many lesions per visit
  - Painful; not tolerated well by young children
  - Freezing periungual warts may result in nail deformation.
  - In darkly pigmented skin, treatment can result in hypo- or hyperpigmentation.
- Light electrocautery with or without curettage
  - Best for warts on the knees, elbows, and dorsa of hands
  - Also good for filiform warts
  - Tolerable in most adults
  - Requires local anesthesia
  - May cause scarring
- Photodynamic therapy: Topical 5-aminolevulinic acid is applied to warts followed by photoactivation (7)[B].
- CO_2 or pulse-dye laser ablation: expensive and requires local anesthesia
- For filiform warts: Dip hemostat into LN_2 for 10 seconds, then gently grasp the wart for 10 seconds and repeat. Wart sheds in 7 to 10 days.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

1/3 of the warts of epidermodysplasia may become malignant.

PROGNOSIS

- More often than not (especially in children), warts tend to “cure” themselves over time.
- In many adults and immunocompromised patients, warts often prove difficult to eradicate.
- Rarely, certain types of lesions may transform into carcinomas.

COMPLICATIONS

- Autoinoculation (pseudo-Koebner reaction)
- Scar formation
- Chronic pain after plantar wart removal or scar formation
- Nail deformity after injury to nail matrix

CODES

ICD10

- B07.9 Viral wart, unspecified
- B07.0 Plantar wart
- A63.0 Anogenital (venereal) warts

CLINICAL PEARLS

- No single therapy for warts is uniformly effective or superior; thus, treatment involves a certain amount of trial and error.
- Because most warts in children tend to regress spontaneously within 2 years, benign neglect is often a prudent option.
- Conservative, nonscarring, least painful, least expensive treatments are preferred.
- Freezing and other destructive treatment modalities do not kill the virus but merely destroy the cells that harbor HPV.

WILMS TUMOR

John K. Uffman, MD, MPH

BASICS

DESCRIPTION

- An embryonal renal neoplasm containing blastemal, stromal, or epithelial cell types, usually affecting children <5 years of age
- Most common renal tumor in children; fifth most common pediatric malignancy
- Staging: In the United States, National Wilms Tumor Study Group (NWTSG) staging is done pretreatment based on radiographic imaging and surgery, whereas in Europe/Asia, Société Internationale d'Oncologie Pédiatrique (SIOP) staging is done *after* neoadjuvant chemotherapy is administered (1):
  - I: tumor limited to kidney; completely excised
  - II: tumor extends beyond kidney; completely excised
  - III: residual nonhematogenous tumor confined to abdomen (lymph nodes positive, spillage of tumor, peritoneal implants, extension beyond resection region)
  - IV: hematogenous metastases
  - V: bilateral renal involvement
- System(s) affected: renal/urologic
- Synonym(s): nephroblastoma

Pediatric Considerations

- Occurs only in children
- Most common renal malignancy in childhood

EPIDEMIOLOGY

Incidence

- Frequency rare in East Asian populations than Whites
- Frequency higher in black children than in whites
- Predominant age: median age of 36.5 months
- Predominant sex: female > male (1.1:1)

- Represents 6–7% of all childhood cancers
  - >80% are diagnosed before 5 years of age (median age is 3.5 years at diagnosis).
  - Wilms tumor makes up 95% of all renal cancers in children <15 years (2).

Prevalence

United States: 0.69/100,000; 7.6 cases/1 million children <15 years old

ETIOLOGY AND PATHOPHYSIOLOGY

- Hereditary or sporadic forms of genetic mutation
- Familial form: autosomal dominant trait with incomplete penetrance (1%)
- Potential of parental occupational exposure (machinists, welders, motor vehicle mechanics, auto body repairmen)

