Phosphorus. The importance of controlling phosphate in patients with early stage disease often is overlooked. Serum phosphorus levels elevate at the same rate as eGFR decreases. Early initiation of phosphate reduction therapies is advantageous for delaying hyperparathyroidism and bone disease. Unfortunately, patients are often asymptomatic during the early phase of hyperparathyroidism and hyperphosphatemia; they may not attend to their modified diets or understand the need to take **phosphate binders** with meals.

Those with an eGFR of less than 60 should be evaluated for renal bone disease and benefit from phosphorus restriction. Ongoing monitoring of patient's phosphorus and use of phosphate binders is recommended. The diet typically is modified to allow no more than 1000 mg of phosphates daily, a limit that allows approximately 1 to 2 dairy foods per day. Because of the decrease in protein intake, the control of phosphorus is somewhat easier to manage. Patients who are in later stages of CKD and intolerant of red meats because of uremic taste alterations often are able to substitute milk foods for meat and still maintain a limited phosphate intake.

Lipids. The important consequence of dyslipidemia is cardiovascular disease. Pediatric patients with frequently relapsing or resistant nephrotic syndrome are at particular risk for premature atherosclerosis. Certain lipid-lowering agents in combination with a cholesterol-lowering diet can reduce total cholesterol, low-density lipoprotein cholesterol, and triglycerides in these patients (see Chapter 33). Lowering protein intake in adult patients also may involve lowering fat and cholesterol intake from animal sources.

Vitamins. CKD patients routinely are recommended a water-soluble renal customized vitamin supplement, because restrictions on fruits, vegetables and dairy foods may cause the diet to be inadequate.

END-STAGE RENAL DISEASE

End-stage renal disease (ESRD) reflects the kidney's inability to excrete waste products, maintain fluid and electrolyte balance, and produce certain hormones. As renal failure slowly progresses, the level of circulating waste products eventually leads to symptoms of uremia (see *Pathophysiology and Care Management Algorithm: Chronic Kidney Disease and End-Stage Renal Disease*). **Uremia** is a clinical syndrome of malaise, weakness, nausea and vomiting, muscle cramps, itching, metallic taste in the mouth, and neurologic impairment that is brought about by an unacceptable level of nitrogenous wastes in the body.

Pathophysiology

ESRD can result from a wide variety of different kidney diseases. Currently 90% of patients reaching ESRD have chronic (1) diabetes mellitus, (2) hypertension, or (3) glomerulonephritis. The manifestations are somewhat nonspecific and vary by patient. No reliable laboratory parameter corresponds directly with the beginning of symptoms. However, as a rule of thumb, BUN of more than 100 mg/dl and creatinine of 10 to 12 mg/dl are usually close to this threshold.

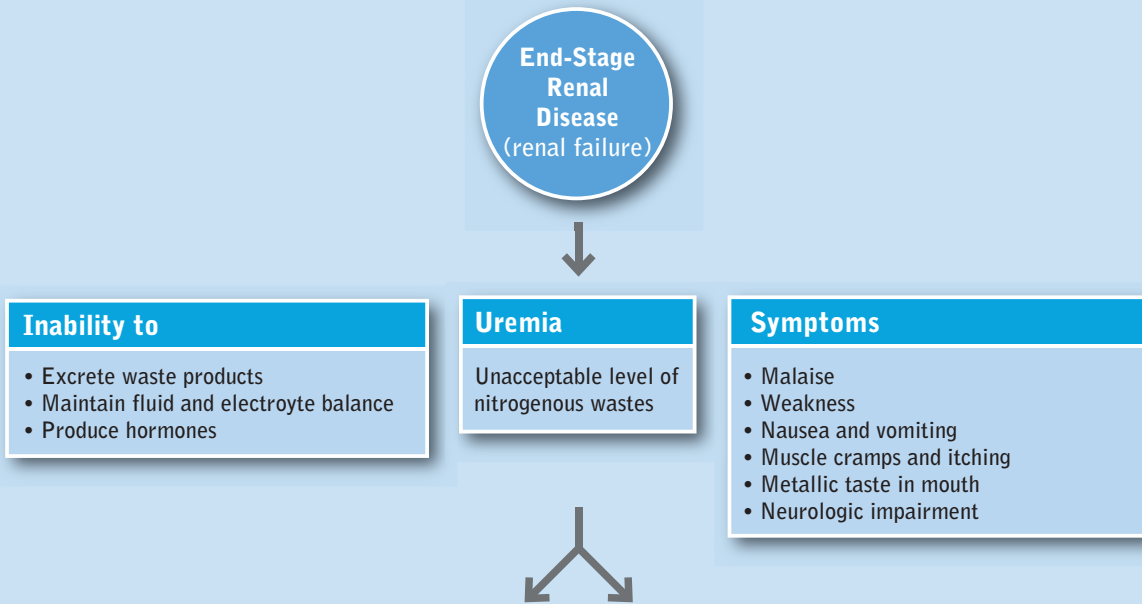

PATHOPHYSIOLOGY AND CARE MANAGEMENT ALGORITHM

Chronic Kidney Disease and End-Stage Renal Disease

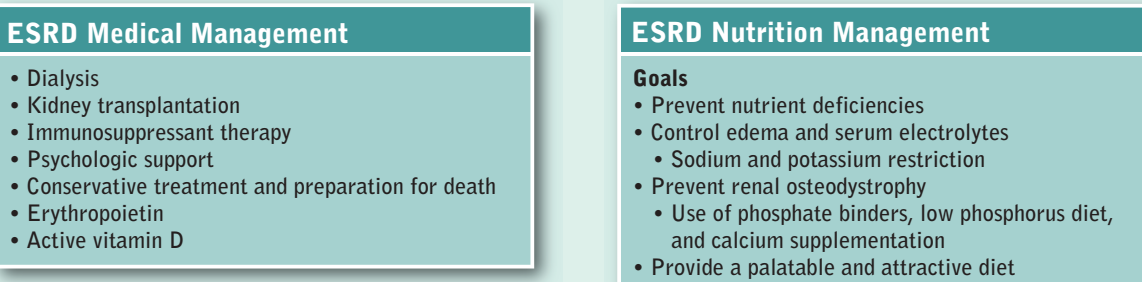

ETIOLOGY

PATHOPHYSIOLOGY

MANAGEMENT

Medical Treatment

Once the patient progresses from stage 4 to stage 5 CKD, options for treatment for ESRD include dialysis, transplantation, or medical management progressing to death. Patients do best if they have some control and choice over their options (Wingard et al, 2007).

Dialysis

Patients may choose to dialyze in an outpatient dialysis facility or they may prefer **hemodialysis (HD)** at home using either conventional daily or nocturnal dialysis. They may choose **peritoneal dialysis (PD)** and have a choice of continuous ambulatory peritoneal dialysis (CAPD) or automated peritoneal dialysis (APD, formerly called continuous cyclic peritoneal dialysis, or CCPD), or combinations of the two. Patients, families, and their physicians together evaluate the therapy that best meets the patient's needs. Factors that come into account in this decision are availability of family or friends to assist with therapy, type of water supply to the home, capability of the patient or involved family (including eyesight and ability to perform sterile technique), previous abdominal surgeries, membrane characteristics of the individual's peritoneal membrane, body size, cardiac status, ability to create a vascular access, desire to travel, and a host of other considerations (see Table 35-9).

HD requires permanent access to the bloodstream through a **fistula** created by surgery to connect an artery and a vein (see Figure 35-2). If the patient's blood vessels are fragile, an artificial vessel called a **graft** may be implanted surgically. Large needles are inserted into the fistula or graft before each dialysis and removed when dialysis is complete. Temporary access through subclavian catheters is common until the patient's permanent access can be created or can mature; however, problems with infection make these catheters undesirable (Gomes et al, 2013).

The HD fluid and electrolyte content is similar to that of normal plasma. Waste products and electrolytes move by diffusion, ultrafiltration, and osmosis from the blood into the dialysate and are removed (see Figure 35-3) (Himmelfarb and Ikizler,

2010). Outpatient HD usually requires treatment of 3 to 5 hours three times per week in a dialysis unit (see Figure 35-4). Newer therapies can shorten the duration of treatment by increasing its frequency. Patients on these more frequent dialysis therapies have lower mortality rates, approaching that of transplantation. Patients on daily dialysis at home typically have treatments lasting from 2 to 3.5 hours 5 to 6 days a week, whereas some home dialysis patients receive nocturnal dialysis 3 to 6 times a week for 8 hours, while they sleep.

Peritoneal dialysis (PD) makes use of the body's own semi-permeable membrane, the peritoneum. A catheter is implanted surgically through the abdomen and into the peritoneal cavity. **Dialysate** containing a high-dextrose concentration is instilled into the peritoneum, where diffusion carries waste products from the blood through the peritoneal membrane and into the dialysate; water moves by osmosis. This fluid then is withdrawn and discarded, and new solution is added multiple times each day.

Several types of PD exist. In CAPD, the dialysate is left in the peritoneum and exchanged manually, by gravity. Exchanges of dialysis fluid are done four to five times daily, making it a 24-hour treatment (see Figure 35-5). In APD, patient treatments are done at night by a machine that mechanically performs the exchanges. During the day these patients sometimes keep a single dialysate exchange in the peritoneal cavity for extended periods (called a long dwell), perhaps the entire day. Several combinations of CAPD and APD are possible and are referred to here as *PD*.

Advantages of PD are avoidance of large fluctuations in blood chemistry, longer residual renal function, and the ability of the patient to achieve a more normal lifestyle. Complications include peritonitis, hypotension that requires fluid and sodium replacement, and weight gain. Tissue weight gain is experienced by most patients as a result of absorbing 400 to 800 calories per day from the glucose in the dialysate. The amount depends on the concentration of the dialysate solution and how many exchanges are done daily. This may be desirable in patients who

TABLE 35-8 Nutrient Requirements of Adults with Renal Disease Based on Type of Therapy

Therapy	Energy	Protein	Fluid	Sodium	Potassium	Phosphorus
Impaired renal function	30-35 kcal/kg IBW	0.6-1.0 g/kg IBW	Ad libitum	Variable, 1.5-2 g/day	Variable, usually ad libitum or increased to cover losses from diuretics	0.8-1.2 g/day or 8-12 mg/kg IBW
Hemodialysis	35 kcal/kg IBW	1.2 g/kg IBW	750-1000 ml/day plus urine output	1.5-2 g/day	2-3 g/day or 40 mg/kg IBW	0.8-1.2 g/day or <17 mg/kg IBW
Peritoneal dialysis (CAPD)(CCPD)	30-35 kcal/kg IBW	1.2-1.5 g/kg BW	Ad libitum (minimum of 1000 ml/day from urine plus output)	1.5-4 g/day	3-4 g/day	0.8-1.2 g/day
Transplant, 4-6 weeks after transplant	30-35 kcal/kg IBW	1.3-2 g/kg IBW	Ad libitum	1.5-2 g/day	Variable; may require restriction with cyclosporine-induced hyperkalemia	Calcium 1.2 g/day No need to limit phosphorus
6 weeks or longer after transplant	Kcal/kg To achieve/maintain IBW Limit simple CHO Fat <35% cal Cholesterol < 400 mg/day PUFA/SFA ratio > 1	1 g/kg BW	Ad libitum	1.5-2 g/day	Variable	Calcium 1.2 g/day No need to limit phosphorus

Modified from National Kidney Foundation: KDOQI clinical practice guidelines for nutrition in chronic renal failure, *Am J Kidney Dis* 35(suppl 2):S1, 2000; Wiggins K: Guidelines for nutrition care of renal patients, ed 3, Chicago, 2002, American Dietetic Association.

CAPD, Continuous ambulatory peritoneal dialysis; CCPD, continuous cyclical peritoneal dialysis; IBW, ideal body weight; PUFA, polyunsaturated fat; SFA, saturated fat.

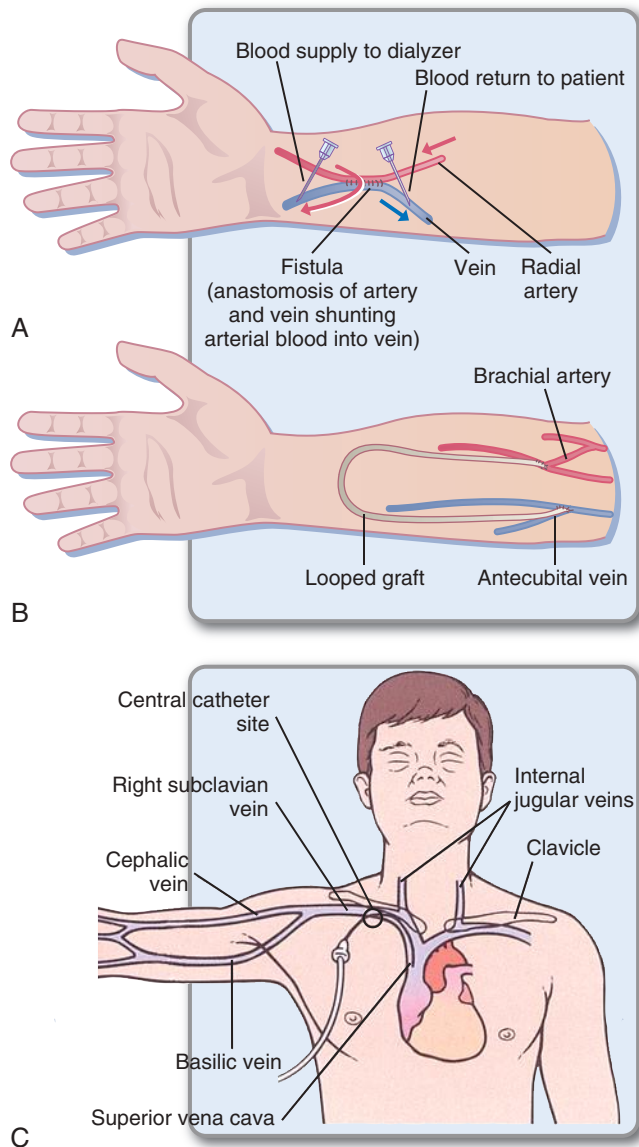

FIGURE 35-2 Types of access for hemodialysis. **A**, Arteriovenous fistula. **B**, Artificial loop graft. **C**, Subclavian catheter (usually temporary). (From Lewis SL, et al: *Medical-surgical nursing: assessment and management of clinical problems*, ed 9, St Louis, 2013, Elsevier Mosby.)

are underweight, but eventually dietary intake or activity must be modified to account for the energy absorbed from dialysate. Icodextrin (Extraneal, Baxter) is a long-chain, nonabsorbable sugar available for long dwell times. It offers superior fluid removal (ultrafiltration) without excess dextrose absorption. This can be useful for patients with diabetes and those with excessive tissue weight gain but can cause other complications.

Evaluation of Dialysis Efficacy

Kinetic modeling is a method for evaluating the efficacy of dialysis that measures the removal of urea from the patient's blood over a given period. This formula, often called **Kt/V** (where *K* is the urea clearance of the dialyzer, *t* is the length of time of dialysis, and *V* is the patient's total body water volume), should ideally produce a result higher than 1.4 per HD, or 3.2 per week. These calculations are somewhat complex and are

typically calculated using a computer program. A more accurate method for determining adequacy of HD is the **eKt/V**, in which *e* stands for equilibrated and takes into account the amount of time it takes for urea to equilibrate across cell membranes after dialysis has stopped. An acceptable eKt/V is 1.2 or greater.

Another method to determine effective dialysis treatment is the **urea reduction ratio (URR)**, which looks at the reduction in urea before and after dialysis. The patient is considered well dialyzed when a 65% or greater reduction in the serum urea occurs during dialysis. Unlike Kt/V, this calculation can be done quickly at the patient's bedside by the practitioner. The method for calculating the efficacy of PD is somewhat different, but a weekly Kt/V of 2 is the goal. The Kt/V can be altered by several patient- and dialysis-associated variables. The calculations for Kt/V can also be used to determine the patient's **protein-nitrogen appearance (PNA) rate**, which compares to a simplified nitrogen balance study in the dialysis patient. The PNA values should be between 0.8 and 1.4. Patients on short daily HD and nocturnal HD require different calculations to estimate their Kt/V.

Medical Nutrition Therapy

Goals of medical nutrition therapy in the management of ESRD are intended to do the following:

1. Prevent deficiency and maintain good nutrition status (and, in the case of children, growth) through adequate protein, energy, vitamin, and mineral intake (see [Table 35-8](#))
2. Control edema and electrolyte imbalance by controlling sodium, potassium, and fluid intake
3. Prevent or slow the development of renal osteodystrophy by balancing calcium, phosphorus, vitamin D, and PTH
4. Enable the patient to eat a palatable, attractive diet that fits his or her lifestyle as much as possible
5. Coordinate patient care with families, dietitian nutritionists, nurses, and physicians in acute care, outpatient, or skilled nursing facilities
6. Provide initial nutrition education, periodic counseling and long-term monitoring of patients, with the goal of patients receiving enough education to direct their own care and diet.

[Table 35-10](#) presents a guide for teaching patients about their blood values and control of their disease. Because dialysis is done at home or in an outpatient unit, most all patients with ESRD assume responsibility for their own diets. Most long-term patients know their diets very well (see [Figure 35-6](#)), having been instructed many times by renal dietitian nutritionists at their dialysis units.

Protein

Dialysis is a drain on body protein, so protein intake must be increased. In addition, exposure of patients' blood to an artificial membrane three or more times a week induces a state of chronic inflammation and distorts protein metabolism. Protein losses of 20 to 30 g can occur during a 24-hour PD, with an average of 1 g/hr. Those receiving PD need a daily protein intake of 1.2 to 1.5 g/kg of body weight. At least 50% should be HBV protein. Patients who receive HD three times per week require a daily protein intake of 1.2 g/kg of body weight. Serum BUN and serum Cr levels, uremic symptoms, and weight should be monitored, and the diet should be adjusted accordingly.

**Diffusion**

is the passage of particles through a semipermeable membrane. Tea, for example, diffuses from a tea bag into the surrounding water.

Osmosis

is the movement of fluid across a semipermeable membrane from a lower concentration of solutes to a higher concentration of solutes. (The water moves into the teabag.)

Diffusion and Osmosis

can occur at the same time. (Particles move out and fluid moves in at the same time.)

Filtration

is the passage of fluids through a membrane.

Ultrafiltration

provides additional pressure to squeeze extra fluid through the membrane.

FIGURE 35-3 Dialysis: how it works. (Modified from Core curriculum for the dialysis technician: a comprehensive review of hemodialysis, 2001, AMGEN, Inc.)

FIGURE 35-4 Hemodialysis. Treatment is usually for 3 to 5 hours, three times per week.

The peritoneal cavity is filled with dialysate, using gravity.

At the end of the exchange, the dialysate is drained into the bag, again using gravity.

FIGURE 35-5 Continuous ambulatory peritoneal dialysis; 20-minute exchanges are given four to five times daily every day.

In renal failure, prealbumin, which is metabolized by the kidney, is not a good nutritional marker, because values are routinely elevated. Albumin is not recommended by the Academy of Nutrition and Dietetics to be used as an indicator of protein nutriture but continues to be routinely used in evaluating ESRD patients (Friedman and Fadem, 2010; Gama-Axelsson et al, 2012). However, because of the complexity of either acute or chronic inflammation, albumin remains predictive more of poor survival in ESRD and less of nutritional status. Hypoalbuminemia is multifactorial and may be related to poor nutrition, inflammation, or comorbid disease. When interpreting albumin

values, it is important to know the laboratory's methodology for measuring serum albumin, because different laboratory techniques give different results in renal failure (see Table 35-10). Federal mandates require some nutrition intervention at levels below 4 g/dl to attempt to improve albumin to this level despite the evidence that low albumin is not a function of nutritional intake.

Most patients find it challenging to consume adequate protein because uremia itself causes taste aberrations, notably to red meats. Some patients cannot even tolerate the smell of meat cooking. Often this protein aversion makes it difficult to achieve

TABLE 35-9 Options for Treatment in ESRD

	Hemodialysis	Peritoneal Dialysis	Short Daily Hemodialysis or Nocturnal Dialysis	Transplant
Primary treatment responsibility	Health care personnel	Patient and/or family member	Patient and/or family member	Patient
Diet	Low K, low PO ₄ , low Na, moderate protein, fluid restriction	High K, low PO ₄ , low Na, high protein, moderate fluid restriction	High K, low PO ₄ , low Na, high protein, moderate fluid restriction	High and moderate protein, no K or PO ₄ restrictions, no fluid restriction.
Location	Clinical dialysis unit	Home, office, vacation	Home, vacation	No limitations
Risks	Bleeding, sepsis, infection	Peritonitis, hernia, constipation, exit site infections, poorly controlled diabetes, weight gain, early satiety	Unattended dialysis, rare user error bleeding	Immuno-compromised, diabetes, cancer
Contraindications	Poor cardiac status, poor blood vessels for access creation	Multiple abdominal surgeries, lack of a clean home, altered mental status	Dementia, illiteracy, inability to communicate, lack of a clean home	High BMI, noncompliance with medications, less than 5 year hx of cancer

TABLE 35-10 Guide to Blood Values in End-Stage Renal Disease Patients

This guide is to help in understanding laboratory reports. In the following table, the normal values are for people with good kidney function. Acceptable values for dialysis patients are also given. Many things affect blood values. Diet is only one of these. Underlying disease, adequacy of treatment, medications, and complications all may affect laboratory values.

Substance	Normal Values	Normal for People on Dialysis	Function	Diet Changes
Sodium	135-145 mEq/L	135-145 mEq/L	Found in salt and many preserved foods. A diet high in sodium causes thirst. When patients drink too much fluid, it may actually dilute their sodium, and serum levels will appear low. If patients eat too much sodium and do not drink water, sodium may be high. Too much sodium and water raise blood pressure and can cause fluid overload, pulmonary edema, and congestive heart failure.	High: Check fluid status. If high fluid gains, tell patient to eat fewer salty foods. If low fluid gains, make sure patient is gaining about 1.5 kg between dialyses (or <4% body weight) and is not dehydrated (this is rare). Low: If high fluid gains, tell patient to eat less salt and fluid. Check fluid status—patient is probably drinking too much fluid. Limit weight gains to less than 4% of body weight between runs, and ask patient to eat fewer salty foods and limit fluid to 3 C plus urine output.
Potassium	3.5-5.5 mEq/L	3.5-5.5 mEq/L	Found in most high-protein foods, milk, fruits, and vegetables. Affects muscle action, especially the heart. High levels can cause the heart to stop. Low levels can cause symptoms such as muscle weakness and atrial fibrillation.	High: Ascertain that no other causes, such as gastrointestinal bleeding, trauma, or medications are creating high potassium values. Tell patient to avoid foods with more than 250 mg/serving and limit daily intake to 2000 mg. Consider lowering potassium in dialysate bath. Recheck blood level next treatment. Low: Add one high-potassium food/day, and recheck blood level. Consider raising potassium in dialysate bath if diet changes not working.
Urea nitrogen (BUN)	7-23 mg/dl	50-100 mg/dl	Waste product of protein breakdown. Unlike creatinine, this is affected by the amount of protein in the diet. Dialysis removes urea nitrogen.	High: Patient is probably underdialyzed. Check eKt/V. Check nPNA. Low: Underdialysis is also a cause. BUN may decrease if patient is not eating because of uremic symptoms. Also decreases with loss of muscle.
Creatinine	0.6-1.5 mg/dl	Less than 15 mg/dl	A normal waste product of muscle breakdown. This value is controlled by dialysis. Patients have a higher amount because they are not dialyzing 24 hours a day, 7 days a week, as they would with normal kidney function.	Dialysis normally controls creatinine. Low creatinine may indicate good dialysis or low body muscle. Check the clearance of urea during dialysis (Kt/V) to assess dialysis adequacy. If patient losing weight, will break down more muscle, so creatinine may be higher. Patient may need to eat more protein and calories to stop weight loss.
URR	N/A	Above 65% (or 0.65)	A measure of reduction of urea that occurs during a dialysis treatment. Postdialysis BUN is subtracted and divided by predialysis BUN to give a percentage.	No diet changes, but catabolism or anabolism will affect values, as with Kt/V and equilibrated clearance of urea during dialysis (eKt/V).

TABLE 35-10 Guide to Blood Values in End-Stage Renal Disease Patients—cont'd

Substance	Normal Values	Normal for People on Dialysis	Function	Diet Changes
eKt/V	N/A	Above 1.2	A mathematic formula that attempts to quantify how well a patient is dialyzed. Represents the clearance of urea by the dialyzer, multiplied by the minutes of treatment, and divided by the volume of water the patient's body holds.	No diet changes. Low: Values below 1.2 are associated with increased morbidity and mortality. High: Higher values are associated with better outcomes.
Kt/V		Above 1.4 for hemodialysis Above 2 for peritoneal dialysis	Not adjusted for urea equilibration. See above.	No diet changes. See above.
nPNA	N/A	0.8-1.4	A calculation used to look at the rate of protein turnover in the body. Assumes patient is not catabolic because of infection, fever, surgery, or trauma. A good indicator of stable patient's protein intake, when combined with dietary history and albumin. The term <i>normalized</i> means that values have been adjusted to the patient's "normal" or ideal weight.	High: Patient may need to decrease protein intake. Have patient consult with nutritionist. Patient may be catabolic. Patient may be eating large amounts of protein. Low: Patient may need to increase protein intake. If patient is putting out urine, a small urine volume can make a big difference in results. Have patient keep a 48-hour urine collection.
Albumin	3.5-5 g/dl (bromocresol green) 3-4.5 g/dl (bromocresol purple)	3.5-5 g/dl Above 4 g/dl	Good measure of health in dialysis patients. Protein is lost with all dialysis. If albumin is below 2.9, fluid will "leak" from blood vessels into the tissue, thus causing edema. When fluid is in the tissue, it is more difficult to remove with dialysis. Low albumin is closely associated with increased risk of death in dialysis patients.	Low: Increase intake of protein-rich foods: meat, fish, chicken, eggs. A protein supplement may be needed. Intravenous albumin corrects short-term problems with oncotic pressure but does not change serum albumin levels.
Calcium	8.5-10.2 mg/dl	8.5-10.2 mg/dl	Found in dairy products. Dialysis patients' intakes are usually low. Active vitamin D is needed for absorption. The calcium value multiplied by the phosphorus value should not exceed 59, or patient will get calcium deposits in soft tissue. Because it is bound to albumin, calcium can be falsely lower if albumin is low. Ionized calcium is a more accurate test in this case.	High: Check with doctor if patient is taking calcium supplement or a form of active vitamin D. These should be temporarily stopped. Low: If albumin is low, suggest an ionized calcium be drawn. Patient may need a calcium supplement between meals and active vitamin D. Check with physician.
Phosphorus	2.5-4.8 mg/dl	3-6 mg/dl	Found in milk products, dried beans, nuts, and meats. Used to build bones and helps the body produce energy. Acceptable levels depend on variety of factors, including calcium, PTH levels, and the level of phosphorus in diet. If calcium and PTH levels are normal, a slightly higher-than-normal level of phosphorus is acceptable.	High: Limit milk and milk products to 1 serving/day. Remind patient to take phosphate binders as ordered with meals and snacks. Noncompliance with binders is the most common cause of high phosphorus. Low: Add 1 serving milk product or other high-phosphorus food per day or decrease phosphate binders.
PTH intact (I-PTH)	10-65 pg/ml	200-300 pg/ml	A high level of PTH indicates that calcium is being pulled out of bone to maintain serum calcium levels. This syndrome is called secondary hyperparathyroidism. Leads to osteodystrophy. Pulsed doses of oral or IV vitamin D usually lower PTH.	High: Check whether patient taking oral or IV active vitamin D. Contact patient's physician regarding therapy. If patient has no symptoms (high phosphorus, bone pain, fractures), treat less aggressively. Low: No treatment available.
Aluminum	0-10 mcg/L	Less than 40 mcg/L	Patients taking aluminum hydroxide phosphate binders may develop aluminum toxicity, which can cause bone disease and dementia. Value should be checked every 6 months.	High: Discontinue aluminum hydroxide treatment.

Continued

TABLE 35-10 Guide to Blood Values in End-Stage Renal Disease Patients—cont'd

Substance	Normal Values	Normal for People on Dialysis	Function	Diet Changes
Magnesium	1.5-2.4 mg/dl	1.5-2.4 mg/dl	Magnesium normally is excreted in the urine and can become toxic to dialysis patient. High levels may be caused by antacids or laxatives that contain magnesium such as Milk of Magnesia or Maalox.	No dietary changes, except to use nontoxic methods such as fiber to aid in relief of constipation. If magnesium is used as a phosphate binder, levels will have to be checked more often.
Ferritin	Male: 20-350 mcg/L Female: 6-350 mcg/L	300-800 mcg/L with EPO; 50 mcg/L without EPO	This is the way iron is stored in the liver. If iron stores are low, red blood cell production is decreased.	Low: Iron in food is not well absorbed. Most patients need an IV iron supplement. Patients should not take oral iron at same time as phosphate binders.
CO ₂	22-25 mEq/L	22-25 mEq/L	Dialysis patients are often acidotic because they do not excrete metabolic acids in their urine. Acidosis may increase the rate of muscle and bone catabolism.	Low: Review eKt/V, BUN, nPNA. Oral sodium bicarbonate may be given to raise CO ₂ , but it presents a significant sodium load to patient.
Glucose	65-114 mg/dl	Same for nondiabetic patients Less than 300 mg/dl (patients with diabetes)	Because the kidney metabolizes insulin, low blood sugar levels caused by a longer half-life of insulin are possible. For patients with diabetes: a high blood sugar may increase thirst.	Most people need 6-11 servings of breads and starches or cereals per day and 2-4 servings of fruit per day to provide energy. Patients with diabetes should avoid concentrated sweets, unless blood sugar level is low.

BUN, Blood urea nitrogen; CO₂, carbon dioxide; DHT, dihydrotachysterol; EPO, erythropoietin; IV, intravenous; N/A, not applicable; nPNA, normalized protein nitrogen appearance; PTH, parathyroid hormone; URR, urea reduction ratio.
Developed by Katy G. Wilkens, MS, RD, Northwest Kidney Centers, Seattle, Washington.

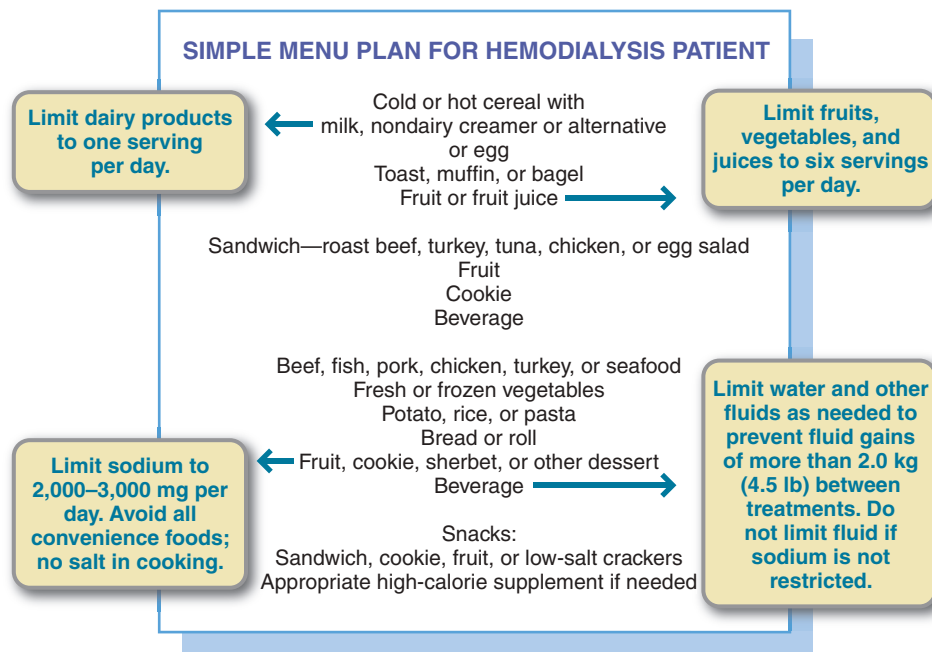

FIGURE 35-6 A simple menu plan for a patient on hemodialysis. The diet should allow for less than 4% fluid weight gain between dialyses.

recommended high biologic value protein intake. Patients may tolerate eggs, tofu, and “white” meats better. They also can use spices to hide the taste of meats, or serve animal proteins cold, to minimize the urea taste. Nutritional supplements may be helpful in some patients, and occasionally the phosphate restriction may have to be lifted to allow the consumption of dairy products to meet protein needs. As with all the nutritional parameters, meeting patient needs must be individualized.

Energy

Energy intake should be adequate to spare protein for tissue protein synthesis and to prevent its metabolism for energy (Therrien, 2015). Depending on the patient’s nutrition status and degree of stress, between 25 and 40 kcal/kg of body weight should be provided, with the lower amount for transplantation and PD patients and the higher level for the nutritionally depleted patient (see *Clinical Insight: Calculating BMI and*

Determining Appropriate Body Weight in Chapter 7). Tools have been developed to allow the renal dietitian to assess the quality of the patient's nutrition status (see Chapter 7 and Appendices 21 and 22).

Fluid and Sodium Balance

The kidney's ability to handle sodium and water in ESRD must be assessed frequently through measurement of blood pressure, edema, fluid weight gain, serum sodium level, and dietary intake. The vast majority of dialysis patients need to restrict sodium and fluid intakes. Excessive sodium intake is responsible for increased thirst, increased fluid gain, and resultant hypertension. Even those patients who do not experience these symptoms but produce minimal amounts of urine benefit from a reduced sodium intake to limit their thirst and prevent large intradialytic fluid gains.

In the patient who is maintained on HD, sodium and fluid intake are regulated to allow for a weight gain of 4 to 5 lb (2 to 3 kg) from increased fluid in the vasculature between dialyses. The goal is a fluid gain of less than 4% of body weight. A sodium intake of 65 to 87 mEq (1500 to 2000 mg) daily and a limit on fluid intake (usually about 750 ml/day plus the amount equal to the urine output) is usually sufficient to meet these guidelines. Only fluids that are liquid at room temperature are included in this calculation. The fluid contained in solid foods is not included in the 750 ml limit. Solid foods in the average diet contribute approximately 500 to 800 ml/day of fluid. This fluid in solid food is calculated to approximately replace the 500 ml/day net insensible water loss.

A 65 to 87 mEq (1500 to 2000 mg) sodium diet requires no salt in cooking; no salt at the table; no salted, smoked, enhanced, or cured meat or fish; no cheese except swiss or cream cheese and no salted snack foods, canned soups, packaged bread products, or high-sodium convenience foods. In today's marketplace, increased intake of convenience foods is the norm and it is estimated that 75% to 90% of sodium intake is consumed in convenience foods, with only 10% to 25% added to foods in cooking or at the table.

The most effective way to reduce the renal patient's thirst and fluid intake is to decrease sodium intake. It is salt intake that drives fluid consumption. Appendix 30 gives the details of a low-sodium meal plan. Attempts to restrict fluid in patients who are not on a restricted sodium diet are futile, because feelings of thirst become overwhelming to the patient with a high sodium intake.

When educating about fluid balance, the health care provider must teach the patient how to deal with thirst without drinking. Sucking on a few ice chips, cold sliced fruit, or sour candies or using artificial saliva are good suggestions. In approximately 15% to 20% of patients, hypertension is not alleviated even after meticulous attention to fluid and water balance. In these patients hypertension usually is perpetuated by a high level of renin secretion and requires medication for control.

Although the majority of patients with ESRD retain sodium, a small number may lose it. Examples of conditions with a salt-losing tendency are polycystic disease of the kidney, medullary kidney disease, chronic obstructive uropathy, chronic pyelonephritis, ostomy losses, and analgesic nephropathy. To prevent hypotension, hypovolemia, cramps, and further deterioration of renal function, extra sodium may be required. A diet for these types of patients may contain 130 mEq (3 g) or more of sodium per day. Not limiting sodium in the diet can satisfy the need for extra sodium. The number of patients who require this

level of sodium intake is small, but these patients exemplify the need for individual consideration of the diet prescription and a thorough understanding of the patient's underlying disease and present diet.

Potassium

Potassium usually requires restriction, depending on the serum potassium level, urine output, medications, and the frequency of HD. The daily intake of potassium for most Americans is 75 to 100 mEq (3 to 4 g). This usually is reduced in ESRD to 60 to 80 mEq (2.3 to 3.1 g) per day and is reduced for the anuric patient on dialysis to 51 mEq (2 g) per day. Some patients (i.e., those on high-flux dialysis or with increased dialysis times or frequencies such as PD, short daily or nocturnal) require higher intakes. Again, a close monitoring of the patient's laboratory values, potassium content of the dialysate, and dietary intake is essential.

The potassium content of foods is listed in Appendix 44. When counseling HD patients on a low-potassium diet, clinicians should take care to point out that some low-sodium foods contain potassium chloride as a salt substitute rather than sodium chloride. Nutrition labels for products such as salt substitutes, LiteSalt, and low-sodium herb mixtures must be checked carefully to be sure they do not contain dangerous levels of potassium. Low-sodium soy sauces, low-sodium soups, and other low-sodium products may require particular review by a trained professional (see Chapter 11 for labeling definitions). Reviewing food preparation techniques should include anyone who may be cooking for the patient, such as family members, a church group, or neighbors.

When a thorough diet history does not reveal the reason for elevated serum potassium, other nondietetic sources of potassium should be researched. Examples include poor dialysis adequacy or missed dialysis treatments, too high a concentration of potassium in the dialysate bath, very elevated blood sugar, acidosis, constipation, significant GI bleeding, some medications, blood transfusions, major trauma, chemotherapy, or radiation therapy. Occasionally, blood samples are handled improperly, resulting in hemolysis and falsely elevated potassium levels.

Phosphorus

More than 99% of excess phosphate is excreted in the urine. However, as GFR decreases, phosphorus is retained in the plasma. Because of the large molecular weight of the phosphate molecule, it is not easily removed by dialysis, and patients experience net "gain" of about one half of the phosphate they consume daily. Phosphate intake is lowered by restricting dietary sources to 1200 mg/day or less. The difficulty in implementing the phosphorus restriction comes from the necessity for a high-protein diet. High-protein foods, such as meats, contain high levels of phosphorus in the form of ATP. In addition, other sources of protein—dairy products, nuts, and legumes—are also high in phosphorus. Thus high-phosphorus foods cannot be eliminated without restricting protein, creating a challenge to balance intake with dietary intervention alone.

The American diet, which contains highly processed foods, has resulted in increases in the types and amounts of phosphorus available for absorption, making compliance with a phosphorus restriction more difficult. Naturally occurring phosphate in food is only approximately 60% absorbed. Commonly used phosphate additives such as trisodium phosphate,

disodium phosphate, and dicalcium phosphate are nearly 100% absorbed, making the processed diet a contributor to elevated phosphorus levels (Leon et al, 2013). Dietary intervention should focus on a balance of limiting dairy, nuts, beans, and processed foods while still encouraging enough HBV proteins to meet dietary needs.

Because dietary restrictions alone are not adequate to control serum phosphorus, nearly all patients who undergo dialysis require phosphate-binding medications. Phosphate binders such as calcium carbonate, calcium acetate, sevelamer carbonate, sucroferric oxyhydroxide, ferric citrate, and lanthanum carbonate are used routinely with each meal or snack to bind to phosphorus in the gut. These medications bind excess dietary phosphate and transport it through the GI tract for elimination, thus preventing its absorption into the blood. Side effects of taking these medications over long periods are common. Some may cause GI distress, diarrhea, or gas. Severe constipation, leading to intestinal impaction, is a potential risk of excessive use of some types of phosphate binders; occasionally this may lead to perforation of the intestine resulting in peritonitis or death. Common medications are listed in Table 35-11 (see *Clinical Insight: Why Don't Clients Take Their Phosphate Binders?*).

CLINICAL INSIGHT

Why Don't Clients Take Their Phosphate Binders?

Phosphate binders are prescribed to be taken with all meals and snacks, whether the client eats at home, at work, or in a restaurant. Reasons clients give for not taking their phosphate binders are that they:

- cause gastrointestinal discomfort and acid reflux
- cause severe constipation and can lead to bowel impaction
- may be difficult to chew or swallow
- may need to take an average of 2 to 5 pills each meal
- forget to take them
- do not like to be reminded of being “sick”
- cannot feel a difference when taking them
- may be expensive and not always covered by insurance

Calcium and Parathyroid Hormone

In ESRD, the body's ability to maintain phosphorus-calcium balance is complicated by calcium and PTH controls. As GFR decreases, the serum calcium level declines for several reasons. First, decreased ability of the kidney to convert to inactive vitamin D to its active form, 1,25-(OH)₂D₃ leads to poor GI absorption of calcium. Second, the need for serum calcium increases as serum phosphate levels increase. Both of these causes lead to hypertrophy of the parathyroid gland, which is responsible for calcium homeostasis. The resultant oversecretion of PTH increases resorption of bone to provide a calcium source.

The resulting metabolic bone disease, **renal osteodystrophy**, is essentially one of four types: (1) **osteomalacia**, (2) **osteitis fibrosa cystica**, (3) **metastatic calcification**, or (4) **adynamic bone disease**. With a deficit of calcium available from dietary absorption, the low calcium level triggers the release of PTH from the parathyroid glands. This acts to increase release of calcium from the bones by stimulating osteoclast activity. This can lead to osteomalacia or bone demineralization, as a result of lack of osteoblast stimulation to replace lost calcium in the bones.

TABLE 35-11 Common Medications and Nutritional Supplements for Patients with End-Stage Renal Disease

Phosphate Binders

Taken with meals and snacks to prevent dietary phosphorus absorption

Calcium carbonate	TUMS, Os-Cal, Calci-Chew, Calci-Mix
Calcium acetate	PhosLo
Mg/Ca ⁺⁺ carbonate	MagneBind
Sevelamer carbonate	Renvela
Lanthanum carbonate	Fosrenol
Aluminum hydroxide	AlternaGEL
Iron-based binders	Velphoro, Auryxia

Vitamins
Increased need for water-soluble vitamins because of losses during dialysis
Fat-soluble vitamins A, E, and K are not supplemented

Dialysis Recommendations

Vitamin C	60 mg (not to exceed 200 mg daily)
Folic acid	1 mg
Thiamin	1.5 mg
Riboflavin	1.7 mg
Niacin	20 mg
Vitamin B ₆	10 mg
Vitamin B ₁₂	6 mcg
Pantothenic acid	10 mg
Biotin	0.3 mg

Brand names include Nephrocap, Nephron FA, Nephplex, Nephrovites, and Dia-tx

Iron

Iron needs are increased because of EPO therapy
IV iron Iron dextran (Infed), Iron gluconate (Ferrlecit), Iron sucrose (Venofer)

EPO

Stimulates bone marrow to produce red blood cells
IV or IM Epogen

Activated Vitamin D

Used for the management of hyperparathyroidism
Oral Calcitriol (Rocaltrol), doxercalciferol (Hectorol)
IV Calcitriol (Calcijex), paricalcitol (Zemlar)

Biphosphonates

Inhibit bone resorption by blocking osteoclast activity
Oral Alendronate (Fosamax)
IV Pamidronate (Aredia)

Calcium Supplements

TUMS, Os-Cal, Calci-Chew

Phosphorus Supplements

Kphos neutral, NutraPhos, NutraPhos K

Calcimimetics

Mimic calcium and bind to parathyroid gland
Cinacalcet (Sensipar)

Cation Exchange Resin

For the treatment of hyperkalemia
Oral or rectal SPS (Kayexalate)

Developed by Fiona Wolf, RD, and Thomas Montemayor, RPh, Northwest Kidney Centers, Seattle, Washington, 2015.
Ca⁺⁺, Calcium; CHO, cholesterol; EPO, epoetin; ESRD, end-stage renal disease; IV, intravenous; IM, intramuscular; MVI, Multiple vitamin injection; SPS, sodium polystyrene sulfonate.

Ongoing low calcium causes the parathyroid glands to continue producing PTH in an attempt to elevate serum calcium levels. In time this leads to secondary hyperparathyroidism, in which even the baseline production of PTH by these enlarged glands is enough to cause severe bone demineralization (**osteitis fibrosis cystica**), which is characterized by dull, aching bone pain.

Even though the serum calcium level is elevated in response to PTH, serum phosphate concentration remains high as the GFR falls lower. If the product of serum calcium multiplied by the serum phosphate level is greater than 70, metastatic calcification is imminent. **Metastatic calcification** occurs when calcium phosphate, removed from bones, is deposited in nonbone cells. This extraskeletal calcification may develop in joints, soft tissue, and vessels.

Calciphylaxis occurs when calcium phosphate is deposited in wound tissues with resultant vascular calcification, thrombosis, nonhealing wounds, and gangrene. It is frequently fatal. Clinical management aims to keep the product of serum calcium multiplied by serum phosphorus below 55 by preventing elevations in serum phosphate and calcium. Phosphorus intake must be controlled to as great a degree as possible to avoid aggravation of the delicate situation posed by hyperparathyroidism, phosphate retention, vitamin D deficiency, and hypocalcemia in renal failure. Newer treatments pair calcium and phosphorus control with increased dialysis, antibiotic therapy, sodium thiosulfate, and hyperbaric chamber treatments (Baldwin et al, 2011; Cohen and Vyas, 2013).

Many patients on dialysis suffer from hypocalcemia, despite calcium supplementation. Because of this, the routine drug of choice is active vitamin D, 1,25-(OH)₂D₃, available as calcitriol (Rocaltrol and Calcijex). Analogs such as doxercalciferol (Hectorol) and paricalcitol (Zemplar) are also effective in lowering PTH and raising calcium levels, but with less enhancement of gut absorption of calcium than the 1,25 forms.

Other mechanisms for controlling PTH include the medication cinacalcet (Sensipar), a calcimimetic or calcium-imitating drug, which binds to sites on the parathyroid gland and gives the gland a false impression that calcium levels are elevated. The drug is effective in suppressing PTH production and also may lower calcium levels dramatically, with significant benefit. Overall, close monitoring is essential.

In more extreme cases of hyperparathyroidism, use of surgical excision of portions of the parathyroid glands can be used in an attempt to restore balance. This creates the risk of low PTH, and can lead to **adynamic (low turnover) bone disease**, characterized by decreased levels of bone turnover and suppression of both osteoclasts and osteoblasts. This condition is unique to ESRD, in which oversuppression of the parathyroid gland and too much active vitamin D lead to decreased bone formation and fragile bones with very little matrix. Usually diagnosed by a low PTH level, this disease results in a high risk of nonhealing fractures. Oversuppression of the parathyroid gland by use of vitamin D or its analogs can mimic this as well.

Overall the dietary balance of phosphorus, the use of phosphate binders and vitamin D analogs, the removal of phosphate by dialysis, and intense monitoring of laboratory values contribute to bone management in ESRD.

Lipid

Atherosclerotic cardiovascular disease is the most common cause of death among patients maintained on long-term dialysis

(Iff et al, 2014). This appears to be a function of underlying disease (e.g., diabetes mellitus, hypertension, nephrotic syndrome) and a lipid abnormality common among patients with ESRD. The patient with ESRD typically has an elevated triglyceride level with or without an increase in cholesterol. The lipid abnormality likely represents increased synthesis of very-low-density lipoprotein and decreased clearance as well as increased reliance on animal-based proteins.

Treatment of hyperlipidemia with diet or pharmacologic agents remains controversial. Epidemiologic evidence demonstrating increased incidence of atherosclerotic coronary disease is balanced by studies that demonstrate that patients with clearly defined clinical evidence of atherosclerosis at the initiation of dialysis are at no increased risk for a cardiovascular event. Although routine treatment appears unwarranted, a good case can be made for dietary and pharmacologic treatment of patients with ESRD with underlying lipid disorders and evidence of atherosclerosis. Lipid-lowering drugs, including most statins, may have a significant effect on better management (see Chapter 33).

On the other hand, low cholesterol levels can be a significant predictor of mortality in ESRD. They can indicate poor oral intake and may be a useful tool in diagnosing malnutrition. Use of lipid-lowering drugs should be monitored and cut back if necessary in these patients, particularly if they are underweight or suffering from malnutrition.

Iron and Erythropoietin

The anemia of chronic renal disease is caused by an inability of the kidney to produce **EPO**, the hormone that stimulates the bone marrow to produce red blood cells, an increased destruction of red blood cells secondary to circulating uremic waste products; and blood loss with dialysis or blood sampling. A synthetic form of EPO, **recombinant human EPO (rHuEPO)**, is used to treat this form of anemia. Clinical trials have demonstrated a dramatic improvement in correcting anemia and restoring a general sense of well being (Trkulja, 2012). Recent studies have indicated that higher dosages of EPO pose increased risk of stroke, adverse cardiac events, and death, so close monitoring and balancing the needs of the patient are essential in good management (Koulouridis et al, 2013).

Use of EPO increases red blood cell production 2.5-fold. Almost always accompanying the rise in hematocrit is an increased need for iron that requires IV supplementation. Oral iron alone is not effective in maintaining adequate iron stores in patients who take EPO. Unless a documented allergic reaction exists, almost all patients taking EPO require periodic IV or intramuscular iron. For patients who are allergic to IV iron, several better-tolerated forms are now available as iron dextran (Infed), iron gluconate (Ferrlecit), and iron sucrose (Venofer).

Serum ferritin is an accurate indicator of iron status in renal failure. Patients who have received several transfusions and who are storing extra iron may have high serum ferritin levels of 800 to 5000 ng/ml (a normal level is 68 ng/ml for women and 150 ng/ml for men; see Appendix 22). In patients who are receiving EPO, ferritin should be kept above 300 ng/ml but below 800 ng/ml. When ferritin values fall below 100 ng/ml, IV iron is usually given. The percent of transferrin saturation is another useful indicator of iron status in these patients and should be between 25% to 30%.

Vitamins

Water-soluble vitamins are rapidly lost during dialysis. In general, ascorbic acid and most B vitamins are lost through dialysate at approximately the same rate they would have been lost in the urine (depending on the type and duration of treatment), with the exception of folate, which is highly dialyzable. Patients who still produce urine may be at increased risk of loss of water-soluble vitamins. Folate is recommended to be supplemented at 1 mg/day based on extra losses. Because vitamin B₁₂ is protein-bound, losses of this B vitamin during dialysis are minimal. Altered metabolism and excretory function, as well as drug administration, also may affect vitamin levels. Little is known about GI absorption of vitamins in uremia, but it may be significantly decreased. Uremic toxins may interfere with the activity of some vitamins, such as inhibition of phosphorylation of pyridoxine and its analogs.

Another cause of decreased vitamin intake in uremia is the restriction of dietary phosphorus and potassium. Water-soluble vitamins are usually abundant in high-potassium foods such as citrus fruits, vegetables, and high-phosphorus foods such as milk. Diets for patients on dialysis tend to be low in folate, niacin, riboflavin, and vitamin B₆. With frequent episodes of anorexia or illness, vitamin intake is decreased further. Whereas levels of water-soluble vitamins decrease as a result of dialysis, replacement of fat-soluble vitamins usually is not required in renal disease.

Several vitamin supplements that fit the needs of the uremic patient or the dialysis patient are now available by prescription: Nephrocaps, Renavite, Dialyvite, Folbee Plus, and Renal Caps. An over-the-counter supplement containing the vitamin B complex and vitamin C often is used and can be less expensive than a prescription, but additional supplements of folic acid and pyridoxine may be needed.

Niacin has been found to be helpful in lowering phosphate levels in ESRD patients. It interferes with the sodium-phosphate pump in the GI lumen, causing decreased transport of phosphate, and thus works with a different mechanism than phosphate binders (Cheng et al, 2006, 2008). It has shown benefit in improving outcomes in patients that struggle with a serum phosphorus of more than 6.0 when used in conjunction with phosphate binders as a once-daily pill. Potential side effects such as GI bleeding, liver disease, and flushing must be carefully considered.

Nutrition Support in End-Stage Renal Disease

Enteral Tube Feeding

Patients with ESRD who require enteral tube feeding generally can use standard formulas used for most tube-fed patients (see Chapter 13) and do not require a “specialty” or renal formula. Formulas marketed as renal products are more calorie-dense, higher in protein and lower in specific nutrients such as potassium and phosphorus. If patients are receiving renal products only, they may develop problems with low phosphorus or potassium levels as these products are designed to be used in conjunction with oral intake.

Oral Protein Supplementation During Dialysis

Recent research has focused on use of oral protein supplements while a patient is receiving dialysis treatments. The theory is that muscle protein will be replaced, offsetting catabolism, which occurs during dialysis. This is thought to be similar to what an athlete might experience using a protein supplement immediately after exercise. Study results show possible links to reduction in mortality from use during dialysis treatments, but no improvement in serum albumin levels (Lacson et al, 2012).

Parenteral Nutrition

Parenteral nutrition (PN) in ESRD is similar to PN used for other malnourished patients with respect to protein, carbohydrates, and fat, but differs in use of vitamins and minerals. Most researchers agree that vitamin needs for ESRD during PN differ from normal requirements; however, they do not agree on recommendations for individual nutrients. Folate, pyridoxine, and biotin should be supplemented. Vitamin A should not be provided parenterally unless retinol-binding protein is monitored during each HD treatment because it is elevated in patients with ESRD. Because there is currently no parenteral vitamin that is specifically designed for patients with renal failure, a standard vitamin preparation usually is administered. Little information related to parenteral trace mineral supplementation is available. Because most trace minerals, including zinc, chromium, and magnesium, are excreted in the urine, a close monitoring of these minerals in the serum seems to be appropriate.

Intradialytic Parenteral Nutrition

Malnourished patients with chronic renal failure who are on HD have easy access to PN because of the direct blood access required by the dialysis therapy itself. **Intradialytic PN (IDPN)** can be administered if necessary without additional invasive procedures or need for a separate port. It is administered typically through a connection to the venous side of the extracorporeal circuit during dialysis. Because of the high blood flow rate achieved through use of the surgically created fistula and the high blood pump speeds that are attained, hypertonic glucose and protein can be administered without danger of phlebitis. Lipids also may be administered. Reimbursement issues are complex because IDPN is a supplemental feeding that requires the patient to have at least a functioning GI tract and only supplies an average of 700 - 1000 calories during each HD treatment, depending on composition, dose, and administration time.

Complications are similar to those encountered in usual PN, with the exception of postdialysis hypoglycemia caused by the abrupt ending of the glucose supply. To avoid this problem, administration of IDPN containing glucose is tapered down during the last half hour of the 3- to 5-hour treatment. Insulin can be given, and may be administered in the bag of the dextrose–amino acid solution so that the patient does not become hypoglycemic if the infusion must be stopped. Blood sugar levels typically are monitored during the therapy. Some patients may benefit from a complex carbohydrate snack toward the end of the treatment or afterwards to avoid posttreatment rebound hypoglycemia. Amino acid losses through the dialysate only average approximately 10%.