Genetics

- Several congenital anomalies are known to be associated with Wilms tumor. A 2-stage mutational model has been proposed: occurrence in either hereditary form or sporadic form. Patients with aniridia have a deletion of the short arm of chromosome 11 (11p13).
- Abnormalities of chromosome 11 at the 11p15 locus are associated with Beckwith-Wiedemann syndrome. Wilms tumor-suppressor gene (*WT1*) has been identified as well as additional candidates for another suppressor gene (*WT2*). Chromosome band 17q12–17q21 has been linked to two kindreds with Wilms tumor, and other kindred are associated with a Wilms tumor predisposition gene at 19q13.3–19q13.4. Loss of heterozygosity at chromosomes 16q and 1p is associated with adverse outcome (1).
- p53 is associated with anaplastic Wilms tumors (2).

RISK FACTORS

- Familial occurrence (5%) (2)
  - These patients tend to have earlier age of onset.
  - Familial patients have greater risk of bilateral disease.
- Parental occupation (machinists, welders, motor vehicle mechanics, auto body repairmen)
- Maternal exposure to pesticides prior to child’s birth (3)
- High birth weight or preterm birth (3)

- Compared with firstborn, being a second or later birth may be associated with significantly decreased risk of Wilms tumor (3).

GENERAL PREVENTION

- Routine surveillance in patients with syndromes associated with Wilms tumor
- Routine screening with serial renal US at 3- to 4-month intervals has been recommended in children who have syndromes associated with an incidence of Wilms tumor >5% (4)[C].
- Routine screening with serial renal US is also recommended for infants born to kindreds with familial Wilms (every 3 to 4 months until age 7 years) (4)[C].

COMMONLY ASSOCIATED CONDITIONS

- Aniridia (partial or complete absence of iris) 600 times normal risk
- Hemihypertrophy (100 times normal risk)
- Cryptorchidism
- Hypospadias
- Duplicated renal collecting systems
- Denys-Drash syndrome (nephropathy, renal failure, male pseudohermaphroditism, Wilms tumor)
- Klippel-Trenaunay syndrome
- Wilms tumor, aniridia, genitourinary malformations, and mental retardation (WAGR) complex
- Beckwith-Wiedemann syndrome (visceromegaly, macroglossia, omphalocele, hyperinsulinemic hypoglycemia)

DIAGNOSIS

- Symptoms of pain, anorexia, vomiting, malaise in 30% (1)
- >90% present with asymptomatic abdominal mass (5)

HISTORY

- History of increasing abdominal size
- Usually asymptomatic; may have fever, abdominal pain

PHYSICAL EXAM

- Palpable upper abdominal mass

- Fever, hepatosplenomegaly
- Rarely, signs of acute abdomen with free intraperitoneal rupture
- Cardiac murmur
- Ascites, prominent abdominal wall veins, varicocele
- Gonadal metastases
- Aniridia (present in 1.1% of Wilms tumor patients)
- Hypertension (20–65%) (1)

DIFFERENTIAL DIAGNOSIS

- Neuroblastoma
- Hepatic tumor
- Sarcoma
- Rhabdoid tumor
- Cystic nephroma
- Renal cell carcinoma (generally occurs in older children)
- Mesoblastic nephroma: distinguished only by histology. Age usually <6 months, essentially benign, although metastases have been reported; tend to be locally invasive
- Nephroblastomatosis: considered premalignant; may present as nodularity of one or both kidneys

DIAGNOSTIC TESTS & INTERPRETATION

- Urinalysis (occasional hematuria, proteinuria)
- CBC (anemia)
- Lactate dehydrogenase
- Plasma renin (rarely helpful)
- Urine catecholamines
- Serum creatinine and calcium
- Coagulation factors
- Chest radiograph
- Abdominal US (with Doppler imaging): best initial test. Gives best information about tumor and extension into inferior vena cava
- CT scan (with IV and oral contrast material) of chest and abdomen. Allows anatomic visualization and excludes synchronous bilateral disease with a high degree of sensitivity (2)

- CT may have high sensitivity and specificity for atriocaval thrombus and obviate the needs for US (2).
- Chest lesions only identified on CT have improved event-free survival with three drug treatment regimens (6)[B].