Another method of nutrition support in PD patients is called **intra-peritoneal nutrition (IPN)** using a peritoneal dialysate solution that contains amino acids instead of dextrose. Typically one bag of this solution is used per day. Some patients experience side effects from this treatment, which may include too much fluid removal. Reimbursement issues with this therapy are significant.

End-Stage Renal Disease in Patients with Diabetes

Because renal failure is a complication of diabetes, approximately 40% to 50% of all new patients starting dialysis have diabetes (MacIsaac et al, 2014). The need to control blood sugar in these patients requires specialized diet therapy. The diet for diabetes management (see Chapter 30) can be modified for the patient on dialysis. In addition, the diabetic patient on dialysis often has other complications such as retinopathy, neuropathy, gastroparesis, and amputation, all of which can place this

patient at high nutritional risk. The National Kidney Foundation (NKF) has established guidelines for managing diabetes in the presence of CKD at the Kidney Disease Outcome Quality Initiative at www.kdoqi.org (National Kidney Foundation, 2012).

Increased osmolality caused by high serum levels of glucose may cause water and potassium to be pulled out of cells, with resultant hyperkalemia. Interpretation of commonly used laboratory values will change when a diabetic patient develops renal failure. Hemoglobin A1C (Hgb A1C) measures the glycosylation of hemoglobin. The shortened half-life of red blood cells from uremia and the losses in the dialysis process cause Hgb A1C values to appear lower than they really are (Vos et al, 2012).

Chronic Kidney Disease and End-Stage Renal Disease in Children

Although CKD may occur in children at any age, from the newborn infant to the adolescent, it is a relatively uncommon diagnosis. Causal factors in children include congenital defects, anatomic defects (urologic malformations or dysplastic kidneys), inherited disease (autosomal-recessive polycystic kidney disease), metabolic disorders that eventually result in renal failure (cystinosis or methylmalonic aciduria), or acquired conditions or illnesses (untreated kidney infections, physical trauma to kidneys, exposure to nephrotoxic chemicals or medications, hemolytic anemia resulting from *E. coli* 0157 ingestion, or glomerular nephritis).

As with all children, the major concern is to promote normal growth and development. Without aggressive monitoring and encouragement, the child with renal failure rarely meets his or her nutritional requirements. If the renal disease is present from birth, nutrition support needs to begin immediately to avoid losing the growth potential of the first few months of life. Growth in children with CKD usually is delayed. Although no specific therapy ensures normal growth, factors capable of responding to therapy include metabolic acidosis, electrolyte depletion, osteodystrophy, chronic infection, and protein-calorie malnutrition. Energy and protein needs for children with chronic renal disease are at least equivalent to the DRIs for normal children of the same height and age. If nutrition status is poor, energy needs may be even higher to promote weight gain and linear growth.

Feeding by tube is required in the presence of poor intake, particularly in the critical growth period of the first 2 years of life. Gastrostomy tubes almost always are placed in these children to enhance nutritional intake and facilitate growth. PN rarely is initiated unless the GI tract is nonfunctional. For the nutritional requirements of children with renal failure see www.kdoqi.org (National Kidney Foundation, 2008).

Control of calcium and phosphorus balance is especially important for maintaining good growth. The goal is to restrict phosphorus intake while promoting calcium absorption with the aid of 1,25-(OH)₂D₃. This helps prevent renal osteodystrophy, which can cause severe growth retardation. Use of calcium carbonate formulations to supplement the dietary intake enhances calcium intake while binding excess phosphorus. Persistent metabolic acidosis is often associated with growth failure in infancy. In chronic acidosis the titration of acid by the bone causes calcium loss and contributes to bone demineralization. Bicarbonate may be added to the infant formula to counteract this effect.

Restriction of protein in pediatric diets is controversial. The so-called “protective” effect on kidney function must be weighed against the clearly negative effect of possible protein malnutrition on growth (Chaturvedi and Jones, 2007). The recommended dietary allowance for protein for age is usually the minimum amount given.

Each child’s diet should be adjusted to his or her food preferences, family eating patterns, and biochemical needs. This is often not an easy task. In addition, care must be taken not to place too much emphasis on the diet to avoid food becoming a manipulative tool and an attention-getting device. Special encouragement, creativity, and attention are required to help the child with CKD consume the necessary energy. When possible, PD is given intermittently during the day and continuously at night because it allows liberalization of the diet. The child is more likely to meet nutritional requirements with fewer dietary restrictions and therefore experience better growth. See www.kidney.org for further tips on pediatric renal nutrition support.

Other treatments that help renal disease in children include the use of rHuEPO and recombinant deoxyribonucleic acid–produced human growth hormone. EPO usually is started when the child’s serum hemoglobin falls below 10 g/dl, with a goal of maintaining hemoglobin between 11 and 12 g/dl. Correction of anemia with the use of rHuEPO may increase appetite, intake, and feeling of well-being, but it has not been found to affect growth, even with seemingly adequate nutrition support.

Medical Nutrition Therapy for Transplantation

The nutritional care of the adult patient who has received a transplanted kidney is based mainly on the metabolic effects of the required immunosuppressive therapy. Medications typically used for the long term include azathioprine (Imuran), corticosteroids (e.g., prednisone), calcineurin inhibitors (cyclosporine A, Gengraf, SangCya, Sandimmune, tacrolimus [Prograf, F506]), sirolimus (Rapamune), everolimus (Zortress), mycophenolate mofetil (CellCept), and mycophenolic acid (Myfortic). Corticosteroids are associated with accelerated protein catabolism, hyperlipidemia, sodium retention, weight gain, hyperglycemia, osteoporosis, and electrolyte disturbances. Calcineurin inhibitors are associated with hyperkalemia, hypertension, hyperglycemia, and hyperlipidemia. The doses of these medications used after transplantation are decreased over time until a “maintenance level” is reached.

During the first 6 weeks after surgery, a high-protein diet is often recommended (1.2 to 1.5 g/kg ideal body weight [IBW]) with an energy intake of 30 to 35 kcal/kg IBW, to prevent negative nitrogen balance. A moderate sodium restriction of 2 to 3 g/day during this period minimizes fluid retention and helps to control blood pressure. After recovery, protein intake should be decreased to 1 g/kg IBW, with calorie intake providing sufficient energy to maintain or achieve an appropriate weight for height. A balanced low-fat diet aids in lowering cardiac complications, whereas sodium intakes are individualized based on fluid retention and blood pressure (see Appendix 30).

Hyperkalemia warrants a temporary dietary potassium restriction. After transplantation, many patients exhibit hypophosphatemia and mild hypercalcemia caused by bone resorption; this is associated with persistent hyperparathyroidism and the effects of steroids on calcium, phosphorus, and vitamin D metabolism. The diet should contain adequate amounts of calcium and phosphorus (1200 mg of each daily) and cholecalciferol (vitamin D₃, 2000 IU daily). Supplemental phosphorus also may be necessary to correct hypophosphatemia.

Hydration must also be monitored closely after transplantation. Because most kidney recipients required a fluid restriction while on dialysis, they must be reminded of the importance of maintaining fluid intake after transplant. Typically, patients are encouraged to drink 2 L/day, but their overall needs depend on their urine output.

The majority of transplant recipients have elevated serum triglycerides or cholesterol for a variety of reasons. Intervention consists of medications, calorie restriction for those who are overweight, cholesterol intake limited to less than 300 mg/day, and limited total fat (see Chapter 33). In patients with glucose intolerance, limiting carbohydrates and a regular exercise regimen are appropriate. Tissue weight gain with resultant obesity is common after transplantation. Medication side effects, fewer dietary restrictions, and the lack of physical exercise can contribute to posttransplant weight gain.

Because of immunosuppression, care must be taken with food safety similar to other significantly at risk groups. Hand-washing, food temperature monitoring, and avoidance of uncooked foods remain appropriate infection control behaviors.

Referral to bariatric surgery is being seen in patients needing weight loss to qualify for a transplant. Much coordination and collaboration is needed between the bariatric RDN and the renal RDN to be sure that the patient's very specific diet needs are met based on their treatment modality and progression of kidney disease (see Chapter 21).

Counseling and Education of Patients with End-Stage Renal Disease

For effective intervention, it is important to look at the long-range goals for educating the patient with ESRD about his or her nutritional needs. The average patient survives on dialysis 7 to 10 years, the average mortality is approximately 20% per year, equal to that of serious cancers such as ovarian cancer. However, some patients with a relatively benign diagnosis may look forward to life spans of 20 to 40 years, particularly if they receive kidney transplants as a part of their treatment. The challenge for the dietitian is educating the patient with a chronic disease who will be primarily responsible for implementing nutritional recommendations for the rest of his or her life. Thus intervention for ESRD and that for diabetes share many similarities.

It is incumbent on the renal dietitian nutritionist to develop a long-standing rapport with the patient and his or her family, and to serve as an ally to help them make the best nutritional choices over an extended period. Understanding the burdens of a complex, challenging, ever-changing diet suggests the transfer of information to the renal patient and family in a workable, flexible, and easily understood manner. Skills for this task are just as challenging, if not more so, than maintaining a patient's iron status or keeping the patient at a good body weight. Empathy and use of techniques such as

motivational interviewing or cognitive behavioral therapy are essential tools (see Chapter 14).

Coordination of Care in End-Stage Renal Disease

The position of the RDN in the care of dialysis patients is unique because it is a federally mandated position. So, too, is the RDN's place on the mandated interdisciplinary health care team that exists within each dialysis unit. The team approach is an important aspect of all health care; however, its importance is magnified in the dialysis team, which consists of the patient, renal nurse, renal social worker, nephrologist, and renal dietitian nutritionist. Care of these complex, long-term ESRD patients requires the skill and compassion of each member of the health care team working together. Advanced levels of practice are available for dietitians who wish to be certified as renal RDNs; they can be certified through examination by the Academy of Nutrition and Dietetics, and become a Board Certified Specialist in Renal Nutrition.

Emergency Diets for Dialysis Patients

When power outages, flooding, storms, hurricanes, or earthquakes threaten a community, they threaten the most vulnerable people in that community. Patients on HD require power and water sources to do their own treatments at home. If they travel to a dialysis unit, they need access to transportation. Because of poor outcomes in recent natural disasters, the federal government's ESRD program has specified that patients and caregivers must be familiar with alternative nutritional therapies when dialysis is not available because of a natural or man-made emergency. [Box 35-2](#) demonstrates the type of nutrient and practical information that must be considered when patients may be without dialysis for days, or because they must be evacuated to a site that cannot meet their urgent nutritional needs.

Medical Management (Conservative Treatment) or Palliative Care

The decision to forego or discontinue dialysis and opt for end-of-life care is a difficult and emotional one. Factors such as religious practices, age, quality of life, and comorbid disease play a role. Patients who are poor candidates for dialysis or transplantation may benefit from a low-protein, low-sodium diet to minimize physical symptoms, such as shortness of breath and uremia. Palliative care can be offered with the goal of balancing patient wishes for food choice with these complex side effects ([Germain et al, 2011](#)).

BOX 35-2 Emergency Dialysis Diet Plan

This plan will work for short periods (5 days or less) when patients cannot dialyze.

The Emergency Diet Plan does not replace dialysis; it should be used only in case of an emergency.

Guidelines

1. Limit meat to 3-4 oz/day.
2. Avoid all high-potassium fruits and vegetables.
3. Consume only one to two 8-oz cups of fluid per day.
4. Choose low-salt foods.
5. Do not use salt or salt substitute.
6. Use fats and sugars for extra calories.
7. If the power is off for a day, foods in refrigerator should be eaten first.
8. Patients should eat food from the freezer while they still have ice crystals in the center.

9. Patients should have a portable Emergency Kit they can take with them to a disaster relief center. Sample foods are listed in the following diet plan.

Emergency Diet Plan

If a food is not on this list, dialysis patients should not eat it.

Meat and Protein Foods (three to four 1-oz choices/day)

- 1 egg
- 1 ounce meat, fish, tofu or poultry
- ¼ cup unsalted or rinsed canned fish or poultry
- 2 tablespoons unsalted peanut butter
- ¼ cup cottage cheese
- ½ can commercial liquid nutritional supplement

BOX 35-2 Emergency Dialysis Diet Plan—cont'd**Starch (six to ten choices/day)**

1 slice white bread
 ½ English muffin or bagel
 5 unsalted crackers
 2 graham crackers
 6 shortbread cookies, vanilla wafers
 1 cup unsalted rice, noodles, pasta
 1 cup puffed wheat, rice, shredded wheat
 1 cup of rice or pasta

Vegetables (one choice/day)

½-cup serving of green beans, summer squash, corn, beets, carrots, or peas
 Should be fresh or frozen, not canned

Fruits (three to four choices/day)

1 small apple
 15 grapes
 ½ cup serving of berries, cherries, applesauce, canned pears or canned pineapple

Fats and Oil (six or more choices/day)

1 tsp butter, margarine, oil or mayonnaise

Fluids (one to two choices/day)

1 cup water, coffee, tea, soda
 ½ cup Ensure Plus, Boost Plus or Nepro

½ cup serving of milk, half and half, soy, or rice milk
 Cranberry, apple, or grape juice; or Kool-Aid

Emergency Kit

Have the following things stored in a box or bag easily accessible:

Foods listed in the Emergency Diet Plan

Can opener

Two gallon jugs of distilled water

Bleach, 1 Tbsp/gallon of water to sterilize

Flashlight and extra batteries

Sharp knife

Aluminum foil

Plastic mixing containers and lids

Measuring cup

Fork, knife, spoon

Battery-operated transistor radio

One-week supply of personal medicines kept in a handy place, including blood pressure medications and phosphate binders (insulin and some other medications must be kept refrigerated or cold)

Storage Tips

1. Store things in a clean, dry place such as a new garbage can or rubber tub.
2. Label and date when food is put in storage.
3. Change all food and water once a year. Eat unused food or donate to a food bank.

Dialysis Emergency Diet information from Katy Wilkens, MS, RD. Copyright Northwest Kidney Centers, 2011. For more emergency diet info see www.nwkidney.org or your local Network Coordinating Council website.

CLINICAL CASE STUDY

Fred, a 67-year-old Caucasian man, is seen by his primary care physician. Fred lives with a significant other and has an active lifestyle (golfing, biking, swimming) and a history of hemicolectomy, diverticulitis, and hypertension. His weight is 240 lb. His laboratory values show serum creatinine of 3.3 mg/dl, BUN of 72 mg/dl, albumin of 4.1 mg/dL, potassium of 5.5 mEq/L, phosphate of 6.7 mg/dl, calcium of 8.3 mg/dl, and his parathyroid hormone is 365 pg/ml. Blood pressure is 160/92.

Nutrition Diagnostic Statement

Altered laboratory values related to hypertension as evidenced by estimated glomerular filtration rate (eGFR) calculation.

Nutrition Care Questions

1. What is Fred's calculated eGFR?
2. What is his stage of chronic kidney disease (CKD)?
3. What is the first goal for your education of Fred?
4. What dietary factors would you address based on Fred's laboratory values?
5. What is the goal for his protein intake?
6. How would you assess Fred for improvement or stability of his CKD?
7. What would you expect for him during the next few years if no diet intervention is followed?

Medical Nutrition Therapy for Cancer Prevention, Treatment, and Survivorship

*Kathryn K. Hamilton, MA, RDN, CSO, CDN, FAND
Barbara L. Grant, MS, RDN, CSO, LD, FAND*

KEY TERMS

antiangiogenic agents	graft-versus-host disease (GVHD)	palliate (palliative care)
antineoplastic therapy	hematopoietic cell transplantation (HCT)	pancytopenia
antioxidants	hematopoietic growth factors	phytochemicals
apoptosis	hormonal therapy	polycyclic aromatic hydrocarbons (PAHs)
benign	hospice	progression
biotherapy	initiation	promotion
bisphenol A (BPA)	insulin-like growth factor-1 (IGF-1)	radiation enteritis
cancer cachexia	integrative medicine	radiation therapy
carcinogen	malignant neoplasm	sinusoidal obstructive syndrome (SOS)
carcinogenesis	metastasis	tumor-node-metastasis (TNM) staging system
certified specialist in oncology nutrition (CSO)	mucositis	trismus
chemoprevention	myelosuppression	tumor
chemotherapy	neoplasm	tumor angiogenesis
complementary therapies	neutropenia	tumor necrosis factor- α (cachectin)
cytokines	nutrition impact symptoms	tumor suppressor genes
dumping syndrome	oncogenes	venoocclusive disease
emetogenic	oncology	
energy balance	osteoradionecrosis	

Cancer involves the abnormal division and reproduction of cells that can spread throughout the body. Usually thought of as a single disease, cancer actually consists of more than 100 distinct types. The American Cancer Society (ACS) predicts the lifetime risk for developing cancer in the United States is slightly less than half of men and a little more than one third of women (ACS, 2014a). Annually in the United States, cancer is responsible for almost one in four deaths (ACS, 2014a). It is estimated that one third of the more than 580,000 anticipated cancer deaths can be attributed to nutrition and lifestyle behaviors such as poor diet, physical inactivity, alcohol use, and overweight and obesity. Tobacco use also contributes significantly to death from cancer with more than 15 million lives lost since the Surgeon General released the warning in 1964. Today, nearly one in five deaths from cancer and other diseases in the United States are caused by tobacco use (ACS, 2014a). Tobacco use has been shown to reduce life expectancy, on average, by approximately 14 years and is responsible for the loss of millions of dollars in health care costs and early loss of life.

The cost of cancer care in the United States is estimated to be more than \$216.6 billion annually, \$86.6 billion for direct medical costs, and \$130 billion for loss of productivity resulting from premature death (ACS, 2014a) (see Figure 36-1).

The ACS established *2015 Challenge Goals* to improve cancer prevention and early detection efforts for lowering cancer incidence and mortality rates. These national recommendations outline specific measures to expand the use of established screening guidelines for the early detection of cancer and ways to influence individual health behaviors, such as protection from the sun, reducing tobacco use, maintaining a healthy body weight, improving diet, and increasing regular physical activity (ACS, 2013).

Overall, fewer Americans are dying from cancer, a trend that began more than 15 years ago. For many, cancer is now a chronic disease, like heart disease and diabetes. According to the American Cancer Society, there are 13.7 million American cancer survivors living with a history of cancer; this means they are cancer free, are living with evidence of disease, or are undergoing cancer treatment (ACS, 2014a). As a result of progress in early detection of cancer and the development of new anticancer therapies, survivorship for all cancers is now 67%, up from 47% in the 1970s (ACS, 2014a). The Annual Report to the Nation on the Status of Cancer, 1975-2010, released in December 2013, found rates of new diagnoses and rates of death from the major cancers continue to decline for men and women, as well as for the major racial and ethnic populations (Edwards et al,

Estimated New Cases

			Males	Females			
Prostate	220,800	20%			Breast	231,840	29%
Lung & bronchus	115,610	14%			Lung & bronchus	105,590	13%
Colon & rectum	69,090	8%			Colon & rectum	63,610	8%
Urinary bladder	56,320	7%			Uterine corpus	54,870	7%
Melanoma of the skin	42,670	5%			Thyroid	47,230	6%
Non-Hodgkin lymphoma	39,850	5%			Non-Hodgkin lymphoma	32,000	4%
Kidney & renal pelvis	38,270	5%			Melanoma of the skin	31,200	4%

Kidney & renal pelvis	9,070	3%			Brain & other nervous system	6,380	2%
All Sites	312,150	100%			All Sites	277,280	100%

FIGURE 36-1 New cases of cancer. (Printed with permission of the American Cancer Society, Cancer Facts & Figures 2015.)

2014). Although cancer rates continue to be higher for men than for women, combined rates of death from cancer decreased by 1.5% per year from 2001 through 2010; overall incidence rates decreased in men and stabilized in women (Edwards et al, 2014).

PATHOPHYSIOLOGY

Carcinogenesis is the origin or development of cancer. **Oncology** is the study of all forms of cancer. Researchers believe changes in gene function cause normal cells to transform into cancerous cells. Thus the study of genetic material and its function, genomics, is of great scientific interest in cancer and its treatment (see Chapter 5 and *Pathophysiology and Care Management Algorithm: Cancer*).

Oncogenes are altered genes that promote tumor growth and change programmed cell death (**apoptosis**). The inhibition of cell death pathways allows for survival of the genetically damaged cancer cells. **Tumor suppressor genes** are the opposite of oncogenes; these genes become deactivated in cancer cells. This loss in function can lead to unregulated cell growth and, ultimately, cancer. Examples of tumor suppressor

genes include adenomatous polyposis coli (APC), breast cancer types BRCA1 and BCRA, and tumor suppressor p53, a protein that is involved in preventing cancer. Only approximately 5% to 10% of all cancers occur as result of inherited genetic alterations (ACS, 2014b). Factors observed in families with hereditary cancers include the following:

- Many cases of an uncommon or rare type of cancer
- A cancer diagnosis at an earlier age than normal for certain kinds of cancer
- Individuals with one type of cancer being diagnosed with a second type of cancer
- More than one childhood cancer diagnosed in a set of siblings
- Certain types of cancers observed in specific ethnic populations (e.g., individuals of Ashkenazi Jewish ancestry with breast and ovarian cancer)
- Recognized cancer syndromes, such as hereditary nonpolyposis colorectal cancer or Lynch syndrome, which cause individuals to be at greater risk for developing gastrointestinal (GI), ovarian, uterine, brain, or skin cancer (NIH)

Genetic counselors assist individuals and their families to evaluate their risk of hereditary predisposition, such as testing positive for gene mutations.

Phases of Carcinogenesis

A **carcinogen** is a physical, chemical, or viral agent that induces cancer. Carcinogenesis is a biologic, multistage process that proceeds on a continuum in three distinct phases: initiation, promotion, and progression. **Initiation** involves transformation of cells produced by the interaction of chemicals, radiation, or viruses with cellular deoxyribonucleic acid (DNA). This transformation occurs rapidly, but cells can remain dormant for a variable period until they are activated by a promoting agent. After the initial cellular damage has occurred, transformation from normal cells to a detectable cancer can take many years or even decades. During **promotion**, initiated cells multiply and escape the mechanisms set in place to protect the body from the growth and spread of such cells. A **neoplasm**, new and abnormal tissue with no useful function, is established. In the third phase, **progression**, tumor cells aggregate and grow into a fully **malignant neoplasm** or a **tumor**.

In the process known as **metastasis**, the neoplasm has the capacity for invasion that can spread to distant tissues and organs. For a cancer to metastasize, it must develop its own blood supply to sustain its growth of rapidly dividing abnormal cells. In normal cells, angiogenesis promotes the formation of new blood vessels, which are essential to supply the body's tissues with oxygen and nutrients. In cancer cells, **tumor angiogenesis** occurs when tumors release substances that aid in the development of new blood vessels needed for their growth and metastasis.

NUTRITION AND CARCINOGENESIS

Nutrition may modify the carcinogenic process at any stage, including carcinogen metabolism, cellular and host defense, cell differentiation, and tumor growth. Gene expression can be promoted or altered by nutrients during pregnancy, childhood, and throughout the lifecycle. Estimates produced by the World Cancer Research Fund indicate a quarter to a third of all of the cancers that occur in higher-income countries such as the United States are due to poor nutrition, physical inactivity, and excess weight (ACS, 2014a). The strong influence of diet and nutrients is seen readily in studies of migration between cultures. Patterns of cancer occurrence often change over time to resemble those of the new country. For example, in Japan mortality from breast and colon cancer is low and mortality from stomach cancer is high; the reverse is true among Japanese individuals living in the United States. After two or three generations, the cancer patterns in individuals become similar to those in the population in the new location.

Studies looking at the role of nutrition and diet as causal factors of cancer seek to identify relationships between the diets of population groups and categories of individuals and the incidence of specific cancers (Thomson et al, 2014). Sets of individuals are compared in case control, cohort, or cross-sectional studies. The strongest evidence comes from consistent findings of these different types of epidemiologic studies in diverse populations. In cancer research, epidemiologists look at human populations and evaluate how many people are diagnosed with cancer, what types of cancer occur in different populations and cultures, and what factors, such as diet and lifestyle, play a role in the development of the cancers.

The sheer complexity of diverse diet patterns presents a difficult challenge for study. Thousands of chemicals are found in a normal diet; some compounds are well studied and some less known and unmeasured. Some dietary carcinogens are naturally

occurring pesticides or herbicides produced by plants for protection against fungi, insects, animal predators, or mycotoxins, which are secondary metabolites produced by molds present in foods (e.g., aflatoxins, fumonisins, or ochratoxin). Food preparation and preservation methods also may contribute to dietary carcinogen ingestion. Fortunately, diets contain both inhibitors, as well as enhancers of carcinogenesis. Dietary carcinogen inhibitors include **antioxidants** (e.g., vitamin C, vitamin A and the carotenoids, vitamin E, selenium, zinc) and **phytochemicals** (biologically active components of plants) (see Table 36-1).

Examples of dietary enhancers of carcinogenesis may be the saturated fat in red meat or the polycyclic aromatic hydrocarbons (PAHs) that form on the surface of meat when grilling at high temperatures. Complicating the study of nutrition, diet, and cancer is the fact that an alteration of one major component of the diet can precipitate a change in other facets of the diet. For example, decreasing animal protein also decreases animal fat. This cascade event makes the interpretation of research findings difficult because the effects cannot be associated clearly with one single factor.

Additional complications in interpretation can result from the fact that cancer cells can either be fast growing or have a long latent or dormant period. The slow-growing, latent, or dormant aspect of the disease progression makes pinpointing dietary patterns at the time of cancer cell initiation or promotion, and not at time of diagnosis, difficult. Select prospective epidemiologic studies attempt to deal with this challenge by measuring diet at one point in time and following the same subjects for several years. Studies done with laboratory animals test this effect, and since the early part of the last century, laboratory scientists have shown that various nutritional manipulations influence the development of cancerous tissue in animals. Epidemiologic research, together with animal studies, provides a viable method for discovering the links between nutrition and cancer in humans.

Alcohol

Alcohol consumption accounted for 3.5% of cancer-related deaths in 2009, representing more than 19,000 deaths and 18 years of potential life lost (Voelker, 2013). It is associated with increased cancer risk for cancers of the mouth, pharynx, larynx, esophagus,

TABLE 36-1 Phytochemicals in Vegetables and Fruits that may have Cancer Protective Properties

Color	Phytochemical	Vegetables and Fruits
Red	Lycopene	Tomatoes and tomato products, pink grapefruit, watermelon
Red and purple	Anthocyanins, polyphenols	Berries, grapes, red wine, plums
Orange	Alpha- and beta-carotene	Carrots, mangos, pumpkin
Orange and yellow	Cryptoxanthin, flavonoids	French cantaloupe, peaches, oranges, papaya, nectarines
Yellow and green	Lutein, zeaxanthin	Spinach, avocado, honeydew, collard and turnip greens, asparagus
Green	Sulforaphanes, indoles	Cabbage, broccoli, Brussels sprouts, cauliflower
White and green	Allyl sulfides	Leeks, onion, garlic, chives

lung, colon, rectum, liver, and breast (pre- and postmenopausal women). For cancers of the mouth, pharynx, larynx, and esophagus, daily consumption of 1½ to 3 drinks increases risk significantly compared with nondrinkers (Voelker, 2013; WCRF and AICR, 2007).

Alcohol can also negatively affect health for cancer survivors. Although the research is inconsistent, alcohol consumption after breast cancer diagnosis has been shown in select studies to increase recurrence risk, especially among postmenopausal and overweight or obese women (Kwan et al, 2010; Rock et al, 2012). However, a clear association has been documented between continued alcohol consumption after treatment for head and neck cancers and its negative impact on survival (Rock et al, 2012). In the United States, alcohol results in 10 times as many deaths as it prevents, after the consideration of possible benefit from low-level consumption on cardiovascular and diabetes risk (Voelker, 2013).

Concurrent tobacco and alcohol use greatly increases cancer risk, particularly for cancers of the upper digestive area and respiratory tract (AICR C.U.P., 2015; WCRF and AICR, 2007). In addition, malnutrition associated with alcoholism is likely to be important in the increased risk for certain cancers. In the United States, if individuals choose to drink, men are recommended to limit alcohol intake to no more than two drinks per day and women to one drink per day. Serving sizes of popular alcoholic drinks include beer (12 oz), wine (5 oz), and liquors (1.5 oz of 80-proof liquors) (Kushi et al, 2012; WCRF and AICR, 2007).

Energy Intake and Body Weight

Obesity is a risk factor for cancer and may account for 14% to 20% of all cancer-related mortality (Kushi et al, 2012). Currently 69.2% of all American adults are overweight or obese (CDC, 2013). The relationship between body weight, body mass index (BMI), or relative body weight and site-specific cancer has been widely investigated; a positive association has been seen with cancers of the esophagus, pancreas, gallbladder, breast (postmenopausal), endometrium, kidney, colon, and rectum (Bender et al, 2013; WCRF and AICR, 2007). Metabolic operations (bariatric surgeries) seem to have a significant impact on cancer incidence and mortality, particularly with female obesity-related cancers (see Chapter 21). Researchers speculate the underlying mechanisms are weight dependent and weight independent with beneficial effects from dramatic weight loss, including improved insulin resistance, decreased oxidative stress and inflammation, modulation of sex steroids, gut hormones, cellular energetics, immune system, and adipokines (Ashrafian et al, 2011).

The optimal adult BMI should be between 21 and 23, depending on the normal range with different populations (WCRF and AICR, 2007). Body weight throughout childhood should be at the lower end of normal BMI, because excessive weight in adolescence has been correlated with increased risk of cancer development in adulthood (Kelsey et al, 2014).

Obesity, age, hyperglycemia, and the incidence of metabolic syndrome play a role in the circulating levels of **insulin-like growth factor-1 (IGF-1)**, a potentially cancer-causing compound. IGF-1 is a polypeptide secreted primarily by the liver and plays a key role in normal growth and development. It can promote the development and progression of prostate, breast, lung, and colon cancer. It has been hypothesized to stimulate the growth of cancer cells and inhibit their death (Pollack, 2008; Zhou et al, 2007). IGF-1 secretion is increased when insulin levels are elevated. Obesity and high simple carbohydrate intakes

TABLE 36-2 American Cancer Society: Moderate and Vigorous Physical Activity

	Moderate Activities*	Vigorous Activities†
Exercise and leisure	Walking, dancing, leisurely bicycling, ice and roller skating, horseback riding, canoeing, yoga	Jogging or running, fast bicycling, circuit weight training, aerobic dance, martial arts, jumping rope, swimming
Sports	Volleyball, golfing, softball, baseball, badminton, doubles tennis, downhill skiing	Soccer, field or ice hockey, lacrosse, singles tennis, racquetball, basketball, cross-country skiing
Home activities	Mowing the lawn, general yard and garden maintenance	Digging, carrying and hauling, masonry, carpentry
Workplace activity	Walking and lifting as part of the job (custodial work, farming, auto or machine repair)	Heavy manual labor (forestry, construction, fire fighting)

potentially increase insulin resistance and raise circulating insulin levels. This area of research connects several known risk factors between nutrition, diet, and cancer (Parekh et al, 2010).

Overweight and obese cancer survivors are at risk for recurrence and for developing additional problems after surgery, including impaired wound healing, lymphedema after lymph node dissections, second cancers, heart disease, and diabetes mellitus (Ligibel et al, 2014).

Physical activity is a critical component of weight management and energy balance. The ACS Nutrition and Physical Activity Guidelines for Cancer Prevention and the Guidelines for Cancer Survivors encourage individuals to strive for a minimum of 150 minutes per week of moderate activity or a minimum of 75 minutes per week of vigorous activity (Kushi et al, 2012; Rock et al, 2012) (see Table 36-2).

Achieving and maintaining **energy balance** and a reasonable weight should be a primary health goal for all individuals, including cancer survivors, because being overweight or obese appears to increase risk of developing cancer, cancer recurrence, and decreased survival (Kushi et al, 2012; Rock et al, 2012) (see the **New Directions** box **Does Eating Less Reduce the Risk for Cancer?**).

NEW DIRECTIONS

Does Eating Less Reduce the Risk for Cancer?

Animal studies have demonstrated that chronic restriction of food inhibits the growth of most experimentally induced cancers and the occurrence of many spontaneous cancers. This effect is observed even when underfed animals ingested more dietary fat than control animals ingested. Caloric restriction, without malnutrition, appears to have a positive effect on cancer prevention in animals; it is unclear whether that effect translates to humans (Longo and Fontana, 2010).

Fat

Dietary fat has been studied in relationship to cancer risk and recurrence, and right now there appears to be an inconsistent link between certain types of cancer and the amount of fat in the diet. Of note, diets that contain a significant amount of fat often contain more meat and more calories, which can contribute to overweight and obese conditions and increased cancer risk.

To further complicate the picture, an additional link between fat, meat, and cancer risk results from meat preparation and processing, such as the presence of heterocyclic amines (HCAs) and or polycyclic aromatic hydrocarbons (PAHs) from cooking, formation of carcinogenic N-nitroso compounds (NOCs) from processing, and the potential cancer-promoting influence of heme-iron (WCRF and AICR, 2007).

Because dietary fat intake is correlated with the intake of other nutrients and dietary components, it is difficult to distinguish between the effects of dietary fat, protein, total calories, and carcinogenic compounds in cancer prevention. So, the current ACS recommendation is to limit consumption of processed meats and red meats (Kushi et al, 2012).

Two large prospective randomized studies examined dietary fat consumption as part of the diet composition, and breast cancer recurrence showed mixed results. The Women's Intervention Nutrition Study (WINS) found that interventions that reduced dietary fat intake to 20% of total calories and precipitated a modest reduction in body weight may favorably influence breast cancer prognosis. However, the Women's Healthy Eating and Living (WHEL) study, which included significant amounts of vegetables, fruit, and dietary fiber and was low in fat, demonstrated no significant survival benefit (Pierce et al, 2007).

What does seem to be important is eating more omega-3 fatty acids (foods such as fatty fish, flaxseed oil, walnuts, and certain algae) in relation to omega-6 fatty acids (polyunsaturated fats such as, safflower oil and sunflower oil) because this potentially reduces risk of cancer by acting to decrease inflammation, cell proliferation, and angiogenesis while increasing apoptosis (Bender et al, 2013).

A Plant-Based Diet

Plant foods may aid in cancer prevention by functioning as cancer inhibitors through antiinflammatory mechanisms and changes in gene expression and hormone activity (Bender et al, 2013). Fruits, vegetables, and whole grains contain biologically active phytochemicals, vitamins, minerals, and dietary fiber that have demonstrated functions in preventing and treating disease (see Table 36-3). In addition, the ACS Prevention Guidelines suggest that individuals who eat more vegetables and fruits further benefit by experiencing less weight gain, and greater satiety and are at a lower risk of developing obesity, thereby reducing overall cancer risk (Kushi et al, 2012).

Nonnutritive and Nutritive Sweeteners

The Food and Drug Administration (FDA) has approved eight nonnutritive sweeteners (acesulfame-K, aspartame, Luo Han Guo fruit extract, neotame, saccharin, stevia, advantame, and sucralose) for use in the food supply and regulates them as food additives; they are generally recognized to be safe (GRAS) when used in moderation (www.fda.gov). Described as "high-intensity" sweeteners, nonnutritive sweeteners provide little or no energy because they sweeten in minute amounts. Nonnutritive sweeteners have been investigated primarily in relation to potential adverse health concerns, including long-term safety and carcinogenicity, but multiple studies during the past 20 or more years have indicated that

TABLE 36-3 Diet and Cancer-Site Risk Reduction

Nutrition and Dietary Factors	Cancer-Risk Correlation
Obesity	Esophagus Colorectum Pancreas Stomach Breast (postmenopausal) Endometrium

when consumed in reasonable amounts, they are safe. Additional sugar substitutes on the market include sugar alcohols (e.g., mannitol, sorbitol, xylitol) and blue agave. Sugar alcohols are not considered nonnutritive sweeteners even though they are used in a similar way. Blue agave is the juice from the *Agave tequiliana* plant and has no proven health benefits over sugar.

Protein

Most diets that contain significant amounts of protein also contain significant amounts of meat and fat and insignificant amounts of fiber. The effect of protein on carcinogenesis depends on the tissue of origin and the type of tumor as well as the type of protein and the calorie content of the diet. In general, tumor development is suppressed by diets that contain levels of protein below that required for optimal growth and development; whereas it is enhanced by protein levels two to three times the amount that is required. The effects may be attributable to specific amino acids, a general effect of protein, or, in the case of low-protein diets, depressed food intake. Epidemiologic studies have found limited and conflicting results. Recommendations for lowering cancer risk and improving overall health encourage intake of plant foods and limiting foods from animal sources, including red meat and processed meats and poultry (WCRF and AICR, 2007).

Smoked, Grilled, and Preserved Foods

Nitrates are added as preservatives to processed meats. Nitrates can be readily reduced to form nitrites, which in turn can interact with dietary substrates such as amines and amides to produce

N-nitroso compounds (NOCs): nitrosamines and nitrosamides, which are known mutagens and carcinogens. Nitrates or nitrites are used in smoked, salted, and pickled foods. Sodium and potassium nitrates are present in a variety of foods and give hot dogs and processed deli meats their pink color, but the main dietary sources are vegetables and drinking water.

NOCs are also produced endogenously in the stomach and colon of people who eat large amounts of red meat. Studies looking at the detrimental effects of smoked foods have not demonstrated a clear, consistent connection between these foods and stomach cancer (WCRF and AICR, 2007). Diets with high amounts of fruits and vegetables that contain vitamin C and phytochemicals that can retard the conversion of nitrites to NOCs should be encouraged (Kushi et al, 2012).

Charring or cooking meat at high temperatures over an open flame (400° F or more) can cause the formation of **polycyclic aromatic hydrocarbons (PAHs)** and heterocyclic amines (HCAs). PAHs have shown clear indications of mutagenicity and carcinogenicity. Normal roasting or frying food does not produce large amounts of PAHs compared with the amount produced when cooking over open flames. Animal proteins that produce the greatest dripping of fat on to the flames register the highest PAH formation. For example, grilled beef produces larger amounts of PAHs than grilled chicken, which produces higher amounts than oven-grilled chicken. The source of the flame can also influence PAH production; charcoal grilling promotes the most, followed by flame gas, and finally oven grilling (Farhadian et al, 2010).

Toxic Environments

The Environmental Protection Agency (EPA) was established in 1970 for the purpose of overseeing the acute and long-term health threats caused by substances in the environment. As part of this protection, the Toxic Substances Control Act passed in 1976 requires manufacturers to submit health and safety information on all new chemicals. However, many were grandfathered in with the passage of this law and are still untested. To date, 54 compounds have been identified by the National Institute of Health as carcinogenic (NIH, NIEHS, 2003).

Everyday activities expose people to a myriad of chemicals through air, water, food, and beverages. In fact, an estimated six percent of cancers diagnosed each year (2% from environmental exposures and 4% from occupational exposures) are likely caused by these very common exposures (Israel, 2010; NIH, NIEHS, 2003). Health care practitioners grapple with assessing exposure to so many different agents. A good environmental history can be performed at clinical visits and then quickly reviewed for outdoor air pollutants such as nitrogen dioxide, ozone, and carbon monoxide, which pose health risks. Exposure to heavy metals, pesticides, herbicides, and occupational exposures also may be noted. In addition to determining the patient's environmental exposure, practitioners must determine exposure of family members or others living in the same household. Oxidative stress caused by these environmental exposures can be alleviated by changes in lifestyle, including eliminating smoking and implementing dietary changes. Routine consumption of antioxidant-rich foods and a nutrient-rich diet (not supplementation) is suggested (Kushi et al, 2012).

Toxicity from Bisphenol A (BPA)

Bisphenol A (BPA) is an industrial chemical used since the 1960s in the manufacturing of many hard plastic bottles and the epoxy linings of metal-based food and beverage cans. It is also an ingredient in the production of epoxy resin used in

BOX 36-1 Tips from FDA to Minimize Exposure to BPA

- Check plastic container recycle codes on the bottom of container. Some, but not all, plastics that are marked with recycle codes 3 or 7 may be made with BPA.
- Avoid putting very hot or boiling liquids in plastic containers made with BPA. BPA levels rise in food when containers and products made with the chemical are heated and come in contact with the food.
- Do not use bottles with scratches, because these may harbor bacteria and, if the bottles are BPA-containing, the damage may lead to greater release of the BPA into the liquid.

FDA, 2014.

paints and adhesives. Studies done when the product was developed indicated it was safe to use in food and beverage containers. However, recent studies have demonstrated that BPA may disrupt the function of some hormones, including sex hormones, leptin, insulin, and thyroxin and it causes hepatotoxic, immunologic, and carcinogenic effects (Michalowicz, 2014).

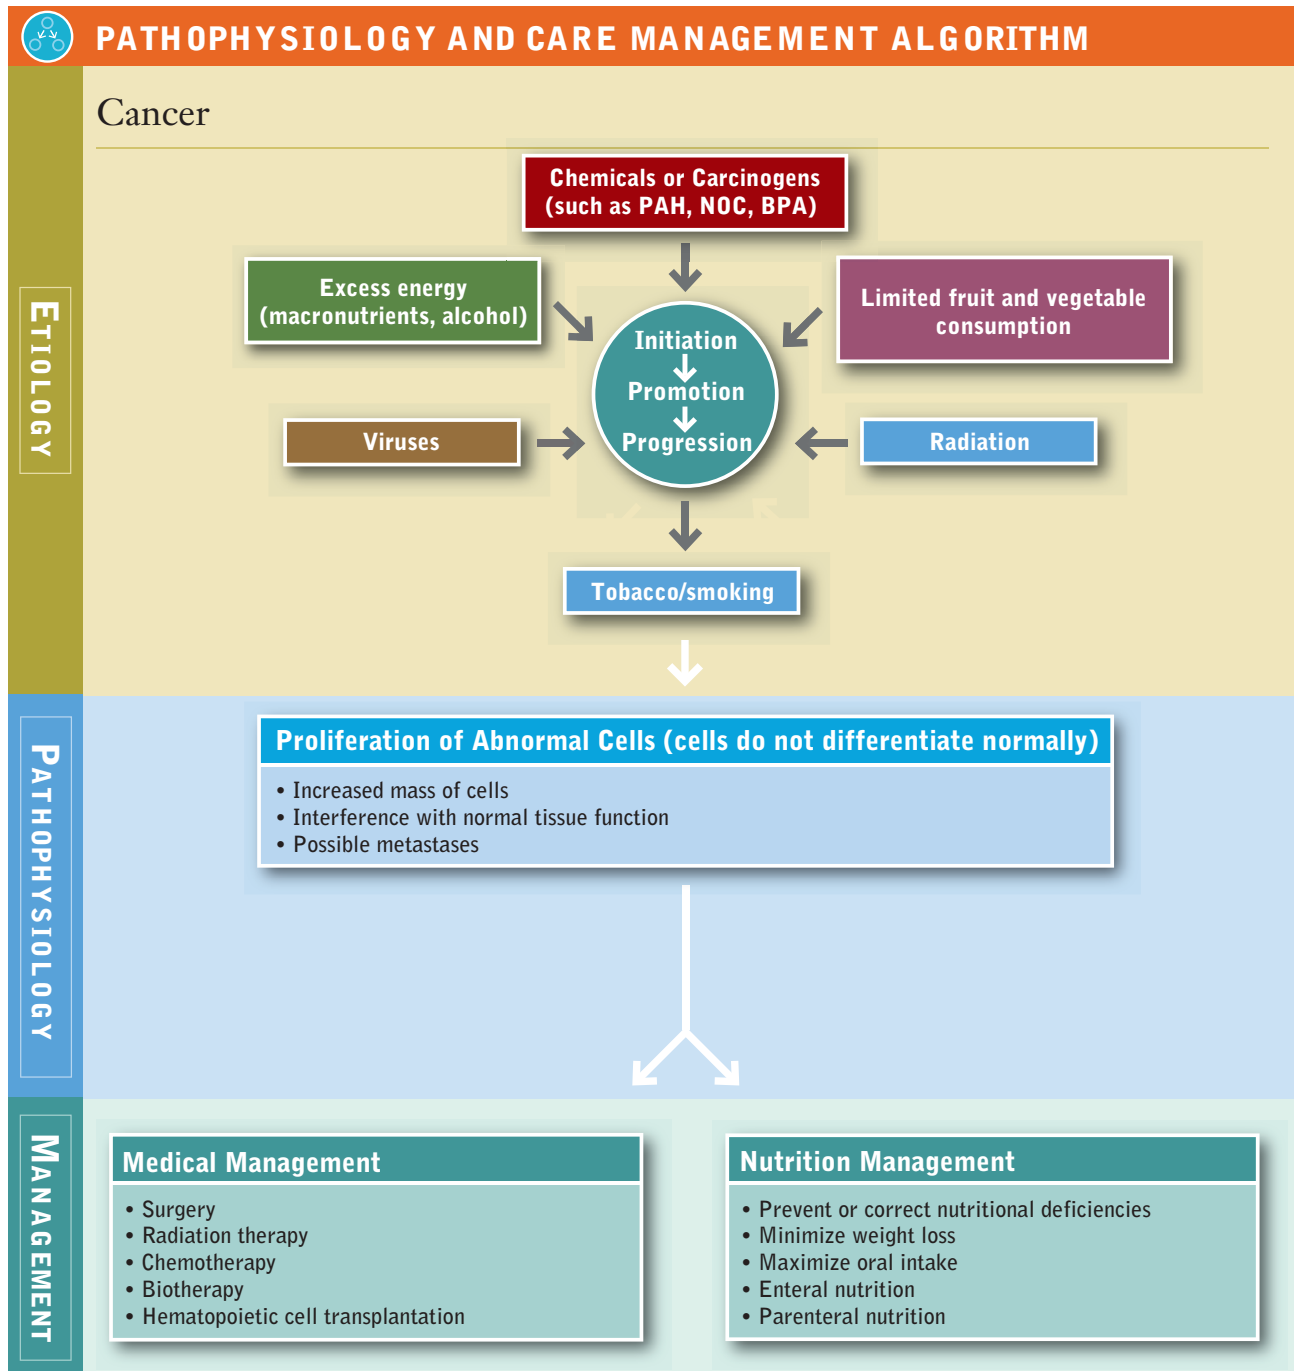

Other findings from the combined efforts of the National Institute of Environmental Health Sciences, the National Toxicology Program, and FDA scientists at the National Center for Toxicological Research Program conclude that the health threat from BPA is less than previously estimated. Health damage from BPA may not be as likely because based on mathematical models, BPA rapidly metabolizes in the body, rather than accumulating (FDA, 2014).

Until more is known, the current goal is to reduce the use and exposure to BPA through several actions: restricting the use of BPA in baby bottles, using alternatives to the glue used in food containers, and increasing the oversight on the use of BPA in manufacturing and testing. The U.S. Department of Health and Human Services (USDHHS) supports eliminating it from all food-related product production. Originally it was thought to leach from the plastic only when exposed to heat; now it is believed to leach even at cold temperatures (FDA, 2014) (see Box 36-1).

CHEMOPREVENTION

Eating behaviors play a very important role in health promotion and disease prevention. **Chemoprevention** is defined as the use of drugs, vitamins, or other agents to reduce the risk of, or delay the development or recurrence of, cancer (NIH, NCI, 2015). Examples include nonsteroidal antiinflammatory drugs that may protect against colon cancer, and metformin, a commonly used medication to treat diabetes; these are currently being explored as cancer prevention and treatment agents (Guppy et al, 2011; Quinn et al, 2013). Other natural products or molecules currently being investigated include the hundreds of polyphenols in fruits and vegetables, green tea, curcumin (turmeric and curry), and resveratrol from red grapes and berries. Phenolic acid, flavonoids, stilbenes, and lignans are the most abundant polyphenols; the chemopreventive potential of these compounds comes from their ability to modulate epigenetic alterations in cancer cells (Choi and Friso, 2010).

The epigenetic modification step occurs early in the development of a cancer cell, at a time when it is potentially reversible. Scientists do not fully understand how this process works, yet it is reasonable to recommend a health-promoting and possibly cancer-preventing diet rich in fruits, vegetables, soy, therapeutic culinary herbs such as turmeric and cinnamon, green tea, and coffee (Link et al, 2010). The overall evidence of association between these and other dietary factors

enable health organizations to draft diet and lifestyle recommendations for the purpose of reducing cancer risk (see the American Cancer Society website (www.cancer.org) and Box 36-2).

Vitamin D and Calcium

Studies have reported an association of poor vitamin D status and greater incidence of cancer. For years, public health messages have encouraged use of sunscreens and less direct exposure to the sun. Because of these recommendations, there is reduced conversion of vitamin D on the skin surface, leading to the potential increase in deficiencies. Studies have reported that higher serum 25-hydroxyvitamin D (25[OH]D) levels are associated with lower incidence of some cancers, while some

studies report a higher risk for other cancers with high levels of vitamin D. More work must be done in this area to determine if supplementation with vitamin D can prevent cancer, or if low levels of the vitamin simply increases an individual's cancer risk (ACS, 2013b). Until more is learned about the interaction between vitamin D₃ and cancer prevention, taking 800 IU of vitamin D per day to maintain normal serum 25(OH)D levels is considered safe (ACS, 2013b). Individuals with abnormal serum levels should consult their medical team for supplement suggestions, monitoring, and evaluation. Correcting a deficiency in vitamin D may be important for its health promotion benefits as well as its effect on calcium absorption, as calcium supplementation and dairy, especially milk, may be associated with lower colorectal cancer risk (Kushi et al, 2012).

BOX 36-2 Cancer Prevention Recommendations**American Cancer Society**

- Adopt a physically active lifestyle. Adults should engage in at least 150 minutes of moderate intensity or 75 minutes of vigorous intensity activity each week, or an equivalent combination, preferably spread throughout the week.
- Achieve and maintain a healthy body weight throughout life. Be as lean as possible throughout life without being underweight. Avoid excess weight gain at all ages.
- Consume a healthy diet, with an emphasis on plant sources. Choose foods and beverages in amounts that help achieve and maintain a healthy weight. Limit consumption of processed meat and red meat. Eat at least 2½ cups of vegetables and fruits each day. Choose whole grains instead of refined grain products.
- If you drink alcoholic beverages, limit consumption. Drink no more than one drink per day for women or two per day for men.

American Institute for Cancer Research

- Body Fatness: Be as lean as possible within the normal range of body weight.
- Physical Activity: Be physically active as part of everyday life.
- Foods and Drinks That Promote Weight Gain: Limit consumption of energy-dense foods. Avoid sugary drinks.
- Plant Foods: Eat foods mostly of plant origin.
- Animal Foods: Limit intake of red meat and avoid processed meat.
- Alcoholic Beverages: Limit alcoholic beverages.
- Preservation, Processing, Preparation: Limit consumption of salt. Avoid moldy cereals (grains) or pulses (legumes).
- Dietary Supplements: Aim to meet nutritional needs through diet alone.
- Breastfeeding: Mothers to breastfeed; children to be breastfed.
- Cancer Survivors: Follow the same recommendations.

Data from Kushi LH et al: American Cancer Society guidelines on nutrition and physical activity for cancer prevention: reducing the risk of cancer with healthy food choices and physical activity, *CA Cancer J Clin* 62:30, 2012; World Cancer Research Fund (WCRF), American Institute for Cancer Research (AIRC): Food, nutrition, physical activity, and the prevention of cancer: a global perspective, Washington, DC, 2007, WCRF and AIRC.

Coffee and Tea

Coffee contains various antioxidant and phenolic compounds, some of which have been shown to have anticancer properties. Coffee also contains caffeine, a compound in the alkaloid phytochemical family. Coffee as a major source of antioxidants in the American diet may offer its drinkers a protective effect against cancer (NIH, NCI, 2010).

Tea is also a good source of phenols and antioxidants. Green tea is made from leaves that have been cooked, pressed, dried and not roasted. Because of this, green tea, more so than black tea, contains catechins that possess biologic activity with antioxidant, anti-angiogenesis, and antiproliferative properties that are relevant to cancer prevention (NIH, NCI, 2010).

Folate and Folic Acid

Folate, from foods, affects DNA methylation, synthesis, and repair. Folate-associated one-carbon metabolism may play an important role in colorectal carcinogenesis because of gene variations (Levine et al, 2010; see Chapter 5). Several epidemiologic studies suggest that higher folate intake is associated with decreased pancreatic and colon cancer risk (ACS, 2011; Oaks et al, 2010). However, excessive folate may contribute to deleterious effects in certain cancers (Bailey et al, 2010; MNT, 2014). More research is needed to evaluate variables such as genetic polymorphisms and folate from food versus folic acid from supplements.

Fruits and Vegetables

Fruit intake is protective against cancers of the mouth, pharynx, larynx, esophagus, cervix, lung, and stomach (WCRF, AICR, 2007). Health benefits from vegetables are more difficult to quantify. Nonstarchy vegetables, such as spinach, tomatoes, and peppers, probably provide protection against mouth, pharynx, larynx, and esophageal cancers; all vegetables, but particularly green and yellow ones, probably protect against stomach cancer (WCRF, AICR, 2007). Most countries have recommendations for the consumption of vegetables and fruits that vary but generally are for three or more servings of vegetables and two or more servings of fruit daily with a serving being approximately 80 g or ½ cup (Norat, 2014).

Anticarcinogenic agents found in fruits and vegetables include antioxidants such as vitamins C and E, selenium, and phytochemicals. Phytochemicals include carotenoids, flavonoids, isoflavones, lignans, organosulfides, phenolic compounds, and monoterpenes. It is still unclear which specific substances of fruits and vegetables are the most protective against cancer (Kushi et al, 2012). These substances have complementary and overlapping mechanisms, including the induction of detoxification enzymes, inhibition of nitrosamine formation, provision of substrate for formation of chemotherapy agents, dilution and binding of carcinogens in the digestive tract, alteration of hormone metabolism, and antioxidant effects. It appears extremely unlikely that any one substance is responsible for all of the observed associations. See Table 36-1 for a discussion of chemoprotective agents in fruits and vegetables.

Soy and Phytoestrogens

Soy is a plant-based protein, and it contains phytoestrogens (very weak plant-based estrogens) and isoflavones such as genistein and daidzein. Diets containing modest amounts of soy protect against breast cancer (ACS, 2012), especially if the soy foods have been consumed before reaching adulthood apparently because of exposure to the weak estrogenic effects of isoflavones early in life (ACS, 2012). However, the use of soy remains controversial for women already diagnosed with hormone-sensitive cancers (e.g., breast, endometrium) and for postmenopausal women.

Commercially prepared soy supplement powders and foods made from soy products can but may not always contain isoflavones at much higher concentrations than traditional whole soy foods such as edamame beans, tofu, or soy milk (U.S. Department of Agriculture [USDA], 2014). The ACS advises breast cancer survivors to limit the consumption of soy foods to no more than three servings daily and to avoid using prepared soy supplement powders and products (Rock et al, 2012). Unlike the advice for women, men with hormone-sensitive cancer such as prostate cancer may benefit from regular consumption of soy foods. Prostate cancer is a testosterone-driven cancer and estrogens (or phytoestrogens) are antagonists.

MEDICAL DIAGNOSIS AND STAGING OF CANCER

Despite the progress made in understanding possible prevention strategies, cancer remains a significant health threat and, for most adults, is second to heart disease as a cause of death in the United States. Assessing symptoms of cancer at the earliest stage is critical for treatment effectiveness and survival. Table 36-4 summarizes constitutional or systemic symptoms of cancer and metastatic disease. Many symptoms of early or metastatic cancer affect an individual's ability to eat, digest, or absorb. According to the ACS, the following early warning signs and symptoms of cancer are described using the acronym "CAUTION":

- Change in bowel or bladder habits
- A sore that does not heal
- Unusual bleeding or discharge
- Thickening or lump in breast or elsewhere
- Indigestion or difficulty in swallowing or chewing
- Obvious change in a wart or mole
- Nagging cough or hoarseness

When symptoms or screening tests suggest cancer, physicians use the following to establish a definitive diagnosis: evaluation of an individual's medical, social, and family histories; physical examination; laboratory tests; imaging procedures; and tissue biopsy. Laboratory evaluation is composed of analysis of blood, urine, and other body fluids. In particular, oncologists evaluate tumor markers (e.g., alpha-fetoprotein [AFP], cancer antigen [CA] 125, CA 19-9, carcinoembryonic antigen [CEA],

prostate-specific antigen [PSA]) and other substances in blood or body fluids that can be elevated in cancer. Imaging procedures and studies help determine a diagnosis (Table 36-5). Pathologists perform cytologic examinations by analyzing body fluids, sputum, urine, or tissue under a microscope. To detect malignant cells, they use a histopathologic examination to review specially stained tissue, flow cytometry to count and examine cells and chromosomes, immunohistochemistry to review antibodies for specific cell proteins, and cytogenetics to visualize genetic defects.

Oxidative damage to lipids in cellular membranes, proteins, and DNA is often permanent. Thus biomarkers may be used to estimate the DNA damage after exposure to cancer-causing agents, such as tobacco smoke, asbestos fibers, heavy metals, and PAHs. 8-hydroxy-2-deoxyguanosine (8-OHdG) is a new biomarker for the measurement of endogenous oxidative DNA damage and risk for cancer (Valavanidis et al, 2009).

Staging is used to identify how much a cancer has spread throughout the body. The stage of the cancer at the time of diagnosis is a strong predictor of survival, and it directs oncologists to the most effective treatment plan. Cancer staging is most frequently described as stage I, II, III, or IV—stage I being the least amount of disease and stage IV being the most advanced. The **tumor-node-metastasis (TNM) staging system** is also commonly used by oncologists. *T* stands for the size of the tumor, *N* stands for nodes or whether it has spread into lymph nodes, and *M* stands for metastasis, or whether the cancer has spread to distant organs.

For classification, tumors are often referred to as *solid* cancers, and hematologic-related cancers of the blood are frequently called *liquid* cancers. The classification of tumors is based on their tissue of origin, their growth properties, and their invasion of other tissues. Tumors that are not malignant typically are described as **benign**.

Because cancer occurs in cells that are replicating, the patterns of cancer are different in children and adults. In early life the brain, nervous system, bones, muscles, and connective tissues are still growing; therefore cancers involving these tissues are more prevalent in children than in adults. Common childhood cancers include neuroblastoma; medulloblastoma; osteosarcoma; and soft tissue sarcomas such as rhabdomyosarcoma, schwannoma, and germ cell tumors. Conversely, adult cancers

TABLE 36-4 Signs and Symptoms of Cancer

Constitutional Symptoms of Cancer	Signs and Symptoms of Metastatic Cancer
Anorexia	Pain
Fatigue	Enlarged lymph nodes or body organs
Weight loss	Cough with or without hemoptysis
Fever	Bone pain with or without fracture
Sweating	Neurologic symptoms
Anemia

TABLE 36-5 Imaging Studies for Cancer Diagnosis and Disease Monitoring

Type of Imaging	Description and Use in Cancer Diagnosis and Treatment
Computed tomography (CT) scan	Description: A CT scan is a radiographic procedure in which a series of detailed pictures of areas inside the body are taken from different angles. Images are created by a computer and are linked to an x-ray machine. Use: A CT scan is used to evaluate for abnormalities of possible cancer in a general anatomic area such as the head, chest, abdomen, or pelvis. Radiologists use CT scans to visualize suspicious lesions, internal organs, and lymph nodes.
Magnetic resonance imaging (MRI) scan	Description: An MRI scan is an imaging procedure that uses radio waves and a powerful magnet linked to a computer to create detailed pictures of areas inside the body. This type of scanning often creates better images of body organs and soft tissue than other type of scanning methods. Use: Images produced show differences between normal and cancerous tissue. In particular, an MRI scan is used to evaluate suspicious areas of the brain, spinal cord, and liver.
Positron emission tomography (PET) scan	Description: A PET scan is a procedure in which a small amount of radioactive glucose is injected into a vein and a scanner is used to make detailed, computerized pictures of areas where glucose is used in the body. Use: Cancerous cells have an enhanced rate of glycolysis (they use more glucose than normal cells). Areas of glucose metabolism with high activity or "hot spots" appearing on the PET scan generally correlate to findings of cancer.

Data from American Cancer Society (ACS): *Cancer Glossary* (website): <http://www.cancer.org/cancer/cancerglossary/index>. Accessed April 16, 2014. frequently involve epithelial tissues that cover and line the body's internal and external surfaces. Cancers of the epithelial tissues include cancers of the skin, and circulatory, digestive, endocrine, reproductive, respiratory, and urinary systems. Cancers arising from these tissues are referred to as carcinomas, and common types are classified as adenocarcinomas, basal cell carcinomas, papillomas, and squamous cell carcinomas.

Leukemias, lymphomas, and myelomas are cancers of the immune system and can occur in children or adults. Leukemias arise most frequently from white blood cells of the bone marrow. Lymphomas are cancers that develop in the lymphatic system—its nodes, glands, and organs. Myeloma is cancer that originates in the plasma cells of the bone marrow and most frequently occurs in older adults.

Other types of cancer are related to infectious causes and cancer experts recommend antibiotics, vaccines, and changes in behavior for their prevention (ACS, 2014b). Examples include hepatocellular carcinoma linked to hepatitis B virus (HBV) exposure and alcoholic-related cirrhosis, oropharyngeal and cervical cancers linked to human papillomavirus infection (HPV), and stomach cancer caused by chronic inflammation by *Helicobacter pylori* (see Chapter 27).

MEDICAL TREATMENT

In the United States and in hundreds of countries across the world, cancer treatment is guided by oncologists, medical doctors specializing in the prevention, treatment, and palliation of cancer, and by evidence-based standards known as the National Comprehensive Cancer Network (NCCN) Clinical Practice Guidelines in Oncology (2015). The NCCN Guidelines encompass evidence-based care for 97% of all cancers treated in oncology practice. Also listed with these guidelines are evidence-based recommendations for providing supportive care (e.g., survivorship, palliative care, cancer-related pain, fatigue, distress, and antiemesis).

Conventional modalities include **antineoplastic therapy** (e.g., chemotherapy, biotherapy, or hormonal therapy), radiation therapy, and surgery used alone or in combination with other cancer therapies. Solid tumors and hematologic malignant diseases such as leukemias, lymphomas, and multiple myelomas may be treated with **hematopoietic cell transplantation (HCT)**.

Chemotherapy is the use of chemical agents or medications to systematically treat cancer. These agents interfere with the steps or phases of the cell-cycle, specifically with the synthesis of DNA and replication of cancer cells. The basic five phases of cell reproduction in normal and malignant cells are the following (Polovich et al, 2014):

G0—resting phase

G1—postmitotic phase; RNA and protein are synthesized

S—DNA is synthesized

G2—premitotic phase; the second phase where RNA and protein synthesized

M—mitosis; cell division

Most chemotherapy agents are categorized by their biochemical activity and their mechanism of action such as alkylating agents (cell-cycle nonspecific), antimetabolites (cell-cycle specific, usually S-phase), and taxanes (m-phase specific). **Biotherapy** is the use of biologic agents to produce anticancer effects indirectly by inducing, enhancing, or suppressing an individual's own immune response. **Antiangiogenic agents** are

used to inhibit the development of new blood vessels needed by cancers (tumor vasculature) and thus prevent their growth, invasion, and spread. **Hormonal therapy** is systemic therapy used for the treatment of hormone-sensitive cancers (e.g., breast, ovarian, prostate) by blocking or reducing the source of a hormone or its receptor site.

Radiation oncologists work in the area of therapeutic **radiation therapy**, which uses high-energy (ionizing radiation) in multiple fractionated doses, or radioactive chemicals to treat cancer. Surgery involves the surgical removal of cancerous tissue.

Response to cancer treatment is defined as complete or partial response (improvement), stable disease (same), or disease progression (worsening). Factors that affect an individual's response to treatment include tumor burden (the larger the tumor, the greater risk of metastatic disease), rate of tumor growth (rapidly growing tumors are usually more responsive to therapy), and drug resistance (tumors mutate as they grow, and with successive mutations new cancer cells become more likely to be resistant to therapy). Other factors contributing to an individual's response to cancer treatment include comorbid diseases (e.g., diabetes, renal disease, cardiopulmonary disease), age, performance status, psychosocial support systems, bone marrow reserve, and overall general health (NIH, NCI, 2014c; Polovich et al, 2014).

Goals of Treatment

The goal of cancer treatment may be to cure, control, or palliate. Cure is a complete response to treatment. Even if a treatment cannot cure a cancer, often there can be cancer control that extends life when a cure is not possible. *Control* measures may obscure microscopic metastases after tumors are surgically removed, reduce the size of tumors before surgery or radiation therapy, or alleviate symptoms and side effects of cancer. If a cancer cannot be cured or controlled, **palliative care** is offered. Palliative care helps individuals be as comfortable as possible. Palliation is designed to relieve pain and manage symptoms of illness; lessen isolation, anxiety and fear; and help maintain independence as long as possible (National Hospice and Palliative Care Organization [NHPCO], 2014). **Hospice** is care for individuals with a life expectancy of months and focuses on relieving symptoms, controlling pain, and providing support to patients and their families. Patients are made as comfortable as possible through the end of their lives.

MEDICAL NUTRITION THERAPY

The Commission on Dietetic Registration has developed a board certification in oncology nutrition: **certified specialist in oncology nutrition (CSO)**. To further assist clinicians working in the cancer care setting the Academy of Nutrition and Dietetics (AND) has developed the Oncology Toolkit with MNT protocols for breast, colorectal, esophageal, gastric, head and neck, hematologic, lung, and pancreatic cancers (AND, 2010). Another Academy resource for clinicians when providing MNT in the cancer care setting is the Pocket Guide to the Nutrition Care Process in Cancer (Grant, 2015).

Nutrition Screening and Assessment

With the recent shift of cancer care from the hospital setting to outpatient settings, nutrition screening and assessment should continue throughout the continuum of care. Ideally, nutrition screening and assessment for risk of nutrition problems should

be interdisciplinary, instituted at the time of diagnosis, and re-evaluated and monitored throughout treatment and recovery. See Chapter 4 for the following screening tools validated for use with individuals diagnosed with cancer (AND, 2013):

- Patient Generated-Subjective Global Assessment (PG-SGA) for inpatient and outpatient settings (<http://www.ncbi.nlm.nih.gov/pubmed/12122555>).
- Malnutrition Screening Tool (MST) for inpatient and outpatient settings (<http://www.ncbi.nlm.nih.gov/pubmed/10378201>).
- Malnutrition Screening Tool for Cancer Patients (MSTC) for inpatient settings (<http://www.ncbi.nlm.nih.gov/pubmed/21813215>).
- Malnutrition Universal Screening Tool (MUST) for inpatient and outpatient settings (<http://www.ncbi.nlm.nih.gov/pubmed/22142968>).

Other assessment tools specific to patients with cancer are the Activities of Daily Living (ADLs) tool, the Common Toxicity Criteria for Adverse Events (CTCAE), and the Karnofsky Performance Scale (KPS) Index. CTCAE is an outcome measure used in anticancer therapy that compares acute toxicities of cancer treatment, and KPS is a scoring index that associates an individual's functional status with disease status and survival (Polovich et al, 2014).

In-depth assessment is undertaken to obtain more information and to identify nutrition problems (see Chapter 7 and Appendix 22). Careful review of the individual's appetite and oral intake is required, with an assessment of symptoms (e.g., nausea, vomiting, and diarrhea), weight status, comorbidities, and laboratory studies. A nutrition-focused physical examination is recommended to evaluate fully nutrition status and degree of risk (see Appendix 21). Components of this type of assessment include a general survey of the body, review of vital signs and anthropometrics, and an evaluation of subcutaneous fat stores, muscle mass, and fluid status (see Chapter 7).

Energy

Determining individualized energy needs is vital to helping people maintain an energy balance and achieve a healthy weight; it is also vital to preventing unintentional weight gain or loss associated with cancer and cancer treatment. Methods used to estimate energy requirements for adults include using standardized equations or measuring resting metabolic rate using indirect calorimetry (Hamilton, 2013; see Chapter 2 for methods for determining energy requirements). To ensure that adequate energy is being provided, the individual's diagnosis, presence of other diseases, intent of treatment (e.g., curative, control, or palliation), anticancer therapies (e.g., surgery, chemotherapy, biotherapy, or radiation therapy), presence of fever or infection, and other metabolic complications such as refeeding syndrome must be considered. Evidence-based guidelines from the American Society for Parenteral and Enteral Nutrition (ASPEN) for quickly estimating energy needs of people with cancer based on body weight are shown in Table 36-6.

Protein

An individual's need for protein is increased during times of illness and stress. Additional protein is required by the body to repair and rebuild tissues affected by cancer treatments and to maintain a healthy immune system (Hamilton, 2013). Adequate energy should be provided, or the body will burn its lean body mass as a fuel source. The degree of malnutrition, extent of disease, degree of stress, and ability to metabolize and use

TABLE 36-6 Estimating Energy Needs of People with Cancer

Condition	Energy Needs
Cancer, nutritional repletion, weight gain	30-35 kcal/kg/day
Cancer, inactive, non-stressed	25-30 kcal/kg/day
Cancer, hypermetabolic, stressed	35 kcal/kg/day
Hematopoietic cell transplant	30-35 kcal/kg/day
Sepsis	25-30 kcal/kg/day

Data from Gottschlich MM, editor: *The A.S.P.E.N. nutrition support core curriculum: a case-based approach—the adult patient*, Silver Spring, Md, 2007, American Society for Parenteral and Enteral Nutrition; Hamilton KK: Nutrition needs of the adult oncology patient. In Leser M et al, editors: *Oncology nutrition for clinical practice*, Chicago, 2013, Oncology Nutrition Dietetic Practice Group of the Academy of Nutrition and Dietetics.

protein are factors in determining protein requirements (Hamilton, 2013). For example, protein needs for a catabolic client may be 1.2 g/kg/day or more, and protein needs for an individual undergoing a hematopoietic cell transplant may be 1.5 g/kg/day. Daily protein requirements generally are calculated using actual body weight rather than ideal body weight.

Fluid

Fluid management in cancer care must ensure adequate hydration and electrolyte balance and prevent dehydration and hypovolemia. Altered fluid balance may occur with fever, ascites, edema, fistulas, profuse vomiting or diarrhea, multiple concurrent intravenous (IV) therapies, impaired renal function, or medications such as diuretics. Individuals need close monitoring for dehydration (e.g., intracellular fluid losses caused by inadequate intake of fluid because of mucositis or anorexia), hypovolemia (e.g., extracellular fluid losses from fever or GI fluids such as vomiting, diarrhea, or malabsorption), and nephrotoxic effects from anti-cancer treatments. Common nephrotoxic chemotherapy agents include the following (Polovich et al, 2014):

- Alkylating agents: cisplatin, oxaliplatin, ifosfamide
- Antimetabolites: methotrexate
- Antitumor antibiotics: mitomycin-c
- Cytokines: interleukin-2

Signs and symptoms of dehydration include fatigue, acute weight loss, hypernatremia, poor skin turgor, dry oral mucosa, dark or strong smelling urine, and decreased urine output. To carefully assess for hypovolemia, levels of serum electrolytes, blood urea nitrogen, and creatinine also should be evaluated.

A general guideline for estimating fluid needs for all adults without renal concerns is 20 to 40 ml/kg (Hamilton, 2013). Another method to assess fluid needs recommends 1 ml fluid per 1 kcal of estimated calorie needs (Hamilton, 2013). Intravenous hydration (IV) may be recommended for individuals struggling to achieve adequate hydration, but infusion frequency and volume must be determined on an individual basis, considering fluid intake and output.

Vitamins and Minerals

Individuals diagnosed with cancer are often interested in taking vitamin and mineral supplements because they believe these dietary supplements can improve their tolerance of treatment, enhance their immune system, or even reverse the course of their disease. Others may see dietary supplementation as a way to make up for presumed nutritional deficiencies at the time of

diagnosis caused by poor diet and lifestyle choices. If individuals are experiencing difficulty with eating and treatment-related side effects, a standard multivitamin and mineral supplement that provides no more than 100% of the dietary reference intakes (DRIs) is considered safe (Rock et al, 2012). In contrast, the American Institute for Cancer Research (AICR) encourages all people (including cancer survivors) not to use dietary supplements for cancer prevention, citing evidence that high-dose dietary supplementation can have cancer-promoting effects (Martinez et al, 2012; Moyer, 2014; WCRF, AICR, 2007). According to the recommendations from leading national scientific groups, whether for primary or secondary prevention, individuals should attempt to meet vitamin and mineral needs through the foods they eat rather than use dietary supplements. In some instances during and after a cancer diagnosis, supplementation or restriction of specific micronutrients may be required above or below DRI levels, depending on medical diagnosis and laboratory analysis (e.g., iron supplementation for iron-deficiency anemia, B₁₂ injections, and folic acid supplementation during treatment with the chemotherapy agent pemetrexed [Alimta]).

Supplement Use

Despite recommendations to the contrary, the majority of cancer survivors continue to use dietary supplements during all phases of anticancer treatment. Unless specifically instructed to do so, oncology practitioners ask that cancer survivors avoid use of dietary supplements during treatment, particularly the antioxidant dietary supplements such as vitamins A, C, E, beta-carotene, zinc, selenium, coenzyme Q10, and green tea extract, as the practice remains controversial. Studies have shown inhibition and enhancement of the antitumor effects of radiation therapy and chemotherapy (Rock et al, 2012). Well-designed studies evaluating larger numbers of individuals are still needed.

Nutrition Diagnosis

Nutrition diagnosis identifies the specific nutrition problems that can be resolved or improved through nutrition intervention (AND, 2012a; see the [Clinical Insight box Common Nutrition Diagnoses for Patients with Cancer](#)).

Nutrition Intervention

Nutrition intervention outlines specific actions to manage a nutrition diagnosis (see Chapter 10). It includes two distinct, interrelated components—planning and implementing nutrition interventions (AND, 2013). The Oncology Toolkit (www.eatright.org) recommends careful appraisal if the planned nutrition intervention will negatively affect patient safety or possibly interfere with the cancer treatment (AND, 2010). The Toolkit also advises evaluation of the nutrition intervention's likely effectiveness for improving nutrition status, possible financial burden, and patient acceptance.

Intervention goals should be specific, achievable, and individualized to encourage cooperation. Goals must be directed toward an objective measure such as body weight or some other meaningful index. Another goal is to minimize the effects of “nutrition impact symptoms” and to maximize the individual's nutritional parameters. **Nutrition impact symptoms** can be defined as symptoms and side effects of cancer and cancer treatment that directly affect the nutrition status. Consultation with the individual, caregivers, or family members regarding expected problems and their possible solutions should be initiated early in the course of cancer therapy and should continue in conjunction with follow-up nutrition assessment and care.

The adverse nutritional effects of cancer can be severe and may be compounded by the effects of the treatment regimens and the psychological effects of cancer. The result is often a profound depletion of nutrient stores and deterioration in nutrition status. Malnutrition, anorexia (loss of appetite), and weight loss are significant issues in cancer care and are often present in many individuals at the time of diagnosis, even in children. The incidence of malnutrition among individuals with cancer has been estimated to be between 15% and 80% (Santarpia et al, 2011). Studies consistently show that even small amounts of weight loss (less than 5% of body weight) before treatment is associated with a poorer prognosis and decreased quality of life, thus reinforcing the importance of early MNT (Fearon, 2008).

CLINICAL INSIGHT

Common Nutrition Diagnoses for Patients with Cancer Using the Problem, Etiology, and Signs and Symptoms Format

Intake Domain

- Inadequate oral intake *related to* pelvic radiation therapy *as evidenced by* diarrhea and 2½ lb weight loss in the preceding week
- Inadequate enteral nutrition (EN) infusion *related to* intolerance of EN *as evidenced by* nausea, abdominal distention, and weight loss of 3 lb in the preceding 5 days
- Malnutrition *related to* cancer cachexia *as evidenced by* wasting of temporalis and interosseous muscles, and weight loss of more than 7.5% in 3 months

Clinical Domain

- Altered GI function *related to* recent ileostomy surgery *as evidenced by* 2 L/day ostomy diarrhea output, and the need for daily IV hydration during the preceding week
- Altered GI function *related to* biweekly chemotherapy *as evidenced by* nausea, vomiting, and anorexia in the preceding 4 days

- Swallowing difficulty *related to* an obstructing esophageal tumor *as evidenced by* dysphagia, odynophagia, and 10-pound weight loss in the preceding month

Behavioral-Environmental Domain

- Limited access to nutrition-related supplies *related to* lack of insurance and financial resources *as evidenced by* not using the prescribed amount of tube feeding formula and continued weight loss to 80% of usual weight during the preceding month
- Intake of unsafe food *related to* exposure to contaminated food while neutropenic *as evidenced by* hospitalization, diarrhea, and positive stool culture for salmonella
- Undesirable food choices *related to* an unwillingness to apply nutrition information *as evidenced by* ongoing diarrhea and diet history of continued high fiber food intake while undergoing pelvic radiation therapy

Oral Nutrition Management Strategies

Oral feeding is the goal, however individuals often experience symptoms that make it difficult. Strategies for modifying dietary intake may be necessary and depend on the specific eating problem and the individual’s nutritional status. Food and its presentation may need modification. Liquid medical food supplements may be recommended for those unable to consume enough energy and protein to maintain weight and nutrition status, however real food is optimal (see Chapter 13). Education materials with suggestions for improving oral intake and managing treatment-related side effects are at the end of the chapter and include Eating Hints, Chemotherapy and You, and Radiation Therapy and You (NIH, NCI, 2011a, 2011b, 2012). Table 36-7 outlines examples of nutrition intervention strategies.

Managing Anorexia and Alterations in Taste and Smell

Sometimes even before diagnosis, and then throughout cancer treatment, individuals may report anorexia, early satiety, and

decreased food intake. Alterations in taste and smell are common problems. Taste alterations can be associated with the disease itself, certain chemotherapy agents, radiation therapy, or surgery to the head and neck. Chemotherapy-induced, learned taste aversions have been reported in adults and children. Individuals also may develop a heightened sense of smell that results in sensitivity to food preparation odors and aversions to nonfood items such as soaps or perfumes. These sensation abnormalities do not consistently correlate with the tumor site, extent of tumor involvement, tumor response to therapy, or food preferences and intake. Nutrition interventions that decrease the aroma of foods, such as serving foods cold instead of hot, may be helpful.

Alterations in Energy Metabolism Resulting from Cancer

Energy metabolism is related intimately to carbohydrate, protein, and lipid metabolism, all of which are altered by tumor growth. Tumors exert a consistent demand for glucose, exhibit a

TABLE 36-7 Nutrition Intervention Strategies for Patients with Cancer

Side Effect or Symptom	Strategies
Anorexia, poor appetite	<ul style="list-style-type: none"> • Encourage small, more frequent nutrient dense meals and snacks. • Recommend adding protein and calories to favorite foods. • Recommend use of protein and calorie-containing supplements (e.g., whey or soy powder, nutritional supplements). • Keep nutrient dense foods close at hand and snack frequently. • Advise capitalizing on times when feeling best. • Recommend eating meals and snacks in a pleasant atmosphere. • Suggest viewing eating as part of treatment. • Encourage activities of daily living and physical activity as able.
Nausea and vomiting	<ul style="list-style-type: none"> • Recommend eating small, more frequent meals and snacks. • Suggest sipping on cool or room temperature clear liquids in small amounts. • Advise the avoidance of high-fat, greasy, spicy, or overly sweet foods. • Advise the avoidance of foods with strong odors. • Encourage the consumption of bland, soft, easy-to-digest foods on scheduled treatment days. • Encourage compliance with medications that are prescribed to control nausea.
Diarrhea	<ul style="list-style-type: none"> • Encourage the intake of hydrating liquids such as water, clear juices, broth, gelatin, popsicles, sports drinks. • Recommend a low-fiber diet and the avoidance of high-fiber foods, such as nuts, raw fruits and vegetables, and whole-grain breads and cereals. • Advise the avoidance of sugar alcohol-containing foods such as sugar-free candies and gums (e.g., mannitol, xylitol, sorbitol). • Encourage the intake of soluble fiber such as applesauce, bananas, canned peaches, white rice, or pasta. • Encourage compliance with medications prescribed to control diarrhea.
Constipation	<ul style="list-style-type: none"> • Recommend increasing the intake of high-fiber foods such as whole grains, fresh or cooked fruits and vegetables, especially those with skins and seeds, dried fruits, beans, and nuts. • Encourage the intake of 64 ounces of fluid each day. • Recommend the use of probiotic-containing foods or supplements. • Encourage activities of daily living and physical activity as able. • Encourage compliance with fiber supplements and/or medications that affect bowel function and are prescribed to manage constipation.
Sore throat, esophagitis	<ul style="list-style-type: none"> • Recommend the intake of softer, moister foods with extra sauces, dressings, or gravies. • Advise the avoidance of dry, coarse, or rough foods. • Avoid alcohol, citrus, caffeine, tomatoes, vinegar, and hot peppers. • Suggest experimenting with food temperatures (e.g. warm, cool, or icy) to find which temperature is the most soothing. • Encourage compliance with medications prescribed to manage esophagitis and/or painful swallowing.
Sore mouth, mucositis, or thrush	<ul style="list-style-type: none"> • Recommend good oral hygiene (e.g., rinse mouth frequently, keep mouth clean). • Recommend the intake of softer, moister foods with extra sauces, dressings, and gravies. • Suggest serving foods at cool or room temperatures. • Advise the avoidance of alcoholic beverages, citrus, caffeine, tomatoes, vinegar and hot peppers; and dry, coarse, or rough foods. • Suggest eating foods at room temperature or chilled. • Encourage compliance with medications prescribed to manage oral pain and/or infection.

Continued

TABLE 36-7 Nutrition Intervention Strategies for Patients with Cancer—cont'd

Side Effect or Symptom	Strategies
Fatigue	<ul style="list-style-type: none"> • Recommend the intake of small, frequent meals and snacks. • Recommend the intake of easy-to-prepare, easy-to-eat foods. • Advise keeping nutrient dense snacks close at hand and snack frequently. • Suggest eating when appetite is best. • Encourage activities of daily living and physical activity as able.
Neutropenia	<ul style="list-style-type: none"> • Advise frequent hand washing and keep kitchen surfaces and utensils clean. • Advise the avoidance of raw or undercooked animal products, including meat, pork, game, poultry, eggs, and fish. • Advise washing all fresh fruits and vegetables before eating. • “When in doubt, throw out” and “No oldy or moldy.”
Altered taste or smell	<ul style="list-style-type: none"> • Recommend good oral hygiene practices (e.g., rinse mouth frequently, keep mouth clean). • Suggest trying marinades and spices to mask strange tastes. • Recommend using plastic utensils if metallic tastes are a problem. • Recommend eating cooler foods, rather than warmer foods.
Thickened saliva	<ul style="list-style-type: none"> • Suggest sipping on liquids throughout the day to keep the oral cavity moist. • Recommend thinning oral secretions with club soda, seltzer water, or papaya nectar. • Suggest trying guaifenesin to help thin oral secretions. • Recommend using a cool mist humidifier while sleeping.
Xerostomia	<ul style="list-style-type: none"> • Suggest sipping on liquids throughout the day to keep the oral cavity moist. • Suggest trying tart foods to stimulate saliva, if open sores are not present. • Recommend alternating bites of food with sips of liquids at meals. • Recommend eating soft, moist foods with extra sauces, dressings, or gravies. • Advise avoidance of alcoholic beverages and alcohol-containing mouthwash. • Recommend good oral hygiene (e.g., rinse mouth frequently, keep mouth clean). • Recommend a cool mist humidifier while resting or sleeping.

Data from Grant BL et al, editors: *American Cancer Society's complete guide to nutrition for cancer survivors*, ed 2, Atlanta, 2010, American Cancer Society; National Cancer Institute (NCI): *Eating Hints* (website): <http://www.cancer.gov/publications/patient-education/eatinghints.pdf>, 2011. Accessed March 29, 2014; Elliot L: Symptom management of cancer therapies. In Leser M et al, editors: *Oncology nutrition for clinical practice*, Chicago, 2013, Oncology Nutrition Dietetic Practice Group of the Academy of Nutrition and Dietetics.

characteristically high rate of anaerobic metabolism, and yield lactate as the end product. This expanded lactic acid pool requires an increased rate of host gluconeogenesis via Cori cycle activity, which is increased in some people with cancer but not in others. Protein breakdown and lipolysis take place at increasing rates to maintain high rates of glucose synthesis. There is glucose intolerance and insulin resistance, characterized by excess fatty acid oxidation and decreased uptake and use of glucose by muscle.

Alterations in protein metabolism appear to be directed toward providing adequate amino acids for tumor growth. Most notable is the loss of skeletal muscle protein caused by increased protein breakdown, as well as decreased protein synthesis.

Managing Cancer Cachexia

A common secondary diagnosis in people with advanced cancer is a variant of protein-energy malnutrition. This syndrome is termed **cancer cachexia** and is characterized by progressive weight loss, anorexia, generalized wasting and weakness, immunosuppression, altered basal metabolic rate, and abnormalities in fluid and energy metabolism. There is also increased loss of adipose tissue, which is related to an increased rate of lipolysis, rather than a decrease in lipogenesis. Increased levels of lipid-mobilizing factor and proteolysis-inducing factor secreted by tumor cells will lead to increased loss of fat and muscle mass. Individuals at the time of diagnosis with breast or hematologic cancers rarely present with significant weight loss, whereas individuals with lung, esophageal, or head and neck cancers often exhibit substantial weight loss. Cancer cachexia is caused in part by **cytokines** (immune-modulating agents), produced by the cancer itself or by the immune system in response to

the cancer. Cytokines can cause metabolic changes and wasting that is similar to changes seen in inflammation (see Chapter 3.) Proinflammatory cytokines include **tumor necrosis factor (TNF)- α (cachectin)** and TNF- β , interleukin (IL)-1, IL-6, and interferon- α . These cytokines have overlapping physiologic activities, which makes it likely that no single substance is the sole cause. Resting energy expenditure (REE) is elevated, which is in contrast to the REE in chronic starvation, wherein the body adapts to conserve energy and preserve body tissue. Cancer cachexia and the associated wasting often increase closer to the time of death.

Pharmacotherapy

The pharmacologic management of cachexia and anorexia requires careful evaluation based on the individual's treatment goals and prognosis and on close monitoring of symptoms. Although cancer cachexia cannot be reversed by conventional nutrition support, anorexia, a common cancer-related condition, is amenable to treatment with nutrition counseling, diet modification, and pharmacotherapy. A number of pharmacologic agents are currently under investigation for their impact on anorexia, including antihistamines (Periactin), corticosteroids (Decadron, Solu-medrol), progestational agents (Provera, Megace), prokinetic agents (Reglan), and antidepressants (Remeron) (Elliot, 2013).

Medical marijuana, or cannabis, is a controlled substance in the United States, and it is illegal except in the few states that have enacted laws to legalize its use. According to the NCI PDQ, cannabinoids, which are the active chemicals in cannabis, can be useful in treating the side effects of nausea and vomiting and anorexia from cancer and cancer treatment (NIH, NCI, 2014b).

The FDA has not approved medical marijuana for cancer or cancer treatment application; however, it has approved two cannabinoids, Marinol and Cesamet, for individuals experiencing chemotherapy-related nausea and vomiting (NIH, NCI, 2014b).

Managing Other Cancer-Related Metabolic Abnormalities

Metabolic alterations vary by tumor type. An individual's immunologic function can be impaired, apparently as the result of the disease, cancer treatment, or progressive malnutrition. In addition to the cancer-induced metabolic effects, the mass of the tumor may anatomically alter the physiology of specific organ systems. The activity of several enzyme systems involved with digestion and absorption can be affected, as can certain endocrine functions.

Critical imbalances in fluid and electrolyte status can occur in people who have cancers or are undergoing cancer treatments that promote excessive diarrhea, vomiting, or malabsorption. Profuse and often severe diarrhea can result from partial bowel obstructions and endocrine-secreting tumors such as those secreting serotonin (carcinoid tumors), calcitonin, or gastrin (Zollinger-Ellison syndrome). The use of anti-metabolites, alkylating agents, and antibiotics may also lead to the development of severe diarrhea. In some instances, people who are immunocompromised or have undergone GI surgery may experience profuse diarrhea that is caused by intestinal pathogens such as *Clostridium difficile*.

Persistent vomiting is associated with intestinal obstruction, radiation therapy to the stomach and abdomen or brain, highly **emetogenic** (nausea-causing) chemotherapy agents, intracranial tumors, and advanced cancer (Iwamoto et al, 2012). Careful assessment and evaluation of the cause of the diarrhea or vomiting is critical for effective management. Malabsorption may be caused by treatment-related pancreatic dysfunction, postsurgical short gut syndrome, acute or chronic **radiation enteritis** (inflammation of the GI tract tissues secondary to radiation), excess serotonin, steatorrhea, or chronic diarrhea.

Hypercalcemia may occur in individuals with bone metastases, caused by the osteolytic activity of tumor cells releasing calcium into the extracellular fluid. Hypercalcemia is potentially fatal and is associated most commonly with multiple myeloma, lung cancer, and advanced breast and prostate cancer. Nausea, weakness, fatigue, lethargy, and confusion occur. Medical management of hypercalcemia includes rehydration and use of antihypercalcemic agents. Calcium supplementation from dietary supplements and antacids should be avoided. Restricting the intake of foods containing calcium is not indicated because the consumption of these foods has little effect in the overall management of hypercalcemia.

NUTRITIONAL IMPACT OF CANCER TREATMENTS

Chemotherapy

Chemotherapy uses chemical agents or medications to treat cancer. Classifications of chemotherapy cytotoxic agents include alkylating agents, antimetabolites, antitumor antibiotics, miscellaneous agents, nitrosoureas, and plant alkaloids (Wilkes and Barton-Burke, 2013). Once in the bloodstream, these agents are carried through the body to reach as many cancer cells as possible. Routes of administration for chemotherapy include the following:

- Oral: capsule, pill, or liquid
- Intravenous (IV): delivery of medication via an injection or an indwelling catheter into a vein

- Intraperitoneal: delivery of medication via a catheter directly into the abdominal cavity
- Intravesicular: delivery of medication via a Foley catheter directly into the bladder
- Intrathecal: delivery of medication via an injection into the central nervous system using an Ommaya reservoir or a lumbar puncture (Polovich et al, 2014)

Whereas surgery and radiation therapy are used to treat localized tumors, chemotherapy is a systemic therapy that affects the malignant tissue and normal cells as well. Cells of the body with a rapid turnover such as bone marrow, hair follicles, and the mucosa of the alimentary tract are the most affected. As a result, nutrition intake and nutrition status can be adversely affected. Nutrition-related symptoms include **myelosuppression** (suppression of bone marrow production of neutrophils, platelets, and red blood cells), anemia, fatigue, nausea and vomiting, loss of appetite, mucositis, changes in taste and smell, xerostomia (mouth dryness), dysphagia, and altered bowel function such as diarrhea or constipation (Table 36-8).

The severity of the side effects depends on the specific agents used, dosage, duration of treatment, number of treatment cycles, accompanying drugs, individual response, and current health status. The timely and appropriate use of supportive therapies such as antiemetics, antidiarrheals, hematopoietic agents, and antibiotics, as well as dietary changes, is important. Many people experience significant side effects, especially in “dose-intensive” multiple-agent chemotherapy regimens; **neutropenia** (reduced white blood cells or neutrophils) and myelosuppression are the primary factors limiting chemotherapy administration. Commonly experienced chemotherapy induced toxicities affecting the GI system include mucositis, nausea, vomiting, diarrhea, and constipation. Chemotherapy related taste abnormalities can lead to anorexia and decreased oral intake. Symptoms of GI toxicity are usually temporary; however, some multiagent chemotherapy regimens may lead to lasting GI side effects.

Diarrhea

Diarrhea is a common side effect of certain chemotherapy agents. Left unmanaged, it can lead to depletion of fluids, electrolytes, malnutrition, and even hospitalization. The intestinal mucosa and digestive processes can be affected, thus altering digestion and absorption to some degree. Protein, energy, and vitamin metabolism may be impaired.

Nausea and Vomiting

Chemotherapy induced nausea and vomiting are commonly classified as anticipatory (occurs before receiving treatment), acute (occurs within the first 24 hours after receiving treatment), or delayed (occurs 1 to 4 days after treatment), each of which is characterized by distinct pathophysiologic events and requires different therapeutic interventions. Effective agents for treatment-related nausea and vomiting are the serotonin antagonists (e.g., ondansetron, granisetron, and dolasetron), neurokinin-1 (NK-1) receptor antagonists (e.g., aprepitant), dopamine antagonists (e.g., metoclopramide, prochlorperazine), and corticosteroids such as dexamethasone (Polovich et al, 2014). Other antiemetic agents include cannabinoids (e.g., dronabinol, nabilone) and benzodiazepines (e.g., lorazepam, diazepam).

Food-Drug Interactions

Nutrition professionals can gain valuable insights regarding possible drug-nutrient interactions and contraindications by reviewing product medication inserts, pharmacy resource books,

Data from Polovich M et al: *Chemotherapy and biotherapy guidelines and recommendations for practice*, ed 4, Pittsburgh, 2014, Oncology Nursing Society; Wilkes GM, Barton-Burke M: *2014 Oncology nursing drug handbook*, Burlington, 2013, Jones and Bartlett; Chu E, Devita VT: *Physician's cancer chemotherapy drug manual*, Boston, 2014, Jones and Bartlett, <http://www.chemocare.com>. Accessed on March 29, 2014.

and medication databases or by consulting with pharmacy personnel (see Chapter 8). Some chemotherapy agents can cause potentially severe adverse events (Grant, 2013), for example:

- Individuals with certain types of lung cancer who are being treated with pemetrexed (Alimta) require vitamin B₁₂ (often by injection) and folic acid supplementation

throughout the duration of their therapy to avoid significant anemia associated with this chemotherapy agent.

- A severe hypertensive event is possible when tyramine-rich foods and beverages are consumed while taking procarbazine (Matulane), a chemotherapy agent commonly used to treat brain cancer (see Box 8-4).

- Individuals with colon cancer receiving oxaliplatin (Eloxatin) should not drink, eat, or handle cold drinks or foods for up to 5 days because of treatment-related dysesthesias or transient paresthesias of the hands, feet, and throat.
- To prevent unnecessary gastric upset, individuals taking the medication capecitabine (Xeloda) must take the medication within 30 minutes of eating food or a meal. Conversely, medications such as erlotinib (Tarceva) should not be taken with food; it can cause a rash and profound diarrhea unless taken on an empty stomach.

Oral Changes

People with altered taste acuity (dysgeusia, hypogeusia, ageusia) may benefit from increased use of flavorings and seasonings during food preparation. Meat aversions may require the elimination of red meats, which tend to be strong in flavor, or the substitution of alternative protein sources. Herpes simplex virus and *Candida albicans* (thrush) account for most oral infections. In addition to causing oral infections, some agents, especially corticosteroids, can cause hyperglycemia and can lead to excessive losses of urinary protein, potassium, and calcium.

Mucositis

Oral **mucositis**, an inflammation of the mucous membranes lining the oropharynx and esophagus, is a common side effect of some types of chemotherapy (Figure 36-2). Although many interventions exist, most strategies lack scientific evidence (Brown, 2009). General care guidelines include recommending daily oral care (e.g., keeping the mouth clean, avoidance of tobacco, alcohol, and irritating foods) and the use of bland rinses (e.g., baking soda or saline rinses). Bland liquids and soft

FIGURE 36-2 Oral mucositis. (From Kanski JL: *Clinical diagnosis in ophthalmology*, ed 1, 2006, Elsevier.)

solids are usually better tolerated in individuals with oral or esophageal mucositis and strong-flavored, acidic, or spicy foods also should be avoided. Commercially prepared liquid medical food supplements can be useful.

Biotherapy

Biotherapy is immunotherapy, in which a group of cancer treatment drugs prescribed to stimulate the body's own immune system and natural defenses are used to treat cancer. Biotherapy is sometimes used by itself, but it is given most often in combination with chemotherapy drugs. Different kinds of biotherapy drugs used to help the immune system recognize cancer cells and strengthen its ability to destroy them include:

- Cytokines such as interferon and IL-2 for treatment of malignant melanoma and metastatic melanoma.
- Monoclonal antibodies such as trastuzumab (Herceptin) for treatment of specific types of breast cancer, and rituximab (Rituxan) for treatment of non-Hodgkin lymphoma.
- Antiangiogenesis inhibitors prevent and reduce the growth of new blood vessels and prevent tumor invasion. These agents are most frequently used in combination with other chemotherapy agents to maximize their effectiveness. An example of an antiangiogenic agent used to treat colon or brain cancer is bevacizumab (Avastin).
- Cancer vaccines such as sipuleucel-T (Provenge) made from an individual's own cancer or substances from tumor cells are currently under investigation in clinical cancer trials (Grant, 2013; Wilkes and Barton-Burke, 2013).

Other types of biotherapy drugs are groups of proteins that cause blood cells to grow and mature (NIH, NCI, 2015). These drugs are called **hematopoietic growth factors**. They include supportive care medications such as darbepoetin (Aranesp) or epoetin alfa (Procrit) to stimulate red blood cell production, and filgrastim (Neupogen) or pegfilgrastim (Neulasta) to stimulate the production of neutrophils in the bone marrow. Individuals receiving these agents may experience fatigue, chills, fever, and flu-like symptoms.

Hormone Therapy

Hormone therapy adds, blocks, or removes hormones to slow or stop the growth of hormone-sensitive breast or prostate cancer (NIH, NCI, 2015). Examples of these agents include tamoxifen (Nolvadex) and anastrozole (Arimidex) for breast cancer and leuprolide (Lupron) or bicalutamide (Casodex) for prostate cancer. Side effects commonly include hot flashes, decreased libido, and bone pain (Wilkes and Barton-Burke, 2013).

Radiation Therapy

Radiation therapy, ionizing radiation used in multiple fractionated doses, is used to cure, control, or palliate cancer. Radiation therapy can be delivered externally into the body from a megavoltage machine or with brachytherapy by placing a radioactive source (implant) in or near the tumor to deliver a highly localized dose. Advances in technology to deliver radiation therapy with precise accuracy include radiation surgery (e.g., stereotactic radiosurgery) and intensity-modulated radiation therapy (IMRT). Whereas chemotherapy is a systemic therapy, radiation therapy affects only the tumor and the surrounding area. The side effects of radiation therapy are usually limited to the specific site being irradiated. Chemotherapy agents may also be given in combination with radiation therapy to produce a radiation-enhancing effect. People receiving

multimodality therapy often experience side effects sooner and with greater intensity.

The acute side effects of radiation therapy when used alone generally occur around the second or third week of treatment and usually resolve within 2 to 4 weeks after the radiation therapy has been completed. Late effects of radiation therapy may happen several weeks, months, or even years after treatment. Commonly experienced nutrition-related symptoms include fatigue, loss of appetite, skin changes, and hair loss in the area being treated (Table 36-9).

Radiation to the Head and Neck

Treatment for head and neck cancer usually includes a multimodality approach with aggressive chemotherapy, radiation therapy, and often surgery. Radiation therapy to the head and neck can cause acute nutrition-related symptoms: sore mouth, altered taste and smell, dysphagia and odynophagia, mucositis, xerostomia, anorexia, fatigue, and weight loss (Havrila et al, 2010). Prophylactic placement of percutaneous endoscopic gastrostomy (PEG) feeding tubes can help to reduce treatment-associated weight loss and malnutrition (NCCN, 2013).

Salivary stimulants and substitutes or oral lubricants are beneficial for temporary relief of xerostomia (diminished salivation or loss of salivation) caused by head and neck radiation therapy or certain types of medications (e.g., pain medications). In addition, liquids and foods with sauces and gravies are usually well tolerated. Late effects of radiation therapy may include dental caries, permanent xerostomia, **trismus** (an inability to fully open the mouth), and **osteoradionecrosis** of the jaw (necrosis of the bone caused by exposure to radiation therapy).

Before beginning therapy, individuals should undergo a dental evaluation and thorough teeth cleaning and receive instruction in good oral hygiene and care, including daily brushing and rinsing (National Institute of Dental and Craniofacial Research [NIDCR], 2014). After therapy has been completed, individuals should continue to have close dental monitoring and follow-up. Individuals may also benefit from a referral to a speech therapist for assessment and evaluation of swallowing function.

Radiation to the Thorax

Nutrition-related symptoms of radiation therapy to the thorax (chest) can include heartburn and acute esophagitis, accompanied by dysphagia and odynophagia. Late effects include possible esophageal fibrosis and stenosis. When this occurs, individuals are generally able to swallow only liquids, and the use of medical food supplements and enteral nutrition support (EN) may be necessary to meet nutritional needs (see Chapter 13.) Often individuals undergo esophageal dilations or swallowing therapy and rehabilitation to improve swallowing function.

Radiation to the Abdomen or Pelvis

Radiation therapy to the abdomen or pelvis may cause gastritis or enteritis that can be accompanied by nausea, vomiting, diarrhea, and anorexia. Late effects can include lasting GI damage such as malabsorption of disaccharides (e.g., lactose), fats, vitamins, minerals, and electrolytes. Proactive management includes encouraging affected individuals to consume soluble fiber, to increase intake of hydrating liquids, and to avoid eating high nonsoluble fiber or lactose-containing foods. To alleviate symptoms, medications such as antidiarrheals like loperamide may be given to reduce intestinal motility.

TABLE 36-9 Nutrition-Related Effects of Radiation Therapy

Site of Radiation Therapy	Common Nutrition-Related Symptom
Central nervous system (brain and spinal cord)	<p>Acute Effects</p> <ul style="list-style-type: none"> Nausea, vomiting Fatigue Loss of appetite Hyperglycemia associated with corticosteroids <p>Late Effects (>90 days after treatment)</p> <ul style="list-style-type: none"> Headache, lethargy

Data from Iwamoto RR et al: *Manual for radiation oncology and nursing practice and education*, ed 4, Pittsburgh, 2012, Oncology Nursing Society; Grant B: Nutritional effects of cancer treatment: chemotherapy, biotherapy, hormone therapy and radiation therapy. In Leser M et al, editors: *Oncology nutrition for clinical practice*, Chicago, 2013, Oncology Nutrition Dietetic Practice Group of the Academy of Nutrition and Dietetics.

Chronic **radiation enteritis** can develop with diarrhea, ulceration, or obstruction, intensifying the risk of malnutrition. Chronic radiation enteritis combined with or without significant bowel resection can result in bowel dysfunction and short bowel syndrome (SBS). The severity of this condition depends on the length and location of the nonfunctional or resected bowel and generally is diagnosed when the individual has less than 150 cm of small intestine remaining. The sequelae of SBS include malabsorption, malnutrition, dehydration, weight loss, fatigue, and lactose intolerance (Havrila et al, 2010) (see Chapter 28).

Initially parenteral nutrition (PN) may be required, and frequent monitoring of fluids and electrolytes may be necessary for weeks or months. Individuals with SBS may require an oral diet restricted to defined formula tube feedings or to frequent small meals high in protein, low in fat and fiber, and lactose free. Dietary supplements that contain vitamin B₁₂, folic acid, thiamin, calcium, and vitamins A, E, and K often are indicated to prevent deficiencies. Serum concentrations of various minerals also should be monitored and adjusted as needed.

Total-Body Irradiation

Total-body irradiation (TBI) is a technique of radiation therapy that is used in hematopoietic cell transplantation (HCT) to eliminate malignant cells, to ablate the bone marrow and make room for the engraftment of the infused hematopoietic cells, and to suppress the immune system to decrease the risk of rejection. Commonly encountered side effects are fever, nausea, vomiting, headache, mucositis, parotitis (inflammation of the parotid glands), xerostomia, diarrhea, anorexia, fatigue, and associated weight loss.

Surgery

The surgical resection or removal of any part of the alimentary tract (mouth to anus), as well as the malignant disease process, can potentially impair normal digestion and absorption. Surgery may be used as a single mode of cancer treatment, or it may be combined with preoperative or postoperative adjuvant chemotherapy or radiation therapy. After surgery, individuals commonly experience fatigue, and temporary changes in appetite and bowel function caused by anesthesia, and pain. They often require additional energy and protein for wound healing and recovery. Most side effects are temporary and dissipate after a few days after surgery. However, some surgical interventions have long-lasting nutritional implications (Table 36-10). When performing a nutrition assessment, it is very important to understand which part of the alimentary tract has been affected or surgically removed so that the appropriate nutrition intervention can be recommended. (Refer to Chapter 1 for a review gastrointestinal physiology).

Head and Neck Cancer

Individuals with head and neck cancer often have difficulty with chewing and swallowing caused by the cancer itself or the specific surgical intervention required to remove cancerous tissues. There can be additional problems because of history of smoking and alcohol abuse, illicit drug use, and subsequent poor nutrition intake, which place these individuals at high risk for malnutrition and postoperative complications. Surgery often necessitates temporary or long-term reliance on EN support (e.g., PEG tube feedings) (see Chapter 13). Individuals who resume oral intake often have prolonged dysphagia and require modifications of food consistency and extensive training in chewing and swallowing. Referrals to a speech therapist can yield dramatic positive results through evaluation and

TABLE 36-10 Nutrition-Related Effects of Surgery in Cancer Treatment

Anatomic Site	Nutrition Impact Symptoms
Oral cavity	Difficulty with chewing and swallowing Aspiration potential Sore mouth and throat Xerostomia Alteration in taste and smell
Larynx	Alterations in normal swallowing, dysphagia Aspiration potential
Esophagus	Gastroparesis Indigestion, acid reflux Alterations in normal swallowing, dysphagia Decreased motility Anastomotic leak
Lung	Shortness of breath Early satiety
Stomach	Dumping syndrome Dehydration Early satiety Gastroparesis Fat malabsorption Vitamin and mineral malabsorption (vitamin B ₁₂ and D; calcium, iron)
Gallbladder and bile duct	Gastroparesis Hyperglycemia Fluid and electrolyte imbalance Vitamin and mineral malabsorption (vitamin A, D, E, and K; magnesium, calcium, zinc, iron)
Liver	Hyperglycemia Hypertriglyceridemia Fluid and electrolyte malabsorption Vitamin and mineral malabsorption (vitamin A, D, E, K, B ₁₂ and folic acid, magnesium, zinc)
Pancreas	Gastroparesis Fluid and electrolyte imbalance Hyperglycemia Fat malabsorption (vitamin A, D, E, K, B ₁₂ ; calcium, zinc, iron)
Small bowel	Chyle leak Lactose intolerance Bile acid depletion Diarrhea Fluid and electrolyte imbalance Vitamin and mineral malabsorption (vitamin A, D, E, K, B ₁₂ ; calcium, zinc, iron)
Colon and rectum	Increased transit time Diarrhea Dehydration Bloating, cramping, gas Fluid and electrolyte imbalance Vitamin and mineral malabsorption (vitamin B ₁₂ , sodium, potassium, magnesium, calcium)
Ovaries and uterus	Early satiety Bloating, cramping, and gas
Brain	Nausea, vomiting Hyperglycemia associated with corticosteroids

individualized instruction in swallowing and positioning techniques, as well as evaluation for aspiration risk (see Chapter 40).

Esophageal Cancer

Surgical intervention for treatment of esophageal cancer often requires partial or total removal of the esophagus. The stomach

is commonly used for esophageal reconstruction. A feeding jejunostomy tube, which allows for early postoperative tube feedings, can be placed before an individual undergoes surgery or at the time of surgery. Usually the individual is able to progress to oral intake with specific dietary recommendations to minimize nutrition-related symptoms, which include reflux, dumping syndrome (discussed later in this chapter), dysmotility, gastroparesis, early satiety, vomiting, and fluid and electrolyte imbalances (Huhmann and August, 2010). Postsurgical recommendations include a low-fat diet with small, frequent feedings of energy-dense foods and avoidance of large amounts of fluids at any one time (see Chapter 27).

Gastric Cancer

Surgery is the most common treatment for cancer of the stomach, although chemotherapy and radiation therapy can be used before or after surgery to improve survival. Surgical interventions include partial, subtotal, or total gastrectomy. Placement of a jejunostomy feeding tube at surgery is advisable, and enteral nutrition (EN) support using a jejunal feeding tube is generally feasible within a few days after surgery.

Postgastrectomy syndrome encompasses a myriad of symptoms, including dumping syndrome, fat malabsorption, gastric stasis, lactose intolerance, anemias, and metabolic bone disease (osteoporosis, osteopenia, osteomalacia). **Dumping syndrome** is a common complication of gastric surgery, manifested by the rapid transit of foods or liquids, and the dilutional response of the small remaining stomach to highly osmotic bolus feedings. Individuals may experience GI and vasomotor symptoms such as abdominal cramps, diarrhea, nausea, vomiting, flushing, faintness, diaphoresis, and tachycardia (Huhmann and August, 2010). Individuals experiencing dumping syndrome should limit simple carbohydrates and liquids at meal times (see Chapter 27).