Diagnostic Procedures/Other

Occasionally, bone marrow aspiration is necessary to distinguish from neuroblastoma.

Test Interpretation

- Favorable findings (mortality of 7%)
  - Bulky lesion, well encapsulated
  - Focal areas of hemorrhage and necrosis
  - Absence of anaplasia and sarcomatous cell types
  - Presence of blastemal, stromal, and epithelial elements (5)
    - Predominance of epithelial elements usually are less aggressive when diagnosed early but tend to be resistant to treatment when diagnosed late.
    - Predominance of blastemal elements indicate more aggressive tumors.
- Unfavorable histology (mortality rate of 57%)
  - Anaplasia: markedly enlarged and multipolar mitotic figures, 3-fold enlargement of nuclei in comparison with adjacent similar nuclei, hyperchromasia of enlarged nuclei; anaplasia may be diffuse or focal.
  - Sarcomatous changes: now considered to be separate from Wilms, not subtypes (mortality 64%)
  - Rhabdoid tumor of the kidney: now considered to be separate tumor from Wilms
- Nephroblastomatosis: considered premalignant
- Nephrogenic rests (5): These are precursor lesions found in 25–40% of Wilms; found in 1% of infants at autopsy, but most do not develop into malignancy.

TREATMENT

GENERAL MEASURES

- Appropriate health care: inpatient workup and treatment until stable

postoperatively and induction chemotherapy completed
- Chemotherapy; some recommend pretreatment with neoadjuvant chemotherapy (1).
  - May decrease incidence of intraoperative tumor rupture (debatable)
  - May result in inappropriate treatment with chemotherapeutic agents of non-Wilms tumors (5%) or benign lesions (1.6%)
  - Results in the inability to directly compare treatment results worldwide
- Radiation therapy in stage II (unfavorable histology), stage III, and stage IV

MEDICATION

First Line

- Children typically treated with protocols based on staging, histology, and other variables as part of a multimodal therapy approach (chemotherapy, radiation, surgery). The following medications may be used as part of a protocol:
  - Dactinomycin (Actinomycin-D)
  - Vincristine
  - Doxorubicin
  - Cyclophosphamide (Cytoxan)
  - Ifosfamide
  - Etoposide
  - Topotecan
  - Irinotecan

Second Line

- Doxorubicin (Adriamycin)
- Cyclophosphamide

SURGERY/OTHER PROCEDURES

- Exploration of contralateral kidney no longer required if adequate CT done preoperatively
- Radical nephroureterectomy and lymph node sampling is needed to provide precise staging information.
- Renal-sparing resection
  - Tumors are usually too large, but 10–15% may be amenable to partial

nephrectomy if given preoperative chemotherapy (4)[C].
  - May be recommended for patients with high risk of bilateral disease or renal failure (4)[C]
- Sampling of any enlarged lymph nodes (absence of any lymph nodes in the surgical specimen mandates treatment as stage III disease) (5)[B]
- Identification of any retained tumor with titanium clips
- Tumor should be given to pathologist fresh, not in formalin.
- Vertical midline incision if tumor extension to right atrium—increased morbidity (2)
- Bilateral Wilms tumors (represent 4–6% of Wilms) (5)[B]
  - Preoperative chemotherapy with reevaluation by CT or MRI after 6 weeks (some are biopsied prior to chemotherapy)
  - Renal-sparing operation at 6 weeks if good response to chemotherapy:
    - Partial nephrectomy or wedge excision of tumor is preferred but only if it does not compromise tumor resection.
    - Kidney with lowest tumor burden is addressed first. If successful resection is accomplished, radical nephrectomy can be done on the contralateral kidney. Bilateral partial nephrectomy may be possible in some cases.
- Preoperative treatment also generally is accepted in a solitary kidney, horseshoe kidneys, intravascular extension of tumor above the intrahepatic vena cava, and in the case of respiratory distress from extensive metastatic tumor.
- Treatment of patients with relapsed Wilms (7)[B]: Current treatment is either with chemotherapy with or without radiation therapy alone or high-dose chemotherapy followed by autologous stem cell rescue.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Multidrug chemotherapy every 3 to 4 weeks for 16 weeks to 15 months depending on stage