Malabsorption is another complication of gastric surgery; deficiency of iron, folic acid, and less commonly vitamin B₁₂ can lead to anemia. Micronutrient deficiencies of calcium and fat-soluble vitamins are also common (Huhmann and August, 2010). Individuals benefit from consumption of six to eight small meals per day, with fluids taken between meals. There may be fat intolerance, especially if the vagal nerve is severed. Administration of pancreatic enzymes with meals may help when the duodenal mixing of food and pancreatic juices is inadequate (see Chapter 27).

Pancreatic Cancer

Cancer of the pancreas, with or without surgical resection, can have significant nutritional consequences. The Whipple procedure and the pylorus-sparing pancreatic duodenectomy are the most common pancreatic cancer surgeries. Postsurgical complications include delayed gastric emptying, early satiety, glucose intolerance, bile acid insufficiency, diarrhea, and fat malabsorption. Pancreatic enzyme replacement, the use of small, more frequent low-fat meals and snacks, and avoidance of simple carbohydrates aid digestion and absorption (see Chapter 29).

Cancers of the Intestinal Tract

Partial or total resections of the intestinal tract because of colorectal cancer or carcinoid syndrome may induce profound losses of fluid and electrolytes secondary to decreased transit time and diarrhea, the severity of which are related to the length and site of the resection. Resections of as little as 15 cm of the terminal ileum can result in bile salt losses that exceed the liver's

capacity for resynthesis, and vitamin B₁₂ absorption is affected. With depletion of the bile salt pool, steatorrhea develops. Nutrition intervention strategies consist of a diet low in fat, osmolality, lactose, and oxalates (see Chapters 28 and 38).

Hematopoietic Cell Transplantation (HCT)

Hematopoietic cell transplantation (HCT) is performed for the treatment of certain hematologic cancers such as leukemia, lymphoma, and multiple myeloma. The stem cells used for HCT arise from bone marrow, peripheral blood, or umbilical cord blood. The preparative regimen includes cytotoxic chemotherapy, with or without total-body irradiation (TBI). This treatment regimen is followed by intravenous (IV) infusion of hematopoietic cells from the individual (autologous), or from a histocompatible related or unrelated donor (allogeneic), or from an identical twin (syngeneic) (National Marrow Donor Program, 2015).

Because HCT procedures can significantly affect nutrition status, the individual undergoing HCT should have a thorough nutrition assessment before the initiation of therapy and reassessments and monitoring throughout the entire transplant course. The acute toxicities of immunosuppression that can last for 2 to 4 weeks after the transplant include nausea, vomiting, anorexia, dysgeusia, stomatitis, oral and esophageal mucositis, fatigue, and diarrhea. In addition, immunosuppressive medications can also adversely affect nutrition status.

Depending upon the transplant regimen, individuals may have little or no oral intake, and the GI tract can be significantly compromised in the early post-transplant period. For many patients, parenteral nutrition (PN) is a standard component of care and is indicated for those who are unable to tolerate oral or enteral feeding (AND EAL, 2013; Macris Charuhos, 2013). In addition, administration of optimal levels of PN often is complicated by the frequent need to interrupt it for the infusion of antibiotics, blood products, and IV medications. Careful monitoring and the use of more concentrated nutrient solutions, increased flow rates and volumes, and double- or triple-lumen catheters often are needed to achieve optimal nutrition intakes.

Autologous HCT involves the use of the individual's own stem cells to reestablish hematopoietic stem cell function after the administration of high-dose chemotherapy. In some cases the use of mobilized stem cell progenitors has replaced autologous bone marrow as the source of hematopoietic progenitors for transplantation. Their use has shortened the period of **pancytopenia** (reduction in the cellular components of the blood), when individuals are at risk for bleeding, serious infections, or sepsis. These advances, along with improved prophylactic antibiotic regimens that are relatively easy to administer, have allowed individuals to receive autologous marrow transplantation in the outpatient setting. The reduced cost of transplantation has made it available to an increased number of people.

Because a majority of people receive much of their care outside the hospital, regular nutrition assessment and monitoring are important. The HCT procedure is associated with severe nutritional consequences that require prompt, proactive intervention. Nausea, vomiting, and diarrhea are caused by the cytotoxic conditioning regimen and may later accompany antibiotic administration. Complications of delayed-onset nutrition-related symptoms include varying degrees of mucositis, xerostomia, and dysgeusia. Mucositis, which is often severe and extremely painful, develops in more than 75% of transplant patients (see Figure 36-2).

BOX 36-3 Safe Food Handling Practices

- Avoidance of foods that contain unsafe levels of bacteria (raw meats, spoiled or moldy foods, and unpasteurized beverages)
- Thorough hand washing
- Special handling of raw meats, game, poultry, and eggs, utensils, cutting boards, and countertops
- Avoidance of untested well water
- Storage of foods at appropriate temperatures (below 40° F and above 140° F)

Nutritional Precautions with Neutropenia

Individuals receiving HCT become immunocompromised and require supportive therapy, including medications and dietary changes to prevent infection. Some cancer centers continue to prescribe a low-microbial or low-bacteria diet for people with low white blood cell counts (neutropenia). However, there is no clear evidence that a strict “neutropenic” diet (only cooked foods) reduces overall rates of infection or death (AND, EAL, 2013). Current recommendations are for nutrition education to include dietary counseling on safe food handling and avoidance of foods that pose a risk of infection while patients are neutropenic and until immunosuppressive therapy has been completed (AND, EAL, 2013; SCCA, 2014) (see Box 36-3).

Graft-versus-Host Disease (GVHD)

Graft-versus-host disease (GVHD) is a major complication seen primarily after allogeneic transplants, in which the donated “donor” stem cells react against the tissues of the transplant recipient “host”. The functions of several target organs (skin, liver, gut, lymphoid cells) are disrupted and are susceptible to infection. Acute GVHD can occur within the first 100 days after the transplant and may be seen as early as 7 to 10 days posttransplant. It may resolve, or it may develop into a chronic form that requires long-term treatment and dietary management. Skin GVHD is characterized by a maculopapular rash. GVHD of the liver, evidenced by jaundice and abnormal liver function tests, often accompanies gastrointestinal GVHD and further complicates nutrition management.

The symptoms of acute GI GVHD can be severe; individuals may experience gastroenteritis, abdominal pain, nausea, vomiting, and large volumes of secretory diarrhea. Immunosuppressive medications and a phased dietary regimen should be instituted (Macris Charuh, 2013; SCCA, 2014). The first phase consists of total bowel rest and the use of PN until diarrhea subsides. Nitrogen losses associated with diarrhea can be severe and are compounded by the high-dose corticosteroids used to treat GVHD. The second phase reintroduces oral feedings of beverages that are isosmotic, low residue, and lactose free so as to compensate for the loss of intestinal enzymes secondary to alterations in the intestinal villi and mucosa. If these beverages are tolerated, phase three includes the reintroduction of solids that contain low levels of lactose, fiber, fat, and total acidity, and no gastric irritants. In phase four dietary restrictions are progressively reduced as foods are gradually introduced and tolerance is established. *Phase five* is the resumption of the individual’s regular diet.

Chronic GVHD can develop up to 3 months after transplant and is observed with increased frequency in nonidentical related donors and unrelated donors. Chronic GVHD can affect the skin, oral mucosa (ulcerations, stomatitis, xerostomia), and the GI tract (anorexia, reflux symptoms, diarrhea) and can cause changes in body weight.

Another transplant-related complication is **sinusoidal obstructive syndrome (SOS)** (also known as **venoocclusive disease**), characterized by chemotherapy- or radiation therapy-induced damage to the hepatic venules. It can develop within 1 to 3 weeks after transplant, and symptoms of right upper quadrant discomfort, hepatomegaly, fluid retention, and jaundice can occur. In severe cases individuals may experience progressive hepatic failure leading to encephalopathy and multiple-organ system failure. Nutrition support requires PN, careful fluid and electrolyte management, close monitoring, and adjustment of macronutrients and micronutrients based on the tolerance and response of each individual.

Other acute or chronic complications of HCT include osteoporosis, pulmonary disease, impaired renal function, rejection of the graft, growth abnormalities in children, sepsis, and infection. Nutrition-related symptoms associated with HCT may persist; individuals receiving outpatient marrow transplantation require frequent monitoring and intervention.

NUTRITION MONITORING AND EVALUATION

Dietetic professionals must determine and quantify their patients’ nutrition care goals by monitoring progress, measuring and evaluating outcomes and changes, and documenting this information throughout the process (Box 36-4). Monitoring and evaluation of these factors is needed to effectively diagnose nutrition problems that should be the focus of future nutrition interventions (AND, EAL, 2013) (see Chapter 10).

Physical Activity

Physical activity is an important part of cancer care. The effect of cancer and cancer treatment on the individual’s quality of life should be addressed throughout cancer treatment and continue until the individual is able to successfully resume activities of daily living. Recovery from cancer treatment also requires physical activity to rebuild muscle; regain strength, energy, and flexibility; and help relieve symptoms of stress,

BOX 36-4 Monitoring and Evaluation of Adult Oncology Patients

- Anthropometric measurements: weight change; BMI
- Food/nutrition-related history: energy and protein intake; changes in food and fluid intake; adequacy and appropriateness of nutrition intake/nutrient administration; actual intake from EN and PN; changes in type, texture, or temperature of foods and fluids; use of medical food supplements; meal/snack pattern changes; prescription medications, over-the-counter medications, herbal preparations and integrative medicine products; factors affecting access to food; and feeding method or need for placement (e.g. oral, enteral, parenteral)
- Biochemical data, medical tests and procedures: biochemical indices; and implications of diagnostic tests and therapeutic procedures
- Nutrition-focused physical findings: vital signs; loss of muscle mass; loss of subcutaneous fat; nutrition impact symptoms including but not limited to: nausea, vomiting, diarrhea, constipation, stomatitis, mucositis, alterations in taste and smell, and anxiety; presence of pressure ulcers or wounds; functional indicators (e.g., KPS, grip strength); and localized or generalized fluid accumulation (see Appendix 21)
- Client history including patient/family/client medical/health history and social history

Academy of Nutrition and Dietetics (AND), Evidence Analysis Library (EAL): *Oncology nutrition evidence-based nutrition practice guidelines*, Chicago, 2013, Academy of Nutrition and Dietetics.

anxiety, and even depression. Physical activity and exercise may be helpful in strengthening the immune system. However, before participating in any type of physical activity and exercise program, individuals should be advised to undergo evaluation by qualified professionals, who can then design an individualized physical assessment and activity plan. The STAR (Survivorship Training and Rehab) certified specialists are available around the country in large and small cancer centers; the program's goal is health care professionals seeking certification how rehab can help cancer patients and about the unique needs of cancer survivors after cancer treatment (ORP, 2015). In addition, the American College of Sports Medicine (ACSM) offers a certification program for trainers working with people diagnosed with cancer (a certified cancer exercise trainer) (ACSM, 2014). Finally, community-based programs such as the YMCA's LiveStrong (www.livestrong.org/LIVESTRONG-at-theYMCA) are available across the United States and offer physical activity and exercise opportunities to support cancer survivors.

PEDIATRIC CANCER

Like adults, children with cancer can experience malnutrition and nutrition-related symptoms as a result of their cancer and its treatment. Malnutrition can have long-term side effects with childhood cancer treatment such as slow or stunted growth and development, compromised bone health, eating disorders, and decreased quality of life (Fatemi et al, 2013).

Psychogenic food refusal in children requires interventions that address underlying psychological issues. Families and caregivers often express their fears of dying through an extreme preoccupation with eating and maintaining weight. Creative efforts are required to minimize the psychologic effects of fear, unpleasant hospital routines, unfamiliar foods, learned food aversions, and pain. Nutrition intervention strategies that use oral intake should stress the maximum use of favorite, nutrient-dense foods during times when intake is likely to be best, and food aversions are least likely to occur. Oral medical foods can be useful, but their acceptance is often a problem; thus children should be offered a selection from which to choose.

EN support by nasogastric tube (up to 3 months) or gastrostomy tube (more than 3 months) may be indicated for some children who are able to cooperate and who have functional GI tracts.

PN is indicated for children who are receiving intense treatment associated with severe GI toxicity (intractable vomiting and severe diarrhea) and for children with favorable prognoses who are malnourished or have a high risk of developing malnutrition. PN is seldom indicated for children with advanced cancer associated with significant deterioration or with diseases that are unresponsive to therapy.

Universally accepted, evidence-based guidelines for children diagnosed with cancer do not exist. However, the American Society for Parenteral and Enteral Nutrition (ASPEN) has established standards for the nutrition screening and specialized nutrition support for all hospitalized pediatric patients. The nutritional requirements of pediatric patients with cancer are similar, with an adjustment for activity, to those of normal growing children. Often pediatric patients with cancer are not bedridden but are as active as their healthy peers. Factors that may alter nutrient requirements in cancer include the effect of the disease on host metabolism, the catabolic effects of cancer therapy, and physiologic stress from surgery, fever, malabsorption, and infection. Fluid requirements are increased during anticancer therapy or in the presence of fever, diarrhea, or renal

failure. Micronutrients may require supplementation during periods of poor intake, stress, or malabsorption.

The best long-term indicator of adequate nutrient intake is growth. Children have increased nutritional requirements for growth and development that must be met despite extended periods of cancer treatment (see Chapters 16 through 18). A special vulnerability exists during the adolescent growth spurt. Ewing sarcoma, common in adolescents and young adults, frequently is associated with malnutrition.

Another reason why children with advanced cancer are at greater risk of severe nutritional depletion than adults is the frequent use of more aggressive, multimodality treatment. Deficiencies in energy and protein can be expected to affect growth adversely, although the effects may be temporary, and catch-up growth depends on how much energy children are able to consistently consume (Fatemi et al, 2013). However, some cancer treatment regimens may have an effect on growth and development that is independent of nutritional deprivation. HCT is now an accepted and increasingly successful intensive therapy for a wide range of disorders in children. Many supportive therapies may be safely managed in the outpatient arena, thus reducing the period of hospitalization.

NUTRITION RECOMMENDATIONS FOR CANCER SURVIVORS

From the time of diagnosis through the balance of life, the ACS defines anyone living with a cancer diagnosis as a cancer survivor (Rock et al, 2012). The ACS guidelines as well as the WCRF and AICR recommendations provide sound diet, nutrition, and physical activity advice for primary cancer prevention and health for all individuals, including cancer survivors. In addition, the ACS published for the first time evidence-based nutrition and physical guidelines for cancer survivors in 2012 (Rock et al, 2012). Up until this point, the ACS specifically declined to call these a set of "guidelines" or "recommendations" because the evidence in this area of study is not as plentiful as in the primary prevention realm.

Cancer survivorship encompasses three phases: active treatment and recovery, living after recovery (including living disease free or with stable disease), and advance cancer and end of life (Rock et al, 2012). Cancer survivors represent one of the largest groups of people living with a chronic disease. It is estimated that there will be 13.7 million survivors in the United States in 2014; approximately 1 in every 25 Americans is a survivor (ACS, 2014a). The majority of individuals with cancer are able to return to full function and regain quality of life. This trend is expected to continue because of recent awareness in cancer prevention, advances in cancer detection, development of more effective cancer treatments, and advancements in determining the genetic causes of cancer. Long-term cancer survivors should now focus on healthy weight management, healthy diets, and physical activity geared toward secondary cancer and chronic disease prevention.

INTEGRATIVE ONCOLOGY

Complementary therapies are typically noninvasive and useful in controlling symptoms and improving quality of life during and after cancer treatment; they are used in addition to conventional medicine. **Integrative medicine** works to combine evidence-based complementary therapies into conventional cancer treatment (see Chapter 12). Integrative medicine uses strategies to promote self-empowerment, individual responsibility, and lifestyle changes that can potentially reduce risk for cancer recurrence and second

primary tumors. Experts agree that a growing proportion of cancer survivors participate in these modalities with 40% to 50% participating in some form of complementary or integrative therapy during and after treatment (ASCO University, 2014).

The health care team working in oncology must be informed on the different therapies and knowledgeable regarding resources used to evaluate and educate the individuals in their care. Some cancer centers are fortunate; increasing consumer demand has encouraged health care institutions to create “Integrative Medicine” departments with onsite complementary services. Cancer survivors look for open, honest discussions or recommendations from their health care team. Medical, nursing, and nutrition assessments should include open-ended questions on dietary supplement use, such as, “What vitamins, minerals, herbs, or other dietary supplements are you currently taking?” and questions regarding the additional integrative or complementary therapies they are following at the time. The core components to discuss integrative or alternative therapies involve understanding and respecting the need people have to do something for themselves; having a willingness to listen to, explore, and respond frankly to questions; taking the time to discuss the options and offer advice; summarizing the discussion; documenting the dialog; and monitoring the progress of the therapy.

The NIH established a National Center for Complementary and Alternative Medicine (NCCAM) in 1999, renamed the National Center for Complementary and Integrative Health

(NCCIH), which works to create a framework in which to evaluate and research these therapies (Box 36-5 and Figure 36-3).

Dietary Supplements

The most common form of integrative medicine practiced in the United States is the use of dietary supplements (see Chapter 12). Based on the last survey done by the National Center for Complementary and Integrative Health (NCCIH) in 2007, consumers spend in excess of \$33.9 billion every year on complementary integrative medicine (CIM), of which \$14.8 billion is spent on natural products marketed to maintain or enhance health

BOX 36-5 The National Center for Complementary and Integrative Health (NCCIH)

- Natural Products:** products such as herbs/botanicals, vitamins and minerals, glandulars, medicinal mushrooms, and probiotics
- Mind and Body Practice:** procedures or techniques delivered or instructed by a trained practitioner or teacher such as acupuncture, massage therapy, meditation, movement therapies, guided imagery, spinal manipulation, tai chi and qi gong, yoga, healing touch, and hypnotherapy
- Other Complementary Health Approaches:** practices of traditional healers, Ayurvedic medicine from India, traditional Chinese medicine, homeopathy, and naturopathy

Data from National Center for Complementary and Integrative Health (NCCIH): Main page (website): <https://nccih.nih.gov/>. Accessed February 20, 2015.

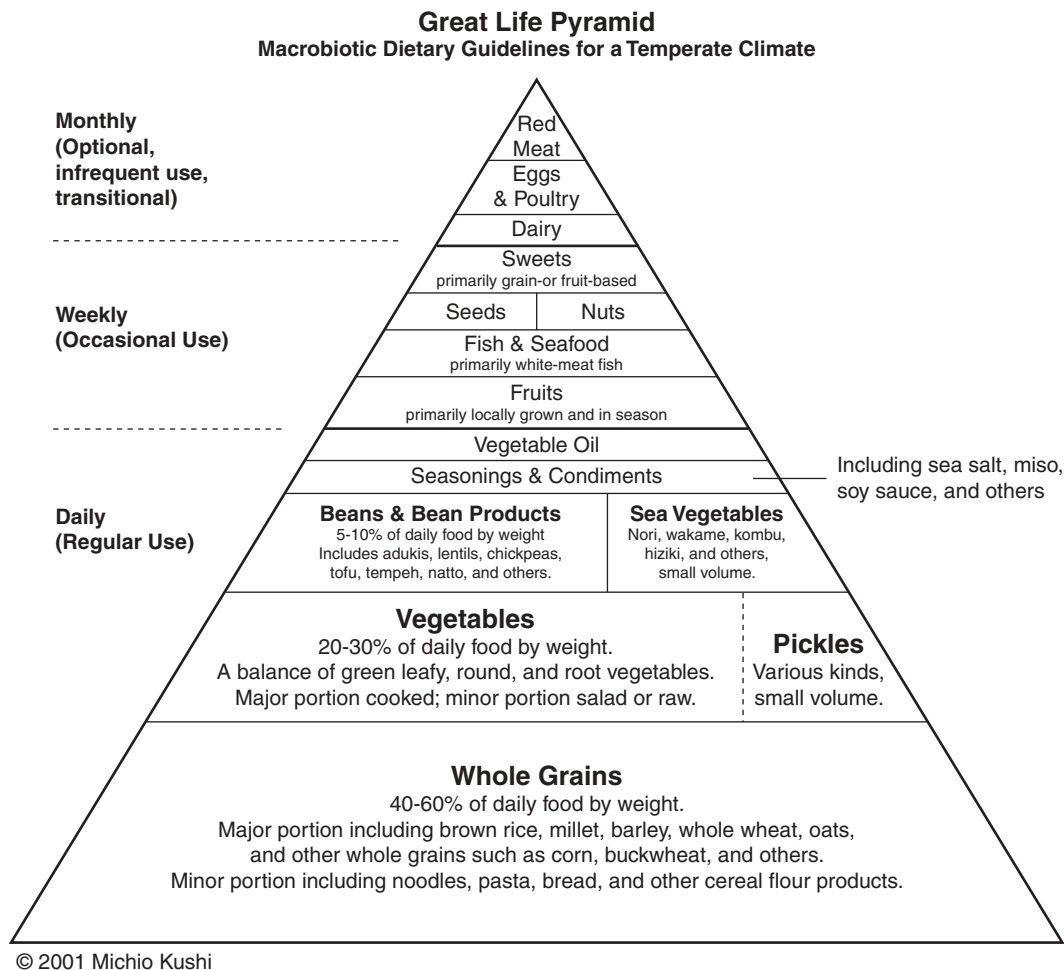

FIGURE 36-3 The Great Pyramid of Life.

(NCCIH, 2009). The largest percentage of use (18%) is nonvitamin, nonmineral natural products such as fish oil supplements and ginseng. That number jumps significantly when surveying cancer survivors, in whom significant use occurs. A primary motivation is symptom management but most also hope for tumor suppression.

Nondisclosure of use is a common occurrence, with a reported 53% of individuals receiving chemotherapy not discussing use of dietary supplements with their health care team (Davis et al, 2012; Hardy, 2008). People may view dietary supplements as a more natural alternative to prescription medications or a quick, easy remedy to an underlying medical problem. Distrust of the medical system, fear of being “fired” or dismissed by their doctor, or anticipated ignorance from the health care team may prevent cancer survivors from discussing use of dietary supplements. When discussing CIM use, the practitioner can take five steps: (1) inquire about use, (2) evaluate the supplement, (3) discuss any relevant regulatory issues, (4) discuss available safety and efficacy data, and (5) compare risks and benefits of use to available conventional therapies. Although time consuming, conversations that include most or all of these steps help open lines of communication between health care provider and survivor and prevent an adverse event or poor treatment decisions. Table 36-11 lists potential adverse effects of some of the commonly used supplements.

Orthomolecular Medicine

Orthomolecular medicine (OM) is the practice of restoring an optimal environment in the body by correcting nutritional imbalances and deficiencies, another alternative medicine practice in cancer care. The treatment is based on the theory that by correcting imbalances and deficiencies, the body will regain health. This has not been proven in clinical trials and instead is extrapolated from basic science. Infusions or supplementation may involve large doses of vitamins, minerals, essential fatty

acids, fiber, amino acids, or enzymes. Orthomolecular practitioners (often medical doctors) consider a number of integrative medicine practices to be consistent with OM philosophy and may incorporate parts of naturopathic medicine, nutrition, acupuncture, mind-body therapies, and manipulative and body-based practices such as massage into their treatments.

Advanced Cancer and Palliative Care

Palliative care is the active total care of an individual when curative measures are no longer considered an option by either the medical team or the individual. Hospice care focuses on relieving symptoms and supporting individuals with a life expectancy of months, not years (NHPCO, 2014). The objectives are to provide for optimal quality of life; relieve physical symptoms; alleviate isolation, anxiety, and fear associated with advanced disease; and to help patients maintain independence as long as possible. The goals of nutrition intervention should focus on managing nutrition-related symptoms such as pain, weakness, loss of appetite, early satiety, constipation, weakness, dry mouth, and dyspnea (Trentham and Grant, 2013). Another important goal is maintaining strength and energy to enhance quality of life, independence, and the ability to perform activities of daily living. Nutrition should be provided “as tolerated or as desired” along with emotional support and awareness of and respect for individual needs and wishes. Thus the pleasurable aspects of eating should be emphasized, without concern for quantity or nutrient and energy content.

The use of nutrition support and hydration in individuals with advanced, incurable cancer is a difficult and often controversial issue and should be determined on a case-by-case basis. Advance directives are legal documents that guide health care providers regarding the specific wishes of individuals, outlining the extent of their desired medical care, including the provision of artificial nutrition and hydration. Whenever providing nutrition care, give consideration to advanced directives that may be in place.

TABLE 36-11 Potential Adverse Events with Dietary Supplements Commonly Used by Cancer Survivors

Dietary Supplement	Claim and Common Uses	Potential Adverse Event
Echinacea	Boosts the immune system	May cause gastrointestinal adverse effects; nausea, abdominal pain, diarrhea, and vomiting are the most common side effects reported
Garlic	Helps lower cholesterol	May increase risk for excessive bleeding, especially when used with certain anticlotting agents
Ginger	Helps with nausea	May increase risk for excessive bleeding, especially when used with certain anticlotting agents
Ginkgo	Helps increase blood circulation and oxygenation	May increase risk for excessive bleeding, especially when used with certain anticlotting agents
Licorice	Enhances memory and mental concentration Helps soothe the stomach	Certain licorice mixtures may cause high blood pressure, increase swelling, and cause electrolyte imbalances
Saw palmetto	Helps with enlarged prostate and urinary inflammation	May interact with other hormone therapies and may increase risk for excessive bleeding, especially when used with certain anticlotting agents
St. John's wort	Helps with mild to moderate depression, anxiety, or sleep disorders	May decrease effectiveness of all currently marketed medication using cytochrome P450 pathway in the liver: HIV and AIDS medications (NNRTIs and PIs), carbamazepine, cyclosporine, irinotecan (Camptosar) for chemotherapy, midazolam (Versed), nifedipine (Procardia), simvastatin (Zocor), theophylline, warfarin (Coumadin)
Valerian	Helps as mild sedative or sleep aid, or muscle relaxant	May increase effects of certain antiseizure medications or prolong effects of anesthetic agents

CLINICAL CASE STUDY 1

Rosa is a 62-year-old woman who has three adult daughters and eight grandchildren. Recently she was diagnosed with breast cancer (estrogen-receptor and progesterone-receptor negative and HER/2 neu positive). Surgery, followed by concurrent chemotherapy and biotherapy and then radiation therapy to her breast are planned for treatment of her disease. Anticipated side effects of her cancer therapy include treatment-related fatigue, mouth sores, nausea, vomiting, diarrhea, and peripheral neuropathy. She is 5'6" tall, weighs 168 lb, and has a history of hypercholesterolemia and hypertension that has been managed with dietary measures. She currently does not engage in regular physical activity other than helping to care for her grandchildren but is motivated to make changes in her lifestyle to improve her fitness and overall health. She also is attracted to the use of multiple vitamins/minerals and dietary supplements and complementary and alternative therapies for managing treatment-related side effects, reducing her cancer recurrence risk and managing her hypercholesterolemia and hypertension.

Nutrition Diagnostic Statement 1

Altered GI function related to prescribed cancer treatment as evidenced by anticipated nausea, vomiting, diarrhea, and mouth sores.

Nutrition Diagnostic Statement 2

Physical inactivity related to lack of a regular exercise plan as evidenced by patient reports of no exercise.

Nutrition Diagnostic Statement 3

Food- and nutrition-related knowledge deficit related to medical nutrition therapy related to cancer treatment and secondary prevention as evidenced by patient requesting more information.

Nutrition Care Questions

- What diet and nutrition recommendations would you give Rosa to prepare her for upcoming cancer treatment?
- List some dietary strategies Rosa may try if she experiences the following: fatigue, intermittent queasiness, mouth sores, and diarrhea.
- Is Rosa at her ideal body weight? If not, what suggestions would you recommend? Consider her lifestyle, hypertension, hypercholesterolemia, and planned cancer treatment.
- What guidance should be provided with regard to the appropriate use of vitamin and mineral supplements and ways to evaluate alternative therapies?

CLINICAL CASE STUDY 2

Daniel is a 54-year-old man with a recent diagnosis of cancer of the gastroesophageal junction. He has experienced gastroesophageal reflux (GERD) for the past 10 years and had been advised to undergo an endoscopic examination to rule out Barrett's esophagus, but he never followed up on his doctor's referral. He lost 30 pounds in the 3 months prior to his diagnosis because of lack of appetite and progressive dysphagia with solid foods. Pre-diagnosis, his diet consisted of drinking "muscle drinks" his son purchased at the local gym. He has been very pleased with his weight loss but knew something was wrong. His medical history also includes hypertension and sleep apnea.

Daniel underwent neo-adjuvant chemotherapy and radiation therapy, followed by an esophagogastrectomy 1½ months ago and recalls that he received some nutrition information from the inpatient registered dietitian nutritionist right before he was discharged. Daniel reports that he was anxious to go home and did not pay attention to the diet instruction and could not find the paperwork once he got home. While hospitalized, Daniel received enteral nutrition via a feeding tube, but the feedings were discontinued and the tube was removed just prior to discharge. He has lost an additional 25 pounds in the past month and has been admitted once for dehydration caused by lack of fluid intake and because of symptoms related to ongoing episodes of diarrhea after eating. He has also stopped using his C-Pap because he feels that it is no longer helpful; however, he states he is not sleeping well and never feels rested.

His current food and nutrition history includes small meals with a usual intake of approximately 1500 calories daily. He eats three times a day. He reports he does not have the energy to prepare food, so, while his wife is at work, he has started drinking the "muscle drinks" again and is warming canned soup in the microwave. He is also drinking sports drinks because he has been encouraged to increase his fluid intake. He has a sweet tooth, and because eating is difficult, he rewards himself with ice cream or sherbet. His beverages include whole milk, apple juice, and an occasional "finger" of scotch each night. He has been referred to see the outpatient registered dietitian nutritionist.

Biochemical Data

Pre-albumin: 14.0 mg/dl
 Blood urea nitrogen: 18 mg/dl
 Creatinine: 0.6 mg/dl
 Blood pressure: 100/55
 Pulse rate of 90

Anthropometric Data

Height: 70"
 Weight history: Usual body weight: 220 lb, preoperative weight: 190 lb,
 1 month postoperative weight: 165 lb
 Current body mass index: 23

Medications

Metoclopramide (Reglan) 30 minutes before each meal
 Metoprolol (Toprol)
 Hydrochlorothiazide
 Sildenafil (Viagra)

Dietary Supplements

One-A-Day for Men
 Saw Palmetto
 Lycopene

Nutrition Diagnostic Statement 1

Food- and nutrition-related knowledge deficit related to lack of education and counseling for appropriate medical nutrition therapy as evidenced by food history with inappropriate food choices.

Nutrition Diagnostic Statement 2

Altered gastrointestinal function related to esophagogastrectomy as evidenced by weight loss, dehydration, and dumping syndrome.

Nutrition Diagnostic Statement 3

Inadequate protein and energy intake related to postsurgery recovery as evidenced by decreased food and beverage intake, weight loss, and muscle wasting causing decreased creatinine.

Nutrition Care Questions

1. What kind of a daily eating plan would you design with Daniel so that he can take in enough food and fluid to meet his nutritional requirements?
2. After reviewing Daniel's medical, social and physical activity history, what other factors could be contributing to his difficulty with eating and his inability to regain weight?
3. Would you include Daniel's wife in your counseling sessions? If so, why? If not, why?
4. As Daniel continues to be seen for Survivorship Care at your clinic, what lingering or late-occurring side effects of cancer treatment should you anticipate and continue to monitor? Could any of these side effects affect his ongoing nutritional status? If so, should any laboratory tests be ordered or evaluated? What other factors should be monitored as a part of your nutritional care?

Nutrition Interventions

Nutrition prescription: Small, frequent meals consisting of energy-dense, lower-fat foods and limited simple carbohydrates; majority of fluid consumption between meals (sips during meals okay to aid in chewing and swallowing).

CLINICAL CASE STUDY 2—cont'd

Nutrition education: Update Daniel's knowledge of appropriate nutrition therapy after an esophagogastrectomy. Discuss tolerance of different food groups; sources of protein; energy-dense, easy-to-prepare menu options; and healthy beverage selections, including advising him to discontinue consumption of daily alcoholic beverage; and goal caloric intake needed for slow, steady weight gain. Suggest he consider eating every 2 hours, on the even hour, to create an external reminder to eat. Recommend he review his hypertension medication types and doses with his physicians because his need for medication may have changed with his significant weight loss.

At follow-up visits address weight stabilization and weight-gain progress, bowel function, food and beverage intake and tolerance; encourage physical activity (physician approved) starting with short walks to regain muscle strength. Daniel should be accompanied by a friend or family member on

these walks. Encourage Daniel to follow-up with his primary care physician to discuss his problems sleeping and that he has stopped using his C-Pap.

Nutrition counseling: Coordinate with patient and wife to ensure appropriate foods and beverages are available for consumption. Discuss expected acute and long-term side effects from surgery. Establish slow, steady weight gain and physical activity goals for next 3 months.

Nutrition Monitoring and Evaluation

1. Body weight trends
2. Hydration status
3. Serum pre-albumin levels and creatinine levels (over 3 months)
4. Physical activity
5. Schedule follow-up session in 2 weeks, with optional phone call between visits

Medical Nutrition Therapy for HIV and AIDS

Kimberly R. Dong, MS, RDN
Cindy Mari Imai, PhD, RDN

KEY TERMS

acquired immune deficiency syndrome (AIDS)
acute HIV infection
antiretroviral therapy (ART)
asymptomatic HIV infection
CD4 + cells
CD4 count

clinical latency
drug resistance
HIV-associated lipodystrophy syndrome (HALS)
HIV ribonucleic acid (RNA)
human immunodeficiency virus (HIV)

lipoatrophy syndrome
long-term nonprogression
opportunistic infections (OIs)
seroconversion
symptomatic HIV infection
T-helper lymphocyte cells
viral load

Acquired immune deficiency syndrome (AIDS) is caused by the **human immunodeficiency virus (HIV)**. HIV affects the body's ability to fight off infection and disease, which ultimately can lead to death. Medications used to treat HIV have enhanced the quality of life and increased life expectancy of HIV-infected individuals. These **antiretroviral therapy (ART)** medications

slow the replication of the virus but do not eliminate HIV infection. With increased access to ART, people are living longer with HIV (see *New Directions: A New Era in HIV Prevention*). Unfortunately, health issues such as cardiovascular disease and insulin resistance are increasingly prevalent, and people living with HIV are at risk of the same chronic diseases as the general population.

NEW DIRECTIONS

A New Era in HIV Prevention

Michael J. Hahn, BA

Even before its identification as a retrovirus in 1983, the battle against HIV had been fought on two fronts: keeping people living with HIV healthy, and preventing new infections. By the time AZT (azidothymidine), the first antiretroviral drug approved by the FDA, was available in 1987, more than 29,000 cases of AIDS had been reported and the epidemic already had claimed more than 25,000 lives (AMFAR, 2014). Although antiretroviral treatment (ART) has been a revolutionary advance in keeping HIV+ individuals from progressing to AIDS, it is estimated that globally an average of 6300 new HIV infections occur daily (UNAIDS, 2014).

The primary route of HIV transmission remains sexual contact. Although prevention efforts have reduced sexual transmission significantly, the rate of new infection demonstrates the need for better tools. Much of the latest prevention efforts have focused on two areas: HIV vaccines and microbicides. Development of a prophylactic HIV vaccine has been difficult; numerous trials have been suspended because of lack of efficacy (National Institute of Allergy and Infectious Diseases, 2013). HIV's ability to elude the immune system makes traditional vaccines like those used for smallpox and measles ineffective. However, each trial has contributed to the body of knowledge to support development of a successful vaccine. Microbicide sponges and gels have shown some promise but to date trials have not led to an approved product because results have been inconsistent.

Three decades after the epidemic began, a new prevention strategy has emerged.

In 2012 the Food and Drug Administration approved an antiretroviral drug combination for preexposure prophylaxis, or PrEP. In a study of heterosexual partners in which one partner was HIV+ and one partner HIV-, consistent use of the drug Truvada (emtricitabine/tenofovir) reduced infections by at least 90% (Baeten et al, 2012). Similarly, in a study of 2500 HIV-negative men and transgender women who have sex with men, participants were randomly assigned to receive either Truvada or placebo once daily. Participants with detectable levels of the antiretrovirals in their blood showed a 92% to 99% greater protection against HIV (Grant et al, 2010).

Detractors of Truvada use contend that problems with adherence and high cost make preexposure prophylaxis an unrealistic solution to decreasing HIV transmission rates (Crary, 2014). A yearly supply of Truvada can cost up to \$13,000 in the United States. However, recent estimates of the annual cost of HIV treatment averages \$23,000, making the financial cost-benefit analysis still favorable for prophylaxis (Gebo et al, 2010).

The long-term health risks of PrEP are unknown. Short-term side effects have been reported to be gastric distress and diarrhea. Monitoring for lactic acidosis, liver damage, and renal issues is important. Common adverse effects of this class of ART also include low body levels of vitamin B₁₂, copper, zinc, and carnitine.

Nutritional status plays an important role in maintaining a healthy immune system and preventing the progression of HIV to AIDS. To develop appropriate nutrition recommendations, the nutrition professional should be familiar with the pathophysiology of HIV infection, the medication and nutrient interactions, and the barriers to adequate nutrition.

EPIDEMIOLOGY AND TRENDS

Global Status of HIV and AIDS

The first cases of AIDS related to HIV were described in 1981. In 1983 HIV was isolated and identified as the core agent leading to AIDS. Since then, the number of people with HIV has increased gradually, leading to a global pandemic affecting socioeconomic development worldwide. The continuing rise in the population of people living with HIV is reflective of new HIV infections and the widespread use of ART, which has delayed the progression of HIV infection to death. Globally, an estimated 35.3 million people were living with HIV or AIDS in 2012. The number of new HIV infections and related deaths has fallen in the last decade. In 2014, there were 2.0 million new HIV infections and 1.2 million AIDS-related deaths reported (Joint United Nations Programme on HIV/AIDS [UNAIDS] and the World Health Organization [WHO], 2013, 2015).

Despite increased prevention efforts and availability of ART, geographic variation in HIV infection is evident. The majority of infections continue to occur in the developing world (see Figure 37-1). Sub-Saharan Africa remains the region most heavily affected by HIV, accounting for 70% of new HIV infections and two-thirds of AIDS-related deaths (UNAIDS and WHO, 2014). However, increases in new infections are being seen in higher-income countries in Eastern Europe such as Ukraine and the Russian Federation. Within sub-Saharan Africa, heterosexual transmission is the most prevalent mode of HIV transmission. Other populations particularly at risk of HIV infection include injection drug users, men who have sex with men, sex workers, and clients of sex workers.

The United States

Within the United States, more than 1.2 million people are living with HIV infection and 13% may be unaware of their HIV status (Centers for Disease Control and Prevention [CDC], 2015). Although more people are living with a diagnosis of HIV or AIDS, incidence has remained relatively stable since the 1990s. In 2013, men accounted for 80% of all diagnoses of HIV infection, and the most common route of transmission was male-to-male sexual contact. The rate of new infections among women, primarily through heterosexual contact, has decreased since 2008 (CDC, 2015b). The largest percentage of persons living with HIV infection is among those aged 45 to 49; this same group accounts for the highest rate of new HIV infections. Ethnic populations disproportionately affected by HIV include African Americans and Latinos, who accounted for 44% and 21% of new HIV diagnoses, respectively, in 2010 (CDC, 2015a). The most common route of transmission among men is male-to-male sexual contact and among women is heterosexual contact (see Figure 37-2).

PATHOPHYSIOLOGY AND CLASSIFICATION

Primary infection with HIV is the underlying cause of AIDS. HIV invades the genetic core of the **CD4 + cells**, which are **T-helper lymphocyte cells**, and which are the principal agents involved in protection against infection. HIV infection causes a progressive depletion of CD4+ cells, which eventually leads to immunodeficiency.

HIV infection progresses through four clinical stages: acute HIV infection, clinical latency, symptomatic HIV infection, and progression of HIV to AIDS. The two main biomarkers used to assess disease progression are **HIV ribonucleic acid (RNA) (viral load)** and CD4+ T-cell count (CD4 count).

Acute HIV infection is the time from transmission of HIV to the host until the production of detectable antibodies against the virus (**seroconversion**) occurs. Half of individuals experience physical symptoms such as fever, malaise, myalgia, pharyngitis, or

FIGURE 37-1 Global prevalence of HIV/AIDS. (Joint United Nations Programme on HIV/AIDS [UNAIDS] and World Health Organization [WHO]: *UNAIDS 2014 Global Fact Sheet* [website]: http://www.unaids.org/sites/default/files/media_asset/20150714_FS_MDG6_Report_en.pdf, 2014. Accessed August 6, 2015.)

*Includes hemophilia, blood transfusion, perinatal exposure, and risk factor not reported or not identified

FIGURE 37-2 Estimated percentage of HIV diagnoses by route of transmission in the United States, 2013. (Centers for Disease Control and Prevention [CDC]: *HIV Surveillance Report* [website]: <http://www.cdc.gov/hiv/library/reports/surveillance>, 2015. Accessed August 6, 2015.)

swollen lymph glands at 2 to 4 weeks after infection, but these generally subside after 1 to 2 weeks. Because of the nonspecific clinical features and short diagnostic window, acute HIV infection is rarely diagnosed. HIV seroconversion occurs within 3 weeks to 3 months after exposure. If HIV testing is done before seroconversion occurs, a “false negative” may result despite HIV being present. During the acute stage, the virus replicates rapidly and causes a significant decline in CD4+ cell counts. Eventually, the immune response reaches a viral setpoint, when the viral load stabilizes and CD4+ cell counts return closer to normal.

A period of **clinical latency**, or **asymptomatic HIV infection**, then follows. Further evidence of illness may not be exhibited for as long as 10 years postinfection. The virus is still active and replicating, although at a decreased rate compared with the acute stage, and CD4+ cell counts continue to steadily decline. In 3% to 5% of HIV-infected individuals, **long-term nonprogression** occurs, in which CD4+ cell counts remain normal and viral loads can be undetectable for years without medical intervention (Department of Health and Human Services [DHHS], 2013). It has been suggested that this unique population has different and fewer receptor sites for the virus to penetrate cell membranes (Wanke et al, 2009).

In the majority of cases, HIV slowly breaks down the immune system, making it incapable of fighting the virus. When CD4+ cell counts fall below 500 cells/mm³ individuals are more susceptible to developing signs and symptoms such as persistent fevers, chronic diarrhea, unexplained weight loss, and recurrent fungal or bacterial infections, all of which are indicative of **symptomatic HIV infection**.

As immunodeficiency worsens and CD4 counts fall to even lower levels, the infection becomes symptomatic and progresses to AIDS. The progression of HIV to AIDS increases the risk of **opportunistic infections (OIs)**, which generally do not occur in individuals with healthy immune systems. The CDC classifies AIDS cases as positive laboratory confirmation of HIV infection in persons with a CD4+ cell count less than 200 cells/mm³ (or less than 14%) or documentation of an AIDS-defining condition (see **Box 37-1**).

BOX 37-1 2008 CDC Case Definition AIDS-Defining Clinical Conditions

Bacterial infections, multiple or recurrent (among children <13 years)
 Candidiasis (bronchi, trachea, or lungs)
 Candidiasis (esophagus)
 Cervical cancer (invasive)
 Coccidioidomycosis (disseminated or extrapulmonary)
 Cryptococcosis (extrapulmonary)
 Cryptosporidiosis (intestinal, >1 month duration)
 Cytomegalovirus disease (other than liver, spleen, or nodes)
 Cytomegalovirus retinitis (with loss of vision)
 Encephalopathy (HIV related)
 Herpes simplex: chronic ulcers (>1 month duration)
 Herpes simplex: bronchitis, pneumonitis, or esophagitis
 Histoplasmosis (disseminated or extrapulmonary)
 Isosporiasis (intestinal, >1 month duration)
 Kaposi sarcoma
 Lymphoid interstitial pneumonia or pulmonary lymphoid hyperplasia complex
 Lymphoma, Burkitt (or equivalent term)
 Lymphoma, immunoblastic (or equivalent term)
 Lymphoma, primary (brain)
Mycobacterium avium complex (disseminated or extrapulmonary)
Mycobacterium kansasii (disseminated or extrapulmonary)
Mycobacterium tuberculosis (any site, pulmonary, disseminated, or extrapulmonary)
Pneumocystis jiroveci pneumonia
 Pneumonia (recurrent)
 Progressive multifocal leukoencephalopathy
Salmonella septicemia (recurrent)
 Toxoplasmosis (brain)

Wasting syndrome attributed to HIV: >10% involuntary weight loss of baseline body weight plus (1) diarrhea (two loose stools per day for ≥30 days) or (2) chronic weakness and documented fever (≥30 days, intermittent or constant) in the absence of concurrent illness or condition other than HIV infection that could explain the findings (e.g., cancer, tuberculosis).

Schneider E et al: Revised surveillance case definitions for HIV infection among adults, adolescents, and children aged <18 months and for HIV infection and AIDS among children aged 18 months to <13 years—United States, 2008, *MMWR Recomm Rep* 57(RR-10):1, 2008. AIDS, Acquired immune deficiency syndrome; CDC, Centers for Disease Control and Prevention; HIV, human immunodeficiency virus.

HIV is transmitted via direct contact with infected body fluids such as blood, semen, preseminal fluid, vaginal fluid, and breast milk. Cerebrospinal fluid surrounding the brain and spinal cord, synovial fluid surrounding joints, and amniotic fluid surrounding a fetus are other fluids that can transmit HIV. Saliva, tears, and urine do not contain enough HIV for transmission. Sexual transmission is the most common way HIV is transmitted, and injection drug use is the second most prevalent method of transmission (see [Figure 37-2](#)).

Most people have HIV-1 infection, which, unless specified, is the type discussed in this chapter. HIV-1 mutates readily and has become distributed unevenly throughout the world in different strains, subtypes, and groups. HIV-2, first isolated in Western Africa, is less easily transmitted, and the time between infection and illness takes longer.

MEDICAL MANAGEMENT

HIV-related morbidity and mortality stem from the HIV virus weakening the immune system as well as the virus's effects on organs (such as the brain and kidney). If untreated, the HIV virion (virus particle) can replicate at millions of particles per day and rapidly progress through the stages of HIV disease. The introduction of three-drug combination ART in 1996 transformed the treatment of patients infected with HIV and has significantly decreased AIDS-defining conditions and mortality (see [Box 37-1](#) for a list of these conditions). Most drugs are formulated as individual medications, but increasingly many are available as fixed-dose combinations to simplify treatment regimens, decrease pill burden, and potentially improve patient medication adherence.

CD4 count is used as the major indicator of immune function in people with HIV infection. It is used to determine when to initiate ART and is the strongest predictor of disease progression. CD4 counts generally are monitored every 3 to 4 months. In addition, HIV RNA (viral load) is monitored on a regular basis because it is the primary indicator to gauge the efficacy of ART. [Table 37-1](#) provides the current guidelines on when to initiate ART.

The fundamental goals of ART are to achieve and maintain viral suppression, reduce HIV-related morbidity and mortality, improve the quality of life, and restore and preserve immune function. This generally can be achieved within 12 to 24 weeks if there are no complications with adherence or resistance to medications ([DHHS, 2013](#)). Because the guidelines for HIV management evolve rapidly, it is beneficial to frequently check for updated recommendations.

Classes of Antiretroviral Therapy Drugs

Currently ART includes more than 25 antiretroviral agents from six mechanistic classes of drugs:

- Nucleoside and nucleotide reverse transcriptase inhibitors (NRTIs)
- Nonnucleoside reverse transcriptase inhibitors (NNRTIs)
- Protease inhibitors (PIs)
- Integrase inhibitors (INSTIs)
- Fusion inhibitors
- CCR5 (chemokine receptor 5) antagonists.

TABLE 37-1 Indications for the Initiation of ART in HIV-infected Individuals

Clinical Category	CD4 Count	Recommendation
Asymptomatic, AIDS	<350 cells/mm ³	Treat
Asymptomatic	350-500 cells/mm ³	Treatment recommended
Asymptomatic	>500 cells/mm ³	Some clinicians recommend initiating therapy and some view treatment as optional
Symptomatic (AIDS, severe symptoms)	Any value	Treat
Pregnancy, HIV-associated nephropathy, HBV coinfection when treatment of HBV is indicated	Any value	Treat

From National Institutes of Health: *Guidelines for the Use of Antiretroviral Agents in HIV-1-Infected Adults and Adolescents* (website): <http://www.aidsinfo.nih.gov/contentfiles/AdultandAdolescentGL.pdf>, 2009 (Accessed 14.10.23.. AIDS, Acquired immune deficiency syndrome; ART, antiretroviral therapy; HBV, hepatitis B virus; HIV, human immunodeficiency virus.

The most widely studied combination regimen for treatment of naïve patients (a general term to refer to individuals that have never started HIV drug therapy) consists of two NRTIs plus either one NNRTI or a PI (with or without ritonavir, used to increase drug levels and half-life in combination therapy, known as boosting). Recently a regimen consisting of raltegravir was approved for treatment-naïve patients, making the combination of an INSTI with two NRTIs another option ([DHHS, 2013](#)).

Although a reasonable number of different antiretroviral medications are currently available for the treatment of HIV infections, there is a growing need for new drugs that have fewer long-term toxicities and greater potency. Because eradication of HIV is not yet possible, and the need for treatment is lifelong, adverse effects of medications, including metabolic complications and other toxicities, become increasingly important as they may lead to nonadherence to the prescribed regimen. Nonadherence to ART can lead to **drug resistance**.

Predictors of Adherence

When initiating ART, patients must be willing and able to commit to lifelong treatment, and should understand the benefits and risks of therapy and the importance of adherence. The patient's understanding about HIV disease and the specific regimen prescribed is critical. A number of factors have been associated with poor adherence, including low levels of literacy, certain age-related challenges (e.g., vision loss, cognitive impairment), psychosocial issues (e.g., depression, homelessness, low social support, stressful life events, dementia, or psychosis), active substance use, stigma, difficulty with taking medication (e.g., trouble swallowing pills, daily schedule issues), complex regimens (e.g., pill burden, dosing frequency, food requirements), adverse drug effects, and treatment fatigue ([DHHS, 2013](#)). Food insecurity has been associated with increased behaviors that can transmit

HIV and decreased access to HIV treatment and care; it also can be a predictor of poor adherence (Anema, 2009; Musumari, 2014; Weiser, 2009) because medications are costly and they often compete with food for available resources.

With the use of boosted PIs and efavirenz, their longer half-lives may permit more lapses in adherence because drug levels stay high in the body for many days (Bangsberg, 2006; Raffa, 2008). However, these drugs are more likely to contribute to drug resistance if discontinued because of rapid viral mutation. Continued encouragement is needed to help patients adhere as closely as possible to the prescribed doses for all ART regimens.

Illicit Drug Use

In the United States, injection drug use is the second most common mode of HIV transmission after sexual contact. The most commonly used illicit drugs associated with HIV infection are heroin, cocaine, and methamphetamine. The chaotic lifestyle associated with drug use is associated with poor or inadequate nutrition, food insecurity, and depression. This complicates treatment of HIV if the individual is using drugs and potentially can lead to poor adherence with ART medications.

Injection drug use is linked strongly to transmission of bloodborne infections such as HIV, hepatitis B virus, and hepatitis C virus (HCV), especially if needles are reused or shared (see *Focus On: HIV and Hepatitis C Virus Coinfection*). Coinfection of HIV and HCV increases the risk of cirrhosis. Chronic HCV infection also complicates HIV treatment because of ART-associated hepatotoxicity. Special medical and nutrition treatment considerations should be taken into account if the liver is damaged from drug use, if there is coinfection with hepatitis, or increased nutrient excretion from diuresis and diarrhea (Hendricks, 2009; Tang, 2010).

FOCUS ON

HIV and Hepatitis C Virus Coinfection

About one quarter of people in the United States who have human immunodeficiency virus (HIV) also are coinfecting with hepatitis C virus (HCV). According to the CDC, 50% to 90% of HIV-infected injection drug users also have HCV (CDC, 2013). Although it is unknown if HCV accelerates HIV disease progression, it has been shown to damage the liver more quickly in HIV-infected persons. In the presence of hepatic impairment, the metabolism and excretion of antiretroviral medications may be impaired, affecting the efficacy of HIV treatment. In addition, three classes of anti-HIV medications (nucleoside and nucleotide reverse transcriptase inhibitors, nonnucleoside reverse transcriptase inhibitors, and protease inhibitors) are associated with hepatotoxicity. Therefore it is important for HIV-infected patients to be tested for HCV, preferably before starting ART, to appropriately manage treatment and prolong healthy liver function.

HCV is viewed as an OI (not an acquired immune deficiency syndrome-defining illness) in HIV-infected persons because there are higher titers of HCV, more rapid progression to liver disease, and increased risk of cirrhosis (DHHS, 2013). Nutrition recommendations and dosing and choice of HIV medications must be adjusted for those with liver failure (see Chapter 29).

Food-Drug Interactions

Some ART medications require attention to dietary intake. It is important to ask individuals with HIV to report all medications, including vitamins, minerals, other supplements, and recreational substances that they consume in order to assess their needs fully and prevent drug interactions and nutrient deficiencies. Some nutrients can affect how drugs are absorbed or metabolized (see Chapter 8). Interactions between food and drugs can influence the efficacy of the drug or may cause additional or worsening adverse effects. For example, grapefruit juice and PIs compete for the cytochrome P450 enzymes; thus individuals taking PIs who also drink grapefruit juice may have either increased or decreased blood levels of the drug. Table 37-2 provides potential nutrient interactions with ART medications (see Appendix 23).

Some ART medications can cause diarrhea, fatigue, gastroesophageal reflux, nausea, vomiting, dyslipidemia, and insulin resistance. Timing is also important for ART efficacy, so patients with HIV must take medications on a schedule. Some medications indicate that they must be taken with food or on an empty stomach. Sometimes food must be taken within a specific time frame of administering a medication. Refer to Table 37-2 for timing considerations with ART.

Medical Management

HIV infection should be confirmed by laboratory testing and not based on patient report (CDC, 2008). The presence of comorbidities such as heart disease, diabetes, hepatitis, and OIs may complicate the patient's treatment profile. The assessment should include the patient's past medical history and pertinent immediate family history for heart disease, diabetes, cancers, or other disorders. Metabolic issues such as dyslipidemia and insulin resistance are common in people with HIV and should be monitored. Biochemical measurements should be documented to determine the course of HIV treatment, need for ART, efficacy of ART, and underlying malnutrition and nutrient deficiencies. Some common biochemical measurements include CD4 count, viral load, albumin, hemoglobin, iron status, lipid profile, liver function tests, renal function tests, glucose, insulin, and vitamin levels. Table 37-3 discusses conditions associated with HIV and their nutritional implications.

MEDICAL NUTRITION THERAPY

For people living with HIV, adequate and balanced nutrition intake is essential to maintain a healthy immune system and prolong life. It has been documented that children and adults who are living with HIV have lower fat-free and total fat mass (American Dietetic Association, 2010). Proper nutrition may help maintain lean body mass, reduce the severity of HIV-related symptoms, improve quality of life, and enhance adherence to and effectiveness of ART. Therefore medical nutrition therapy (MNT) is integral to successfully manage HIV (see *Pathophysiology and Care Management Algorithm: Human Immunodeficiency Virus Disease*).

A registered dietitian nutritionist (RDN) can help the patient manage many of the necessary requirements for medications,

TABLE 37-2 Medication Interactions and Common Adverse Effects

TIMING CONSIDERATIONS			
Medication Name	Take with Meal or Snack	Take on Empty Stomach	Take without Regard to Food
NRTI			
emtricitabine (Emtriva, FTC)*			X
lamivudine (EpiVir, 3TC) [†]			X
zidovudine (Retrovir, ZDV, AZT) [†]			X
abacavir, lamivudine, and zidovudine (Trizivir) [†]			X
didanosine (Videx, Videx EC, DDL) [‡]	Do not mix with acidic foods or antacids with magnesium or aluminum	X	
tenofovir (Viread, TDF)*			X
stavudine (Zerit, Zerit XR, d4T) [‡]			X
abacavir (Ziagen, ABC) [†]			X

Abbreviations: NRTI, nucleoside and nucleotide reverse transcriptase inhibitor, NNRTI, non-nucleoside reverse transcriptase inhibitors

Notes: NRTI medications in general can potentially lead to anemia, loss of appetite, low vitamin B12, low copper, low zinc, and low carnitine. Taking NRTIs with snacks may help limit gastrointestinal upset.

Additional side effects may also be associated with these HIV medications. It is important to be aware of potential interactions with other medications and to be up-to-date with HIV medications by regularly checking the following sources:

PATHOPHYSIOLOGY AND CARE MANAGEMENT ALGORITHM

Human Immunodeficiency Virus Disease

ETIOLOGY

PATHOPHYSIOLOGY

Clinical Findings

Acute HIV infection (Acute retroviral syndrome) Fever, fatigue, rash, headache, generalized lymphadenopathy, pharyngitis, myalgia, nausea/vomiting, diarrhea, night sweats, adenopathy, oral ulcers, genital ulcers, neurological symptoms, malaise, anorexia, weight loss, wasting syndrome

Seroconversion

HIV Positive Test HIV rapid tests; ELISA test, Western blot; PCR test

Asymptomatic HIV infection Abnormal metabolism, change of body composition (body cell mass loss with/without weight loss, lipoatrophy, lipohypertrophy), vitamin B₁₂ deficiency, susceptibility to pathogens

Symptomatic HIV infection Weight loss, thrush, fever, loss of LBM with/without weight loss, diarrhea, oral hairy leukoplakia, herpes zoster, peripheral neuropathy, idiopathic thrombocytopenic purpura, pelvic inflammatory disease

Asymptomatic AIDS

Symptomatic AIDS (AIDS defined conditions) CD4 cell count <200/mm³, opportunistic infectious diseases (pneumocystitis jirovecii, pneumonia, others), Kaposi's sarcoma, lymphoma, HIV-associated dementia, HIV-associated wasting, vitamins/minerals deficiencies

MANAGEMENT

Medical Management

Treat possible co-morbidities

Hyperglycemia, hyperlipidemia, hypertension, body composition changes, pancreatitis, kidney and liver diseases, hypothyroidism, hypogonadism, osteopenia, hepatitis-C

Monitoring

Fasting blood lipid, fasting glucose/insulin level, protein status, blood pressure, TSH/testosterone level, CD4 cell count, and viral load

Medication

Antiretroviral therapy, lipid lowering agents, antidiabetic agents, antihypertensive agents, appetite stimulants, hormone replacement therapy, treatment for coinfectious diseases (i.e. hepatitis), prophylaxis and treatment for opportunistic infectious diseases

Nutrition Management

- Complete nutrition assessment 2-6 times/year. See Fig. 37-3
- Emphasize importance of early/ongoing nutritional intervention
- Promote adequate intake of nutrients and fluids
- Emphasize importance of food and water safety and sanitation
- Emphasize regular exercise and physical activity
- If psycho-social economic barriers to food, give resources
- Dietary multiple vitamin and mineral supplements
- Inform patient of possible side effects, symptoms, and/or complications
- Monitor/manage metabolic abnormalities
- Small, frequent, nutrient-dense meals
- If mouth ulcers present, foods made need to be mashed or ground
- Appetite stimulants if necessary
- Parenteral nutrition if necessary
- Anabolic therapies

TABLE 37-3 HIV-Related Conditions with Specific Nutrition Implications

Condition	Brief Description	Nutrition Implications
PCP	Potentially fatal fungal infection	Difficulty chewing and swallowing caused by shortness of breath
TB	Bacterial infection that attacks the lungs	Prolonged fatigue, anorexia, nutrient malabsorption, altered metabolism, weight loss
Cryptosporidiosis	Infection of small intestine caused by parasite	Watery diarrhea, abdominal cramping, malnutrition and weight loss, electrolyte imbalance
Kaposi sarcoma	Type of cancer causing abnormal tissue growth under the skin	Difficulty chewing and swallowing caused by lesions in oral cavity or esophagus Diarrhea or intestinal obstruction caused by lesions in intestine
Lymphomas	Abnormal, malignant growth of lymph tissue	
Brain	Changes in motor and cognitive abilities	Inability to prepare food and coordinate movement
Small bowel	Malabsorption	Weight loss, diarrhea, loss of appetite
Cytomegalovirus (disseminated)	Infection caused by herpes virus	Loss of appetite, weight loss, fatigue, enteritis, colitis
Candidiasis	Infection caused by fungi or yeast	Oral sores in mouth, difficulty chewing and swallowing, change in taste
HIV-induced enteropathy	Idiopathic, direct or indirect effect of HIV on enteric mucosa	Chronic diarrhea, weight loss, malabsorption, changes in cognition and behavior
HIV encephalopathy (AIDS dementia)	Degenerative disease of brain caused by HIV infection	Loss of coordination and cognitive function, inability to prepare food
<i>Pneumocystis jiroveci</i> pneumonia	Infection caused by fungi	Fever, chills, shortness of breath, weight loss, fatigue
<i>Mycobacterium avium</i> complex (disseminated)	Bacterial infection in lungs or intestine, spreads quickly through bloodstream	Fever, cachexia, abdominal pain, diarrhea, malabsorption

minimize adverse effects, and address nutritional concerns. Some common nutrition diagnoses in this population include the following:

- Inadequate oral food and beverage intake NI-2.1
- Increased nutrient needs NI-5.1
- Swallowing difficulty NC-1.1
- Altered gastrointestinal (GI) function NC-1.4
- Food-medication interaction NC-2.3
- Involuntary weight loss NC-3.2
- Overweight and obesity NC-3.3
- Food- and nutrition-related knowledge deficit NB-1.1
- Oversupplementation of nutrients
- Impaired ability to prepare foods or meals NB-2.4
- Inadequate access to food NB-3.2
- Intake of unsafe or undercooked foods NB-3.1.

All individuals with HIV infection should have access to an RDN or other qualified nutrition professional. Patients should undergo a baseline nutrition assessment once they are diagnosed with HIV (see Chapters 4 and 7). Follow-up should be ongoing and take into consideration the multifactorial complications that can affect patient care. The Academy of Nutrition and Dietetics (AND) recommends that an RDN should provide at least one to two MNT encounters per year for individuals with asymptomatic HIV infection and at least two to six MNT encounters per year for those with symptomatic, but stable HIV infection. Individuals diagnosed with AIDS usually need to be seen more often because they may require nutrition support (see Chapter 13).

Ultimately, MNT should be individualized, and frequency of nutrition counseling should be determined by the patient's needs. The major goals of MNT for persons living with HIV

infection are to optimize nutritional status, immunity, and well-being; to maintain a healthy weight and lean body mass; to prevent nutrient deficiencies and reduce the risk of comorbidities; and to maximize the effectiveness of medical and pharmacologic treatments. Thus screening should be performed on all patients medically diagnosed with HIV to identify those at risk for nutritional deficiencies or in need of MNT.

Patients who exhibit the various HIV-related symptoms or conditions listed in [Figure 37-3](#) should be referred to a RDN with expertise in managing this disease. A comprehensive nutrition assessment should be performed at the initial visit. In addition, regular monitoring and evaluation are essential to detect and manage any undesirable nutritional consequences of medical treatments or the disease process. Strategies for managing the adverse effects are given in [Table 37-4](#). Key factors to assess are listed in [Table 37-5](#).

Physical Changes

The physical presentation of the patient should be considered during initial and follow-up assessments. Patients with HIV are aware of changes in their body shape and are instrumental in identifying these changes. Health care professionals should remember to ask patients about body shape changes every 3 to 6 months. Changes in body shape and fat redistribution can be monitored by anthropometric measurements. Commonly these are taken as circumferences around the waist, hip, mid-upper arm, and thigh, and as skinfold measurements of the triceps, subscapular, suprailiac, thigh, and abdomen. If a dorsocervical fat pad (fat behind the neck) is present, measurement of the neck diameter can help track changes in this area. These physical changes are referred to as **HIV-associated**

I. Nutrition Screen and Referral Criteria for Adults with HIV/AIDS			
			Today's Date _____
Name _____	Phone _____	Messages: <input type="checkbox"/> Yes <input type="checkbox"/> No <input type="checkbox"/> Discreet

TABLE 37-4 Nutrition Recommendations for Typical Adverse Effects

Adverse Effect	Nutrition Recommendations
Nausea, vomiting	Eat small, frequent meals. Avoid drinking liquids with meals. Drink cool, clear liquids. Try dry crackers or toast. Try bland foods such as potatoes, rice, or canned fruits. Limit high-fat, greasy foods or foods that have strong odors such as ripe cheese or fish. Eat foods at room temperature or cooler. Wear loose-fitting clothes. Rest sitting up after meals. Keep a log of when nausea and vomiting occur and which foods seem to trigger it.
Diarrhea	Try plain carbohydrates such as white rice, rice congee, noodles, crackers, or white toast. Try low-fiber fruits like bananas and applesauce. Drink fluids that will replace electrolytes such as broths and oral hydration drinks. Try small, frequent meals. Avoid fatty, greasy foods. Avoid highly spiced foods. Avoid sugary items such as soda and fruit juice. Avoid milk and milk products. Limit caffeine.
Loss of appetite	Eat small, frequent meals. Focus on nutrient-dense foods such as milkshakes, lean protein, eggs, nut butters, vegetables, fruits, and whole grains. Try to eat in a pleasant environment.
Taste alterations	Add spices and herbs to foods. Avoid canned foods or canned oral supplements.
Hyperlipidemia	NCEP diet (see Chapter 33)
Hyperglycemia	Diet for patients with diabetes (see Chapter 30)
Mouth and esophageal ulcers and sore throat	Try soft foods such as oatmeal, rice, applesauce, scrambled eggs, milkshakes, or yogurt. Avoid acidic foods such as citrus, vinegar, spicy, salty, or hot foods. Moisten foods with gravy or sauces. Drink liquids with meals. Avoid acidic beverages. Try foods and beverages at room temperature.
Pancreatitis	Focus on low-fat foods and limit fat at each meal (see Chapter 29). May need pancreatic enzymes to aid in digestion.
Weight loss	Eat small, frequent meals (see Chapter 21). Focus on nutrient-dense foods such as milkshakes, lean protein, eggs, nut butters, vegetables, fruits, whole grains, trail mixes, and tofu. Add rice, barley, and legumes to soups. Add dry milk powder or protein powder to casseroles, hot cereals, and milkshakes. Try oral supplements.

NCEP, National Cholesterol Education Program.

lipodystrophy syndrome (HALS). Unintentional weight changes should be monitored closely because they can indicate progression of HIV disease. Peripheral neuropathy is a potential side effect, most frequently associated with the use of NRTIs. The resulting nerve damage causes stiffness, numbness, or tingling, generally in the lower extremities. Patients

TABLE 37-5 Factors to Consider in Nutrition Assessment

Medical	Stage of HIV disease Comorbidities Opportunistic infections Metabolic complications
Physical	Biochemical measurements Changes in body shape Weight or growth concerns Oral or gastrointestinal symptoms Functional status (i.e., cognitive function, mobility) Anthropometrics
Social	Living environment (support from family and friends) Behavioral concerns or unusual eating behaviors Mental health (i.e., depression)
Economical	Barriers to nutrition (i.e., access to food, financial resources)
Nutritional	Typical intake Food shopping and preparation Food allergies and intolerances Vitamin, mineral, and other supplements Alcohol and drug use

HIV, Human immunodeficiency virus.

experiencing neuropathy may be unable to work or be physically active.

Social and Economic Factors

Depending on a patient's mental status, psychosocial issues may take precedence over nutrition counseling. Depression is common, so the need to treat and provide services for mental health issues should be monitored. When individuals are unable to care for themselves, discussion with caretakers may be necessary to understand the patient's nutrition history. Particular habits, food aversions, timing of meals with medications, and related concerns should be documented.

Access to safe, affordable, and nutritious food should be evaluated. Common barriers include cost, location of supermarkets, lack of transportation, and lack of knowledge of healthier choices. Furthermore, stigma not only is a predictor of ART adherence, but also may prevent individuals with HIV from using nutrition programs and seeking support systems.

Nutrient Recommendations

When collecting the diet history, the clinician should include a review of current intake, changes in intake, limitations with food access or preparation, food intolerances or allergies, supplement use, current medications, and alcohol and recreational drug use to help determine the potential for any nutrient deficiencies and assist in making individualized recommendations (see Chapter 4).

Adequate nutrition intake can help patients with HIV with symptom management and improve the efficacy of medications, disease complications, and overall quality of life (see [Figure 37-3](#) for a sample nutrition screening form). Note that a one-size-fits-all approach does not address the complexity of HIV. Recommendations in [Box 37-2](#) to improve nutritional status, immunity, and quality of life, address drug-nutrient interactions or side effects, and identify barriers to desirable food intake should be personalized for the patient.

In the early years of nutrition therapy for HIV, the focus was on treatment and prevention of unintentional weight loss and wasting. Now with access to ART, new nutrition issues have

BOX 37-2 Nutrition Education for the HIV Infected

Pregnancy, Lactation, Infancy, and Childhood

Nutrition and food choices for healthy pregnancy and lactation
Transmission risk in breastfeeding and replacement feeding alternatives
Growth failure and developmental delay in children
Support for normal growth trends in children

Adolescents and Adults

Basic nutrition concepts and healthy habits
Physical activity recommendations
Body image and altered body weight and shape
Nutrition and food-related knowledge related to cultural or ethnic practices

Nutrition Interactions

Prevention, restoration, and maintenance of optimal body composition with an emphasis on lean tissues
Medication-nutrition interactions
Management of barriers to nutritional wellness, nutrition-related side effects of treatments, and symptoms requiring attention
Review of oral beverage or nutrient supplements
Review of potential interactions with nonprescription medications and herbal supplements
Evaluation of interactions with alcohol and recreational drugs

Life Skills and Socioeconomic Issues

Safe food handling and water sources
Access to adequate food choices
Food preparation skills and abilities

arisen caused by HALS. HIV-related death from OIs has shifted to other chronic disease conditions such as heart disease and diabetes in healthier individuals who are living with HIV (Leyes, 2008).

Energy and Fluid

When determining energy needs, the clinician must establish if the individual needs to gain, lose, or maintain weight. Other factors such as altered metabolism, nutrient deficiencies, severity of disease, comorbidities, and OIs should be taken into account when evaluating energy needs. Calculating energy and protein needs for this population is difficult because of other issues with wasting, obesity, HALS, and lack of accurate prediction equations. Some research suggests that resting energy expenditure is increased by approximately 10% in adults with asymptomatic HIV (Polo, 2007). After an OI, nutritional requirements increase by 20% to 50% in adults and children (WHO, 2005a). Continuous medical and nutrition assessment is necessary to make adjustments as needed. Individuals with well-controlled HIV are encouraged to follow the same principles of healthy eating and fluid intake recommended for the general population (see Chapter 11).

Protein

The current recommended dietary reference intake (DRI) is 0.8 g of protein per kilogram of body weight per day for healthy individuals. Deficiency of protein stores and abnormal protein metabolism occur in HIV and AIDS, but no evidence exists for

increased protein intake over and above that necessary to accompany the required increase in energy (WHO, 2005b). For people with HIV who have adequate weight and are not malnourished, protein supplementation may not be sufficient to improve lean body mass (Sattler, 2008). However, with an OI, an additional 10% increase in protein intake is recommended because of increased protein turnover (WHO, 2005b). If other comorbidities such as renal insufficiency, cirrhosis, or pancreatitis are present, protein recommendations should be adjusted accordingly (see Chapter 29).

Fat

Evidence indicates that fat oxidation increases with HIV infection and thus, dietary fat requirements may be different (WHO, 2005b). However, the mechanism is multifaceted and at present, general heart-healthy guidelines should be the focus for dietary fat intake. Recent research has focused on immune function and omega-3 fatty acids. There is some research to suggest increasing the intake of omega-3 fatty acids in individuals with HIV who have elevated serum triglycerides may be beneficial.

Micronutrients

Vitamins and minerals are important for optimal immune function. Nutrient deficiencies can affect immune function and lead to disease progression. Micronutrient deficiencies are common in people with HIV infection as a result of malabsorption, drug-nutrient interactions, altered metabolism, gut infection, and altered gut barrier function. Vitamin A, zinc, and selenium serum levels are often low during a response to infection, so it is important to assess dietary intake to determine whether correction of serum micronutrients is warranted.

There are benefits to correcting some depleted serum levels of micronutrients. Low levels of vitamins A, B₁₂, and zinc are associated with faster disease progression. Higher intakes of vitamins C and B have been associated with increased CD4 counts and slower disease progression to AIDS (Coynne-Meyers and Trombley, 2004). The Nutrition for Healthy Living study found that minorities and women tend to have lower micronutrient intakes and may benefit from nutrition counseling and dietary assessment (Jones, 2006).

Studies on micronutrients are difficult to interpret because there are a variety of study designs and outcomes. Serum micronutrient levels reflect conditions such as acute infection, liver disease, technical parameters, and recent intake. Adequate micronutrient intake through consumption of a balanced, healthy diet should be encouraged. However, diet alone may not be sufficient in people with HIV. A multivitamin and mineral supplement that provides 100% of the DRI also may be recommended. Megadosing on some micronutrients such as vitamins A, B₆, D, E, and copper, iron, niacin, selenium, and zinc may be detrimental to health outcomes and may not protect against prevention of chronic diseases.

Research has been increasing in the area of micronutrient supplementation in people with HIV. It is important to consider the populations in which these studies have been conducted, and the findings should be individualized to the client's needs. Factors that should be considered are underlying nutritional status, the stage of HIV infection or AIDS, use of ART medications, the presence of coinfections, and indication of an actual micronutrient deficiency (preferably from laboratory documentation), as well as intended length of supplement use. Caution should be used when recommending micronutrient

supplementation for all people with HIV, because megadosing on some micronutrients such as vitamin A and zinc can have adverse outcomes, such as disease progression.

Recent studies have suggested that selenium supplementation may slow HIV progression (Baum, 2013). Conversely, low serum 25-hydroxy vitamin D levels may hasten HIV disease progression, alluding to a possible benefit of vitamin D supplementation in people with HIV with a vitamin D deficiency (Shepherd, 2014). The challenging question is whether a low serum micronutrient laboratory value is indicative of a true deficiency or an acute phase response to the virus (Forrester, 2011). Because of these uncertainties, micronutrient supplementation should be thoroughly evaluated before being prescribed and if indicated, be monitored to determine the optimal length of time for supplementation.

The most beneficial levels of micronutrient supplementation have yet to be determined. There is evidence which supports micronutrient supplementation at the RDA amounts is as efficacious as supplementation at two to four times the RDA (Forrester, 2011). At this time, no evidence supports micronutrient supplementation in adults with HIV infection above the recommended levels of the DRI (Kawai, 2010, WHO, 2005c) (see Table 37-6).

SPECIAL CONSIDERATIONS

Wasting

Wasting implies unintentional weight loss and loss of lean body mass, and is strongly associated with an increased risk of disease progression and mortality. Despite the efficacy of ART, wasting continues to be a common problem in those with HIV. Wasting may be caused by a combination of factors, including inadequate dietary intake, malabsorption, and increased metabolic rates from viral replication or complications from the disease. Inadequate dietary intake can be caused by several issues related to conditions that affect the ability to chew or swallow food, gastrointestinal motility, neurologic diseases that affect perceptions of hunger or ability to eat, food insecurity related to psychosocial or economic factors, and anorexia from medications, malabsorption, systemic infections, or tumors (Mankal, 2014). Until the underlying cause of weight loss is discovered, it will remain difficult to target effective nutrition therapy.

Obesity

Obesity in people with HIV also has been noted. Unintentional weight loss in HIV infection has been associated with mortality, but more careful review in overweight or obese HIV-infected

TABLE 37-6 Common Micronutrient Deficiencies and Indications for Supplementation

Vitamin or Mineral	Potential Cause for Deficiency	Results of Vitamin Deficiency	Supplementation Indications
B ₁₂	Malabsorption Inadequate intake	Increased risk of progression to AIDS Dementia Peripheral neuropathy Myelopathy Diminished performance (information processing and problem-solving skills)	Little evidence for benefits of supplementation beyond correcting low serum levels
A	Inadequate intake	Increased risk of progression to AIDS	Necessary to correct low levels Should not exceed DRI when serum levels are normal High intakes beyond correcting low levels can be detrimental to health and potentially increase risk of mortality from AIDS (Coyne-Meyers and Trombley, 2004) Needs more research
Beta-carotene	Inadequate intake Fat malabsorption	Potential relationship with oxidative stress Potentially weakens immune function	Potential increased progression to AIDS Oxidative stress Impaired immune response Immune suppression
E	Inadequate intake		Recommend only amounts found in multivitamin supplement Needs more research
D	Inadequate intake Inadequate exposure to sunshine		High intake: may be associated with increased surrogate markers of atherosclerosis Needs more research Correct low levels Needs more research
Selenium	Inadequate intake	Potential increased progression to AIDS Weakened immune function Oxidative stress	Multivitamin/mineral providing DRI Higher doses not recommended at this time until further research
Zinc	Inadequate intake	Increased risk for HIV-related mortality Weakened immune system Impaired healing processes Lower CD4 counts	Recommend supplementing to intakes of DRI High levels above DRI may lead to faster disease progression Needs more research
Iron	Low levels during initial asymptomatic HIV infection caused by inadequate absorption Inadequate intake	Anemia Progression and mortality in HIV infection Increased susceptibility to and severity from other infections such as TB	Correct low levels as needed Recommend intakes at DRI High levels potentially lead to increased viral load Needs more research

Coyne-Meyers K, Trombley LE: A review of nutrition in human immunodeficiency virus infection in the era of highly active antiretroviral therapy, *Nutr Clin Prac* 19:340, 2004; Falcone EL et al: Micronutrient concentrations and subclinical atherosclerosis in adults with HIV, *Am J Clin Nutr* 91:1213, 2010; McDermid JM et al: Mortality in HIV infection is independently predicted by host iron status and SLC11A1 and HP genotypes, with new evidence of a gene-nutrient interaction, *Am J Clin Nutr* 90:225, 2009; Pitney CL et al: Selenium supplementation in HIV-infected patients: is there any potential clinical benefit? *J Assoc Nurses AIDS Care* 20:326, 2009; Rodriguez M et al: High frequency of vitamin D deficiency in ambulatory HIV-positive patients, *AIDS Res Hum Retroviruses* 25:9, 2009.

AIDS, Acquired immune deficiency syndrome; DRI, dietary reference intake; TB, tuberculosis.

individuals is needed. Recently a lower risk of developing a noncommunicable disease was observed among overweight HIV-infected adults initiating ART compared with normal weight adults with HIV infection on ART (Koethe, 2014). However, excess adiposity is associated with cardiovascular risk factors and inflammation so weight changes in either direction should be monitored closely. In the era of ART, it is no longer believed that continuously gaining body weight is a protective cushion against HIV-related wasting and progression to AIDS.

Some of the ART medications increase the risk of hyperlipidemia, insulin resistance, and diabetes. It is important to monitor these risk factors and provide nutrition recommendations to maintain a healthy weight. Physical activity, aerobic exercise, and resistance training are recommended to work synergistically with optimal nutrition intake to achieve a healthy weight and maintain lean body mass.

HIV-Associated Lipodystrophy Syndrome (HALS)

HIV-associated lipodystrophy syndrome (HALS) refers to the metabolic abnormalities and body shape changes seen in patients with HIV, similar to the metabolic syndrome found in the general

population. The typical body shape changes include fat deposition (generally visceral adipose tissue (VAT) in the abdominal region or as breast hypertrophy and a dorsocervical fat pad, see [Figure 37-4, A](#)) or fat atrophy (**lipoatrophy**) seen as loss of subcutaneous fat in the extremities, face, and buttocks (see [Figure 37-5](#) which shows a facial lipoatrophy scale). The metabolic abnormalities include hyperlipidemia (particularly high triglycerides and low-density lipoprotein [LDL] cholesterol and low high-density lipoprotein [HDL] cholesterol) and insulin resistance. There is no consensus on the clinical definition of HALS and the manifestations vary greatly from patient to patient. Each part of the syndrome may occur independently or simultaneously.

The cause of HALS is multifactorial and includes duration of HIV infection, duration and type of ART medications, age, gender, race and ethnicity, increased viral load, and increased body mass index. Physical changes should be discussed with the health care team. It is important to monitor these changes by taking anthropometric measurements. Monitoring trends with body weight is important; however, doing so will not likely identify body shape changes. Generally, there is a shift in body composition even though weight remains stable. Taking waist, hip, arm,

FIGURE 37-4 **A**, Preoperative view of a 48-year-old man with cervicodorsal lipodystrophy that developed 7 years before his initial consultation. He also complained of anterior neck lipodystrophy and facial lipoatrophy. **B**, Postoperative view 21 months after excisional lipectomy, SAL of the cervicodorsal fat pad, rhytidectomy, anterior neck lift with submental fat excision, and autologous fat transfer from the abdomen to the nasolabial folds bilaterally.

FIGURE 37-5 Note: Zygoma = cheekbone. Source: St Stephens AIDS Trust, Chelsea and Westminster Hospital

mid-upper arm, and thigh circumference measurements and triceps, subscapular, suprailiac, abdominal, and thigh skinfold measurements are useful in monitoring exact locations of either fat hypertrophy or atrophy. Currently, some treatments address HALS-associated body shape changes, such as facial injections for lipotrophy and surgical excisions for removal of dorsocervical fat pads (see [Figure 37-4, B](#)). The long-term efficacy of these procedures has yet to be determined, and most health care insurance companies do not provide coverage for these surgeries.

Nutrition interventions associated with HALS are limited ([Loonam, 2012](#)). For nutrition recommendations, the guidelines set by the National Cholesterol Education Program and American Diabetes Association are followed (see Chapters 30 and 33). Recommendations for physical activity, including aerobic exercise and resistance training, should complement dietary intake. In addition, special focus should be on achieving adequate dietary fiber intake. This can potentially decrease the risk of fat deposition ([Dong et al, 2006](#); [Moyle, 2010](#)) and improve glycemic control.

For patients who have high triglycerides, omega-3 fatty acids may be useful. Omega-3 fatty acids decrease serum triglycerides and may reduce inflammation and improve depression. Studies focusing on the impact of omega-3 fatty acids in individuals with HIV are limited. Some studies have shown 2 to 4 g of fish oil supplements per day lower serum triglyceride levels in patients with HIV ([Wohl, 2005](#); [Woods, 2009](#)). In a recent meta-analysis, which included four studies, omega-3 fatty acids intake lowered serum triglyceride concentrations in people with HIV on ART ([Oliveira, 2011](#)). However, because the studies were not homogenous with regards to dose, population, and length of intervention, it is challenging to determine the amount of omega-3 needed to see positive benefits, including the threshold of triglycerides with the most beneficial impact. In addition, optimal effects are seen with highly concentrated marine omega-3 fatty acids with high EPA and DHA levels. Potential side effects from supplementation include GI distress, hyperglycemia, and increased LDL cholesterol levels. Use of supplements should be monitored and discussed with the health care team.

HIV IN WOMEN

Around the world, women represent about half the people who are living with HIV or AIDS. In the United States women accounted for 9500 (20%) of the estimated number of new HIV infections in 2010 (CDC, 2013a). The highest rate of new HIV infection was seen in African American women, which was 20 times as high as that of Caucasian women, although the rate has decreased by 21% since 2008 (CDC, 2013a).

Women contract HIV less than men in the United States, but several factors put them at higher risk. Biologically, women are more likely to get HIV during unprotected vaginal sex because the lining of the vagina provides a larger area that can be exposed to HIV-infected semen. Barriers to receiving appropriate medical care also exist. Social and cultural stigma, lack of financial resources, responsibility of caring for others, and fear of disclosure may prevent women from seeking proper care.

Preconception and Prenatal Considerations

HIV-infected women of childbearing age should receive counseling before conception to learn how to decrease the risk of mother-to-child transmission. Current recommendations include prenatal screening for HIV, hepatitis C virus, and tuberculosis infection, initiation of ART during pregnancy, and ART for the child once he or she is born. In the United States these interventions have reduced the risk of mother-to-child transmission to less than 2% ([DHHS, 2012](#)). Similar to HIV-negative women, nutritional status and potential nutrient deficiencies should be monitored during pregnancy. Supplementation of vitamins B, C, and E have been shown to reduce the incidence of adverse pregnancy outcomes (e.g., low birth weight, fetal death) and decrease rates of mother-to-child transmission in women with compromised immune and nutrition status ([Kawai, 2010](#)). It is important to note if women have deficient serum vitamin A levels before supplementation, because different serum levels may affect risk of HIV transmission. Benefits may be noted only in those needing repletion to reach normal levels.

Postpartum and Other Considerations

In the United States breastfeeding is not recommended for HIV-infected women, including those on ART, or where safe, affordable, and feasible alternatives are available and culturally appropriate (DHHS, 2013). Banked milk from human milk banks is an option (see *Focus On: What Is a Human Milk Bank?* in Chapter 42). In developing countries, recommendations may differ depending on safety and availability of formula and access to clean drinking water and availability of human milk banks.

HIV IN CHILDREN

An estimated 260,000 new HIV infections occurred globally among children younger than the age of 15 in 2012 (UNAIDS and WHO, 2013). In the United States an estimated 200 HIV-infected children are born each year. The majority of these infections stem from mother-to-child transmission in utero, during delivery, or through consumption of HIV-infected breastmilk. Premastication (chewing foods or medicine before administering to a child) also has been reported as a route of transmission through blood in saliva (CDC, 2011).

Growth is the most valuable indicator of nutritional status in childhood. Poor growth may be an early indicator for progression of HIV disease. Growth failure can result from HIV infection itself and HIV-associated OIs (Guillen, 2007). Weight and height of HIV-infected children generally lags behind uninfected children of the same age. Loss of lean body mass with no changes in total body weight also can occur. To appropriately measure body changes, serial anthropometric measurements should be recorded, along with tracking of height and weight on growth charts (Sabery, 2009) (see Appendices 4 through 11).

HIV treatment has improved the clinical outcomes for children, with ART initiation resulting in significant catch-up in weight and height, but not to the level of uninfected children. The presence of HALS seen in adults is also common in children. With the increasing number of years on ART, more morphologic and metabolic abnormalities, as described in the section on HALS, are being documented in children (Dimock, 2011; Miller, 2012; Sabery and Duggan, 2009). Multivitamin and micronutrient supplementation may be beneficial at the DRI levels for children who are malnourished. Research does not currently support any supplementation at higher doses.

COMPLEMENTARY AND INTEGRATIVE THERAPIES

In general, any treatment method that is not practiced in conventional medicine is considered complementary and integrative medicine (CIM) or sometimes integrative medicine. Dietary supplements, herbal treatments, megavitamins, acupuncture, yoga, and meditation are just a few of the therapies that are categorized as CIM (see Chapter 12).

The use of CIM is prevalent in patients with HIV infection. National studies suggest CIM use in people living with HIV and AIDs is about 55%. Vitamins, herbs and supplements are the most common followed by prayer and other spiritual approaches (Lorenc, 2013). People experiencing greater HIV symptom severity and longer disease duration are more likely to use CIM (Lorenc, 2013).

Despite the high percentage of CIM use, only one third of patients disclose CIM use to their health care providers (Liu, 2009). Some patients with HIV have noted benefits with

taking dietary supplements; however, potential interactions with ART medications should be addressed. In addition, caution with anecdote-based remedies should be monitored regarding credibility for a vulnerable population such as people living with HIV (Kalichman, 2012). Kalichman et al recruited more than 300 individuals from infectious disease clinics in Atlanta, Georgia, and discovered that one in four used at least one dietary supplement. Kalichman's cross-sectional study found that antioxidant supplements and teas were the common products used, and individuals spent approximately \$50 per month on products. Therefore it is important that each patient be questioned carefully about use of integrative therapies, particularly those taken orally or subcutaneously. Information should be collected on the brands, dosage, frequency, timing, duration, and cost of the supplements. This should be compared with additional clinical information such as current medications, biochemical parameters, and nutrition intake. Each item should be researched for potential drug-drug and drug-nutrient interactions because there may interference with ART use. For example, garlic and St. John's wort (*Hypericum perforatum*) decrease blood levels of ART medications, decreasing the efficacy of ART and potentially leading to drug resistance.

A key point in counseling patients who are using integrative therapies is to understand why they choose to use them. Most studies have found that there may not be any additional benefit to supplementing beyond correcting deficiencies. Food should be recommended first.

CLINICAL CASE STUDY

Edwin is a 42-year-old male who has been HIV+ for 20 years. His viral load is undetectable and his CD4+ count is 643. His current HIV antiretroviral regimen is raltegravir (Isentress), atazanavir (Reyataz), ritonavir (Norvir), and emtricitabine (Emtriva); he also takes atorvastatin (Lipitor) and ranitidine (Zantac). His height is 5'9" and his weight is 188 lb. His fasting lipid profile shows a total cholesterol 184 mg/dl, triglycerides 304 mg/dl, high-density lipoprotein 25 mg/dl, and low-density lipoprotein 96 mg/dl. Since his last visit 6 months ago, he has noticed changes in his body composition including loss of buccal fat and increasing abdominal girth. Edwin lives by himself and doesn't like to cook; he also receives one meal per day from a community program. He walks for 30 minutes daily. Upon taking a 24-hour recall, you find his caloric intake to be 2700 kcal/day.

Nutrition Care Statements

Excessive dietary intake caused by frequent intake of prepackaged meals as evidenced by diet history. NB-1.7.

Altered nutrition laboratory values as evidenced by results of lipid profile assessment. NC-2.2

Unintended body composition change of increased adiposity as evidenced by increased abdominal girth. NC-3.4

Nutrition Care Questions

1. What factors may be contributing to the body shape changes that Edwin is experiencing?
2. What nutrition and lifestyle interventions would you recommend to address his nutrition diagnoses?
3. What are some biochemical and nutritional parameters you would monitor to determine whether the nutrition interventions are effective?
4. How would you evaluate the desired nutrition outcomes to determine whether they have been met?
5. Edwin has also been complaining of nausea and diarrhea. What recommendations do you suggest for these symptoms? Are there any drug-nutrient interactions of which you need to be aware?

adrenocorticotrophic hormone
catecholamines
cortisol
counterregulatory hormones
Curling ulcers
cytokines
ebb phase

epithelial barrier function (EBF)
flow phase
hemodynamic
ileus
interleukin-1 (IL-1)
interleukin-6 (IL-6)
multiple organ dysfunction syndrome (MODS)
nutrition support therapy

sepsis
shock
systemic inflammatory response syndrome (SIRS)
tight junctions
total body surface area (TBSA) burned
tumor necrosis factor (TNF)

Critical care is the complex medical management of a seriously ill or injured person. This level of illness or injury involves acute impairment of one or more vital organ systems with a high probability of life-threatening deterioration of the patient's condition. Critical care requires complex decision making and support of vital organ systems to prevent failure involving one or more of the following: the central nervous system, the circulatory system, the renal and hepatic systems, the metabolic and respiratory systems, and shock. Critical care patients are treated in an intensive care unit (ICU) that contains specialized equipment and highly trained staff. The presence of multiple monitors, tubes, catheters, and infusions makes these patients difficult to assess nutritionally (see Figure 38-1). Critical illness and injury results in profound metabolic alterations, beginning at the time of injury and persisting until wound healing and recovery are complete. Whether the event involves sepsis (infection), trauma, burns, or surgery, the systemic response is activated. The physiologic and metabolic changes that follow may lead to shock and other negative outcomes (see Figure 38-2). Disorders that frequently are treated in an ICU include, but are not limited to, acute respiratory distress syndrome (ARDS), asthma, burn, chronic obstructive pulmonary disease (COPD), pneumonia, respiratory distress syndrome, sepsis, and trauma.

METABOLIC RESPONSE TO STRESS

The metabolic response to critical illness, traumatic injury, sepsis, burns, or major surgery is complex and involves most metabolic pathways. Accelerated catabolism of lean body or skeletal mass occurs, which clinically results in net negative nitrogen balance and muscle wasting. The response to critical illness, injury, and sepsis characteristically involves ebb and flow phases. The

FIGURE 38-1 Common equipment used in the critically ill patient. (Courtesy of Afford Medical Technologies Pvt Ltd.)

ebb phase, occurring immediately after injury, is associated with hypovolemia, shock, and tissue hypoxia. Typically decreased cardiac output, oxygen consumption, and body temperature occur in this phase. Insulin levels fall in direct response to the increase in glucagon, most likely as a signal to increase hepatic glucose production. Increased cardiac output, oxygen consumption, body temperature, energy expenditure, and total body

FIGURE 38-2 Neuroendocrine and metabolic consequences of injury. *ACTH*, adrenocorticotropic hormone. (Reprinted from Lowry SF, Perez JM: *Modern nutrition in health and disease*, Philadelphia, 2006, Lippincott Williams & Wilkins, pp 1381-1400.)

protein catabolism characterize the **flow phase** that follows fluid resuscitation and restoration of oxygen transport. Physiologically, in this phase is a marked increase in glucose production, free fatty acid release, circulating levels of insulin, **catecholamines** (epinephrine and norepinephrine released by the adrenal medulla), glucagon, and cortisol. The magnitude of the hormonal response appears to be associated with the severity of injury.

HORMONAL AND CELL-MEDIATED RESPONSE

Metabolic stress is associated with an altered hormonal state that results in an increased flow of substrate but poor use of carbohydrate, protein, fat, and oxygen. **Counterregulatory hormones**, which are elevated after injury and sepsis, play a role in the accelerated proteolysis. Glucagon promotes gluconeogenesis, amino acid uptake by the liver, ureagenesis, and protein catabolism. **Cortisol**, which is released from the adrenal cortex in response to stimulation by **adrenocorticotropic hormone** secreted by the anterior pituitary gland, enhances skeletal muscle catabolism and promotes hepatic use of amino acids for gluconeogenesis, glycogenolysis, and acute-phase protein synthesis (see [Table 38-1](#)).

After injury or sepsis, energy production increasingly depends on protein. Branched-chain amino acids (BCAAs leucine, isoleucine, and valine) are oxidized from skeletal muscle as a source of energy for the muscle; carbon skeletons are made available for the glucose-alanine cycle and muscle glutamine synthesis. The mobilization of **acute-phase proteins**, those secretory proteins in the liver that are altered in response to injury or infection, results in rapid loss of lean body mass and an increased net negative nitrogen balance, which

TABLE 38-1 The Metabolic Response to Injury

Physiologic Changes in Catabolism

Carbohydrate metabolism	<ul style="list-style-type: none"> ↑ Glycogenolysis ↑ Gluconeogenesis Insulin resistance of tissues Hyperglycemia
Fat metabolism	<ul style="list-style-type: none"> ↑ Lipolysis Free fatty acids used as energy substrate by tissues (except brain) Some conversion of free fatty acids to ketones in liver (used by brain) Glycerol converted to glucose in the liver
Protein metabolism	<ul style="list-style-type: none"> ↑ Skeletal muscle breakdown Amino acids converted to glucose in liver and used as substrate for acute-phase proteins Negative nitrogen balance
Total energy expenditure is increased in proportion to injury severity and other modifying factors	
Progressive reduction in fat and muscle mass until stimulus for catabolism ends	

From Forsythe JLR, Parks RW: *The metabolic response to injury; principles and practice of surgery*, ed 6, 2012, Elsevier, Churchill Livingstone.

continues until the inflammatory response resolves. Breakdown of protein tissue also causes increased urinary losses of potassium, phosphorus, and magnesium. Lipid metabolism also is altered in stress and sepsis. Increased circulation of free fatty acids is thought to result from increased lipolysis caused by elevated catecholamines and cortisol, as well as a marked elevation in the ratio of glucagon to insulin.

Most notable is the hyperglycemia observed during stress. This initially results from a marked increase in glucose production and uptake secondary to gluconeogenesis and elevated levels of hormones, including epinephrine, that diminish insulin release. Stress also initiates the release of aldosterone, a corticosteroid that causes renal sodium retention, and vasopressin (antidiuretic hormone), which stimulates renal tubular water resorption. The action of these hormones results in conservation of water and salt to support the circulating blood volume.

The response to injury also is regulated by metabolically active **cytokines** (proinflammatory proteins) such as **interleukin (IL)-1**, **IL-6**, and **tumor necrosis factor (TNF)**, which are released by phagocytic cells in response to tissue damage, infection, inflammation, and some medications. IL-6 is secreted by T cells and macrophages to stimulate the immune response to trauma or other tissue damage leading to inflammation; it has proinflammatory and antiinflammatory actions (see Chapter 3). Cytokines are thought to stimulate hepatic amino acid uptake and protein synthesis, accelerate muscle breakdown, and induce gluconeogenesis. IL-1 appears to have a major role in stimulating the acute-phase response. The vagus nerve helps to regulate cytokine production through a cholinergic antiinflammatory pathway, releasing nicotinic acetylcholine receptor alpha-7 to reduce excessive cytokine activity.

As part of the acute-phase response, serum iron and zinc levels decrease, and levels of ceruloplasmin increase, primarily because of sequestration and, in the case of zinc, increased urinary zinc excretion. The net effect of the hormonally and cell-mediated response is an increase in oxygen supply and a greater availability of substrates for metabolically active tissues.

STARVATION VERSUS STRESS

The metabolic response to critical illness is very different from simple or uncomplicated starvation, in which loss of muscle is much slower in an adaptive response to preserve lean body mass. Stored glycogen, the primary fuel source in early starvation, is depleted in approximately 24 hours. After the depletion of glycogen, glucose is available from the breakdown of protein to amino acids, depicted in **Figure 38-3**. The depressed glucose levels lead to decreased insulin secretion and increased glucagon secretion. During the adaptive state of starvation, protein catabolism is reduced, and hepatic gluconeogenesis decreases.

Lipolytic activity is also different in starvation and in stress. After approximately a week of fasting or food deprivation, a state of ketosis develops, in which ketone bodies supply the bulk of energy needs, thus reducing the need for gluconeogenesis and conserving body protein to the greatest possible extent. In late starvation, as in stress, ketone body production is increased, and fatty acids serve as a major energy source for all tissues. Starvation is characterized by decreased energy expenditure, diminished gluconeogenesis, increased ketone body production, and decreased ureagenesis. Conversely, energy expenditure in stress is increased markedly, as are gluconeogenesis, proteolysis, and ureagenesis. As discussed, the stress response is activated by hormonal and cell mediators—counterregulatory hormones such as catecholamines, cortisol, and growth hormone. This mediator activation does not occur in starvation.

FIGURE 38-3 Metabolic changes in starvation. FFAs, Free fatty acids; RBCs, red blood cells; WBCs, white blood cells. (From Simmons RL, Steed DL: *Basic science review for surgeons*, Philadelphia, 1992, Saunders.)

SYSTEMIC INFLAMMATORY RESPONSE SYNDROME (SIRS) AND MULTIPLE ORGAN DYSFUNCTION SYNDROME (MODS)

Pathophysiology

Sepsis and the systemic inflammatory response syndrome (SIRS) often complicate the course of a critically ill patient. The term **sepsis** is used when a patient has a documented infection and an identifiable organism. Bacteria and their toxins lead to a stronger inflammatory response. Other microorganisms that lead to an inflammatory response include viruses, fungi, and parasites.

Systemic inflammatory response syndrome (SIRS) describes the widespread inflammation that can occur in infection, pancreatitis, ischemia, burns, multiple trauma, hemorrhagic shock, or immunologically mediated organ injury. The inflammation is usually present in areas remote from the primary site of injury, affecting otherwise healthy tissue. Each condition leads to release of cytokines, proteolytic enzymes, or toxic oxygen species (free radicals) and activation of the complement cascade. The American College of Chest Physicians (ACCP)–Society of Critical Care Medicine (SCCM) consensus conference definitions of sepsis are shown in **Box 38-1**.

BOX 38-1 Diagnosis for Systemic Inflammatory Response Syndrome (SIRS)

Site of infection established and at least two of the following are present:

- Body temperature above 100.4° F or less than 96.8° F
- Heart rate more than 90 beats/min
- Respiratory rate greater than 20 breaths/min (tachypnea)
- PaCO₂ of less than 32 mm Hg (hyperventilation)
- White blood cell count above 12,000/mm³ or less than 4000/mm³
- Bacteremia—the presence of more than 10% bands (immature neutrophils) in the absence of chemotherapy-induced neutropenia and leukopenia

A common complication of SIRS is the development of **multiple organ dysfunction syndrome (MODS)**. The syndrome generally begins with lung failure and is followed by failure of the liver, intestines, and kidney in no particular order. Hematologic and myocardial failures usually manifest later; however, central nervous system changes can occur at any time. MODS can be primary as the direct result of injury to an organ from trauma. Examples of primary MODS include pulmonary contusion, acute kidney injury caused by hypoperfusion, or coagulopathy from multiple blood transfusions. Secondary MODS occurs in the presence of inflammation or infection in organs remote from the initial injury.

Patients with SIRS and MODS are clinically hypermetabolic and exhibit high cardiac output, low oxygen consumption, high venous oxygen saturation, and lactic acidemia. Patients generally have a strong positive fluid balance associated with massive edema and a decrease in plasma protein concentrations.

Multiple hypotheses have been proposed to explain the development of SIRS or MODS. In some studies, SIRS leading to MODS appears to be mediated by excessive production of proinflammatory cytokines and other mediators of inflammation. The gut hypothesis suggests that the trigger is injury or disruption of the gut barrier function, with corresponding translocation of enteric bacteria into the mesentery lymph nodes, liver, and other organs. Unique gut-derived factors carried in the intestinal lymph but not the portal vein usually lead to acute injury- and shock-induced SIRS and MODS. **Shock** results in gut hypoperfusion; the hypoperfused gut is a source of proinflammatory mediators. Early gut hypoperfusion causes an **ileus** or lack of peristalsis in the stomach and small bowel, and late infections cause further worsening of this gut dysfunction. Early enteral feeding is thought to restore gut function and influence the clinical course. The mechanism for this effect is due to the enhanced functional and structural integrity of the gut.

Enteral nutrition (EN) may have a role in maintaining **tight junctions** between the intraepithelial cells, stimulating blood flow and inducing the release of trophic factors (see [Figure 38-4](#)). Maintenance of villous height supports the secretory immunocytes that

FIGURE 38-4 Tight junction in the intestinal villus, supporting gut membrane integrity.

make up the gut-associated lymphoid tissue. With central parenteral nutrition (PN), mucosal atrophy and a loss of **epithelial barrier function (EBF)** may occur. A rise in interferon gamma and decline in IL-10 contribute to the loss of EBF in animal models along with a dramatic decline in the expression of tight junction and adherens junction proteins (Yang et al, 2009). Studies in animals suggest that glutamine added to the parenteral solution may protect the EBF (Nose et al, 2010). However, clinicians should use caution when considering the addition of glutamine in EN and PN formulations for patients who have shock or multiple organ failure as research suggests the possibility of harm (Heyland et al, 2013). Although evidence is inconclusive to support the routine use of glutamine in critically ill patients, it could be considered in selected burn and trauma patients (Dhaliwal et al, 2014).

MALNUTRITION: THE ETIOLOGY-BASED DEFINITION

The historical approach to defining malnutrition in the patient undergoing the stress response has recently been reevaluated. In an effort to provide consistency in its definition, in 2009 an international group of nutrition support leaders developed an etiology basis for the definition of malnutrition for hospitalized adult patients (see Appendix 20). This approach focuses on the following three causes: starvation-related malnutrition, chronic disease-related malnutrition, or acute disease-related malnutrition (see Figure 38-5). Using this redefinition, a collaborative workgroup of the American Society for Parenteral and Enteral Nutrition (A.S.P.E.N.) and the Academy of Nutrition and Dietetics published a consensus document outlining specific criteria for diagnosing severe and nonsevere malnutrition. Each malnutrition cause is defined by specific criteria and thresholds (see Box 38-2 for criteria specific to the acute illness and injury malnutrition cause). This specific category includes those patients experiencing SIRS and MODS and is characterized by a heightened

BOX 38-2 Consensus Malnutrition Criteria for Acute Illness and Injury Cause

Severe Malnutrition	Non-Severe Malnutrition

cytokine response, which in turn leads to profound losses in fat-free mass. Of note, in this setting, despite adequate provision of nutrition support therapy, repletion of lean body mass cannot occur (Jensen et al, 2009, 2010).

Medical Nutrition Therapy

The critically ill patient typically enters an intensive care unit (ICU) because of a cardiopulmonary diagnosis, intraoperative or postoperative complication, multiple trauma, burn injury, or sepsis. Traditional methods of assessing nutritional status are often of limited value in the ICU setting. The severely injured patient is usually unable to provide a dietary history. Values for weight may be erroneous after fluid resuscitation, and anthropometric measurements are not easily attainable,

FIGURE 38-5 Diagram of malnutrition definitions. (Adapted from Jensen GL et al: Malnutrition syndromes: a conundrum versus continuum, *J Parenter Enteral Nutr* 33:710, 2009; Jensen G et al: Adult starvation and disease-related malnutrition: a proposal for etiology-based diagnosis in the clinical practice setting from the International Consensus Guideline Committee, *J Parenter Enteral Nutr* 34:156, 2010.)

nor are they sensitive to acute changes. Hypoalbuminemia reflects severe illness, injury, and inflammation; thus serum albumin should not be used as a marker of nutritional status. Other plasma proteins such as prealbumin and transferrin often drop precipitously, related not to nutrition status but to an inflammation-induced decrease in hepatic synthesis and changes caused by compartmental shifts in body fluid. This is part of the acute-phase response in which secretory and circulating proteins are altered in response to inflammation or injury (see Chapter 7).

The critical role of physical assessment cannot be overlooked. Loss of lean body mass and accumulation of fluid are common to the ICU patient, and the ability to recognize these, as well as other important physical parameters, is essential. In general, assessment and care planning focus on the preadmission, preoperative, or preinjury nutrition status; presence of any organ system dysfunction; the need for early nutrition support therapy; and options that exist for enteral or parenteral access. When designing and monitoring the nutrition prescription (see Chapter 13) for critically ill patients, focus should be on laboratory data, not on defining or determining nutrition status.

Because the patient is so ill, oral intake of food or fluid may be severely limited. Therefore some common nutrition diagnoses include the following:

- Inadequate oral food and beverage intake (requiring another mode of nutrient or fluid administration)
- Inadequate or excessive intake from EN or PN infusion
- Inappropriate infusion of EN or PN (e.g., using PN when EN is possible)
- Inadequate or excessive fluid intake (from intravenous [IV] infusions, nutrient solutions, tube flushes)
- Increased nutrient needs (such as protein for wound healing)
- Excessive carbohydrate intake (as when giving a parenteral solution to a chronically malnourished patient, with potential for refeeding syndrome)
- Abnormal nutrition-related laboratory values
- Altered gastrointestinal (GI) function (such as vomiting, diarrhea, constipation)

If malnutrition or an inflammatory response is present, the nutrition diagnosis should be framed around those conditions. The rationale for focusing on malnutrition and the inflammatory response is that these conditions increase the risk of complications related to nutritional status. An example of such a PES statement would be: Increased nutrient needs (energy and protein) *related to* an inflammatory response to injury *as evidenced by* elevated body temperature and minute ventilation.

Nutrition Support Therapy

Nutrition support therapy incorporates early EN when feasible, appropriate macro- and micronutrient delivery, and glycemic control. Favorable expected outcomes from these practices include reduced disease severity, decreased length of time in the ICU, and decreased infectious disease morbidity and overall mortality.

The traditional goals of nutrition support therapy during sepsis and after injury include minimization of starvation, prevention or correction of specific nutrient deficiencies, provision

of adequate calories to meet energy needs while minimizing associated metabolic complications, and fluid and electrolyte management to maintain adequate urine output and normal homeostasis (see *Pathophysiology and Care Management Algorithm: Hypermetabolic Response*). We currently focus more on attenuating the metabolic response to stress, preventing oxidative cellular injury, and modulating the immune response. The first emphasis of care in the ICU is establishing **hemodynamic stability** (maintenance of airway and breathing, adequate circulating fluid volume and tissue oxygenation, and acid-base neutrality). It is important to follow the patient's heart rate, blood pressure, cardiac output, mean arterial pressure, and oxygen saturation to assess hemodynamic stability because this determines when nutrition support therapy can commence.

Glycemic control and its relationship to improved outcomes has been the focus of extensive study. It is now recognized that more moderate (blood glucose 150 to 180 mg/dL), rather than tight (blood glucose 80 to 110 mg/dL), control is associated with positive outcomes in critically ill patients (Academy Evidence Analysis Library – (EAL)). Dietitians must recognize the significant contribution of dextrose in PN formulas and its influence on glycemic control.

Nutritional Requirements

Energy. Ideally, indirect calorimetry (IC) should be used to determine energy requirements for critically ill patients (see Chapter 2). Oxygen consumption is an essential component in the determination of energy expenditure. Septic and trauma patients have substantial increases in energy expenditure associated with the magnitude of injury. IC can be performed serially as a patient's clinical status changes (EAL); this allows a more accurate assessment of energy requirements during a patient's stay in the ICU. IC is not appropriate for all patients, however, and should be performed and interpreted by experienced clinicians (EAL). High oxygen requirements, the presence of a chest tube, acidosis, and the use of supplemental oxygen, are factors that may lead to invalid results. In these situations measurement of energy expenditure by IC is not recommended (EAL).