- Every 4 months for 1 year, every 6 months for second to third year; yearly after that
- CBC, CT of chest and abdomen with each visit
- Patients at high risk for developing Wilms tumor should be monitored with renal US every 3 to 4 months until 5 years of age. Patients with Beckwith-Wiedemann syndrome or Simpson-Golabi-Behmel syndrome should have yearly US until 7 years of age (8)[C].

PATIENT EDUCATION

- Possibility of second malignancy (up to 12% by age 50 years)
- Side effects of chemotherapy, radiation therapy

PROGNOSIS

- With favorable histology (1)
  - Children <2 years of age and stage I, favorable histology: 98% survival in NWTSG 1 to 3 studies
  - Children with stage III, favorable histology tumor: overall survival of 89% in NWTSG 3 to 4 studies
- With diffuse anaplasia (1)
  - Children with stage I, diffuse or focal anaplasia: overall survival 82.6%
  - Stage II tumors with anaplasia: overall survival 81.5%
  - Stage III tumors with anaplasia: overall survival 66.7%
  - Stage IV tumors with anaplasia: overall survival 33.3%
- With bilateral involvement (stage V): 4-year survival 81.7% (1)
- With rhabdoid features: 19% 3-year survival
- Survival of patients with relapsed Wilms tumor is 40–70% (8)[B]:
  - Patients with pulmonary relapse only had higher 4-year survival rate (77.7%) compared to other sites (41.6%).

COMPLICATIONS

- Complication rate of 6–10%
- 1–2% will develop second malignant neoplasms (leukemia, lymphoma, hepatocellular carcinoma, soft tissue sarcoma): 12.2% by 50 years of age
- High risk of delivering low-birth-weight infants, perinatal mortality in offspring of female survivors of Wilms tumor

- Chest is usual site of recurrence.
- Occurrence of second malignant neoplasms in 2% of patients 7 to 34 years after treatment
  - Bone and soft tissue sarcomas, breast cancer, hepatocellular carcinoma, lymphoma, gastrointestinal tract tumors, melanoma, leukemias
- Surgical complications
  - Postoperative small bowel obstruction (5–7%)
  - Tumor rupture with spillage in 15.3% according to NWTSG-5; this may be spontaneous or surgical and results in upstaging the tumor. Only 2.7% of spills are considered avoidable. Incidence of tumor spillage is reported at 2.2% by SIOP following preoperative neoadjuvant chemotherapy (5)[B].
- Local tumor recurrence
  - Abdominal tumor recurrence after tumor spillage is reduced by radiation therapy (10 or 20 Gy).
- Renal failure
- Cardiomyopathy (usually related to doxorubicin and radiation therapy)
- Impaired pulmonary function (radiation therapy)

CODES

ICD10

- C64.9 Malignant neoplasm of unsp kidney, except renal pelvis
- C64.1 Malignant neoplasm of right kidney, except renal pelvis
- C64.2 Malignant neoplasm of left kidney, except renal pelvis

CLINICAL PEARLS

- Wilms is the most common renal tumor in children; it is an embryonal renal neoplasm containing blastemal, stromal, or epithelial cell types, usually affecting children <5 years of age.
- Nephrectomy performed as soon as possible after completing radiographic evaluation is the major component in tumor staging.
- Sampling regional lymph nodes or specifically mentioning "No nodes present" in the operative report is necessary or the tumor will automatically be considered stage III.