In the absence of a metabolic cart for IC, energy requirements may be calculated as 25 to 30 kcal/kg/day (SCCM and A.S.P.E.N., 2009) or by using one of the many published predictive equations (see Chapter 2). Avoidance of overfeeding in the critically ill patient is important. Although adequate energy is essential for metabolically stressed patients, excess calories can result in complications such as hyperglycemia, hepatic steatosis, and excess carbon dioxide production, which can exacerbate respiratory insufficiency or prolong weaning from mechanical ventilation.

Some debate exists in practice regarding what value should be used for body weight in predictive equations. Actual body weight is a better predictor of energy expenditure than ideal body weight in obese individuals (Breen and Ireton-Jones, 2004). The 2012 Critical Illness Update recommends that when IC is unavailable, the Penn State University [PSU(2003b)] equation, using actual body weight, should be used in obese and nonobese patients who are younger than 60 years of age. For obese patients 60 years or older, the PSU (2010) equation should be used. Research indicates that these equations have the best prediction accuracy (EAL).

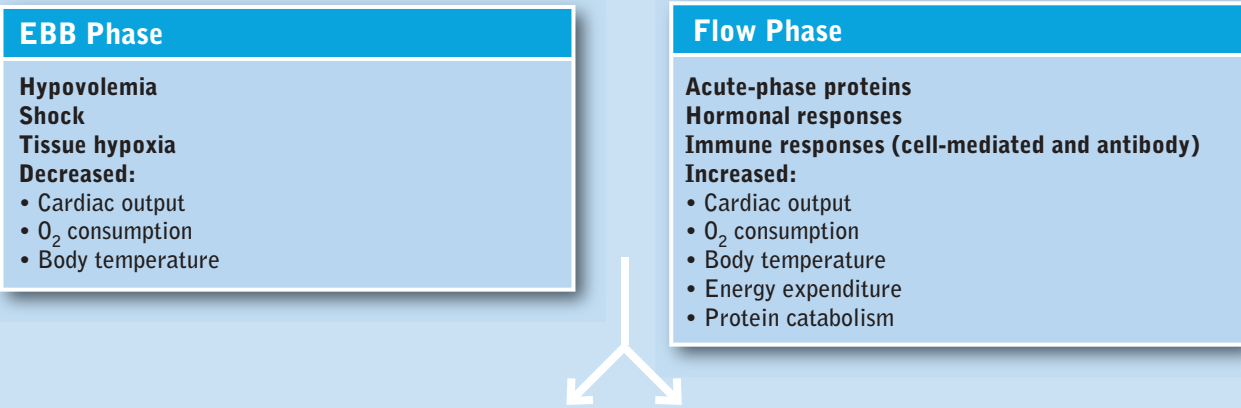

PATHOPHYSIOLOGY AND CARE MANAGEMENT ALGORITHM

Hypermetabolic Response

ETIOLOGY

PATHOPHYSIOLOGY

EBB Phase

Hypovolemia
Shock
Tissue hypoxia
Decreased:

- Cardiac output
- O₂ consumption
- Body temperature

Flow Phase

Acute-phase proteins
Hormonal responses
Immune responses (cell-mediated and antibody)
Increased:

- Cardiac output
- O₂ consumption
- Body temperature
- Energy expenditure
- Protein catabolism

MANAGEMENT

Medical Management

- Treat cause of hypermetabolism
- Hemodynamic stability

Nutrition Management

- Minimize catabolism
- Meet energy requirements, but do not overfeed
 - Use indirect calorimetry if possible
 - Non-obese: 25-30 kcal/kg/day
 - Obese: 14-18 kcal/kg/day of actual body weight
- Meet protein, vitamin, and mineral needs
- Establish and maintain fluid and electrolyte balance
- Plan nutrition therapy (oral, enteral, and/or parenteral nutrition)
- Need for pharmaconutrients
- Physical therapy
- Exercise

Available research suggests that hypocaloric, high-protein nutrition support therapy or “permissive underfeeding” in critically ill obese patients results in achievement of net protein anabolism and minimizes complications resulting from overfeeding. A.S.P.E.N., in its 2013 Guidelines for Hospitalized Adult Patients with Obesity, suggests that clinical outcomes in patients supported with high-protein hypocaloric feeding are at least equivalent to those supported with high-protein eucaloric feeding. A trial of hypocaloric high-protein feeding is suggested in those patients who do not have severe renal or hepatic dysfunction. The Guidelines recommend that hypocaloric feeding may be started with 50% to 70% of estimated energy requirements or less than 14 kcal/kg actual weight. High-protein feeding may be started with 1.2 g/kg actual weight or 2 to 2.5 g/kg ideal body weight, with adjustment of goal protein intake based on the results of nitrogen balance studies. Moreover, hypocaloric low protein feedings are associated with unfavorable outcomes. Clinical vigilance for adequate protein provision is suggested in patients who do not have severe renal or hepatic dysfunction. More research is needed to validate hypocaloric feeding as the standard approach to nutrition support in obese patients, especially because of the wide variability in body composition (Choban and Dickerson, 2005; Port and Apovian, 2010).

Protein. Determination of protein requirements is difficult for critically ill patients. Patients typically require 1.2 to 2 g/kg/day depending on their baseline nutritional status, degree of injury and metabolic demand, and abnormal losses (e.g., through open abdominal wounds or burned skin) (Hoffer and Bistrrian, 2012). Patients with acute kidney injury undergoing continuous renal replacement therapy (CRRT) may have a higher protein requirement because of the increased loss via the filtration process (see Chapter 35). A recent systematic review of protein requirements in critical illness concluded that protein delivery of 2.0 to 2.5 g/kg/day is safe and may be optimal for most critically ill patients except for those with refractory hypotension, overwhelming sepsis, or severe liver disease (Hoffer and Bistrrian, 2012). Administration of excessive amounts of protein does not decrease the characteristic net negative nitrogen balance seen among hypermetabolic patients.

Vitamins, Minerals, and Trace Elements. No specific guidelines exist for the provision of vitamins, minerals, and trace elements in metabolically stressed individuals. Micronutrient needs are elevated during acute illness because of increased urinary and cutaneous losses and diminished GI absorption, altered distribution, and altered serum carrier protein concentrations. With increased caloric intake there may be an increased need for B vitamins, particularly thiamin and niacin. Catabolism and loss of lean body tissue increase the loss of potassium, magnesium, phosphorus, and zinc. GI and urinary losses, organ dysfunction, and acid-base imbalance necessitate that mineral and electrolyte requirements be determined and adjusted individually. Fluid and electrolytes should be provided to maintain adequate urine output and normal serum electrolytes.

Feeding Strategies. The preferred route for nutrient delivery is an orally consumed diet of whole foods. However, critically ill patients are often unable to eat because of endotracheal intubation and ventilator dependence. Furthermore, oral feeding may be delayed by impairment of chewing, swallowing, by anorexia induced by pain-relieving medications, or by posttraumatic

shock and depression. Patients who are able to eat may not be able to meet the increased energy and nutrient requirements associated with metabolic stress and recovery. They often require combinations of oral nutritional supplements, enteral tube nutrition, and PN. When EN fails to meet nutritional requirements or when GI feeding is contraindicated, PN support should be initiated (see Figure 38-6).

Timing and Route of Feeding. EN is the preferred route of feeding for the critically ill patient who cannot eat food and yet has good intestinal function. Feedings should be initiated early within the first 24 to 48 hours of ICU admission and advanced toward goal during the next 48 to 72 hours. Intake of 50% to 65% of goal calories during the first week of hospitalization is thought to be sufficient to achieve the clinical benefit of EN. This practice is intended for patients who are hemodynamically stable. In the setting of hemodynamic instability (large volume requirements or use of high-dose catecholamine agents), tube feeding should be withheld until the patient is resuscitated fully or stable to minimize risk of ischemic or reperfusion injury (see Figure 38-6).

Either gastric or small-bowel feedings can be used. Small-bowel feedings are indicated when gastric residuals exceed 250 mL. Nasoenteric or surgically placed feedings tubes can be placed intraoperatively for patients with severe head, major thoracic, or spinal injury; facial injury requiring jaw wiring; proximal gastric or esophageal injuries, major pancreatic or duodenal injury; and severe trauma with plans for repeated surgeries.

Enteral tolerance should be monitored by assessing the level of pain, presence of abdominal distention, passage of flatus and stool, physical examination and, if appropriate, abdominal x-ray examination. Elevating the head of the bed and using promotility medication can reduce aspiration risk. The cause of diarrhea, when present, should be determined, including assessment for infectious diarrhea. Patients should be evaluated for intake of hyperosmolar medications and broad-spectrum antibiotics. PN is indicated for patients in whom EN is unsuccessful or contraindicated.

Formula selection, fluid, energy, and nutrient requirements, as well as GI function determine the choice of an enteral product. Most standard polymeric enteral formulas can be used to feed the critically ill patient. However, some are intolerant of these standard formulas because of the fat content and temporarily require a lower-fat formula or a product containing a higher ratio of medium-chain triglycerides. Several commercially available products are marketed specifically for patients with trauma and metabolic stress. These products typically have higher protein content and a higher ratio of BCAAs or additional glutamine or arginine.

Immune modulating enteral formulations that contain arginine, glutamine, nucleic acids, antioxidants, and omega-3 fatty acids potentially have beneficial effects and favorable outcomes for critically ill patients who have undergone GI surgery, as well as for trauma and burn patients. However, these formulations should not be used routinely for ICU patients with sepsis because they may worsen the inflammatory response (SCCM and A.S.P.E.N., 2009). Insoluble fiber should be avoided in critically ill patients; however, soluble fiber may be beneficial for the hemodynamically stable, critically ill patient who develops diarrhea (SCCM and A.S.P.E.N., 2009). Patients at high risk for bowel ischemia initially should not receive fiber-containing formulas or diets.

TRAUMA AND THE OPEN ABDOMEN

After major abdominal trauma, bowel distention, and states of shock, some patients experience increased intraabdominal pressure leading to hypoperfusion and ischemia of the intestines and other peritoneal and retroperitoneal structures. **Abdominal compartment syndrome** occurs with increased intraabdominal

pressure, often after major abdominal trauma or sepsis. This condition has profound consequences, including hemodynamic instability and respiratory, renal, and neurologic abnormalities. Because the abdominal cavity has become too small, management consists of emergent decompressive laparotomy to relieve the intraabdominal pressure. Closure of the abdomen is not performed and instead a temporary sterile dressing may be applied.

Patients with an open abdomen have severe metabolic alterations, increased loss of fluids, and elevated nutritional requirements. The open abdomen also may be a significant source of protein loss depending on the amount of drainage (Hourigan et al, 2010). There has been some controversy as to whether patients with an open abdomen can be fed enterally. As long as the patient is hemodynamically stable and does not require large-volume fluid resuscitation or increasing doses of pressor agents, enteral feeding should be possible (Burlew et al, 2012). Ideally, a nasojejunal feeding tube should be positioned at the time of surgery to facilitate early EN support therapy.

Management of patients with intestinal fistulas and large draining wounds is also challenging surgically and nutritionally because these patients have metabolic abnormalities associated with losses of fluid, electrolytes, and nutrients (Friese, 2012; Majercik et al, 2012). The priorities for management of intestinal fistulas are to restore blood volume, replace fluid and electrolyte losses, treat sepsis, control fistula drainage, protect the surrounding skin, and provide optimal nutrition support therapy. The use of PN has decreased mortality associated with fistulas and is associated with spontaneous fistula closure; however, these same outcomes are possible with EN if a feeding tube can be placed through or distal to the fistula site (see Chapter 13).

MAJOR BURNS

Pathophysiology

Major burns result in severe trauma. Energy requirements can increase as much as 100% above resting energy expenditure (REE), depending on the extent and depth of the injury (see Figure 38-7). Exaggerated protein catabolism and increased urinary nitrogen excretion accompany this hypermetabolism. Protein also is lost through the burn wound exudate.

Burn patients are particularly susceptible to infection, and this markedly increases requirements for energy and protein. Because patients with major burns may develop an ileus and are anorexic, nutrition support therapy can be a real challenge. Inhalation injury may be present in those patients who sustained burns and have been in a smoke environment for prolonged periods of time. Patients who have airway compromise may require intubation and mechanical ventilation. These patients are at increased risk of dysphagia as a result of the inhalation injury or prolonged intubation and may require enteral nutrition. In children, healing after burn and trauma requires not only restoration of oxygen delivery and adequate calories to support metabolism and repair but also awareness of how children differ from adults in metabolic rate, growth requirements, and physiologic response (Cook and Blinman, 2010).

Medical Management

Fluid and Electrolyte Repletion

The first 24 to 48 hours of treatment for thermally injured patients are devoted to fluid resuscitation. The volume of resuscitation fluid is approximately 2 to 4 mL/kg body weight per percentage of burn depending on the patient's physiologic demands or response. Generally half of the calculated volume for the first 24 hours is given during the first 8 hours after burn injury and the remaining half in the next 16 hours. Urine output is used to titrate the rate of IV fluid replacement.

The volume of fluid needed is based on the age and weight of the patient and the extent of the injury designated by percentage of **total body surface area (TBSA) burned**. Once resuscitation is complete, ample fluids must be given to cover maintenance requirements and evaporative losses that continue through open wounds. Evaporative water loss can be estimated at 2 to 3.1 mL/kg

FIGURE 38-7 Interpretation of burn classification based on damage to the integument.

of body weight per 24 hours per percent of TBSA burn. Serum sodium, osmolar concentrations, and body weight are used to monitor fluid status. Providing adequate fluids and electrolytes as soon as possible after injury is paramount for maintaining circulatory volume and preventing ischemia.

Wound Management

Wound management depends on the depth and extent of the burn. Current surgical management promotes use of topical antimicrobial agents and biologic and synthetic dressings, early debridement, excision, and grafting. Energy expenditure may be reduced slightly by the practice of covering wounds as early as possible to reduce evaporative heat and nitrogen losses and prevent infection.

Ancillary Measures

Passive and active range of motion exercises should be started early in the hospital to prevent contracture formation. Physical and occupational therapy helps maintain function and prevents muscle wasting and atrophy. A warm environment minimizes heat loss and the expenditure of energy to maintain body temperature. Thermal blankets, heat lamps, and individual heat shields often are used to maintain environmental temperature near 86° F. Minimizing fear and pain with reassurance from the staff and adequate pain medication also can reduce catecholamine stimulation and help avoid increases in energy expenditure. Treatments such as biofeedback, guided imagery, and good sleep hygiene are helpful. Finally, antacids are given to patients with major burns to prevent formation of stress-related **Curling ulcers**, which may occur because of reduced plasma volume and lead to ischemia and sloughing of gastric or duodenal mucosa. A number of pharmacologic strategies have been used to attenuate the hypermetabolic state and net protein loss sustained by burn patients (Abdullahi and Jeschke, 2014). These anabolic agents including insulin, oxandrolone, and propranolol improve lean body mass through metabolic effects on skeletal muscle or fat tissue. Insulin decreases protein breakdown and fat oxidation, oxandrolone decreases protein breakdown and fat oxidation, and propranolol decreases fat oxidation and promotes glucose homeostasis. These pharmacologic agents are used now in conjunction with nutrition support in the care of burn patients.

Medical Nutrition Therapy

A burn patient has greatly accelerated metabolism and needs increased energy, carbohydrates, proteins, fats, vitamins, minerals, and antioxidants to heal and prevent detrimental sequelae. A healthy liver is also essential. Hepatic acute phase proteins are strong predictors for postburn survival through their roles in gluconeogenesis, glycogenolysis, lipolysis, and proteolysis.

The goals of nutrition support therapy after major burn injury include provision of adequate calories to meet energy needs while minimizing associated metabolic complications, prevention or correction of specific nutrient deficiencies, and fluid and electrolyte management for adequate urine output and normal homeostasis. Adequate surgical care, infection control, and nutrition should be implemented as soon as possible after burn resuscitation. Delays in admission to an organized burn unit can be detrimental, especially for children, because malnutrition is a common concern. Nutritional assessment of the adult burn patient should include evaluation of any preexisting substance abuse, psychiatric illness, or chronic disease

that may be associated with malnutrition and could influence energy and nutrient requirements.

Many burn patients will be able to eat food and nutrition counseling should focus on selection of high protein and calorically dense food and fluids. Enteral nutrition should be considered for those patients who are unable to eat or cannot achieve adequate intake by food alone. Achievement of enteral access and provision of a sufficient volume of enteral nutrients early in the hospital course of a critically ill burn patient affords an opportunity to improve the outcome of that patient (Mosier et al, 2011). Enteral feeding provides a conduit for the delivery of immune stimulants and serves as effective prophylaxis against stress-induced gastropathy and GI hemorrhage. Tube placement beyond the stomach into the small bowel in hypermetabolic, severely ill patients prone to ileus and disordered gut motility may aid delivery of enteral nutrients while reducing risk of aspiration. Placement of enteral tubes during surgery has been practiced at some burn centers in an effort to minimize the length of time a burn patient is without nutrition support therapy (see Box 38-3 for the nutritional care goals for the burned person).

Energy

Increased energy needs of the burn patient vary according to the size of the burn, with severely burned patients often approaching twice their predicted energy expenditure. Burn size makes the largest contribution to measured energy expenditure, followed by age (Shields et al, 2013). Most predictive equations used to calculate energy expenditure in severely burned adults do not correlate strongly with measured energy expenditure (Shields et al, 2013). Therefore measuring energy expenditure via indirect calorimetry is the most reliable method for assessing energy expenditure in burn patients. Increasing energy requirements by 20% to 30% is necessary to account for energy expenditure associated with wound care and physical therapy.

Additional calories may be required to meet the needs because of fever, sepsis, multiple traumas, or the stress of surgery. Although weight gain may be desirable for the severely underweight patient, this is generally not feasible until acute illness has resolved. Generally, caloric goals should not exceed more than two times the REE. Adjustments in caloric goals may be required when patients receive a large amount of intravenous dextrose solutions and propofol (an anesthetic in a lipid-delivery system).

BOX 38-3 Medical Nutrition Therapy Goals for Burn Patients

1. Minimize metabolic stress response by
 - Controlling environmental temperature
 - Maintaining fluid and electrolyte balance
 - Controlling pain and anxiety
 - Covering wounds early
2. Meet nutritional needs by
 - Providing adequate calories to prevent weight loss of greater than 10% of usual body weight
 - Providing adequate protein for positive nitrogen balance and maintenance or repletion of circulating proteins
 - Providing vitamin and mineral supplementation as indicated
3. Prevent Curling stress ulcer by
 - Providing antacids or continuous enteral feedings

Weight maintenance should be the goal for overweight patients until the healing process is complete. Obese individuals may be at higher risk of wound infection and graft disruption. The energy requirement for the obese burned person is probably more than that calculated when ideal body weight is used but less than that calculated when actual body weight is used. IC is the most accurate method of determining the energy needs of the obese person who is burned.

Protein

The protein needs of burn patients are elevated because of losses through urine and wounds, increased use in gluconeogenesis, and wound healing. Recent evidence promotes the feeding of high amounts of protein. Providing 20% to 25% of total calories as protein of high biologic value also is recommended.

The adequacy of energy and protein intake is best evaluated by monitoring wound healing, graft take, and basic nutrition assessment parameters. Wound healing or graft take may be delayed if weight loss exceeds 10% of the usual weight. An exact evaluation of weight loss may be difficult to obtain because of fluid shifts or edema, or because of differences in the weights of dressings or splints. The coordination of weight measurement with dressing changes or hydrotherapy may allow recording of a weight without dressings and splints. Generally the fluid gained during the resuscitation period is lost within 2 weeks. Trends in weight change then can be identified.

Nitrogen balance often is used to evaluate the efficacy of a nutritional regimen, but it cannot be considered accurate without accounting for wound losses, which is difficult to accomplish in a clinical setting. Nitrogen excretion should begin to decrease as wounds heal, are grafted, or are covered. However, serum albumin levels usually remain depressed until major burns are healed. Measurements of C-reactive protein in conjunction with shorter half-life proteins such as prealbumin and retinol binding protein (RBP) may help to assess the resolution of the inflammatory response and therefore allow interpretation of the adequacy of nutrition support therapy of burn patients.

Micronutrients and Antioxidants

Vitamin needs generally increase for burn patients, but exact requirements have not been established. Supplements may be needed for patients who are eating food; however, most patients who receive tube feeding or PN with vitamins and minerals receive amounts of vitamins and minerals in excess of the dietary reference intakes because of the high calorie intake. Vitamin C is involved in collagen synthesis, fibroblast and capillary formation, and immune system maintenance; it also acts as a powerful antioxidant (Nordlund et al, 2014). Furthermore, vitamin C levels decrease after burn injury and may be a result of cutaneous losses (Vinha et al, 2013). Vitamin C frequently is supplemented to promote wound healing, although not in high-doses, as results from studies are conflicting (Nordlund et al, 2014). A recent survey of 65 burn centers showed that 100% provided a multivitamin after burn injury and more than half of the centers also provided supplemental vitamin C and zinc (Graves et al, 2009).

Vitamin A is also an important nutrient for immune function and epithelialization. Vitamin A deficiency impairs collagen synthesis and may affect wound healing negatively. Few clinical data suggest routine supplementation of vitamin A in

burns. Some immune-modulating enteral formulas contain additional beta-carotene, therefore it is important to check the contents before recommending additional supplementation.

Vitamin D deficiency has been reported in pediatric burn patients; however, limited data are available for adult patients. Burn survivors have an increased risk of vitamin D deficiency because the major source of vitamin D synthesis is in the skin (Schumann et al, 2012).

Electrolyte imbalances that involve serum sodium or potassium usually are corrected by adjusting fluid therapy. Hyponatremia may be seen in patients whose evaporative losses are reduced drastically by the application of dressings or grafts; who have had changes in maintenance fluids; or who have been treated with silver nitrate soaks, which tend to draw sodium from the wound. Restricting the oral consumption of free water and sodium-free fluids may help correct hyponatremia. Hypokalemia often occurs after the initial fluid resuscitation and during protein synthesis. Slightly elevated serum potassium may indicate inadequate hydration.

Depression of serum calcium levels may be seen in patients with burns that involve more than 30% TBSA. Hypocalcemia often accompanies hypoalbuminemia. Calcium losses may be exaggerated if the patient is immobile or being treated with silver nitrate soaks. Early ambulation and exercise should help minimize these losses. Administration of calcium supplements may be necessary to treat symptomatic hypocalcemia.

Hypophosphatemia also has been identified in patients with major burns. This occurs most commonly in patients who receive large volumes of resuscitation fluid along with parenteral infusion of glucose solutions and large amounts of antacids for stress ulcer prophylaxis. Serum levels must be monitored and appropriate phosphate supplementation provided. Magnesium levels also may require attention because a significant amount of magnesium can be lost from the burn wound. Supplemental phosphorus and magnesium often are given parenterally to prevent GI irritation.

A depressed serum zinc level has been reported in burn patients, but whether this represents total body zinc nutrition or is an artifact of hypoalbuminemia is unclear, because zinc is bound to serum albumin. Zinc is a cofactor in energy metabolism and protein synthesis. Supplementation with 220 mg of zinc sulfate (50 mg elemental zinc) is common (Nordlund et al, 2014). The anemia initially seen after a burn usually is unrelated to iron deficiency and is treated with packed red blood cells.

Methods of Nutrition Support Therapy

Methods of nutrition support therapy must be implemented on an individual basis. Most patients with burns of less than 20% TBSA are able to meet their needs with a regular high-calorie, high-protein oral diet. Often the use of concealed nutrients such as protein added to puddings, milks, and gelatins is helpful because consuming large volumes of foods can be overwhelming to the patient. Patients should have immediate access to food and fluids at the bedside. They should be encouraged to consume calorically dense, high-protein drinks. Involving family and caregivers during mealtimes helps to promote good oral intake.

Patients with major burns, elevated energy expenditure, or poor appetites may require tube feeding or PN. Enteral feeding is the preferred method of nutrition support therapy for burn patients, but PN may be necessary with early excision and grafting to avoid the frequent interruptions of tube feeding

required for anesthesia. Because ileus is often present only in the stomach, severely burned patients can be fed successfully by tube into the small bowel. PN may be needed for patients with persistent ileus who do not tolerate tube feedings or who have a high risk of aspiration. With careful monitoring, central lines for PN can be maintained through burn wounds (see Chapter 13).

SURGERY

The delivery of correctly formulated and safely administered nutritional and metabolic support is a matter of life or death in surgical and critical care units; obese patients have a higher surgical risk (Blackburn et al, 2010). Although surgical morbidity correlates best with the extent of the primary disease and the nature of the operation performed, malnutrition also may compound the severity of complications. A well-nourished patient usually tolerates major surgery better than a severely malnourished patient. Malnutrition is associated with a high incidence of operative complications, morbidity, and death. If a malnourished patient is expected to undergo major upper GI surgery and EN is not feasible, PN should be initiated 5 to 7 days preoperatively and continued into the postoperative period if the duration of therapy is anticipated to be longer than 7 days (SCCM and A.S.P.E.N., 2009; see Chapter 13).

Medical Nutrition Therapy Preoperative Nutrition Care

The routine practice of requiring a patient take nothing by mouth (NPO) at midnight before surgery has been discontinued in many settings. The American Society of Anesthesiologists historically recommended withholding solids for 6 hours preoperatively and clear liquids for 2 hours before induction of anesthesia. This practice was intended to minimize aspiration

and regurgitation. The use of a carbohydrate-rich beverage in the preoperative period has been shown to enhance glycemic control and decrease losses of nitrogen, lean body mass, and muscle strength after abdominal and colorectal surgery (Bilku et al, 2014).

Postoperative Nutrition Care

Postoperative patients who are critically ill and in the ICU should receive early EN unless there is an absolute contraindication (SCCM and A.S.P.E.N., 2009). This practice after major GI surgery is associated with reduced infection and decreased hospitalization. If the patient is malnourished (severe or nonsevere), however, the use of PN is indicated to provide perioperative support until patients are able to tolerate goal enteral feeding regimens (SCCM and A.S.P.E.N., 2009). The use of arginine-containing immune-enhanced enteral formulas is associated with a decrease in wound complications and a reduced hospital length of stay in patients who have undergone GI surgery (Drover, 2011; Marik and Zaloga, 2010).

If oral feeding is not possible or an extended NPO period is anticipated, an access device for enteral feeding should be inserted at the time of surgery. Combined gastrostomy-jejunoscopy tubes offer significant advantages over standard gastrostomies because they allow for simultaneous gastric drainage from the gastrostomy tube and enteral feeding via the jejunal tube.

The timing of introduction of solid food after surgery depends on the patient's degree of alertness and condition of the GI tract. A general practice has been to progress over a period of several meals from clear liquids to full liquids and finally to solid foods. However, no physiologic reason exists for solid foods not to be introduced as soon as the GI tract is functioning and a few liquids are tolerated. Surgical patients can be fed a regular solid-food diet rather than a clear liquid diet.

CLINICAL CASE STUDY

Chronologic Clinical Case Study with Suggested Answers

First Assessment

A 44-year-old man was admitted to a hospital with an incarcerated ventral hernia and probable bowel compromise. He underwent a small bowel resection and hernia repair and required re-exploration 2 days later because of wound evisceration. His abdominal wound was left open. His postoperative course was complicated by acute respiratory distress syndrome and sepsis related to aspiration pneumonia. He was mechanically ventilated and sedated. On hospital day six, he underwent a third surgical procedure in which his recurrent hernia was repaired, his abdomen incision was closed, and a wound vacuum system was placed. He was (NPO) since admission with a nasogastric tube in place draining more than 1 L of green fluid.

Screening and Assessment Data

Height = 72" (183 cm)
 Weight = 364 lb (165 kg)
 Body mass index = 49 kg/m²
 Ideal body weight = 178 lb (81 kg)
 Weight change in the 1 months before admission: no
 Decreased intake in the previous month: no
 Physical examination: bilateral severe pitting edema of ankles and upper extremities.
 Abdominal examination: distended with absent bowel sounds
 Radiologic examination: moderately dilated small bowel loops consistent with adynamic ileus
 Currently receiving 0.45% normal saline @ 120 mL/hr
 Intake/Output = 3305/3725 mL

Laboratory Values

Sodium: 138 mmol/dL
 Potassium: 3 mmol/dL
 Chloride: 105 mmol/dL
 Carbon dioxide: 27 mmol/dL
 Blood urea nitrogen: 13 mg/dL
 Creatinine: 1.28 mg/dL

Glucose: 185 mg/dL

Ionized calcium: 1.12 mm/L
 Magnesium: 1.6 mg/dL
 Phosphorus: 2.1 mg/dL
 Albumin: 1.9 gm/dL

- Write pertinent nutrition diagnosis statements (problem, cause, and signs and symptoms [PES] format) in order of priority for this patient. Malnutrition in the context of acute illness as evidenced by energy intake <50% of requirements (≥ 5 days) and severe fluid accumulation. Altered nutrition-related laboratory values related to the metabolic response to stress and a lack of electrolyte intake in diet and intravenous fluids as evidenced by low serum sodium, potassium, and phosphorus.
- Should he be started on parenteral nutrition (PN)? Explain. By the information presented in the case, he should be started on PN because he is malnourished, has been NPO for 6 days, and does not appear to be ready to begin enteral feeding (secondary to ileus). It will be important to discuss enteral feeding via jejunal access with the physicians once ileus has resolved.

CLINICAL CASE STUDY—cont'd

Chronologic Clinical Case Study with Suggested Answers

3. Calculate his nutritional needs.

His caloric requirement should be estimated using the hypocaloric, high-protein approach because he is morbidly obese (Grade III) and renal function is normal. Ideal body weight should be used.

Hypocaloric regimen for this patient is 14 kcal/kg actual body weight: 2310 kcal/day.

Protein requirement may be set at 2 to 2.5 g/kg ideal body weight or 162 to 203 g/day.

First Change of Status with Reassessment

On hospital day 10 the patient's body temperature spikes to 39° C, and he is found to have multiple infected abdominal abscesses. He goes to the operating room for abscess drainage. During this time his blood pressures (BP) and urine output drop considerably requiring initiation of fluid resuscitation and vasopressive agents for BP stabilization. His kidney function is noted to worsen. There is no plan for renal replacement therapy at the present.

Current status is noted:

T_{max} 39.3° C

VE = 15.6 L/min (minute ventilation)

PN continues

Intravenous fluids: 0.45% normal saline solution 150 mL/hr + additional fluid boluses

Sodium: 131 mmol/dL

Potassium: 5.1 mmol/dL

Chloride: 96 mmol/dL

Carbon dioxide: 15 mmol/dL

Blood glucose: 225 mg/dl

Ionized calcium: 1.01 mm/L

Magnesium: 2.8 mg/dL

Phosphorus: 4.8 mg/dL

Albumin: 1.2 gm/dL

Arterial blood gas: 7.31/24/115/11

4. Upon monitoring, what is his metabolic state?

He has become hypermetabolic, hypercatabolic and with worsening kidney function

Hyperglycemia has worsened.

Electrolyte excess (potassium, phosphorus, magnesium).

5. What is his acid-base status?

He has a metabolic acidosis resulting from an impaired renal excretion of acid, and reabsorption and regeneration of bicarbonate.

6. Write updated PES statements:

Increased nutrient needs (energy and protein) related to a systemic inflammatory response as evidenced by fever and elevated minute ventilation.

Altered nutrition-related laboratory values (hyperglycemia) related to stress metabolism and glucose intake as evidenced by blood glucose of 225 mg/dL.

Altered nutrition-related laboratory values related to acute kidney injury as evidenced by elevated potassium, phosphorus, and magnesium.

7. Is the patient's blood glucose control adequate? If not, why and what should be done?

His blood glucose is not adequately controlled. There is evidence that when glucose levels are controlled between 180 to 215 mg/dL, survival is better.

The dextrose load in his PN should be reduced or a standardized insulin protocol should be instituted, or both. In addition, energy intake should be assessed to confirm absence of overfeeding because this could result in hyperglycemia.

8. Why is his serum albumin level falling?

Decreased acute-phase proteins are a response to the inflammatory process his body has mounted to try to reestablish homeostasis.

9. Recalculate his nutritional needs.

Energy assessment methodology will change due to the patient's acute kidney injury and the need to provide normal protein requirements.

Calorie requirement via Penn State Equation 2003b = 3035 kcal/day
Penn State Equation 2003b:

Mifflin-St. Jeor equation $\times (0.96) + V_e (31) + T_{max} (167) - 6212$

Mifflin-St Jeor equation using actual weight, V_e is minute ventilation in L/min, T_{max} is maximum body temperature in the past 24 hours in degrees centigrade.

Protein requirement has decreased (1.2 to 1.3 g/kg ideal body weight or 97 to 105 g/day).

Second Change of Status with Reassessment

On hospital day 13, an abdominal film showed improvement in the patient's ileus picture. The patient has not yet stooled, but his abdomen is soft and he has hypoactive bowel sounds. His acute kidney injury continues, although hemodialysis has been initiated and electrolyte levels have normalized. On rounds, the dietitian asks whether the patient is stable enough to start tube feeding through the nasojunal tube. The surgical and critical care teams believe that the patient's gastrointestinal status has improved sufficiently to initiate an enteral feeding.

10. What feeding formula should be used? Is an immune-enhancing tube feeding formula indicated?

Commercial immune-enhancing formulas that combine several nutrients thought to enhance immune function are not indicated for routine use, and may be contraindicated in the severely critically ill, such as this patient.

A polymeric nonfiber formula can be chosen. If a 1 kcal/mL formula is utilized, the infusion volume will be 3 L/day, if 1.5 kcal formula is used, the infusion volume will be approximately 2 L/day; and if a 2 kcal/mL formula is chosen, the volume will be approximately 1.5 L/day.

A polymeric enteral feeding was initiated via nasojunal access and gradually advanced to goal rate during the next 3 to 4 days. Tolerance was demonstrated via no change in abdominal distention, pain, or nausea and vomiting. As the feeding advanced, the PN was gradually weaned, then discontinued when goal enteral feeding was achieved.

CLINICAL INSIGHT

Factors to consider when interpreting the literature with respect to conflicting data among nutrition support outcomes studies

- Study designs may differ
- Sample size may be too small
- Patient sample may be heterogeneous; subjects may differ by underlying illness or injury, acuity level, mortality risk
- Inclusion of well-nourished patients who would likely not show an effect of nutrition intervention
- Preexisting malnutrition may or may not be present and may or may not be diagnosed with similar criteria
- Length of ICU stay may vary
- Short interval time of nutrition therapy in the ICU

- Differences may be present with respect to timing of initiation of EN or PN
- Contribution of non-nutritional calorie sources such as D5W (5% dextrose in water) and medications in lipid delivery systems
- Differences in techniques to establish target energy goals (e.g., indirect calorimetry, predictive equations, kcal/kg)

CLINICAL INSIGHT

Enhanced Recovery After Surgery (ERAS)

First presented in the late 1990s, this multimodal pathway for care of the surgical patient has become a standard of care for colon resections, complicated pancreatic procedures, and for bladder cancer procedures in many countries. This management approach involves aspects of the patient's care preoperatively, during the surgical procedure and postoperatively (see Figure 38-8). The central elements of the ERAS pathway address key factors including pain control, gut dysfunction and the need for intravenous fluids, and lastly, ambulation. The ERAS components help to clarify how these areas interact to affect patient recovery, and mounting evidence demonstrates that use of the ERAS pathway results in positive outcomes compared with standard surgical care.

In a recent meta-analysis, Varadhan and colleagues reported the ERAS pathway was shown to reduce surgical care time by more than 30% and reduce postoperative complications by up to 50% (Varadhan et al, 2010). An international ERAS society was formed in 2010 with its mission to "develop perioperative care and to improve recovery through research, audit education and implementation of evidence-based practice" (Gustafsson et al, 2012).

uric acid
uricostatic
uricosuric

Rheumatic disease and related conditions include more than 100 different manifestations of inflammation and loss of function of connective tissue and supporting body structures, including joints, tendons, ligaments, bones, muscles, and sometimes internal organs. Some of these rheumatic diseases clearly have an autoimmune component, whereas the origin of others remains unknown. Therefore medical nutrition therapy (MNT), pharmacotherapy, and physical and occupational therapies must be tailored and designed to treat each disease and its symptoms. A diet with adequate protein and energy content, rich in vitamins, minerals, and omega-3 **polyunsaturated fatty acids (PUFAs)** can promote a beneficial protective effect against tissue damage and suppression of inflammatory activity. [Table 39-1](#) provides an overview of these disorders and their nutritional management.

Arthritis and the related disorders are among the most prevalent chronic disease conditions in the United States. The annual cost for medical care to treat all forms of arthritis and joint pain is estimated to be \$281.5 billion ([American Academy of Orthopaedic Surgeons \[AAOS\], 2009](#)).

Rheumatic disease affects all population groups. The Centers for Disease Control and Prevention (CDC) analyzed data from the 2010 to 2012 National Health Interview Survey (NHIS), and estimated that 52.5 million U.S. adults suffer from arthritis, equal to about 23%. Among persons with heart disease, diabetes, and obesity, the prevalence of doctor-diagnosed arthritis was 49.0%, 47.3%, and 31.2%, respectively ([CDC, 2013](#)).

The National Arthritis Data Workgroup reviewed data to estimate national prevalence rates of various rheumatic diseases based on 2005 U.S. census data, finding that in the United States rheumatoid arthritis (RA) affects 1.3 million adults; juvenile arthritis 294,000 people, spondylarthritides (the contemporary name of spondyloarthropathies) 0.6 to 2.4 million adults over 15, systemic lupus erythematosus (SLE) 161,000 to 322,000 adults, systemic sclerosis 49,000 adults, Sjögren syndrome (SS) 0.4 to 3.1 million adults, clinical osteoarthritis 27 million people aged 25 and older, **polymyalgia rheumatic** 711,000 people, gout 8 million adults, and fibromyalgia 5 million people ([Helmick et al, 2008; Lawrence et al, 2008](#)).

Arthritis is a generic term that comes from the Greek word *arthro*, which means “joint,” and the suffix *-itis*, which means “inflammation.” There are two distinct categories of disease: systemic, autoimmune **arthritis** and nonsystemic **osteoarthritis (OA)**. The more debilitating **autoimmune arthritis** group includes RA, juvenile rheumatoid arthritis, gout, SS, fibromyalgia, SLE, and scleroderma. The **OA** group includes OA, bursitis, and tendonitis. Other rheumatic diseases include spondylarthritides, polymyalgia rheumatica, and polymyositis.

ETIOLOGY

Body changes associated with aging—including decreased somatic protein, body fluids, and bone density—and obesity may contribute to the onset and progression of arthritis. The

TABLE 39-1 Summary of Medical Nutrition Therapy for Rheumatic Diseases

Disease	Medical Nutrition Therapy	Complementary and Alternative Medicine (CAM)	Supplements or Herbs that can be Safely Considered	Therapies Without Adequate Evidence
Rheumatoid arthritis	Vegan, Mediterranean diet; anti-inflammatory diet; appropriate calories for maintenance of normal body weight; RDA for protein unless malnutrition present; moderate-fat diet with emphasis on omega-3 PUFAs and fish 1-2 times per week; modifications as needed for jaw pain, anorexia	Exercise, meditation, tai chi, spiritual practice, relaxation techniques; topical rubbing gels based on capsaicin.	Supplement diet as needed to meet DRI for antioxidant nutrients and, calcium, folate, vitamins B ₆ , B ₁₂ , D; GLA from evening primrose oil, black currant oil, and borage oil; fish oils; bromelain, rosemary, curcumin, curry, ginger, and other culinary herbs	China root, willow bark, valerian, feverfew, boswellia, copper or copper salts, devil's claw
Osteoarthritis	Weight management; diet adequate in calcium, folate, vitamins B ₆ , D, K; magnesium; antiinflammatory diet (see Box 39-2)	Exercise, acupuncture; SAM-e; topical rubbing gels based on capsaicin	Supplement diet as needed to meet DRI for antioxidant nutrients and, calcium, folate, vitamins B ₆ , B ₁₂ , and D; glucosamine, chondroitin; fish oils; diacerein; avocado soybean unsaponifiables, bromelain, hyaluronic acid	Shark cartilage
Gout	Weight management; purine-controlled diet; adequate fluid consumption; alcohol, particularly beer, restricted or eliminated; fructose from sweetened beverages and juices restricted.	Exercise; alkaline-ash foods; see <i>Clinical Insight</i> on Urinary pH in Chapter 35.	Cherry, cherry juice (see New Directions: Can Cherries Prevent a Gout Attack?)	
Lupus	Tailor diet to individual needs; calories to maintain IBW; restriction of protein, fluid, and sodium if renal involvement; check for gluten intolerance		Supplement diet as needed to meet DRI for antioxidant nutrients	
Scleroderma	Adequate fluid; high-energy, high-protein supplements as needed to prevent or correct weight loss; moist foods; modifications for GERD if needed			
Sjögren syndrome	Balanced diet with adequate B ₆ or vitamin supplementation; restrict sugary foods and beverages; modify food portions to smaller size and soft consistency to improve chewing and swallowing processes		GLA improves eye discomfort and tear production	
TMD	Balanced diet with soft foods in small pieces to improve chewing and reduce pain			

DRI, Dietary reference intake; GERD, gastroesophageal reflux disease; GLA, Gamma-linolenic acid; IBW, ideal body weight; RDA, recommended dietary allowance; SAM-e, S-adenosyl-L-methionine; TMD, temporomandibular disorder.

aging body mass causes changes in neuroendocrine regulators, immune regulators, and metabolism, which affect the inflammatory process. Therefore recent increases in the frequency of these conditions may be the result of aging of the U.S. population. It is estimated that by 2030 approximately 67 million Americans will be at risk for rheumatic disease (CDC, 2013).

Rheumatic conditions are usually chronic and have no known cure but may present as acute episodes with short or intermittent duration. Chronic arthritic conditions are associated with alternating periods of remission without symptoms and flares with worsening symptoms that occur without any identifiable cause. Risk factors include repetitive joint injury, genetic susceptibility, and environmental factors, particularly smoking. Gender is a risk factor because women are more

susceptible than men for most rheumatic diseases; the female/male ratio varies from 3:1 for RA, to 9:1 for SLE and SS. Only in gout, is there a clear dominance of male over female patients. Recently a transcriptome analysis of RNA levels showed that healthy women carry a “proinflammatory profile,” particularly to develop RA (Jansen et al, 2014).

PATHOPHYSIOLOGY AND INFLAMMATION

Inflammation plays an important role in health and disease. The inflammatory process normally occurs to protect and repair tissue damaged by infections, injuries, toxicity, or wounds via accumulation of fluid and cells. Once the cause is resolved, the inflammation usually subsides. Whether inflammation is due to stress on the joints as in OA, or to an autoimmune

response as in RA, an uncontrolled and long-lasting inflammatory reaction causes more damage than repair (see Chapter 3 for discussion of the Inflammation and the Pathophysiology of Chronic Disease) (see *Focus On: The Biochemistry of Inflammation*).

FOCUS ON

The Biochemistry of Inflammation

COX, officially known as *prostaglandin-endoperoxide synthase (PTGS)*, has three isoforms: COX-1, COX-2, and COX-3 (the latter is a splice variant of COX-1, so it is sometimes called COX-1b or COX-1var). COX-1 is widely distributed and constitutively expressed in most tissues, whereas COX-2 is induced by inflammatory and proliferative stimuli. The difference in tissue distribution of COX expression may explain the existence of the two COX isoforms: COX-1 providing PG that are required for homeostatic functions (including gastric cytoprotection), and COX-2 playing the predominant role in PG formation during pathophysiological states, such as in inflammation (Ricciotti and FitzGerald, 2011).

In the synthesis of prostanoids, COX consumes two double bonds from the original PUFA, whereas LOX consumes none; therefore, depending on the PUFA used as substrate, different eicosanoids are produced. For instance, **arachidonic acid (ARA)** (20:4, omega-6) has four double bonds and is the precursor of the series 2 of PG and Tx, and of the series 4 of LT, which are the most potent inflammatory eicosanoids (Patterson et al, 2012). The series 2 of prostanoids (PG₂ and Tx₂) are abundant because ARA is the most abundant in plasma membranes of cells involved in inflammation (macrophages, neutrophils, fibroblasts). If the substrate is **eicosapentaenoic acid (EPA)** (20:5, omega-3) that has five double bonds, series 3 of PG and Tx, and series 5 of LT are produced. **Dihomo-gamma-linolenic acid (DGLA)** (20:3, omega-6) has three double bonds and is the precursor of series 1 of PG and Tx, and of series 3 of LT that have antiinflammatory activities (Food and Agricultural Organization [FAO] of the United Nations [UN], 2010). Finally, **docosahexaenoic acid (DHA)** (22:6, omega-3) and EPA are converted to novel bioactive lipid mediators termed **resolvins (Rv)**, **protectins**, and **maresins**, which promote the resolution of inflammation. Resolvins of the E series (RvE1 to 2) derived from EPA, and Rv of the D series (RvD1 to 6) derived from DHA, are produced by the sequential actions of the enzymes 15-lipoxygenase (15-LO) and 5-lipoxygenase (5-LO) (Norling and Perretti, 2013). Recent studies have shown that PUFAs also may regulate the expression of genes associated with the inflammatory response (Calder, 2013).

Based on this information, it is desirable to increase the omega-3/omega-6 ratio by increasing the consumption of antiinflammatory EPA, DGLA, and DHA (oily fish), while reducing the intake of ARA (vegetable oils and meat). Similarly, the increase in vegetables and fruits consumption also results in reduced risk of rheumatic diseases by contributing phytonutrients that have antiinflammatory effects (Boeing et al, 2012).

PUFAs play an important role in inflammation as precursors of a potent group of modulators of inflammation termed **eicosanoids** (*eicos* means “20” in Greek), which include the **prostanoids** and the **leukotrienes (LT)**. The prostanoids are the products of the enzyme **cyclooxygenase (COX)** and include the **prostaglandins (PG)** and **thromboxanes (Tx)**, whereas LTs are produced by the enzyme **lipoxygenase (LOX)** (see Box 39-1).

MEDICAL DIAGNOSIS AND TREATMENT

A thorough history of symptoms and a detailed physical examination are the cornerstones for an accurate diagnosis. However, laboratory testing can help to further refine the diagnosis and identify appropriate treatment.

BOX 39-1 Production of Bioactive Lipid Mediators from Omega-3 and Omega-6 PUFAs

Eicosapentaenoic acid EPA (20:5, omega-3)

Thromboxane A₃: Weak vasoconstrictor and weak platelet aggregator
 Prostacyclin PG_I₂: Vasodilator and platelet antiaggregator
 Leukotriene B₅: Weak inflammation inducer and weak chemotactic agent
 E-series resolvins (RvE1 and 2): promote resolution of inflammation

Arachidonic Acid (20:4, omega-6)

Thromboxane A₂: Vasoconstrictor and potent platelet aggregator
 Prostaglandin E₂: Vasodilator and platelet antiaggregator
 Leukotriene B₄: Inflammation inducer and potent leukocyte chemotaxis and adherence inducer

Dihomo-gamma-linolenic acid DGLA (20:3, omega-6)

Thromboxane A₁: Antiinflammatory and pain reducer
 Prostaglandin E₁: Vasodilator, inhibits monocyte and neutrophil function, platelet antiaggregator
 Leukotriene B₃: Very weak proinflammatory effects

Docosahexaenoic acid DHA (22:6, omega-3)

D-series resolvins (RvD 1 to 6): promote resolution of inflammation, analgesics, reduce leukocyte recruitment and activation, reduce IL-1 and TNF production
 Protectin 1 (PD1) and Maresin 1 (MaR1): promote resolution of inflammation

Calder PC: Long chain fatty acids and gene expression in inflammation and immunity, *Curr Opin Clin Nutr Metab Care* 16:425, 2013.

Biochemical Assessment

Acute-phase proteins are plasma proteins whose concentrations increase more than 25% during inflammatory states. Two acute-phase proteins traditionally used to screen for and monitor rheumatic disease are **rheumatoid factor (RF)** and **C-reactive protein (CRP)**, although they are nonspecific and, in the case of C-reactive protein, also may indicate an infection or even a recent cardiac event. The term **RF** is used to refer to a group of self-reacting antibodies (an abnormal IgM against normal IgG) found in the sera of rheumatic patients. The American College of Rheumatology (ACR) recommends periodic measurements of RF and CRP in addition to a detailed assessment of symptoms and functional status and radiographic examination to determine the current level of disease activity.

The detection of autoantibodies to a variety of antigens is important in the diagnosis of several rheumatic diseases (Watts, 2014). These antibodies can be directed against the nucleus (**antinuclear antibodies, ANA**) either to double-stranded DNA (dsDNA), ribonucleoproteins (RNPs), or other nuclear structures. Some autoantibodies recognize intracellular structures, or proteins that constitute extracellular matrices. Very often, the presence of a particular set of autoantibodies is a distinct characteristic of a rheumatic disease such as anti-dsDNA and anti-Sm for SLE, anticitrullinated protein antigens (ACPAs) for RA, and anti-Ro/SSA, and anti-La/SSB for SS (Demoruelle and Deane, 2011; Tincani et al, 2013). Routine blood testing also should include complement levels, a complete blood count, serum creatinine and hematocrit; urine or synovial fluid may be tested as well.

PHARMACOTHERAPY

Many of the drugs used in treating rheumatic disease provide relief from pain and inflammation, with hopes of controlling symptoms and slowing disease progress rather than providing a cure. Table 39-2 describes the commonly used drugs and their nutritional side effects (also see Appendix 31).

Analgesics

Analgesics are drugs designed specifically to relieve pain. There are several types of analgesics: acetaminophen (Tylenol) and a variety of opioid analgesics (also called narcotics). Some products combine acetaminophen with an opioid analgesic for added relief. Opioid analgesics work by binding to receptors on cells mainly in the brain, spinal cord, and gastrointestinal system.

TABLE 39-2 Medications Used in the Treatment of Rheumatic Diseases and their Nutritional Side Effects

Group/Name	Brand	Nutritional Side Effects*
Analgesics		
Acetaminophen	Excedrin, Tylenol Arthritis	
Acetaminophen with codeine	Tylenol with Codeine	Constipation, nausea, vomiting, urinary retention
Hydrocodone with acetaminophen	Hydrocet, Lorcet, Vicodin, Lortab	Constipation, nausea, vomiting, urinary retention
Hydrocodone with ibuprofen	Vicoprofen, Ibucoden	Abdominal pain, diarrhea, dry mouth, flatulence, infection, insomnia, urinary retention, vomiting
Methadone hydrochloride	Dolophine	Constipation, nausea, vomiting, urinary retention
Morphine sulfate	Avinza, Oramorph SR	Constipation, nausea, vomiting, urinary retention
Morphine sulfate with naltrexone	Embeda	Constipation, nausea, vomiting
Oxycodone	OxyContin, Roxycodone, OxyFAST, OxyIR	Constipation, nausea, vomiting, dry mouth
Oxycodone hydrochloride with acetaminophen	Percocet	Constipation, nausea, vomiting, dry mouth
Oxycodone with aspirin	Percodan	Abdominal or stomach cramps, constipation, diarrhea, heartburn or indigestion
Tapentadol	Nucynta ER	
Tramadol	Ultram, ConZyp, Rybix	Constipation, nausea, vomiting, urinary retention
Biologic Response Modifiers		
TNF Inhibitors		
Adalimumab	Humira	—
Certolizumab pegol	Cimzia	—
Etanercept	Enbrel	—
Golimumab	Simponi, Simponi Aria	—
Infliximab	Remicade	—
Selective B-Cell Inhibitors		
Belimumab	Benlysta	Nausea, vomiting
Rituximab	Rituxan	Abdominal pain
Selective Costimulation Modulator		
Abatacept	Orencia	—
IL-1 Inhibitors		
Anakinra	Kineret	—
Canakinumab	Ilaris	Diarrhea, stomach ache
IL-6 Inhibitors		
Tocilizumab	Actemra	—
IL-12 Inhibitors		
Ustekinumab	Stelara	Diarrhea
NSAIDs		
Traditional NSAID		
Diclofenac potassium	Cambia, cataflam, zipsor	Abdominal cramps, pain or discomfort, peptic ulcer, constipation, diarrhea, gastrointestinal bleeding, heartburn or indigestion, nausea or vomiting
Diclofenac sodium	Voltaren, Voltaren XR	Abdominal cramps, pain or discomfort, peptic ulcer, constipation, diarrhea, gastrointestinal bleeding, heartburn or indigestion, nausea or vomiting
Diclofenac sodium with misoprostol	Arthrotec	Abdominal cramps, pain or discomfort, diarrhea, (both with increased risk), constipation, gastrointestinal bleeding, heartburn or indigestion, nausea or vomiting, peptic ulcer (decreased risk)
Diflunisal	Generic only	Abdominal cramps, pain or discomfort, peptic ulcer, constipation, diarrhea, gastrointestinal bleeding, heartburn or indigestion, nausea or vomiting

TABLE 39-2 Medications Used in the Treatment of Rheumatic Diseases and their Nutritional Side Effects—cont'd

Group/Name	Brand	Nutritional Side Effects*
Etodolac	Generic only	Abdominal cramps, pain or discomfort, peptic ulcer, constipation, diarrhea, gastrointestinal bleeding, heartburn or indigestion, nausea or vomiting
Fenoprofen calcium	Nalfon	Abdominal cramps, pain or discomfort, peptic ulcer, constipation, diarrhea, gastrointestinal bleeding, heartburn or indigestion, nausea or vomiting
Ibuprofen	Motrin, Advil, Dyspel, Genpril	Abdominal cramps, pain or discomfort, peptic ulcer, constipation, diarrhea, gastrointestinal bleeding, heartburn or indigestion, nausea or vomiting
Indomethacin	Indocin	Abdominal cramps, pain or discomfort, peptic ulcer, constipation, diarrhea, gastrointestinal bleeding, heartburn or indigestion, nausea or vomiting
Ketoprofen	Generic only	Abdominal cramps, pain or discomfort, peptic ulcer, constipation, diarrhea, gastrointestinal bleeding, heartburn or indigestion, nausea or vomiting
Meloxicam	Mobic	Abdominal cramps, pain or discomfort, peptic ulcer, constipation, diarrhea, gastrointestinal bleeding, heartburn or indigestion, nausea or vomiting
Naproxen	Naprosyn	Abdominal cramps, pain or discomfort, peptic ulcer, constipation, diarrhea, gastrointestinal bleeding, heartburn or indigestion, nausea or vomiting
Naproxen sodium	Aleve, Naprelan	Abdominal cramps, pain or discomfort, peptic ulcer, constipation, diarrhea, gastrointestinal bleeding, heartburn or indigestion, nausea or vomiting
Piroxicam	Feldene	Abdominal cramps, pain or discomfort, peptic ulcer, constipation, diarrhea, gastrointestinal bleeding, heartburn or indigestion, nausea or vomiting.
Sulindac	Clinoril	Abdominal cramps, pain or discomfort, peptic ulcer, constipation, diarrhea, gastrointestinal bleeding, heartburn or indigestion, nausea or vomiting
COX-2 Inhibitors		
Celecoxib	Celebrex	Abdominal pain, acid reflux, diarrhea, nausea, vomiting, upset stomach
Salicylates		
Acetylsalicylic acid	Anacin, Ascriptin, Bayer, Bufferin, Ecotrin, Aspir-81, AspiTab	Abdominal cramps, pain or discomfort, diarrhea, heartburn or indigestion, nausea or vomiting, stomach ulcers or bleeding
Choline and magnesium trisalicylates	Tricosal, Trilisate, CMT	Abdominal cramps, pain or discomfort, constipation, diarrhea, heartburn or indigestion; nausea or vomiting
Magnesium salicylate	MST 600	Abdominal cramps, pain or discomfort, constipation, diarrhea, heartburn or indigestion; nausea or vomiting
DMARD		
Azathioprine	Azasan, Imuran	Liver problems, loss of appetite, nausea or vomiting
Cyclophosphamide	Cytosan	Loss of appetite, nausea or vomiting
Cyclosporine	Neoral, Gengraf	Abdominal pain, gingivitis, high blood pressure, kidney problems, loss of appetite, nausea
Gold sodium thiomalate	Myochrysin	Irritation and soreness of tongue, irritated or bleeding gums, metallic taste, ulcers or white spots on lips or in mouth or throat
Hydroxychloroquine	Plaquenil	Abdominal cramps, diarrhea, loss of appetite, nausea or vomiting
Leflunomide	Arava	Gastrointestinal problems, heartburn, high blood pressure, liver problems, stomach pain
Methotrexate	Otrexup, Rheumatrex, Trexall	Folic acid antagonist, abdominal pain, liver problems, mouth sores, nausea
Minocycline	Minocin	Diarrhea, gastrointestinal ulcers or bleeding, nausea, vomiting
Mycophenolate mofetil	CellCept	Diarrhea, stomach ulcers or bleeding
Sulfasalazine	Azulfidine	Abdominal discomfort, diarrhea, headache, loss of appetite, nausea and vomiting
Tofacitinib	Xeljanz	Diarrhea, hypertension, increased lipid level
Corticosteroids		
Betamethasone	Celestone	Elevated blood fats (cholesterol, triglycerides), elevated blood sugar, hardening of arteries (atherosclerosis), hypertension, increased appetite, indigestion, weight gain, ulcers
Cortisone acetate	Generic only	Elevated blood fats (cholesterol, triglycerides), elevated blood sugar, hardening of arteries (atherosclerosis), hypertension, increased appetite, indigestion, weight gain, ulcers
Dexamethasone	DexPak, ZemaPak, Baycadron	Elevated blood fats (cholesterol, triglycerides), elevated blood sugar, hardening of arteries (atherosclerosis), hypertension, increased appetite, indigestion, weight gain, ulcers
Hydrocortisone	Cortef	Elevated blood fats (cholesterol, triglycerides), elevated blood sugar, hardening of arteries (atherosclerosis), hypertension, increased appetite, indigestion, weight gain, ulcers
Methylprednisolone	Medrol	Elevated blood fats (cholesterol, triglycerides), elevated blood sugar, hardening of arteries (atherosclerosis), hypertension, increased appetite, indigestion, weight gain, ulcers
Prednisolone	AsmalPred, Flo-Pred, Millipred, Orapred, Pediapred, Prelone	Elevated blood fats (cholesterol, triglycerides), elevated blood sugar, hardening of arteries (atherosclerosis), hypertension, increased appetite, indigestion, weight gain, ulcers
Prednisone	Prednisone Intensol, Rayos	Elevated blood fats (cholesterol, triglycerides), elevated blood sugar, hardening of arteries (atherosclerosis), hypertension, increased appetite, indigestion, weight gain, ulcers

Arthritis Foundation: Arthritis today, Drug Guide. <http://www.arthritis-today.org/arthritis-treatment/medications/drug-guide/>, 2014. Accessed January 10, 2015.

*These side effects are usually short term and go away gradually after treatment stops.

Nonsteroidal Antiinflammatory Drugs (NSAIDs)

Nonsteroidal antiinflammatory drugs (NSAIDs) are used to relieve pain and inflammation associated with arthritis and related conditions. All NSAIDs work by blocking the synthesis of PG, which are involved in pain and inflammation, as well as many other bodily functions including protecting the stomach lining.

Traditional NSAIDs include more than twenty different drugs. They work by blocking PG synthesis by inhibiting COX-1 and COX-2, making the lining of the stomach vulnerable to ulcers and bleeding. Aspirin (acetylsalicylic acid) is the only NSAID that inhibits all COX proteins by covalent modification; all other NSAIDs act noncovalently.

Ibuprofen and naproxen slow down the body's production of PG by inhibiting COX-1. They are considered useful tools in the management of most rheumatic disorders; however, long-term use of NSAIDs may cause gastrointestinal problems such as gastritis, ulcers, abdominal burning, pain, cramping, nausea, gastrointestinal bleeding, or even renal failure.

Because of the damage to the gastric mucosa caused by COX-1 inhibitors, a new type of drug was developed to block only COX-2; among these drugs are the "coxibs," which include celecoxib (Celebrex), rofecoxib (Vioxx), and valdecoxib (Bextra). Because they only inhibit COX-2 without affecting COX-1, these drugs do not harm the stomach and are well tolerated by patients requiring long-term antiinflammatory therapy. However, the coxibs are not exempt from side effects, such as increased thrombotic events, skin reactions, and cardiotoxicity, so continuous medical monitoring is advised.

Calcitriol (1,25-dihydroxy- D_3 , the active form of vitamin D), flavonoids, and BDMC33 (a curcumin derivative) are also specific blockers of COX-2, but they act by interfering with COX-2 gene expression (Lee et al, 2013). In addition, calcitriol also blocks PG receptor expression in their target cells (Krishnan and Feldman, 2012).

Disease-Modifying Antirheumatic Drugs

Disease-modifying antirheumatic drugs (DMARD) is a category of otherwise unrelated drugs defined by their use in RA and other diseases such as SLE and SS, to slow down disease progression. Each DMARD works in different ways to slow or stop the inflammatory process that damages the joints and internal organs.

Of particular interest is the drug methotrexate (MTX), originally used to treat certain types of cancer, which is widely used to treat RA alone, or in combination with other DMARD. MTX works by competitively inhibiting dihydrofolate reductase (DHFR), an enzyme that converts folic acid to its active metabolite tetrahydrofolate (THF), which is required for nucleic acid (DNA and RNA) synthesis. Therefore patients taking MTX must consume supplemental folate to reduce the adverse effects caused by MTX such as abdominal pain, nausea, and mouth sores. Supplemental folate can be in the form of folic acid, folinic acid, or 5-methyltetrahydrofolate (5-MTHF) (see Appendix 46). Folinic acid (Leucovorin) is a folate derivative that is easily converted to THF and is unaffected by the inhibition of DHFR by MTX, while relieving some of the side effects of MTX (Shea et al, 2013). 5-MTHF (Metafolin) is the active form of folic acid used at the cellular level for DNA synthesis and also is not affected by MTX (Scaglione and Panzavolta, 2014). MTX should not be taken by pregnant and lactating women (Sammaritano and Bermas, 2014).

Biologic Response Modifiers (BRM) or Biologics

Biologic response modifiers (BRM), or biologics, are medications genetically engineered from a living organism, such as a virus, gene, or protein, to simulate the body's natural response to infection and disease. BRM target proteins, cells, and pathways responsible for the symptoms and damage of RA and other types of inflammatory arthritis.

The biologics used in arthritis treatment work in one of several ways: 1) by blocking proteins that are produced in response to injury such as interleukin-1 (IL-1), IL-6, tumor necrosis factor alpha (TNF- α); 2) by blocking B-cells, which produce antibodies that are produced excessively in some forms of arthritis; and 3) by inhibiting the activation of T-cells, thereby preventing the chain reactions that result in inflammation. These molecules are administered by injection (intravenously or subcutaneously) because they are proteins and oral administration would destroy their biologic activities. Patients taking these drugs should be monitored for chronic infections or malignancies (Ramiro et al, 2014). The main drawback is their high cost, on average \$18,000 dollars per patient per year (see Arthritis Foundation [AF]).

Corticosteroids

Corticosteroids, sometimes called glucocorticoids, are medications that mimic the effects of the hormone cortisol, which is produced naturally by the adrenal glands. Cortisol affects many parts of the body, including the immune system. Corticosteroids are prescribed for patients who need quick relief from severe inflammation by lowering the levels of PG. In some cases of RA, corticosteroids pills are taken while waiting for other DMARD to start to take effect. Low-dose corticosteroids also may be prescribed long term for some patients with RA. However, the use of corticosteroids in RA is debated, because some doctors believe the long-term benefits do not outweigh the risk of side effects. If used alone, the immediate relief corticosteroids provide may defer the start of treatment, which could make a difference in the course of the disease.

As the most potent of the antiinflammatory drugs used to treat RA, steroids have extensive catabolic effects that can result in negative nitrogen balance. Hypercalciuria and reduced calcium absorption can increase the risk of osteoporosis (see Chapters 8 and 24). Concomitant calcium and vitamin D supplementation and monitoring of bone status should be considered to minimize osteopenia.

Vitamin D

Vitamin D deficiency has been linked to several autoimmune diseases, including type 1 diabetes, multiple sclerosis, Crohn's disease, dementia, cardiovascular diseases, and rheumatic disorders such as SLE and RA. Vitamin D acts by suppressing Th17 and Th1 cells that are proinflammatory, giving way to Th2 and T regulatory (T_{reg}) cells, which are antiinflammatory. As most studies indicate that vitamin D insufficiency is associated with high disease activity of RA, it would be logical to supplement these patients with vitamin D. In murine models of experimental arthritis, supplementation with 1,25-dihydroxyvitamin D_3 (calcitriol) prevents the onset and progression of the disease. Supplementation of 500 IU calcitriol daily given to previously DMARD-naïve patients with early RA along with triple DMARD therapy resulted in significant higher pain relief (50% vs. 30%) at the end of 3 months, compared with patients treated with triple DMARD and calcium (Haga, 2013). Most clinicians agree that with the increasing adverse health outcomes associated with hypovitaminosis D, screening and supplementation should be performed routinely in RA patients.

BOX 39-2 The Antiinflammatory Diet

General principles: Aims for variety, with plenty of fresh food, the least amount of processed foods and “fast foods,” and abundant fruits and vegetables

Includes plenty of fruits and vegetables, except onions and potatoes, which contain the alkaloid solanine

Low in saturated fat and devoid of trans fats

Low in omega-6 fats, such as vegetable oils and animal fat

High in omega-3 PUFAs such as those found in olive oil, flax, walnuts, pumpkin seeds, and fatty cold-water oily fish such as salmon, sardines, mackerel, and herring. Other healthy oils include grapeseed, walnut, and canola.

Low in refined carbohydrates such as pasta, white bread, white rice, and other refined grains, and sucrose (table sugar) and sucrose-containing products such as pastries, cookies, cakes, energy bars, and candy

Favors intake of whole grains such as brown rice, bulgur wheat, and other unrefined grains such as amaranth, quinoa, and spelt.

Includes lean protein sources such as chicken and fish

Low in eggs, red meat, butter, and other full-fat dairy products

Low in refined and processed foods

Includes spices such as ginger, curry, turmeric, and rosemary, which have antiinflammatory effects

Includes good sources of phytonutrients: fruits and vegetables of all bright and dark colors, especially berries, tomatoes, orange and yellow fruits, and dark leafy greens; cruciferous vegetables (cabbage, broccoli, brussels sprouts, cauliflower); soy foods, tea (especially white, green or oolong), dark plain chocolate in moderation

Additionally, weight should be maintained within healthy parameters, and exercise should be included.

ANTIINFLAMMATORY DIET

The **antiinflammatory diet**, a diet resembling the Mediterranean diet, has been useful for the treatment of inflammatory diseases, including RA. The diet aims for the inclusion of as much fresh food as possible, the least amount of processed foods and fast food, minimal amounts of sugar, particularly fructose and sucrose, and an abundance of fruits (especially berries) and vegetables, lean proteins, from animal sources such as chicken and fish, and vegetarian sources such as legumes and nuts, essential fatty acids, and dietary fiber. Although this diet is not intended for weight loss, people often lose weight on it (AF, 2014a) (see Box 39-2 and Appendix 31). Changing the dietary habits to a Mediterranean diet reduces the inflammatory status in healthy persons, as well as in patients with obesity, cardiovascular disease, and Crohn's disease (Castañer et al, 2013; Marlow et al, 2013; van Dijk et al, 2012). The antiinflammatory diet works by reducing the expression of genes involved in the inflammatory process such as IL-1, IL-6, and TNF- α .

COMPLEMENTARY OR INTEGRATIVE THERAPIES

Because of the chronic nature of arthritic diseases, their effects on quality of life, and the fact that most treatments result only in modest improvement in symptoms and function, patients commonly try alternative methods of treatment. Favorable effects of self-help treatments are often reported anecdotally, but usually no cause-and-effect relationships are documented. In addition, with unlimited access to the Internet, patients have greater exposure to remedies and controversial treatments. In a recent survey, rheumatologists in the United States showed a widespread favorable

opinion toward complementary and alternative medicine (CAM) for patients with rheumatic diseases (Manek et al, 2010).

The World Health Organization (WHO) has defined CAM as “a broad set of health care practices that are not part of the country's own tradition and are not integrated into the dominant healthcare system” (WHO, 2014). The terms complementary and alternative refer to health-related products and practices that are not generally considered part of conventional medicine. Complementary medicine is used together with conventional medicine, and alternative medicine is used in place of conventional medicine. The term complementary integrative medicine (CIM) is being used more frequently to describe the new practice developing from conventional medicine (see Chapter 12).

There is not a lot scientific proof that CIM helps with some of the symptoms of arthritis, although this does not mean some CIM may work for all patients. Therapies vary from aromatherapy to reflexology, herbal, natural products and supplements, physical activities, body work, and many more. Some of the main categories in which CIM can be grouped are presented below. (National Institute of Health [NIH], National Center for Complementary and Integrative Health [NCCIH], 2014).

Mind and body practices include a large and diverse group of procedures or techniques administered or taught by a trained practitioner or teacher. These include acupuncture, massage therapies, meditation, movement therapies (Feldenkrais method, Alexander technique, Pilates), relaxation techniques (breathing exercises, guided imagery, progressive muscle relaxation), spinal manipulation, tai chi, qi gong, and yoga.

Natural products encompass herbs (botanicals), vitamins and minerals, and probiotics. They are widely marketed, available to consumers, and often sold as “dietary supplements,” including glucosamine, chondroitin, S-adenosyl methionine (SAM-e), fish oil, extra virgin olive oil, curcumin, turmeric, boswellia, comfrey, alfalfa, cat's claw, thunder god vine, coenzyme Q10 (CoQ-10), Frankincense, and methylsulfonylmethane (MSM). Capsaicin, the compound responsible for the burning sensation produced by chili peppers, is used as a rubbing topical gel to relieve pain, particularly in joints of OA and RA patients (see Chapter 12 for further discussion of botanicals).

Other CIM includes the use of bracelets (usually made of copper), magnets, aromatherapy, and hypnotherapy.

A patient's decision to try any CIM should be discussed with his or her physician. If a type of CIM (or any combination of two or more) works, reduction of medication use can be considered. The main drawback for some patients is the additional costs of CIM.

Elimination Diets

Many people have the belief that certain foods may contain harmful substances that can worsen their arthritis symptoms. One theory is that they are having an allergic reaction to the food (see Chapter 26 for strategies for testing for food allergies or sensitivities and implementing an elimination diet). According to the NIH, the nightshade elimination diet for arthritis management is considered CIM and falls into this category of elimination diets. It is believed that nightshade plants aggravate the inflammation that causes pain, swelling, and stiffness in the joints of some patients with arthritis.

Nightshades are a diverse group of foods, herbs, shrubs, and trees that include more than 2800 species of plants of the *Solanaceae* family, such as potatoes, tomatoes, sweet and hot peppers, and eggplants. They contain a group of chemicals termed alkaloids, like solanine and chaconine, which are believed to cause damage to the

joints and increase the loss of calcium from the bones. The nightshade elimination diet is believed to be safe, but there is always the risk that when eliminating certain foods from their diet, arthritis patients may not get enough of the necessary nutrients (vitamins, minerals, antioxidants; see Chapter 26). Although there are anecdotal claims of its effectiveness, the nightshade elimination diet has not been studied in depth, and no formal research has ever confirmed its beneficial effects (AF, 2014b).

MICROBIOTA AND ARTHRITIS

Increased levels of antibodies directed against antigens of certain species of gut bacteria point to the relationship between bacteria and arthritis. The idea that intestinal microorganisms are associated with the development of RA is not new: germ-free experiments have provided insight into host–microbial interactions and have shown that gut bacteria can induce autoimmunity in genetically predisposed animal models (Scher and Abramson, 2011). Mechanisms through which the microbiota may be involved in the pathogenesis of rheumatic diseases include altered epithelial and mucosal permeability, loss of immune tolerance to components of the indigenous microbiota, and trafficking of activated immune cells and antigenic material to the joints.

In 2007, based on phenotypic and phylogenetic analysis, a previously unrecognized bacterium termed *Prevotella copri* was recovered from human feces. *P. copri* is an obligate anaerobic, nonmotile, gram-negative rod. The importance of this discovery lies in that *P. copri* has been recovered in 75% of patients with new-onset untreated RA (NORA) and only in 21.4% of healthy individuals. Furthermore, there is an inverse correlation between HLA susceptibility alleles in patients with NORA and the abundance of *P. copri* detected in their fecal samples, which suggests a pathogenic role for *P. copri* in the development of RA, although its mechanism of damage remains unclear (Bernard, 2014).

Studies on the effect of diet on the microbiota, particularly with regard to the proinflammatory effects of the Western diet, are needed to gain insight into the treatment of rheumatic diseases. Potential future therapeutic approaches may include modification of the microbiota through the use of probiotics or prebiotics (Yeoh et al, 2013).

Some bacterial infections have been related to the development of reactive arthritis, the most widely documented from infection with *Streptococcus pyogenes*, a Group A beta-hemolytic bacteria that is the cause of streptococcal pharyngeal infection. **Rheumatic fever** is a systemic disease affecting the peri-arteriolar

connective tissue and can occur after an untreated *S. pyogenes* infection. Acute rheumatic fever commonly appears in children between the ages of 6 and 15, with only 20% of first-time attacks occurring in adults. The illness is so named because of its similarity in presentation to RA.

Diagnosis of acute rheumatic fever is based on the presence of documented Group A streptococcal infection. The most common symptoms include arthritis (most of the time unilateral, instead of the common bilateral presentation in RA), carditis (inflammation of the heart tissue), and Sydenham chorea (involuntary movements of the face, hands, and feet, also known as “Saint Vitus’ dance”) (Burke and Chang, 2014). Heart complications may be long term and severe, particularly if valves are involved.

Molecular mimicry accounts for the tissue injury that occurs in rheumatic fever. In this process, the patient’s immune responses are unable to distinguish between *S. pyogenes* structures and certain host tissues, attacking both. The resultant inflammation may persist well beyond the acute infection and produces the manifestations of rheumatic fever. The recurrence of rheumatic fever is relatively common in the absence of maintenance of low-dose antibiotics, especially during the first 3 to 5 years after the first episode. Survivors of rheumatic fever often have to take penicillin to prevent streptococcal infection, which could possibly lead to another case of rheumatic fever that could prove fatal.

OSTEOARTHRITIS

Osteoarthritis (OA), formally known as degenerative arthritis or degenerative joint disease, is the most prevalent form of arthritis. Obesity, aging, female gender, white ethnicity, greater bone density, and repetitive-use injury associated with athletics have been identified as risk factors. OA is not systemic or autoimmune in origin, but involves cartilage destruction with asymmetric inflammation. It is caused by joint overuse, whereas RA is a systemic autoimmune disorder that results in symmetric joint inflammation.

Pathophysiology

OA is a chronic joint disease that involves the loss of habitually weight-bearing articular (joint) cartilage. This cartilage normally allows bones to glide smoothly over one another. The loss can result in stiffness, pain, swelling, loss of motion, and changes in joint shape, in addition to abnormal bone growth, which can result in osteophytes (bone spurs) (see Figure 39-1 and *Pathophysiology and Care Management Algorithm: Osteoarthritis*).

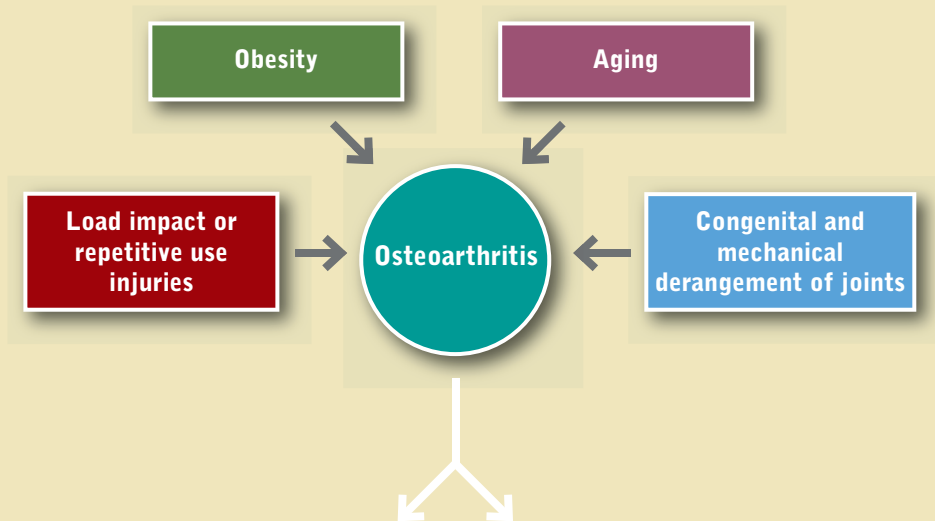

FIGURE 39-1 A healthy joint and a joint with severe osteoarthritis. (From National Institutes of Health, National Institute of Arthritis and Musculoskeletal and Skin Diseases: *Handout on health: osteoarthritis*, NIH Publication No. 13-4617, National Institutes of Health, August 2013, revised March 2014.)

PATHOPHYSIOLOGY AND CARE MANAGEMENT ALGORITHM

Osteoarthritis

ETIOLOGY

PATHOPHYSIOLOGY

Clinical Findings

- Breakdown of articular cartilage
- Changes in joint shape
- Osteophytes/bone spurs
- Cartilage or bone fragments in synovial fluid

Joint Symptoms

- Stiffness
- Pain
- Swelling
- Loss of motion
- Crunching feeling of bone on bone

MANAGEMENT

Medical Management

Drug Therapy: NSAIDs, corticosteroids, topical and other pain relievers
Health Behavior Changes: Exercise, weight control, rest and relief from stress on joints
Non-Drug Pain Relief: Heat and cold, TENS, massage

Nutrition Management

- Balanced diet with appropriate kcal for weight loss or maintenance of appropriate weight
- Anti-inflammatory diet
- Supplementation with omega-3 PUFA
- Adequate calcium and vitamin D
- Consideration of glucosamine and chondroitin

The joints most often affected in OA are the distal interphalangeal joints, the thumb joint, and, in particular, the joints of the knees, hips, ankles, and spine, which bear the bulk of the body's weight (see [Figure 39-2](#)). The elbows, wrists, and ankles are less often affected. OA generally presents as pain that worsens with weight bearing and activity and improves with rest, and patients often report morning stiffness or “gelling” of the affected joint after periods of inactivity. Diseases of the joints influenced by congenital and mechanical derangements may

contribute to OA as well. Inflammation occurs at times but is generally mild and localized.

Medical and Surgical Management

The patient's medical history and level of pain should determine the most appropriate treatment. This should include nonpharmacologic modalities (patient education, physical and occupational therapy), pharmacologic agents, and surgical procedures with the goals of pain control, improved function and

FIGURE 39-2 Joints commonly affected by osteoarthritis.

health-related quality of life, and avoidance of toxic effects from treatment. Weight loss and/or achievement of ideal body weight (body mass index [BMI] of 18.5 to 24.9 kg/m²) should be part of the medical treatment because it improves OA dramatically (see Chapter 21).

Patients with severe symptomatic OA pain who have not responded adequately to medical treatment and who have been progressively limited in their activities of daily living (ADLs), such as walking, bathing, dressing, and toileting, should be evaluated by an orthopedic surgeon. Surgical options include arthroscopic debridement (with or without arthroplasty), total joint arthroplasty, and osteotomy. Surgical reconstruction has been successful but should not be viewed as a replacement for overall good nutrition, maintenance of healthy body weight, and exercise.

Exercise

OA limits the ability to increase energy expenditure through exercise. It is critical that the exercise be done with correct form so as not to cause damage or exacerbate an existing problem. Physical and occupational therapists can provide unique expertise for OA patients by making individualized assessments and recommending appropriate exercise programs and assistive devices, in addition to offering guidance regarding

joint protection and energy conservation. Nonloading aerobic (swimming), range-of-motion, and weight-bearing exercises have been shown to reduce symptoms, increase mobility, and lessen continuing damage from OA. Non-weight-bearing exercise also may serve as an adjunct to NSAID use.

Sports or strenuous activities that subject joints to repetitive high impact and loading increase the risk of joint cartilage degeneration. Therefore increased muscle tone and strength, correct form, general flexibility, and conditioning help protect these joints in the habitual exerciser. A walking program and lower-extremity strength training are beneficial for individuals with knee OA.

Medical Nutrition Therapy

Weight and Adiposity Management

Excess weight puts an added burden on the weight-bearing joints. Epidemiologic studies have shown that obesity and injury are the two greatest risk factors for OA. The risk for knee OA increases as the BMI increases. Controlling obesity can reduce the burden of inflammation on OA and thus delay disease progression and improve symptoms. A well-balanced diet that is consistent with established dietary guidelines and promotes attainment and maintenance of a desirable body weight is an important part of MNT for OA.

The antiinflammatory diet combined with moderate exercise and diet-induced weight loss has been shown to be an effective intervention for knee OA. There is also an antiinflammatory effect from weight loss in OA management because the reduced fat mass results in the presence of less inflammatory mediators from adipose tissue (see Chapters 3 and 21).

Vitamins and Minerals

Cumulative damage to tissues mediated by reactive oxygen species has been implicated as a pathway that leads to many of the degenerative changes seen with aging. However, large doses of dietary antioxidants, including vitamins A, C, or D, alone or in combination, showed no benefit for the management of OA (Rosenbaum et al, 2010).

Many patients with OA consume deficient levels of calcium and vitamin D. Low serum levels of 25-OH-vitamin D are frequent and there is an inverse association between serum 25-OH-vitamin D and clinical findings (cartilage loss in the joint space) and joint pain (Cao et al, 2013). Calcitriol (1,25-dihydroxyvitamin D₃) functions as a transcription factor regulating the expression of several genes. Calcitriol binds to the vitamin D receptor (VDR) followed by their interaction with specific sequences in the DNA. However, the VDR gene also presents polymorphisms, and some of these have been associated with OA and another condition called intervertebral disc degeneration. Given the role of vitamin D in the cartilaginous tissue, the very common low levels of serum vitamin D, and the genetic polymorphism of the VDR, more studies are necessary to determine the role of vitamin D in the pathogenesis of OA (Colombini, et al, 2013).

Complementary Integrative Therapies

A meta-analysis have found that capsaicin gel and SAME are useful in treating OA; artichin F (an ayurvedic mixture of withania, boswellia, curcuma, and zinc) improved pain and function; Indian Frankincense, MSM, and rose hip were somewhat effective; collagen, devil's claw, vitamin K, hyaluronic acid, and many more, proved to be ineffective for OA (De Silva et al, 2011).

Glucosamine and Chondroitin

Glucosamine and chondroitin are involved in cartilage production, but their mechanism for eliminating pain has not been identified. Limited data suggest that glucosamine sulfate administered orally, intravenously, intramuscularly, or intraarticularly may produce a gradual and progressive reduction in joint pain and tenderness, as well as improved range of motion and walking speed. Glucosamine has produced consistent benefits, including greater than 50% improvement in symptom scores in patients with OA, in some cases equal to or superior to ibuprofen. Together glucosamine and chondroitin rank third among all top-selling nutritional products in the United States.

The NIH undertook the Glucosamine/Chondroitin Arthritis Intervention Trial (GAIT), the first, large-scale, multicenter clinical trial in the United States to test the effects of these supplements on knee OA (NIH, NCCIH, 2008). A dose of 1500 mg of glucosamine (500 mg, three times daily) with 1200 mg of chondroitin (400 mg, three times daily) resulted in statistically significant pain relief for a small subset of participants who had moderate to severe pain, but not for those in the mild pain subset. Compared with 54% of those taking placebo, 79% of those taking glucosamine and chondroitin reported a 20% or greater reduction in pain. A more recent study over a 6-year period found that glucosamine/chondroitin prevented some cartilage loss when compared to placebo in patients with knee OA (Raynauld, 2016).

Although it is not effective for all afflicted individuals, a safe dose of glucosamine and chondroitin sulfate is 1500 mg/day and 1200 mg/day in divided doses, respectively. GAIT and other studies have found no change in glucose tolerance: a meta-analysis report that looked at more than 3000 human subjects found no adverse effects of oral glucosamine administration on blood, urine, or fecal parameters and no serious or fatal side effects (Anderson et al, 2005). In contrast, chondroitin is chemically similar to commonly used blood thinners and could cause excessive bleeding if used in combination with blood thinners;

chondroitin also may elicit a reaction in those with shellfish allergies.

Another meta-analysis of the efficacy of glucosamine, chondroitin, and MSM for the treatment of spinal degenerative joint disease and degenerative disc disease (disc desiccation and retrolisthesis), reported that data are insufficient to support the use of any of these nutritional supplements for spinal degeneration (Stuber et al, 2011).

RHEUMATOID ARTHRITIS

Rheumatoid arthritis (RA) is a debilitating and frequently crippling autoimmune disease with overwhelming personal, social, and economic effects. Although less common than OA, RA is usually more severe, occurs more frequently in women than in men, with a peak onset commonly between 20 and 45 years.

RA affects the interstitial tissues, blood vessels, cartilage, bone, tendons, and ligaments, as well as the synovial membranes that line joint surfaces. Measurements of RF, and **antinuclear antibodies (ANA)** and antibodies to citrullinated protein antigens (ACPAs), are useful in the diagnosis as well as the prediction of the course and outcomes of RA (Demoruelle and Deane, 2011).

Numerous remissions and exacerbations generally follow its onset, although for some people it lasts just a few months or years and then goes away completely. Although any joint may be affected by RA, involvement of the small joints of the extremities—typically the proximal interphalangeal joints of the hands and feet—is most common (see Figure 39-3). Although the exact cause of RA is still unknown, certain genes have been discovered that play a role (Chatzikyriakidou et al, 2013).

Pathophysiology

RA is a chronic, autoimmune, systemic disorder in which **cytokines** and the inflammatory process play a role. RA has

FIGURE 39-3 A female patient with advanced rheumatoid arthritis. The twisted hands (A) and feet (B), and the puffiness of the metacarpal joints are typical of the disease. (Photos courtesy Dr. F. Enrique Gómez. Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán. Mexico City, México, 2015.)

articular manifestations that involve chronic inflammation that begins in the synovial membrane and progresses to subsequent damage in the joint cartilage (see *Pathophysiology and Care Management Algorithm: Rheumatoid Arthritis*). Citrullination, also termed deimination, is a modification of arginine side chains catalyzed by peptidylarginine deiminase (PAD) enzymes. This posttranslational modification has the potential to alter the structure, antigenicity, and function of proteins. Four citrullinated antigens, fibrinogen, vimentin, collagen type II, and alpha-enolase, are expressed in the joints. In RA, antibodies to cyclic citrullinated peptides are now well established for clinical diagnosis (Demoruelle and Deane, 2011).

The appearance of rheumatoid factor (RF) may precede symptoms of RA. Pain, stiffness, swelling, loss of function, and anemia are common. The swelling or puffiness is caused by the accumulation of synovial fluid in the membrane lining the joints and inflammation of the surrounding tissues (see Figure 39-4).

Some controversy exists regarding green tea: it has been suggested that drinking large amounts of tea may increase the risk of developing RA, whereas other studies suggest a protective role (Walitt et al, 2010; Wu et al, 2012). Smoking is the environmental risk factor that is most associated with RA followed by coffee consumption, whereas dietary antioxidants and breast-feeding may be protective (Lahiri et al, 2012).

FIGURE 39-4 Comparison of a normal joint and one affected by rheumatoid arthritis, which has swelling of the synovium. (From National Institute of Arthritis and Musculoskeletal and Skin Diseases: *Handout on health: rheumatoid arthritis*, NIH Publication No. 12-4179, April 2013, Revised March 2014. National Institutes of Health.)

Medical Management

RA patients are at increased risk for cardiovascular disease, explained by the systemic inflammatory response. This is especially significant considering findings regarding COX-2 selective NSAIDs. In fact, many of the drugs used to treat RA (see Chapter 8 and Appendix 23) can result in hyperhomocysteinemia, hypertension, and hyperglycemia, all risk factors for cardiovascular disease. Conveniently, treatment aimed at reducing inflammation may benefit both diseases.

Pharmacologic Therapy

Medications to control pain and inflammation are the mainstay of treatment for RA. Salicylates and NSAIDs are often the first line of treatment. Methotrexate (MTX) commonly is prescribed as well, but these drugs may cause significant side effects. The choice of drug class and type is based on patient response to the medication, incidence and severity of adverse reactions, and patient compliance. Drug-nutrient side effects can occur with any of the drugs (see Chapter 8 and Appendix 23).

Salicylates are used commonly. However, chronic aspirin ingestion is associated with gastric mucosal injury and bleeding, increased bleeding time, and increased urinary excretion of vitamin C. Taking aspirin with milk, food, or an antacid often alleviates the gastrointestinal symptoms. Vitamin C supplementation is prescribed when serum levels of ascorbic acid are abnormally low (see Appendix 42).

DMARD may be prescribed because of their unique ability to slow or prevent further joint damage caused by arthritis. These include MTX, sulfasalazine (Azulfidine), hydroxychloroquine (Plaquenil), azathioprine (Imuran), and leflunomide (Arava). In fact, the ACR recommends that the majority of patients with newly diagnosed RA be prescribed a DMARD within 3 months of diagnosis. Depending on which drug is selected, side effects can include myelosuppression or macular or liver damage. A main adverse effect of the DMARD MTX treatment is folate antagonism. Treatment with MTX induces a significant rise in serum homocysteine, which is corrected by folic acid supplementation and a properly balanced diet. Folate supplementation is advised to offset the toxicity of this drug, for protection against gastrointestinal disturbances, and for maintenance of red blood cell production without reducing the efficacy of MTX therapy. Long-term folate supplementation in

patients on MTX is also important to prevent neutropenia, mouth ulcers, nausea, and vomiting (see Appendices 31 and 46 and Chapters 8 and 32).

D-penicillamine acts as an immunosuppressor by reducing the number of T cells, inhibiting macrophage function, and decreasing IL-1 and RF production. Additional DMARD include gold salt therapy and antimalarials and may lead to a remission in RA symptoms. Proteinuria may occur with administration of gold and D-penicillamine; therefore toxicity must be monitored continually.

Surgery

Surgical treatment for RA may be considered if pharmacologic and nonpharmacologic treatment cannot adequately control the pain or maintain acceptable levels of functioning. Common surgical options include synovectomy, joint replacement, and tendon reconstruction.

After substantial weight loss from bariatric surgery, obese patients with RA showed lower disease activity, decreased inflammatory markers (CRP, erythrocyte sedimentation rate, total leukocytes) and less RA-related medication use. These findings show that weight loss is important to reduce RA disease activity and should be encouraged by nutrition professionals (Sparks JA, 2015).

Exercise

Physical and occupational therapy are often part of the initial therapy for newly diagnosed RA but also may be integrated into the treatment plan as the disease progresses and ADLs are affected. To maintain joint function, recommendations may be given for energy conservation, along with range-of-motion and strengthening exercises. Although the patient may be reluctant at first, individuals with RA can participate in conditioning exercise programs without increasing fatigue or joint symptoms while improving joint mobility, muscle strength, aerobic fitness, and psychological well-being.

Medical Nutrition Therapy

The nutrition care process and model serve as a guide for implementing MNT with RA patients. A comprehensive nutrition assessment of individuals with RA is essential, with a review of systems to determine the systemic effects of the disease process.

A physical examination provides diagnostic signs and symptoms of nutrient deficiencies (see Appendix 29). Current weight and history of weight change over time are the least expensive, least invasive, and most reliable assessment tools to use. Weight change is an important measure of RA severity. The characteristic progression of malnutrition in RA is attributed to excessive protein catabolism evoked by inflammatory cytokines and by disuse atrophy resulting from functional impairment.

The diet history should review the usual diet; the effect of the handicap; types of food consumed; and changes in food tolerance secondary to oral, esophageal, and intestinal disorders. The effect of the disease on food shopping and preparation, self-feeding ability, appetite, and intake also must be assessed. The use of elimination or other diets purported to treat or cure arthritis should be identified.

Articular and extraarticular manifestations of RA affect the nutrition status of individuals in several ways. Articular involvement of the small and large joints may limit the ability to perform nutrition-related ADLs, including shopping for, preparing, and eating food. Involvement of the temporomandibular joint can affect the ability to chew and swallow and may necessitate changes in diet consistency. Extraarticular manifestations include increased metabolic rate secondary to the inflammatory process, SS, and changes in the gastrointestinal mucosa.

Increased metabolic rate secondary to the inflammatory process leads to increased nutrient needs, often in the face of a diminishing nutrient intake. Taste alterations secondary to xerostomia and dryness of the nasal mucosa; dysphagia secondary to pharyngeal and esophageal dryness; and anorexia secondary to medications, fatigue, and pain may reduce dietary intake. Changes in the gastrointestinal mucosa affect intake, digestion, and absorption. The effect of RA and the medications used may be evident throughout the gastrointestinal tract. Based on the patient's unique profile, a registered dietitian nutritionist can determine the most appropriate nutrition intervention, followed by monitoring and evaluation.

The association of foods with disease flares should be discussed. Whether food intake can modify the course of RA is an issue of continued scientific debate and interest. Dietary manipulation by either modifying food composition or reducing body weight may give some clinical benefit in improving RA symptoms. A vegan, gluten-free diet causes improvement in some patients, possibly because of the reduction of immunoreactivity to food antigens (see Chapter 28). Identification of possible food allergies and use of an elimination diet may be useful (see Chapter 26).

Fasting has been practiced for millennia, but, only recently, studies have shed light on its role in adaptive cellular responses that reduce oxidative damage and inflammation. In humans it helps reduce hypertension, asthma, and symptoms of RA. Thus fasting has the potential to delay aging and help prevent and treat diseases while minimizing the side effects caused by medications (Longo and Mattson, 2014). Intermittent fasting during the acute phase of RA may provide some pain relief, but it has never been shown as an effective treatment for RA symptoms.

The antiinflammatory diet described in Box 39-2 should be considered. The similar Mediterranean-style eating plan includes foods that almost everyone should aim to consume on a daily basis, such as moderate amounts of lean meat, unsaturated fats instead of saturated fats, plenty of fruits and vegetables, and fish (AF, 2014a; Boeing et al, 2012). These diets are also nutritionally

adequate and cover all of the food groups (see Appendix 31 for additional description of the antiinflammatory diet).

Energy

There are three unique aspects of energy metabolism in RA. One is elevated resting energy expenditure. RA causes cachexia, a metabolic response characterized by loss of muscle mass and elevated resting energy expenditure. Another is elevated whole-body protein catabolism, a destructive form of muscle metabolism that translates to muscle wasting. And yet another is low body cell mass, which leads to increased fat mass. People with RA tend to be less active than people without it; the stiffness and swelling caused by inflammation naturally prompt them to pursue less physical, more sedentary lifestyles. Such habits lead in turn to overall gains in fat mass. Being overweight puts an extra burden on weight-bearing joints when they are already damaged or under strain.

Total energy expenditure is significantly lower in RA patients, mainly because of less moderate-intensity physical activity performance. Disease activity and fatigue are important contributing factors. Energy requirements should be adjusted according to the weight and activity level of the individual (Henchoz et al, 2012) (see Chapter 21).

People with RA should consume nutrient-rich diets and incorporate physical activity throughout the day to boost their total energy expenditure. This helps them improve their physical function and quality of life and maintain a healthy weight.

Protein

Protein requirements for individuals who are poorly nourished or who are in the inflammatory phase of the disease are 1.5 to 2.0 g protein/kg body weight. Well-nourished individuals do not have increased requirements.

Fat

Fat should contribute less than 30% of the total energy intake for the purposes of healthy eating and weight management. The type of fat included in the diet is important: an increase in the amount of omega-3 fatty acids primarily from fish oils and alpha-linolenic acid (found in flaxseed, soybean oils, and green leaves) have been shown to reduce inflammation in RA. The antiinflammatory diet (see Box 39-2) with higher omega-3 fatty acids can reduce inflammatory activity and allow for increased physical function, and improved vitality for RA patients.

There is evidence of a fairly consistent, but modest, benefit of marine omega-3 PUFAs on joint swelling and pain and duration of morning stiffness (Miles and Calder, 2012; Norling and Perreti, 2013). Fish oil at a high dose (3.5 g/day) has been shown to have additional benefits to those achieved by combination DMARD with similar MTX use, including reduced triple DMARD failure and a higher rate of remission (Proudman et al, 2015). Omega-3 fatty acids have increased in popularity in the management of RA because of their role in inflammatory pathways.

Some other oils of marine origin and a range of vegetable oils (olive and evening primrose oil) have indirect antiinflammatory actions probably mediated via PGE₁ (see *Clinical Insight: Fatty Acids and the Inflammatory Process*). The beneficial effects are generally delayed for up to 12 weeks after they are started, but last up to 6 weeks after discontinuing therapy (Bhangle and Kolasinski, 2011) (see Appendix 40 for omega-3 and omega-6 fatty acid content of foods). Although these benefits along with improved dietary habits are known, they usually cannot replace conventional drug therapies.

CLINICAL INSIGHT

Fatty Acids and the Inflammatory Process

Inflammation is the body's attempt at self-protection to remove harmful stimuli, including damaged cells, irritants, or pathogens, and begin the healing process. When the offending stimuli are removed, inflammation subsides. The resolving phase of inflammation is not a passive process, but actively "switches off" via the biosynthesis of endogenous antiinflammatory mediators. It could therefore be considered that chronic, nonresolving inflammation not only is associated with excessive production of proinflammatory mediators but also is attributed to a defect in the synthesis of antiinflammatory compounds.

Two classes of polyunsaturated omega-6 and omega-3 fatty acids are metabolized competitively, including conversion to their corresponding prostanoids (prostaglandins [PG] and thromboxanes [Tx]) and leukotrienes (LT). Eicosapentaenoic acid (EPA, 20:5) and docosahexaenoic acid (DHA, 22:6) are omega-3 polyunsaturated fatty acids (PUFA) that are abundant in cold-water fish such as salmon, sardines, mackerel, herring, tuna, fish oils, and some algae. Alpha-linolenic acid (ALA, 18:3) is also an omega-3 PUFA found in abundance in flaxseed, walnuts, and soy and canola (rapeseed) oils. EPA, DHA, and ALA have all been shown to replace the synthesis of inflammatory eicosanoids by competing with the conversion of arachidonic acid (ARA, 20:4 omega-6) to the series 2 of PG and Tx. Also, EPA and DHA are enzymatically converted to novel bioactive lipid mediators, termed resolvins, protectins, and maresins, which promote the resolution of inflammation. ARA comes exclusively from animal foods. Linoleic acid (LA, 18:2), an omega-6 PUFA found in safflower and other vegetable oils, is a precursor of ARA; therefore its consumption should be limited in rheumatic patients.

The type of mediator that is produced is determined by the type of PUFAs present in the phospholipids of the cell membrane, which in turn is influenced by the type of PUFAs in the diet. Theoretically, a person can replace omega-6 PUFAs with omega-3 PUFAs by increasing omega-3 PUFA consumption. This, in turn, will result in the synthesis of prostanoids (PG and Tx) with antiinflammatory effects. Similarly, reducing the amount

of ARA minimizes inflammation and can enhance the benefits of fish oil supplementation.

Studies during the last 20 years clearly show beneficial changes in eicosanoid metabolism with fish oil supplementation in patients with RA, even when administered parenterally (Bahadori et al, 2010; Miles and Calder, 2012). Although fish oil seems to exert an antiinflammatory effect in short-term studies, these effects may vanish during long-term treatment because of decreased numbers of autoreactive T-cells via apoptosis.

These oils should be used in conjunction with improved eating that includes more omega-3 PUFA. This means a diet that includes baked or broiled fish one to two times per week. However, the Food and Drug Administration (FDA) has identified shark, swordfish, king mackerel, and tilefish as high-mercury fish that should be avoided (see *Focus On: Childhood Methylmercury Exposure and Toxicity: Media Messaging* in Chapter 17).

An average of 3.5 g/day of omega-3 PUFA (mainly EPA and DHA) can be recommended for RA patients (Lee et al, 2012; Norling and Perretti, 2013). Although the quality of fish oil supplements is steadily improving, these supplements are not without their own side effects, such as their fishy taste or odor, causing increased bleeding time or gastrointestinal distress; although these manifestations are usually dose dependent (Bhangle and Kolasinski, 2011).

The combination of fish oils with olive oil results in greater clinical improvements in RA patients than those consuming fish oils alone. These results are attributed to oleocanthal, a naturally occurring phenolic compound found in extra-virgin olive oil. Oleocanthal exerts its antiinflammatory activity by inhibiting COX-1 and COX-2, in a similar way as ibuprofen does, and by suppressing of MIP-1alpha and IL-6 (mRNA and protein synthesis) in macrophages and chondrocytes (Fezai et al, 2013; Scotecce et al, 2012). Although these are promising results, further studies are required before oleocanthal can be recommended safely for human trials because its absorption, metabolism, and distribution are not known.

Minerals, Vitamins, and Antioxidants

Several vitamins and minerals function as antioxidants and therefore affect inflammation. Vitamin E is just such a vitamin, and along with omega-3 fatty acids and omega-6 fatty acids, may affect cytokine and eicosanoid production by decreasing proinflammatory cytokines and lipid mediators. Synovial fluid and plasma trace element concentrations, excluding Zn, change in inflammatory RA. Altered trace element concentrations in inflammatory RA may result from changes of the immunoregulatory cytokines. Degradation of collagen and eicosanoid stimulation are associated with oxidative damage.

RA patients often have nutritional intakes below the Dietary Reference Intakes (DRIs) for folic acid, calcium, vitamin D, vitamin E, zinc, vitamin B, and selenium. In addition, the commonly used drug MTX is known to decrease serum folate levels with the result of elevated homocysteine levels. Low serum level of pyridoxal-5-phosphate correlates with increased markers of inflammation (Sakakeeny et al, 2012) and continuous use of NSAID (Naproxen) also impairs pyridoxine metabolism by a mechanism related to COX inhibition (Chang et al, 2013).

Thus, in these patients, adequate intakes of folate and vitamins B₆ and B₁₂ should be encouraged.

Calcium and vitamin D malabsorption and bone demineralization are characteristic of advanced stages of the disease, leading to osteoporosis or fractures. Prolonged use of glucocorticoids also can lead to osteoporosis. Therefore supplementation with calcium and vitamin D should be considered. Vitamin D status should be assessed and supplementation started if below normal. Indeed, vitamin D is a selective immunosuppressant and greater intakes of

vitamin D may be beneficial. Because of drug-induced alterations in specific vitamin or mineral levels, mounting evidence supports supplementation beyond the minimum levels for vitamins D, E, folic acid, and vitamins B₆ and B₁₂ (Haga, 2013).

Elevated levels of copper and ceruloplasmin in serum and joint fluid are seen in RA. Plasma copper levels correlate with the degree of joint inflammation, decreasing as the inflammation is diminished. Elevated plasma levels of ceruloplasmin, the carrier protein for copper, may have a protective role because of its antioxidant activity.

Complementary and Integrative Therapies

The increasing popularity of the use of complementary treatments appears to be particularly evident with people afflicted with RA. Herbal therapy is popular; however, concerns of toxicity must also be addressed because the Food and Drug Administration (FDA) provides relatively little regulation of herbal therapies.

Gamma-linolenic acid (GLA) is an omega-6 fatty acid found in the oils of black currant, borage, and evening primrose that can be converted into the antiinflammatory PGE₁ or into ARA, a precursor of the inflammatory PGE₂. Because of competition between omega-3 and omega-6 fatty acids for the same enzymes, the relative dietary contribution of these fats appears to affect which pathways are favored. The enzyme delta-5 desaturase converts GLA into ARA, but a diet high in omega-3 fats pulls more of this enzyme to the omega-3 pathway, allowing the body to use GLA to produce PGE₁ (see *Clinical Insight: Fatty Acids and the Inflammatory Process*). This antiinflammatory

PGE₁ may relieve pain, morning stiffness, and joint tenderness with no serious side effects. Further studies are required to establish optimum dosage and duration.

Thunder god vine (*Tripterygium wilfordii*) has been used for centuries in traditional Chinese medicine. Extracts are prepared from the skinned root of the herb, as other parts of the plant are highly poisonous. A systematic review of the research on thunder god vine for RA concluded that serious side effects occurred frequently enough that the risk of using it outweighs its benefits. Depending on the dose and type of extract, it affects the reproductive system, possibly causing menstrual changes in women and infertility in men and long-term use may decrease bone mineral density in women, potentially increasing the risk of osteoporosis. Other side effects can include diarrhea, upset stomach, hair loss, headache, and skin rash (NIH, NCCIH, 2013).

SJÖGREN SYNDROME (SS)

Sjögren syndrome (SS) is a chronic autoimmune inflammatory disease that affects the exocrine glands, particularly the salivary and the lacrimal glands, leading to dryness of the mouth (xerostomia) and of the eyes (xerophthalmia). SS can present alone (primary SS) or secondary as a result of a previous rheumatic disorder (commonly RA or SLE). It mainly affects middle-age women, with a female/male ratio of 9:1.

Common oral signs include thirst, burning sensation in the oral mucosa, inflammation of the tongue (glossitis), and lips (cheilitis), cracking of the corners of the lips (cheilosis), difficulties in chewing and swallowing (dysphagia), severe dental caries, oral infections (candidiasis), progressive dental decay, and nocturnal oral discomfort. Patients may also suffer from extraglandular disorders affecting the skin, lung, kidney, nerve, connective tissue, and digestive system (Ebert, 2012; Tincani et al, 2013). SS patients also may develop disturbances in smell perception (dysosmia) and in taste acuity (dysgeusia) (Ebert EC, 2012; Gomez et al, 2004).

Pathophysiology

Although the pathogenesis of SS remains elusive, environmental, genetic and hormonal contributors seem to be involved (Tincani et al, 2013). The majority of lymphocytes infiltrating the salivary glands are mostly CD4 T-cells. Increased levels of IL-1 and IL-6 in the saliva of SS patients suggest that a Th1 response participates in the pathogenesis of the disease. Although T-cells were originally considered to play the initiating role in SS, whereas B-cells were restricted to autoantibody production, it has been shown that B-cells play a central role in the development of the disease. A distinctive hallmark of SS is the presence of anti-Ro/SSA and anti-La/SSB autoantibodies. Interestingly, anti-Ro/SSA may be found either solely or concomitantly with anti-La/SSB antibodies, whereas exclusive anti-La/SSB positivity is rare (Huang et al, 2013).

Medical Management

The therapeutic management of SS is based on symptomatic treatment of glandular manifestations and on the use of DMARD for systemic involvement. Symptomatic treatment has beneficial effects on oral and ocular dryness and prevents further complications such as oral candidiasis, periodontal disease, and corneal ulceration and perforation.

Topical treatment of xerostomia begins by avoiding irritants such as caffeine, alcohol, and tobacco, followed by appropriate hydration (small sips of water) and the use of saliva substitutes, lubricating gels, mouth rinses, chewing gum, lozenges, or oils.

Any of these treatments is effective in the short term, but none improves saliva production. After consumption of sugary foods or beverages, the teeth should be brushed and rinsed with water immediately to prevent dental caries. Topical treatment for xerophthalmia starts by avoiding dry, smoky, or windy environments and prolonged reading or computer use. Artificial tears can be used. The muscarinic receptor agonists pilocarpine (Salagen) and cevimeline (Evoxac) may be used for the treatment of dry mouth and dry eyes only in patients with residual gland function (Tincani et al, 2013).

B-cell depletion therapy with rituximab (anti-CD20) improves the stimulated whole saliva flow rate and lacrimal gland function, as well as other variables including RF levels, extraglandular manifestations (arthritis, skin vasculitis), fatigue, and quality of life, indicating a major role of B-cells in the pathogenesis of SS (Tincani et al, 2013).

IL-1 and tumor necrosis factor-alpha (TNF-alpha) play a major role in the development of SS. Blocking IL-1 (anakinra) is beneficial in the treatment of SS, whereas blocking TNF-alpha (etanercept) is ineffective in controlling SS symptoms (Yamada et al, 2013; Yao et al, 2013). Etanercept exacerbated IFN-alpha and BAFF expression, providing a possible explanation for the lack of efficacy in blocking TNF-alpha in SS.

The management of extraglandular features must be tailored to the specific organs involved. Antimalarials (hydroxychloroquine), besides improving salivary flow, can help SS patients with arthromyalgia. The use of corticosteroids may be used in patients with extraglandular manifestations, although they have no effect in salivary or lacrimal flow rates.

Medical Nutrition Therapy

The first goal of dietary management for patients with SS is to help them relieve their oral symptoms and reduce the eating discomfort derived from the difficulty with chewing and swallowing. Very often SS patients modify their dietary habits on a “trial and error” basis to cope with their oral symptoms, particularly to improve biting (cutting fruits, vegetables, and meats in small pieces), chewing (making foods softer by preparing them as soups, broths, casseroles, or as tender cooked vegetables and meats), and swallowing (moistening foods with sauces, gravies, yogurts, or salad dressings). Foods that worsen oral symptoms should be limited, such as citrus fruits, as well as irritating, hot, or spicy foods (Sjögren’s Syndrome Foundation, 2013).