ZOLLINGER-ELLISON SYNDROME

Douglas S. Parks, MD

BASICS

DESCRIPTION

- Zollinger-Ellison syndrome (ZES) triad
  - Markedly elevated gastric acid secretion
  - Peptic ulcer disease
  - A gastrinoma or non-*β* islet cell tumor of the pancreas or duodenal wall that produces gastrin
    - Gastrinomas (at the time of diagnosis) may be single or multiple (1/2 to 2/3), large or small, benign or malignant (2/3), sporadic (70–75%) or associated with *multiple endocrine neoplasia type 1* (MEN1) (25–30%).
- System(s) affected: endocrine/metabolic, gastrointestinal
- Synonym(s): Z-E syndrome; pancreatic ulcerogenic tumor syndrome; multiple endocrine neoplasia, partial; ulcerogenic islet cell tumor

EPIDEMIOLOGY

Incidence

- 1 to 3 per million per year in the United States
- Predominant age: middle age (30 to 65 years). Mean age of onset is 43 years. Presents a decade earlier in patients with ZES/MEN1.
- Predominant sex: male > female (1.3:1)

Pediatric Considerations

Aggressive cases have been reported in teenagers.

Pregnancy Considerations

Rare, pregnancy alters medication choices and surgical timing.

ETIOLOGY AND PATHOPHYSIOLOGY

- Gastrinoma is equally distributed between the head of the pancreas and the first or second portion of the duodenum; if in the pancreas, the lesion is more likely to metastasize to the liver.

- Hypergastrinemia results in gastric mucosal hypertrophy and increased acid production. Increased acid production causes mucosal ulceration. Diarrhea and malabsorption are also common in ZES.
- Also may be found rarely in the mesentery, peritoneum, spleen, skin, or mediastinum (possibly metastasis with primary not identified)

Genetics

~25–30% of cases occur in association with the MEN1 syndrome—tumors of pancreas, pituitary, and parathyroid.

RISK FACTORS

- MEN1
- Family history of ulcer disease

GENERAL PREVENTION

Screen first-degree relatives of patients with MEN1.

COMMONLY ASSOCIATED CONDITIONS

- MEN1
- Insulinoma
- Carcinoid tumors

DIAGNOSIS

HISTORY

Average of 5 years of symptoms, including recurrent ulcers before diagnosis is made

- Abdominal pain is the most common symptom (80%).
- Diarrhea (postprandial and fasting) (70%)
- Heartburn (60%)
- Nausea (30%)
- Reflux esophagitis
- Vomiting that is unresponsive to standard therapy
- Weight loss

PHYSICAL EXAM

- Hepatomegaly with metastasis
- Conjunctival pallor if anemic
- Jaundice (tumor compressing common bile duct)
- Epigastric tenderness
- Dental erosions
- Heme + stools on rectal exam
- Complications of severe peptic ulcer disease, including hemorrhage, perforation, and obstruction
- Signs of MEN1 are hypercalcemia, hyperparathyroidism, and Cushing syndrome.

Geriatric Considerations

Consider the diagnosis in a patient with persistent or recurring peptic ulcer disease; it is a less aggressive disease if it appears after 65 years.

DIFFERENTIAL DIAGNOSIS

- Elevated serum gastrin with hypochlorhydria/achlorhydria
  - Atrophic gastritis
  - Drug-induced (associated with proton pump inhibitors [PPIs])
  - Gastric cancer
  - Pernicious anemia
  - Postvagotomy
- Elevated serum gastrin with normal or increased gastric acid
  - Antral G-cell hyperfunction
  - Chronic renal failure
  - *Helicobacter pylori* infection
  - Gastric outlet obstruction
  - Retained gastric antrum
- Consider gastrinoma in all patients with the following symptoms:
  - Recurrent or refractory ulcer disease
  - Gastric hypertrophy and ulcers
  - Duodenal and jejunal ulcers
  - Ulcers and diarrhea
  - Ulcers and kidney stones
  - Hypercalcemia and ulcers

- Pituitary disease
- Family history of ulcer disease or endocrine tumors suggestive of MEN1

DIAGNOSTIC TESTS & INTERPRETATION

- Preferred test is secretion stimulation test: gastrin level >100 pg/mL (>100 ng/L) (1,2)[A].
- Some gastrin assays undermeasure serum gastrin. If have strong index of suspicion but gastrin levels low, may need to repeat with a different lab (3) [B].
- Gastric secretory studies: basal acid output
- Alternative test is calcium infusion test: gastrin level >400 pg/mL (test is less specific and more dangerous because of IV calcium infusion).
- Elevated serum gastrin fasting level: >1,000 pg/mL with ulcers diagnostic; >200 pg/mL with ulcers is suggestive.
- Elevated basal gastric acid output: >15 mEq/hr (>15 mmol/hr)
- Gastric pH <2 with elevated gastrin
- Check serum calcium, phosphorus, cortisol, and prolactin to rule out MEN1.
- Drugs may alter lab results:
  - Histamine (H_2) blockers and PPIs may increase gastric pH and serum gastrin.
  - Hold PPIs 7 days and H_2 blockers 2 days prior to drawing gastrin level.
- Endoscopic US: finds 24–38% of primary tumors
- Endoscopic findings include esophagitis, duodenal ulceration with multiple ulcers, and prominent gastric and duodenal folds.
- Used to localize tumor for possible resection
- Much more likely to find tumors >3 cm (95%) than <1 cm (<15%) (4)[B]
- Abdominal CT scan: most useful for pancreatic tumors and metastasis >3 cm
- Abdominal US, MRI, and angiography are not typically useful except in large tumors.
- Somatostatin receptor scintigraphy (SRS): more sensitive than radiologic studies, still only finds 30% of small tumors
- Portal venous sampling and selective venous sampling for gastrin can localize the area of tumor and metastasis (80–90% sensitivity).
- Brain imaging (MRI) and serum calcium are useful if MEN1 is suspected.

- Because pancreatic tumors are most likely to be large and to metastasize to the liver (worse prognosis), SRS and an abdominal CT scan are suggested to look for resectable tumors. Surgical resection may improve prognosis (5)[B].

Diagnostic Procedures/Other

Endoscopy may reveal tumors in the duodenal wall; multiple ulcers, including jejunal ulcers; and prominent gastric and duodenal folds.

Test Interpretation

- 90% of gastrinomas are found in the gastric triangle (the borders are the bile duct, the junction of second and third portions of the duodenum, and the junction of the head and body of pancreas).
- ~50% of gastrinomas are in the head of the pancreas (more likely >3 cm, metastasis to liver).
- ~50% of gastrinomas are in the wall of the first or second portion of duodenum (more likely to be small, solitary).
- 2/3 of gastrinomas are malignant.
- 50% of gastrinomas stain positive for adrenocorticotropic hormone (ACTH), vasoactive intestinal polypeptide, insulin, or neurotensin.
- 1/3 of patients have metastasis on presentation: regional nodes > liver > bone, > peritoneum, spleen, skin, and mediastinum.
- Biopsy shows hyperplasia of antral gastrin-producing cells, and histology is similar in appearance to carcinoid.

TREATMENT

GENERAL MEASURES

- Goals are to control acid hypersecretion and resect the tumor.
- Advanced imaging initially to evaluate for resection
- Surgical removal when primary tumor can be identified and as adjunct to control symptoms
- Medical treatment for symptom control when primary tumor is not found or metastasis on initial diagnosis

MEDICATION

- PPIs are the first-line treatment; add H_2 blockers.
- Medications heal 80–85% of ulcers, most of which recur. Lifelong medication use should be anticipated.
- 4- to 8-fold higher PPI dose often necessary
  - Start at a lower dose, and titrate to symptoms (or maximum recommended dosage).
- If hyperparathyroidism is present (MEN1), correct hypercalcemia.

First Line

- PPIs
  - Omeprazole 60 to 120 mg/day
  - Lansoprazole 60 to 180 mg/day (doses >120 mg need to be divided BID)
  - Rabeprazole 60 to 100 mg/day up to 60 mg BID
  - Pantoprazole 40 to 240 mg/day PO; 80 to 120 mg q12h IV
- H_2 blockers
  - Cimetidine 300 mg q6h up to 2.4 g/day
  - Ranitidine 150 mg q12h up to 6 g/day
  - Famotidine 20 mg q6h; up to 640 mg/day
- Contraindications
  - Known hypersensitivity to the drug
  - H_2 blockers: antiandrogen effects, drug interactions due to cytochrome P450 inhibition
  - PPIs: none
- Precautions
  - Adjust doses for geriatric patients and patients with renal insufficiency.
  - Gynecomastia has been reported with high-dose cimetidine (>2.4 g/day).
  - PPIs may induce a profound and long-lasting effect on gastric acid secretion, thereby affecting the bioavailability of drugs depending on low gastric pH (e.g., ketoconazole, ampicillin, iron).
- Significant possible interactions: Consider drug–drug interactions and consult prescribing materials accordingly.

Second Line

- Octreotide may slow growth of liver metastases, or (occasionally) promote regression. Octreotide LAR can be given every 28 days (4)[B].

- Chemotherapy regimens using streptozocin, 5-fluorouracil, and doxorubicin shows limited response.
- Interferon shows a limited response but may be useful in combination with octreotide.

SURGERY/OTHER PROCEDURES

- Laparotomy may be necessary to search for resectable tumors unless patient has liver metastasis on presentation or MEN1; surgery improves outcomes (6) [B].
- Definitive therapy: removal of identifiable gastrinomas (95% of tumors are found at the time of surgery; 5-year cure is 40% when all are removed)
- Total gastrectomy is rarely indicated.
- In MEN1, parathyroidectomy, by lowering calcium, may also decrease acid production and decrease antisecretory drug use. Gastrinomas in MEN1 are generally small, benign, and multiple, and surgery is not usually curative in this situation.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Titrate medication to symptom control
- Appropriate surveillance postoperatively to look for metastasis

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Longitudinal follow-up to evaluate for metastases
- Titrate medical therapy to control symptoms.
- Advise patients of potential danger of stopping antisecretory treatment. Rare cases have been reported of severe adverse outcomes within 2 days of stopping PPIs (7)[B]. Gastric acid analysis can help guide medical therapy to maintain basal gastric acid output at <10 mEq/hr (<2 mEq/hr if patient has complications such as perforation or esophagitis).

DIET

Restrict foods that aggravate symptoms.

PATIENT EDUCATION

Inform patients as to the nature of disease and prognosis.

PROGNOSIS

- Overall survival rate: 5 to 10 years: 69–94%
- The prognosis improves with complete surgical removal of the tumor.
- If liver metastasis is present on initial surgery, 5-year survival is 30–40%; 10-year survival is 25%.
- Mortality is directly related to liver metastasis tumor size and presence of pancreatic tumors (4,5)[B].

COMPLICATIONS

- Complications of peptic ulcer disease (bleeding, perforation, obstruction)
- 2/3 of gastrinomas are malignant with metastasis.
- Paraneoplastic phenomena (e.g., production of ACTH with resulting Cushing syndrome) is possible.
- Decrease in vitamin B_{12} levels is possible with long-term PPI use (8)[A].

CODES

ICD10

E16.4 Increased secretion of gastrin

CLINICAL PEARLS

- Consider ZES if peptic ulcers recur or if high doses of PPI are needed to control symptoms/ulcers.
- ~25–30% of cases of ZES occur in association with MEN1.
- Once ZES is diagnosed, it is important to search for gastrinomas in the head of the pancreas and the first or second portion of the duodenum.

- PPIs heal ZES ulcers. Patients should anticipate lifelong therapy.