Malnutrition or weight loss are not common in SS patients, although deficiencies of several nutrients are common. These include vitamin D, vitamin B₆, vitamin B₁₂, folate, and iron, which can be corrected easily by proper nutritional counseling or supplementation (Erten et al, 2014). More importantly single nutrient deficiencies in SS have been associated with other diseases, such as low levels of vitamin D with neuropathy and lymphoma, suggesting a possible role of vitamin D deficiency in the development of other symptoms, and the plausible beneficial effect for vitamin D supplementation (Tincani et al, 2013).

TEMPOROMANDIBULAR DISORDERS

Temporomandibular disorders (TMDs) affect the temporomandibular joint, which connects the lower jaw (mandible) to the temporal bone. TMDs can be classified as myofascial pain, internal derangement of the joint, or degenerative joint disease. One or more of these conditions may be present at the same time, causing pain or discomfort in the muscles or joint that control jaw function.

Pathophysiology

Besides experiencing a severe jaw injury, little scientific evidence suggests a cause for TMD. It is generally agreed that physical or mental stress may aggravate this condition.

Medical Nutrition Therapy

The goal of dietary management is to alter food consistency to reduce pain while chewing. According to the National Institute of Dental and Craniofacial Research (NIDCR), diet should be mechanically soft in consistency; all foods should be cut into bite-size pieces to minimize the need to chew or open the jaw widely; and chewing gum, sticky foods, and biting hard foods such as raw vegetables, candy, and nuts should be avoided (NIH, NIDCR, 2013). Nutrient intake of TMD patients appears to be the same as for the general population with regard to total calories, protein, fat, carbohydrates, vitamins, and minerals. However, during times of acute pain, intake of fiber is often reduced.

GOUT

Gout is one of the oldest diseases in recorded medical history. It is a disorder of purine metabolism in which abnormally high levels of uric acid accumulate in the blood (**hyperuricemia**). Contrary to what is observed in most rheumatic diseases, gout affects predominantly men. All studies have consistently shown that gout affects older men (older than 45 years) with a male to female ratio of 4:1. This ratio changes to 3:1 above 65 years, which reflects that gout rarely affects young women but the frequency increases in postmenopausal women. The incidence and prevalence of gout have increased markedly in the last few decades; in the United States gout is more prevalent than RA (Lawrence et al, 2008). The presence of metabolic syndrome that includes central obesity, hypertension, insulin resistance, and hyperlipidemia, occurs in approximately 60% of patients with gout. Gout is associated with significant morbidity, mortality (mainly because of coronary heart disease), functional impairment, and reduced quality of life (Suresh and Das, 2012).

Pathophysiology

Gout is a crystal deposition disease in which the clinical symptoms are caused by the formation of **monosodium urate (MSU) crystals** in the joints and soft tissues, and the elimination of these crystals “cures” the disease. **Uric acid** is the end-product of purine metabolism in humans, but it is an intermediary product in most other mammals. It is produced primarily in the liver by the action of the enzyme xanthine-oxidase, a molybdenum-dependent enzyme. In most mammals, uric acid is further degraded by the enzyme urate oxidase (uricase), to allantoin, which is more soluble than uric acid, and hence more readily excreted by kidneys. In humans and higher primates, the gene encoding for uricase is nonfunctional and due to this evolutionary event, uric acid levels are higher in humans than in many other mammals. Uric acid homeostasis is determined by the balance between production and renal excretion (Bobulescu and Moe, 2012). Endogenous production of uric acid from degradation of **purines** accounts for two thirds of the body urate pool, the remainder being of dietary origin. Because most uric acid is excreted via the kidney (approximately 70%), hyperuricemia results from reduced efficiency of renal urate clearance.

Two proteins have been well characterized in urate clearance: the urate transporter 1 (URAT1) and the glucose and fructose transporter (GLUT9). URAT1 localizes in the brush border membrane of the proximal tubule kidney and is responsible mainly for renal reabsorption of uric acid, whereas GLUT9 is

located in the apical and basolateral membrane of the distal tubule where it functions as the main exit of urate from the body (Bobulescu and Moe, 2012).

In the vast majority of people with gout, hyperuricemia results from reduced renal urate clearance. MSU crystals preferentially form within cartilage and fibrous tissues; however if “shed” from these sites, they are highly immunogenic particles that are quickly phagocytosed by monocytes and macrophages, activating the NALP3 inflammasome and triggering the release of IL-1 and other cytokines, thus initiating an inflammatory response that affects the joint. MSU crystals act as a “danger signal” that can be recognized by pattern recognition receptors at the cell surface and in the cytoplasm, indicating the importance of innate immunity in gout (Rock et al, 2013). Persistent accumulation of MSU crystals causes joint damage through mechanical effects (pressure erosion) leading to chronic symptoms of arthritis (see Figure 39-5). MSU crystals can deposit in the small joints and surrounding tissues, producing recurrent episodes of extremely painful and debilitating joint and soft tissue inflammation (acute gout). In chronic gout, classic sites are the big toe, wrists and finger joints, elbow (see Figure 39-6), ankle, knee, and the helix of the ear.

Medical Management. Colchicine is used to treat the pain associated with acute flares of gout (within 12 to 24 hours) by reducing the inflammation caused by MSU crystals; it has no effect on serum urate levels. Colchicine may be used with other NSAIDs and only for a limited time because of its toxicity.

Because monocytes and macrophages produce IL-1 in response to MSU crystals, treatment with IL-1 antagonists (Anakinra) or with soluble IL-1 receptor (Rinolcept) results in rapid and complete pain relief (Suresh and Das, 2012).

Two classes of drugs have been used to lower serum urate: **uricostatic** drugs, which reduce the synthesis of uric acid by inhibiting xanthine oxidase, and **uricosuric** drugs, which increase the excretion of uric acid by blocking its renal tubular reabsorption. Allopurinol (Zyloprim) and febuxostat are uricostatic drugs; they are the drugs of choice for long-term treatment of hyperuricemia. On the other hand, sulfinpyrazone, probenecid, and benzbromarone are uricosuric drugs that act by inhibiting URAT1, therefore increasing the urinary excretion of uric acid (Bobulescu and Moe, 2012).

Pegloticase, a recombinant uricase, reduces serum urate levels by converting uric acid to allantoin, which is excreted rapidly in the urine. Pegloticase is used for rapid debulking of tophi and together with colchicine, in patients with severe and acute gout flares (Suresh and Das, 2012).

Medical Nutrition Therapy

Historically, gout has long been linked with a rich lifestyle involving excesses of meat and alcohol. There is an increased risk of gout associated with higher consumption of red meat (beef, pork, and lamb) and seafood, but not with consumption of vegetable protein. Diets high in purine-rich vegetables (beans, peas, lentils) do not increase the risk of gout.

On the other hand, diets high in low-fat dairy products and supplemental vitamin C have been associated with reduced risk of gout (Bobulescu and Moe, 2012). Consumption of coffee, but not green tea, is associated with low levels of serum urate, therefore, protective for gout.

Alcohol consumption, particularly beer (which is rich in purines), increases the risk of gout. Consumption of fructose, mainly as soft drinks sweetened with high fructose corn syrup, is associated with higher risk for gout. It is unclear whether this is a particular effect of fructose derived from corn, or whether

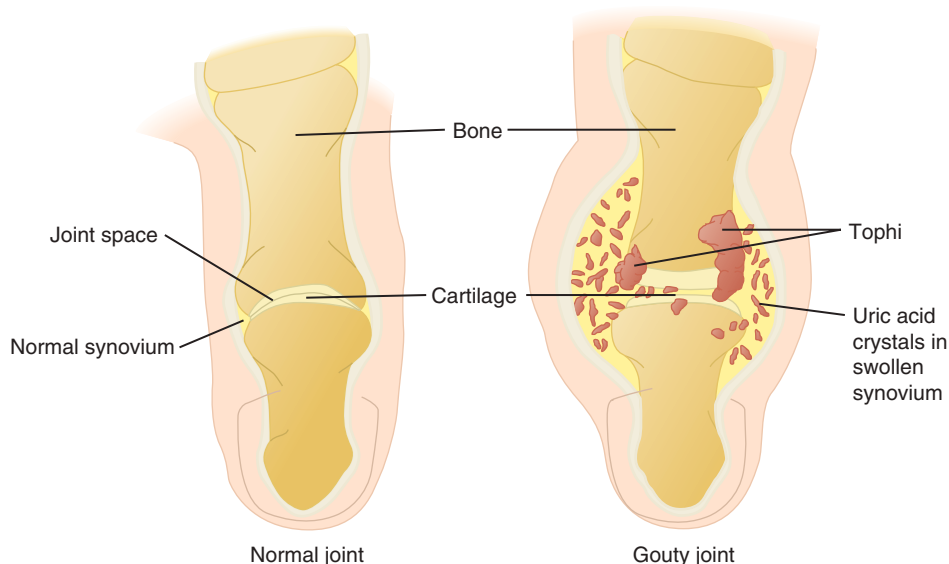

FIGURE 39-5 Comparison of a gouty joint and a normal joint in the toe. (From Black JM, et al: *Medical surgical nursing*, ed 7, Philadelphia, 2005, Saunders.)

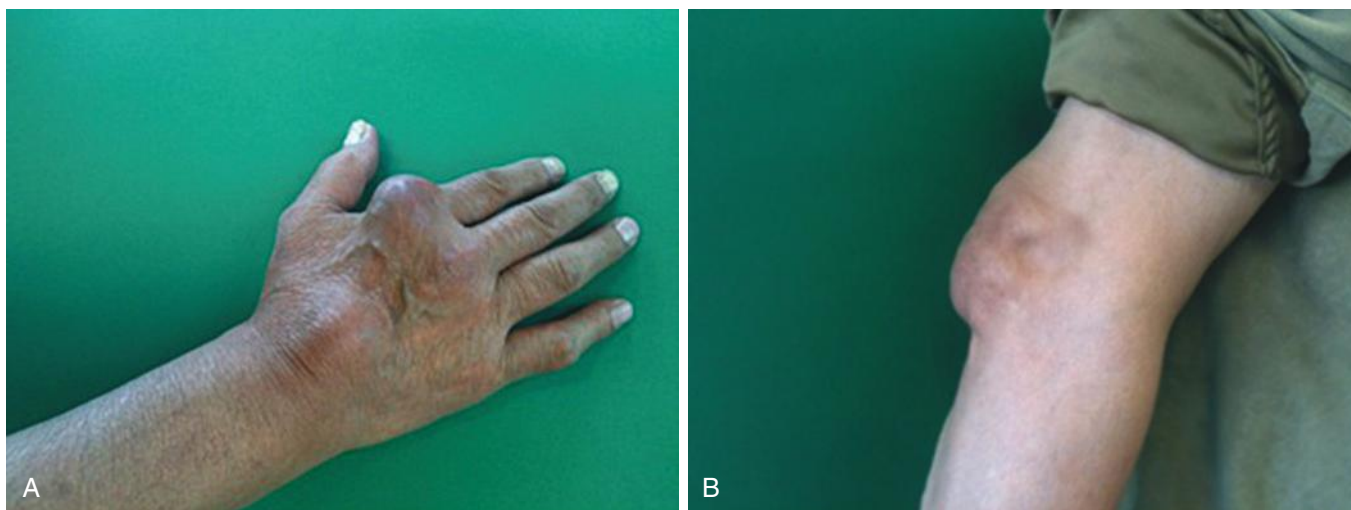

FIGURE 39-6 A male patient with advanced gout. Severe deposits of monosodium urate (MSU) crystals in the hand (A, wrist and fingers) and in the elbow (B). (Photos courtesy Dr. F. Enrique Gómez. Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán. Mexico City, México, 2015.)

it extends to sucrose. Fructose is known to raise the serum urate level by a mechanism recently linked to polymorphisms in GLUT9 (Dalbeth et al, 2013). Consumption of naturally occurring fructose such as in fruit or juices also may increase risk of gout, for example, eating an apple or orange a day, increase the risk by approximately 64% (Suresh and Das, 2012).

It is prudent to advise patients to consume a balanced meal plan with limited intake of animal foods and beer, avoidance of high-purine foods (see Box 39-3), limited consumption of sources of fructose (sweetened soft drinks and juices, candies, and sweet pastries), and controlled food portion sizes, and reduced noncomplex carbohydrate intake to achieve weight loss and improve insulin sensitivity (Li and Micheletti, 2011). Dairy products (milk or cheese), eggs, vegetable protein, cherries, (see *New Directions: Can Cherries Prevent a Gout Attack?*), and coffee appear to be protective, possibly because of the alkaline ash effect of these foods (Li and Micheletti, 2011). (see *Clinical Insight: Urine pH—How Does Diet Affect It?* in Chapter 35).

NEW DIRECTIONS

Can Cherries Prevent a Gout Attack?

Over the past few decades, cherries have gained considerable public attention as a potentially effective option in the prevention and management of gout. The first study on the effect of cherries in gout attacks was conducted in 1950. Lately there have been a few studies using fresh and canned cherries, as well as cherry juice and cherry extract, to assess whether consumption of cherries lowers the risk of gout attacks. Small experimental studies have demonstrated that cherry intake lowers uric acid levels in healthy individuals. A recent study with gout patients showed that cherry intake was associated with a 35% lower risk of gout attacks compared with no intake; when cherry intake was combined with allopurinol, the risk of gout attacks was 75% lower (Zhang et al, 2012). The mechanism by which cherries and cherry juice concentrate prevent gout attack is still unclear, but is related to its potentially antiinflammatory properties. These findings suggest that cherry intake is associated with a lower risk of gout attacks but large, prospective randomized controlled trials are needed to further evaluate the efficacy of cherries and cherry juice concentrate for the prevention of attacks in patients with gout.

BOX 39-3 Purine Content of Foods

High Purine Content (100-1000 mg of Purine Nitrogen per 100 g of Food): Foods in this List Should be Omitted from the Diet of Patients Who have Gout (Acute and Remission Stages).

Anchovies	Meat extracts
Bouillon	Mince meat
Brains	Mussels
Broth	Partridge
Consommé	Roe
Goose	Sardines
Gravy	Scallops
Heart	Sweetbreads
Herring	Yeast (baker's and brewer's), taken as supplement
Kidney	
Mackerel	

Moderate Purine Content (9-100 mg of Purine Nitrogen per 100 g of Food): One Serving (2-3 oz) of Meat, Fish, or Poultry or 1 Serving (½ C) of Vegetables from this Group is Allowed Daily.

Meat and fish	Vegetables
Fish	Asparagus
Poultry	Beans, dried
Meat	Lentils
Shellfish	Mushrooms
	Peas, dried
	Spinach

Negligible Purine Content: Foods Included in this Group may be Used Daily.

Bread (white) and crackers	Fruit
Butter or margarine (in moderation)*	Gelatin desserts
Cake and cookies	Herbs
Carbonated beverages†	Ice cream
Cereal beverage (e.g., Postum)	Milk
Cereals and cereal products	Macaroni products
Cheese	Noodles
Chocolate	Nuts
Coffee	Oil
Condiments	Olives
Cornbread	Pickles
Cream (in moderation)*	Popcorn
Custard	Puddings
Eggs	Relishes
Fats (in moderation)*	Rennet desserts
Vegetables (except those in group 2)	Rice
	Salt
	Sugar and sweets (in moderation)†
	Tea
	Vinegar
	White sauce

*Recommended in moderation because of fat content.

†Recommended in moderation because of fructose content.

SCLERODERMA

Scleroderma is a chronic, systemic sclerosis or hardening of the skin and visceral organs characterized by deposition of fibrous connective tissue. Women tend to be afflicted four times more often than men. **Raynaud syndrome** occurs, with ischemia or coldness in the small extremities, causing difficulty in preparation and consumption of meals. Sjögren syndrome is often also present, but there is variability among patients.

Pathophysiology

Scleroderma is considered an autoimmune rheumatic disease with a genetic component. Free-radical, oxidative damage from cytokines, in which fibroblast proteins are modified, is involved

(Pohl and Benseler, 2013). Gastrointestinal symptoms include gastroesophageal reflux, nausea and vomiting, dysphagia, diarrhea, constipation, fecal incontinence, and small intestine bacterial overgrowth. Joint stiffness and pain, renal dysfunction, hypertension, pulmonary fibrosis, and pulmonary arterial hypertension are also common (AF, 2014d). Renal crisis is a rare complication of scleroderma characterized by hypertension and oliguric or anuric acute renal failure. The occurrence of scleroderma renal crisis (SRC) is more common in patients treated with glucocorticoids (Guillevin et al, 2012).

Medical Management

The disease is usually, but not always, progressive, and no current treatment corrects the overproduction of collagen; therefore treatment is aimed at relieving symptoms and limiting damage. Some studies on the use of anti-TNF therapies have some promising results (Fett, 2013). SRC remains associated with severe morbidity and mortality despite treatment with angiotensin-converting enzyme inhibitors and dialysis (Guillevin et al, 2012).

Medical Nutrition Therapy

The dysphagia with this disease requires nutrition intervention (see Chapter 40 and Appendix 35). Dry mouth with resultant tooth decay, loose teeth, and tightening facial skin can also make eating difficult. Consuming adequate fluids, choosing moist foods, chewing sugarless gum, and using saliva substitutes help moisten the mouth and offer temporary relief. If gastroesophageal reflux is a concern, small, frequent meals are recommended along with avoidance of late-night eating, alcohol, caffeine, and spicy or fatty foods (see Chapter 27).

Malabsorption of lactose, vitamins, fatty acids, and minerals can cause further nutrition problems; supplementation may be required. A high-energy, high-protein supplement or enteral feeding may prevent or correct weight loss. Home enteral or parenteral nutrition often is required when problems such as chronic diarrhea persist (see Chapter 13).

SYSTEMIC LUPUS ERYTHEMATOSUS

Systemic lupus erythematosus (SLE) is known commonly as *lupus*. SLE is a chronic autoimmune disease characterized by production of autoantibodies directed against nuclear (anti-dsDNA, anti-SM, anti-nRNP) and cytoplasmic antigens affecting several organs (Fortuna and Brennan, 2013; Watts, 2014). SLE is most prevalent in women of childbearing age with a female to male ratio of 9:1, suggesting that sex-related factors are important in its development; and it has been shown that SLE is more common in African Americans and women of Hispanic, Asian, and Native American descent than in Caucasians.

Pathophysiology

The cause of SLE is multifactorial and involves multiple genes and environmental factors such as infections, hormones, and drugs. In SLE, circulating autoantibodies (ANA) can deposit in several tissues, causing inflammation and production of cytokines such as type 1 interferon (IFN) (Shrivastav and Niewold, 2013). This type 1-IFN, produced by cells of the innate immunity, activates B- and T-cells and propagates the signal to produce more IFN by dendritic cells. This up-regulation of the "type 1-IFN pathway" is critical in the severity and progression of SLE.

Common symptoms include extreme fatigue, painful or swollen joints, muscle pain, sensitivity to the sun, unexplained

fever, skin rashes most commonly on the face, mouth ulcers, pale or purple fingers or toes from cold or stress (Raynaud phenomenon), and kidney problems (NIH, NIAMS, 2013). SLE is characterized by periods of remission and relapse and may present with various constitutional and organ-specific symptoms.

Medical Management

General treatment of SLE includes sun protection, diet and nutrition, smoking cessation and exercise, whereas organ-specific treatments include use of steroids, NSAID, DMARD, and biologics (Fortuna and Brennan, 2013). Pharmacologic treatment includes the cytotoxic agents cyclophosphamide and azathioprine; their combination with corticosteroids must be employed early if there is major organ involvement in order to prevent or minimize irreversible damage.

The hallmark of SLE is B-cell activation and the production of harmful autoantibodies. Therefore B-cell depletion therapies, alone or combined with cytotoxic drugs, have been used to treat SLE. Treatment with rituximab and belimumab improved clinical and serologic parameters such as reduction in ANA (especially anti-dsDNA) and activated B-cells, as well as a reduction in SLE-related flares (Jordan et al, 2013).

Hydroxychloroquine (Plaquenil), an antimalarial drug, appears to be effective in clearing up skin lesions for some individuals with lupus, but has side effects that include nausea, abdominal cramping, and diarrhea. Immunosuppressives such as cyclophosphamide may be useful when there is renal involvement, but gastrointestinal and fertility problems may occur (Jordan et al, 2013).

Medical Nutrition Therapy

Because kidney problems are common in SLE, total protein intake must be adjusted accordingly (see Chapter 35). Although the total diet energy intake is normal, SLE patients tend to have higher consumption of carbohydrates, together with low intake of dietary fiber and omega-3 (EPA and DHA) and omega-6 fatty acids. The latter has been negatively associated with increased disease activity, altered serum profile, and increased carotid plaque presence (Elkan et al, 2012). In addition, SLE patients often have inadequate intakes of calcium, fruits, vegetables, and dairy products and high consumption of oils and fats (Borges et al, 2012).

Photosensitivity, sunlight avoidance, the use of sun protection and low dietary intake, in combination with medications prescribed to treat the symptoms of the disease, may be responsible for the observed low levels of vitamin D (Mok, 2013). Decreased conversion of 25-hydroxyvitamin D to its active form, 1,25-dihydroxyvitamin D (calcitriol), is possible because of renal impairment common in SLE, putting additional stress on vitamin D metabolism. Vitamin D supplementation (2000 IU/day) in patients with SLE is recommended because increased vitamin D levels seem to ameliorate inflammatory and hemostatic markers and show a tendency toward subsequent clinical improvement (Abou-Raya et al, 2013).

Diet therapy is a promising approach and nutritional counseling to improve the intake of vitamin D and calcium, omega-3 PUFA and fiber, may offer a better quality of life to patients with SLE.

Complementary Integrative Therapies

More than an estimated 50% of patients with SLE have used CIM to reduce symptoms and manage their health. Supplements of N-acetyl cysteine and turmeric reduce SLE activity and, together with mind-body methods (cognitive-behavioral therapy and other counseling interventions), improve mood and

quality of life of SLE patients (Greco et al, 2013). A mouse model of lupus nephritis treated with curcumin, showed promising clinical (reduced proteinuria) and serologic (reduced anti-dsDNA antibodies) improvements. The depletion of regulatory T-cells (T-reg) eliminated the therapeutic effects of curcumin, suggesting a potential role of T-reg in the pathogenesis of SLE (Lee et al, 2013).

SPONDYLARTHRTIDES

The most important clinical features of this group of diseases are inflammatory back pain, asymmetric peripheral oligoarthritis, predominantly of the lower limbs, and enthesitis (inflammation at the site where the tendon attaches to the bone). Conventional medical treatment is based mainly on the use of NSAIDs (ibuprofen, COX-2 inhibitors), DMARD (sulfasalazine); patients with persistently active disease are also treated with blocking agents (TNF, IL-6). Physiotherapy is of major importance in the general approach to patients with any of these spondylarthritides. Nutritional therapy must emphasize keeping a healthy body weight, as well as increasing the consumption of foods rich in antioxidants and with antiinflammatory activities (see Box 39-2 and Appendix 31).

Ankylosing spondylitis (AS) is the major subtype of the spondylarthritides. AS (from Greek *ankylos*, fused; *spondylos*, vertebra; *-itis*, inflammation) affects joints in the spine and the sacroiliac joint in the pelvis and can cause eventual fusion of the spine. Ankylosing spondylitis most often develops in young adult men and it lasts a lifetime. Enthesitis accounts for much of the pain and stiffness of AS. This inflammation eventually can lead to bony fusion of the joints, where the fibrous ligaments transform to bone, and the joint permanently grows together. Other joints also can develop synovitis, with lower limb joints more commonly involved than upper-limb joints. Pain in the low back and buttocks are usually the first symptoms of AS. In contrast to mechanical low back pain, low back pain and stiffness in AS patients are worse after a period of rest or on waking up in the morning and improve after exercise, a hot bath, or a shower. Progressive stiffening of the spine is usual, with ankylosis occurring after some years of disease in many, but not all, patients. A majority of patients have mild or moderate disease with intermittent exacerbations and remissions and maintain some mobility and independence throughout life. Complete fusion results in a complete rigidity of the spine, a condition known as “bamboo spine.”

Polymyalgia rheumatica (PMR) means “pain in many muscles”; and is a syndrome with pain or stiffness, usually in the neck, shoulders, and hips. It may be caused by an inflammatory condition of blood vessels such as temporal arteritis (inflammation of blood vessels in the face, which can cause blindness if not treated quickly). Most PMR sufferers wake up in the morning with pain in their muscles; however, there have been cases in which the patient has developed the pain during the evenings. Treatment for PMR includes the use of corticosteroids (prednisone) alone or with a NSAID (ibuprofen) to relieve pain, exercises to strengthen the weak muscles, and a healthy diet (antiinflammatory diet) (see Box 39-2 and Appendix 31).

Polymyositis (PM) which means “inflammation of many muscles” is a type of chronic inflammation of the muscles (inflammatory myopathy) and is more common in adult women. Symptoms include pain, with marked weakness or loss of muscle mass in the muscles of the head, neck, torso, and upper arms and legs. The hip extensors are often severely affected,

leading to particular difficulty in ascending stairs and rising from a seated position. Early fatigue while walking is caused by weakness in the upper leg muscles. Sometimes the weakness presents itself as an inability to raise from a seated position without help or an inability to raise one's arms above one's head. Dysphagia (difficulty swallowing) or other problems with esophageal motility occur in as many as one third of

patients; foot drop in one or both feet can be a symptom of advanced PM.

Treatment for PM includes corticosteroids, specialized exercise therapy, and a healthy diet. Patients with dysphagia may benefit by changing the consistency of foods (softened, increased moisture) as in patients with Sjögren syndrome or with TMD (see Chapter 40).

CLINICAL CASE STUDY 1

Edith is a 33-year-old college teacher and mother of two. She is an active smoker with periodontal disease. Six months ago, she presented with chronic additive symmetrical polyarthritis, involving the wrists, hands, knees, and toes. Edith has morning stiffness for about an hour; symptoms improve with movement and worsen with rest. She has taken several NSAIDs with no major changes. At examination, the doctor noted inflammation in the joints.

Laboratory tests showed mild normocytic normochromic anemia, elevated erythrocyte sedimentation rate, and high C-reactive protein. She was positive for rheumatoid factor and antibodies to cyclic citrullinated peptide (ACPAs). Marginal erosions in the metacarpophalangeal joints were found by X-ray imaging.

Edith was diagnosed with rheumatoid arthritis. Based on polyarthritis, positivity of antibodies and erosions, it was determined to be a severe case, and she was started on DMARDs and corticosteroids.

Nutrition Assessment

Patient is 33-year-old woman with a recent diagnosis of rheumatoid arthritis.

Anthropometric Data

Ht 5'8" (1.73m); Wt 152 lb (69 kg) (lost 6 lb over past 2 months)

BMI = 23

Biochemical data: Hgb 10.5 g/dL

Food and Nutrition History:

Changes in food preparation due to difficulty in shopping and cooking.

Caloric intake: 1600 kcal/day (less than energy requirements)

EER 2070 kcal (30 kcal/kg) and 104 g protein (1.5 g/kg BW for acute phase).

Nutrition Diagnostic Statements

1. Presence of iron deficiency anemia as evidenced by a serum hemoglobin of 10.5 g/dL. (NI-5.10.2)
2. Inadequate energy intake as evidenced by involuntary weight loss. (NI-2.1) (NC-3.2)

Nutrition Interventions

1. 2000 kcal diet, 104 g protein; emphasis on vegetables and whole grains, oily fish and fat free dairy.
2. Regular intake of green leaves and legumes as source of iron and folic acid; lean meats two or three times a week, increase consumption of extra-virgin olive oil to 1-2 oz daily as salad dressing.
3. Omega-3 fatty acid supplementation (3000 mg daily).
4. Advice to cease smoking and perform moderate intensity physical activity
5. Education to improve Edith's cooking skills with a variety of easy recipes.

Nutritional Monitoring and Evaluation

Monthly weight measurements; although Edith's BMI is currently adequate in spite of her weight loss, it is important to stop weight loss.

Repeat Hgb exam 3 months from date.

Evaluate energy, protein, iron and vitamin intake. If arthritis is not active, adjust protein to 1 g/kg BW.

CLINICAL CASE STUDY 2

Robert is a 55-year-old truck driver with a long-standing history of tophaceous gout and several recurrent episodes of severe pain during the past 10 years. He has been taking allopurinol. His episodes worsen with beer and red meat consumption. Sometimes he tries taking NSAIDs without improvement. Medical examination revealed multiple tophi overlying the first and second metacarpophalangeal joints of his left hand and the interphalangeal joints of his right hand, wrist, elbow, both ankles and interphalangeal and metatarsophalangeal joints of the feet and heels. The affected joints are swollen, erythematous and exquisitely painful, with a limited range of motion related to pain. Robert has a history of hypertension and hyperlipidemia. He continues to gain weight.

Nutrition assessment

Patient is a 55 year-old man with diagnosis of gout, hypertension and hyperlipidemia.

Anthropometric Data

Ht 6'3" (1.90m) Wt 242 lb (110 kg) BMI 30 IBW 194 lb (88 kg)

BP: 155/90 mm Hg

Biochemical data:

Serum uric acid level is 10.2 mg/dL

Lipid profile

- TC: 228 mg/dL
- TG: 160 mg/dL
- HDL-C: 39 mg/dL
- LDL-C: 136 mg/dL
- Non-HDL-C: 189 mg/dL

Food and Nutrition History

Due to his job, Robert is often away from home for extended periods of time, when he eats at truck stop diners, where he selects hamburgers,

fried eggs with bacon and deep fried foods; he eats large quantities of chips and beef jerky as snacks. He drinks almost no water. On weekends, when Robert is at home, he enjoys drinking beer (8 to 10 12-oz cans) and making barbecues. Diet is high in red meat, processed foods and refined carbohydrates, and low in fiber and vitamins.

EER: 2420 kcal (22 kcal/kg) and 110 g protein (1 g/kg BW)

Nutrition diagnostic statements

1. Obesity related to caloric intake higher to caloric expenditure as evidenced by elevated BMI. (NI-1.3)(NC-3.3)
2. Excessive alcohol and fat intake as evidenced from a diet history and flaring of gout symptoms. (NI-4.3) (NI – 5.6.2)

Nutrition Interventions

Patient will include fruit and vegetables as frequently as possible in his diet, especially in substitution of high fat, high sugar snacks.

Patient will reduce alcohol consumption and increase non-sweetened drinks.

Education: Patient will be provided with guidelines for choosing meals and snacks with a low content of salt, processed sugars and saturated and *trans* fat.

Goals: Patient will be able to identify sources of purines from list of foods and make food choices for a low purine daily intake.

Patient will be physically active, taking 20-minute walks after dinner.

A weight loss of 6 lbs is desired the first month.

Monitoring and Evaluation:

Follow up a month from date to evaluate goal achievement.

Evaluate energy, water, alcohol, sugar, salt, fat and purine intake.

Medical Nutrition Therapy for Neurologic Disorders

*Beth Zupec-Kania, RDN,
Therese O'Flaherty, MS, RDN*

KEY TERMS

absence seizure (petit mal)	embolic stroke	otorrhea
adrenomyeloleukodystrophy (ALD)	epidural hematoma	paraplegia
amyotrophic lateral sclerosis (ALS)	epilepsy	paresthesia
anosmia	Frazier Water Protocol	Parkinson's disease (PD)
aphasia	Glasgow Coma Score	peripheral neuropathy
apraxia	Guillain-Barré syndrome (GBS)	rhinorrhea
areflexia	hemiparesis	seizure
aspiration	hemianopsia	spinal cord injury (SCI)
aspiration pneumonia	hydrocephalus	stroke (cerebrovascular accident)
chronic inflammatory demyelinating polyneuropathy (CIDP)	hyposmia	subarachnoid hemorrhage (SAH)
concussion	intracranial pressure (ICP)	subdural hematoma
cortical blindness	intraparenchymal hemorrhage	tetraplegia
deglutitory dysfunction	ketogenic diet	thromboembolic event
diffuse axonal injury	medium-chain triglyceride (MCT) oil	thrombotic stroke
dysarthria	multiple sclerosis (MS)	tonic-clonic (grand mal) seizure
dysosmia	myasthenia gravis (MG)	transient ischemic attack (TIA)
dysphagia	myelin	traumatic brain injury (TBI)
	neglect	Wernicke-Korsakoff syndrome (WKS)

Neurologic conditions arise from causes that vary in complexity. Some neurologic disorders result from a simple deficiency or excess of a nutrient, such as the neuropathy associated with thiamin deficiency, whereas others have more complex causes such as diabetic neuropathy, stroke, or trauma. Some conditions arise with the interaction of genetics and metabolic or environmental factors, as is the case with multiple sclerosis (MS), Parkinson's disease (PD), and alcoholism. Epilepsy, the most common neurologic condition, affecting 1% of the population, occurs as a symptom of many neurologic disorders. The medical and health history is often the most important part of a neurologic evaluation.

Numerous symptoms and malnutrition may accompany neurologic diseases. Complaints of even minor symptoms such as headaches, dizziness, insomnia, fatigue, weakness, pain, or discomfort must be skillfully evaluated for the presence of a nutrition component in their cause and treatment. Although not all neurologic diseases have a nutritional cause, nutritional considerations are integral to effective medical and clinical management (see [Table 40-1](#)). Some neurologic dysfunctions such as **peripheral neuropathy** occur secondary to disease or a chronic deficiency of a single or several vitamins, whereas other diseases of the nervous system may be attributed to dietary deficiency or excess (see [Table 40-2](#)). This chapter emphasizes conditions with nutritionally significant dysfunction.

In those neurologic diseases with a nonnutritional cause, nutrition therapies are important adjuncts to effective medical management and are beginning to show promise in early studies. Therapeutic use of macro- and micronutrients will someday play a role in recovery from traumatic head, brain, and spinal cord injuries and are of increasing interest to some researchers secondary to athletic or sports trauma as well as injuries to military personnel. Many elements of nutrition care for neurologic diseases and conditions are similar regardless of the origin of the disease process.

THE CENTRAL NERVOUS SYSTEM

The central nervous system (CNS) in mammals is differentiated functionally into three segments, so lesions in the nervous system leave a unique “calling card” for localized dysfunction. Localizing the defect (lesion) to muscle, nerve, spinal cord, or brain is part of the medical diagnosis. Nerve tracts coming to and from the brain cross to opposite sides in the CNS (see [Figure 40-1](#)). Therefore a lesion in the brain that affects the right arm is found on the left side of the brain. [Figure 40-2](#) shows the segments of the brain.

Signs of weakness are the most quantifiable clinical signs of nervous system disease. The neurons in the motor strip (upper motor neurons) receive input from all parts of the brain and project their axons all the way to their destinations in the spinal cord. Axons

TABLE 40-1 Nutritional Considerations for Neurologic Conditions

Medical Condition	Relevant Nutrition Therapy
Adrenoleukodystrophy	Dietary avoidance of VLCFAs has not been proven. Lorenzo's oil may lower VLCFA levels.
Alzheimer's disease (see Table 40-7)	Recommend antioxidants and antiinflammatory diet. Minimize distractions at mealtime. Initiate smell or touch of food. Guide hand to initiate eating. Provide nutrient-dense foods, omega-3 fatty acids.
Amyotrophic lateral sclerosis (see Table 40-9)	Intervene to prevent malnutrition and dehydration. Possibly ketogenic diet. Monitor dysphagia. Antioxidant use (vitamins C, E, selenium, methionine) is well tolerated, but not proven.
Epilepsy Guillain-Barré	Provide ketogenic diet (see Table 40-10). Attain positive energy balance with high-energy, high-protein tube feedings. Possibly gluten-free diet. Assess dysphagia.
Migraine headache	Follow general recommendations for food avoidance. Maintain adequate dietary and fluid intake. Keep extensive records of symptoms and foods.
Myasthenia gravis	Provide nutritionally dense foods at beginning of meal. Small, frequent meals are recommended. Limit physical activity before meals. Place temporary feeding tube.
Multiple sclerosis	Recommend antioxidants and antiinflammatory diet. Possibly recommend linoleic acid supplement. Evaluate health and especially vitamin D status of patient. Nutrition support may be needed in advanced stages. Distribute fluids throughout waking hours; limit before bed.
Neurotrauma	Enteral or parenteral nutrition support when needed.
Parkinson's disease (see Table 40-11)	Focus on drug-nutrient interactions. Minimize dietary protein at breakfast and lunch. Recommend antioxidants and antiinflammatory diet.
Pernicious anemia	Administer vitamin B ₁₂ injections. Provide diet liberal in HBV protein. Provide diet supplemented with Fe ⁺ , vitamin C, and B complex vitamins.
Spinal trauma	Provide enteral or parenteral nutrition support. Provide high-fiber diet, adequate hydration to minimize constipation. Provide dietary intake to maintain nutrition health and adequate weight.
Stroke	Dietary alterations for primary prevention. Maintain good nutrition status. Assess possible dysphagia. Nutrition support may be needed.
Wernicke-Korsakoff syndrome	Provide thiamin supplementation. Provide adequate hydration. Provide diet liberal in high-thiamin foods. Eliminate alcohol. Dietary protein may have to be restricted.

Fe⁺. Iron; HBV, high biologic value; MCT, medium chain triglycerides fat; VLCFA, very-long-chain fatty acid.

TABLE 40-2 Neurologic Syndromes Attributed to Nutritional Deficiency or Excess

NUTRITIONAL DEFICIENCY		
Site of Major Syndrome	Name	
Encephalon	Hypocalcemia and tetany seizures from lack of vitamin D Impaired intellectual and cognitive function (protein-calorie deprivation) Cretinism (iodine deficiency) Wernicke-Korsakoff syndrome (thiamin deficiency)	
Optic nerve	Nutritional deficiency optic neuropathy ("tobacco-alcohol amblyopia")	
Brainstem	Central pontine myelinolysis (sodium)	
Cerebellum	Alcoholic cerebellar degeneration Vitamin E deficiency caused by bowel disease	
Spinal cord	Combined system disease (B ₁₂ deficiency) Tropical spastic paraparesis	
Peripheral nerves	Beriberi (thiamin deficiency), pellagra (nicotinic acid deficiency) Hypophosphatemia Tetany (vitamin D deficiency)	
Muscle	Myopathy of osteomalacia	
NUTRITIONAL EXCESS		
Syndrome	Condition	Agent
Increased intracranial pressure	Self-medication	Vitamin A
Encephalopathy	Phenylketonuria	Phenylalanine
	Water intoxication	Water
	Hepatic encephalopathy	Protein (and NH ₃)
	Ketotic or nonketotic coma in diabetes	Glucose, insulin
Stroke	Hyperlipidemia	Lipid
Peripheral neuropathy	Hypochondriasis	Pyridoxine
Myopathy	Insomnia, anxiety	Tryptophan
	Anorexia nervosa, bulimia	Emetine, ipecac
Myoglobinuria	Constipation	Licorice

connect to the spinal cord motor neurons (lower motor neurons). These neurons extend from the spinal cord to muscles without interruption. The location of a lesion in the nervous system often can be deduced clinically by observing stereotypical abnormalities and function of either upper or lower motor neurons (see Table 40-3).

Pathophysiology and Signs of Mass Lesions

The frontal lobes in the brain are the source of the most complex activities and commonly offer the most complex presentations. Psychiatric manifestations such as depression, mania, or personality change may herald a tumor or other frontal lobe mass, either right or left. With a lesion or tumor near the skull base, one may lose the sense of smell or have visual changes because olfactory and optic nerves track along the bottom of these frontal lobes. Chemosensory losses of smell have been described as **anosmia** (absence of smell), **hyperosmia** (increased sensitivity of smell), or **dysosmia** (distortion of normal smell).

Frontal lobes are larger and the posterior portions of the frontal lobes contain the motor strips, which control muscle movement. Lesions that develop in the central frontal lobe may present as motor apraxia. A person with **apraxia** cannot perform a complex activity such as independent eating despite a willingness to do so.

FIGURE 40-1 Spinal cord lying within the vertebral canal. Spinal nerves are numbered on the left side; vertebrae are numbered on the right side; body areas supplied by various levels are in blue.

Temporal lobes control memory and speech; lesions there may affect these abilities, as seen with the dementia of Alzheimer's and with stroke. Although any lesion of cerebral gray matter may produce seizures, the temporal lobes are particularly prone to seizures. A right parietal lobe mass or insult may result in chronic inability to focus attention, thus completely ignoring the body's left side. Because speech centers are located near the junction of the left temporal, parietal, and frontal lobes, pathologic conditions in this region may cause speech problems.

The occipital lobes are reserved for vision, and dysfunction here may bring about **cortical blindness** of varying degrees. In this condition the person is unaware that he or she cannot see.

Lesions of the cerebellum and brainstem may obstruct the ventricular system where it is the narrowest. This obstruction may precipitate life-threatening **hydrocephalus**, a condition of increased **intracranial pressure (ICP)** that may quickly result in death. Other signs of hydrocephalus include trouble with balance, walking and coordination, marked sleepiness, and complaints of a headache that is worse on awakening. Lesions in the brainstem may infiltrate any of the cranial nerves that innervate structures of the face and head, including the eyes, ears, jaw, tongue, pharynx, and facial muscles (see **Table 40-3**). These lesions have consequences for nutrition because the patient is often unable to eat without risking aspiration of food or liquids into the lung. Tumors or other lesions in the medulla

FIGURE 40-2 Parts of the brain. Trauma or disease in one area may affect speech, vision, movement or eating ability. (From <http://projectflexner.sites.medinfo.ufl.edu/files/2009/04/brain-regions.jpg>. From Scully C: Medical problems in dentistry, ed 6, 2010, Churchill Livingstone.)

TABLE 40-3 Basic Functions of Cranial Nerves

Number	Nerve Function
Olfactory (I)	Smell
Optic (II)	Vision
Oculomotor (III)	1. Eye movement 2. Pupil constriction
Trochlear (IV)	Eye movement
Trigeminal (V)	1. Mastication 2. Facial heat, cold, touch 3. Noxious odors 4. Input for corneal reflex
Abducens (VI)	Eye movement
Facial (VII)	1. All muscles of facial expression 2. Corneal reflex 3. Facial pain 4. Taste on anterior two thirds of tongue
Vestibulocochlear (VIII)	Hearing and head acceleration and input for oculocephalic reflex
Glossopharyngeal (IX)	1. Swallowing 2. Gag reflex 3. Palatal, glossal, and oral sensation
Vagus (X)	1. Heart rate, gastrointestinal activity, sexual function 2. Cough reflex 3. Taste on posterior third of tongue
Spinal accessory (XI)	1. Trapezius 2. Sternocleidomastoid muscle
Hypoglossal (XII)	Tongue movement

may infiltrate respiratory and cardiac centers, and dysregulation of these centers has grim consequences.

Lesions in the spinal cord are much less common than brain tumors and ordinarily cause lower motor neuron signs at the level of the lesion and upper motor signs in segments below the

level of the lesion. **Spinal cord injury (SCI)** is the most common pathologic condition in this region. Other examples of spinal cord abnormalities are MS, amyotrophic lateral sclerosis (ALS), tumor, syrinx (fluid-filled neurologic cavity), chronic meningitis, vascular insufficiency, and mass lesions of the epidural space.

Lesions of the pituitary gland and hypothalamus are often heralded by systemic manifestations that may include electrolyte and metabolic abnormalities secondary to adrenocortical, thyroid, and antidiuretic hormone dysregulation. Because of the proximity to the visual pathways, changes may occur in visual field or acuity. The syndrome of inappropriate antidiuretic hormone secretion (SIADH) is often a complication; volume status and hyponatremia are part of the medical diagnosis (see Chapter 6). Because the hypothalamus is the regulatory center for hunger and satiety, lesions here may present as anorexia or overeating.

Finally, disorders of peripheral nerves and the neuromuscular junction affect one's ability to maintain proper nutrition. Disorders such as Guillain-Barré syndrome (GBS) or myasthenia gravis (MG) may counteract the efforts to maintain nutritional balance. To eat and drink effectively, many parts of the nervous system are required. A problem at any location of the nervous system can affect ability to meet nutritional requirements.

ISSUES COMPLICATING NUTRITION THERAPY

The nutritional management of patients with neurologic disease is complex. Severe neurologic impairments often compromise the mechanisms and cognitive abilities needed for adequate nourishment. A common result is **dysphagia** (difficulty swallowing), and the ability to obtain, prepare, and present food to the mouth can be compromised. Modified food textures are often required for the individual with swallowing problems. For an example of how diets are modified for dysphagia see **Box 40-1**. Early recognition of signs and symptoms, implementation of an appropriate care plan to

BOX 40-1 Development of Dysphagia Diets**Texture Modifications****Level 3: Dysphagia Advanced (Previously: Mechanical Soft):**

- Soft-solid foods. Includes easy-to-cut whole meats, soft fruits and vegetables (i.e. bananas, peaches, melon without seeds, tender meat cut into small pieces and well moistened with extra gravy or sauce).
- Crusts should be cut off of bread.
- Most is chopped or cut into small pieces.

EXCLUDES hard, crunchy fruits and vegetables, sticky foods, and very dry foods. NO nuts, seeds, popcorn, potato chips, coconut, hard rolls, raw vegetables, pot Pudding-thick Liquids: also called pudding-thick; should hold their shape, and a spoon should stand up in them; they are not pourable and are eaten with a spoon. ato skins, corn, etc. Most food is chopped/cut into small pieces.

Level 2: Dysphagia Mechanically-Altered (Previously: Ground):

- Cohesive, moist, semisolid foods that require some chewing ability.
- Includes fork-mashable fruits and vegetables (i.e. soft canned, or cooked fruits with vegetables in pieces smaller than 1/2 inch).
- Meat should be ground and moist. Extra sauce and gravy should be served.

EXCLUDES most bread products, crackers, and other dry foods. No whole grain cereal with nuts, seeds and coconut. No food with large chunks. Most food should be ground texture.

Level 1: Dysphagia Puree:

- Smooth, pureed, homogenous, very cohesive, pudding-like foods that require little or no chewing ability.
- No whole foods.
- Includes mashed potatoes with gravy, yogurt with no fruit added, pudding, soups pureed smooth, pureed fruits and vegetables, pureed meat/poultry/fish, sauces/gravies, and pureed desserts without nuts, seeds, or coconut.

AVOID scrambled, fried, or hard boiled eggs.

Fluid Modifications

Thin Liquids: includes water, soda, juice broth, coffee, tea. This also includes foods like jello, ice cream and sherbet that melt and become thin when swallowed.

Nectar-thick Liquids: are pourable and the consistency of apricot nectar

Honey-thick Liquids: slightly thicker than nectar and can be drizzled; consistency of honey.

Pudding-thick Liquids: also called pudding-thick; should hold their shape, and a spoon should stand up in them; they are not pourable and are eaten with a spoon.

Courtesy: Clinical Nutrition Department, Providence Mt. St. Vincent , Seattle, WA.

meet the nutritional requirements of the individual, and counseling for the patient and family members on dietary choices are essential. Regular evaluation of the patient's nutrition status and disease management are priorities, with the ultimate goal of improving outcomes and the patient's nutritional quality of life.

Nutrition assessment requires detailed histories. The diet history and mealtime observations are used to assess patterns of normal chewing, swallowing, and rate of ingestion. Weight loss history establishes a baseline weight; a weight loss of 10% or more is indicative of nutritional risk. Assessment for nutrients involved in neurotransmitter synthesis is particularly important in these patients. Nutrition diagnoses common in the neurologic patient population include the following:

- Chewing difficulty
- Increased energy expenditure
- Inadequate energy intake
- Inadequate fluid intake
- Physical inactivity
- Poor nutritional quality
- Difficulty with independent eating
- Swallowing difficulty
- Underweight
- Elimination problems
- Inadequate access to food or fluid

Meal Preparation

Confusion, dementia, impaired vision, or poor ambulation may contribute to difficulty with meal preparation, thus hindering oral food and beverage intake. Assistance with shopping and meal planning are frequently necessary.

Eating Difficulties and Inadequate Access to Food or Fluid

With chronic neurologic diseases, a decline in function may hinder the ability for self-care and nourishment. Access to food and satisfying basic needs may depend on the involvement of family, friends, or professionals. With acute neurologic situations such as seizures, trauma, stroke, or GBS, the entire process of eating can be interrupted abruptly. The patient may require enteral nutrition for a time until overall function improves and adequate oral intake is resumed (see Chapter 13).

Eating Issues: Presentation of Food to the Mouth

The patient with neurologic disease may be unable to eat independently because of limb weakness, poor body positioning, hemianopsia, apraxia, confusion, or neglect. Tremors in PD, spastic movements, or involuntary movements that occur with cerebral palsy, Huntington disease, or tardive dyskinesia may further restrict dietary intake. The affected region of the CNS determines the resulting disability (see Table 40-4).

If limb weakness or paralysis occurs on the dominant side of the body, poor coordination resulting from a new reliance on the nondominant side may make eating difficult and unpleasant. The patient may have to adjust to eating with one hand and also to using the nondominant hand. **Hemiparesis** is weakness on one side of the body that causes the body to slump toward the affected side; it may increase a patient's risk of aspiration.

Hemianopsia is blindness for one half of the field of vision. The patient must learn to recognize that he or she no longer has a normal field of vision and must compensate by turning the head. **Neglect** is inattention to a weakened or paralyzed side of the body; this occurs when the nondominant (right) parietal side of the brain is affected. The patient ignores the affected body part, and his or her perception of the body's midline is shifted. Hemianopsia and neglect can occur together and severely impair the patient's function. A patient may eat only half of the contents of a meal because he or she recognizes only half of it (see Figure 40-3).

FIGURE 40-3 A, Normal vision. B, Vision with hemianopsia.

TABLE 40-4 Common Impairments with Neurologic Diseases

Site in the Brain	Impairment	Results
Cortical lesions of the parietal lobe (perception of sensory stimuli)	Sensory deficits	Fine regulation of muscle activities impossible if the patient is unable to perceive joint position and motion and tension of contracting muscles
Lesions of the nondominant hemisphere	Hemi inattention syndrome (neglect)	Patient neglects that side of the body
Optic tract lesions (usually of the middle cerebral artery or the artery near the internal capsule)	Visual field cuts	Patient reads one half of a page, eats from only half of the plate, etc. (see Figure 40-3)
Loss of subcortically stored pattern of motor skills	Apraxia	Inability to perform a previously learned task (e.g., walking, rising from a chair), but paralysis, sensory loss, spasticity, and incoordination are not present
No identification with a particular brain disorder or a specifically located lesion	Language apraxia	Inability to produce meaningful speech, even though oral muscle function is intact and language production has not been affected
Lesion of Broca area	Nonfluent aphasia	Thought and language formulation are intact, but the patient is unable to connect them into fluent speech production
Lesion of Wernicke area	Fluent aphasia	Flow of speech and articulation seem normal, but language output makes little or no sense
Extensive brain damage	Global aphasia	Expression and speech perception are severely impaired
Brainstem lesions, bilateral hemispheric lesions, cerebellar disorders	Dysarthria	Inability to produce intelligible words with proper articulation

Another potential deterrent to independent eating is apraxia because the person is unable to carry out an action and follow directions. Demonstration may make it possible for the action to occur; however, judgment may be affected as well and can result in the performance of dangerous tasks. This makes it unsafe to leave the patient alone.

DYSPHAGIA

Dysphagia often leads to malnutrition because of inadequate intake. Symptoms of dysphagia include drooling, choking, or coughing during or following meals; inability to suck from a straw; a gurgly voice quality; holding pockets of food in the buccal recesses (of which the patient may be unaware); absent gag reflex; and chronic upper respiratory infections. Patients with intermediate or late-stage PD, MS, ALS, dementia, or stroke are likely to have dysphagia.

A swallowing evaluation by a speech-language pathologist (SLP) is important in assessing and treating swallowing disorders. The SLP is often consulted for individual patients following traumatic brain injury (TBI), stroke, or cancers of the head and neck, and for those at risk of **aspiration** (inhaling foreign material into the lungs) or with other conditions that result in a lack of coordination in swallowing. Many registered

dietitian nutritionists (RDNs) have acquired additional training in swallowing therapies to help coordinate this evaluative process.

Phases of Swallowing

Proper positioning for effective swallowing should be encouraged (i.e., sitting bolt upright with the head in a chin-down position). Concentrating on the swallowing process can also help reduce choking. Initiation of the swallow begins voluntarily but is completed reflexively. Normal swallowing allows for safe and easy passage of food from the oral cavity through the pharynx and esophagus into the stomach by propulsive muscular force, with some benefit from gravity. The process of swallowing can be organized into three phases, as shown in **Figure 40-4**.

Oral Phase

During the preparatory and oral phases of swallowing, food is placed in the mouth, where it is combined with saliva, chewed if necessary, and formed into a bolus by the tongue. The tongue pushes the food to the rear of the oral cavity by gradually squeezing it backward against the hard and soft palate. Increased ICP or intracranial nerve damage may result in weakened or poorly coordinated tongue movements and lead to problems in completing the oral phase of swallowing. Weakened lip muscles

FIGURE 40-4 Swallowing occurs in three phases: Voluntary or oral phase: Tongue presses food against the hard palate, forcing it toward the pharynx. Involuntary, pharyngeal phase: Early: wave of peristalsis forces a bolus between the tonsillar pillars. Middle: soft palate draws upward to close posterior nares, and respirations cease momentarily. Late: vocal cords approximate, and the larynx pulls upward, covering the airway and stretching the esophagus open. Involuntary, esophageal phase: Relaxation of the upper esophageal (hypopharyngeal) sphincter allows the peristaltic wave to move the bolus down the esophagus.

result in the inability to completely seal the lips, form a seal around a cup, or suck through a straw. Patients are often embarrassed by drooling and may not want to eat in front of others. The patient may have difficulty forming a cohesive bolus and moving it through the oral cavity. Food can become pocketed in the buccal recesses, especially if sensation in the cheek is lost or facial weakness exists

Pharyngeal Phase

The pharyngeal phase is initiated when the bolus is propelled past the faucial arches. Four events must occur in rapid succession during this phase. The soft palate elevates to close off the nasopharynx and prevent oropharyngeal regurgitation. The hyoid bone and larynx elevate, and the vocal cords adduct to protect the airway. The pharynx sequentially contracts while the cricopharyngeal sphincter relaxes, allowing the food to pass into the esophagus. Breathing resumes at the end of the pharyngeal phase. Symptoms of poor coordination during this phase include gagging, choking, and nasopharyngeal regurgitation.

Esophageal Phase

The final or esophageal phase, during which the bolus continues through the esophagus into the stomach, is completely involuntary. Difficulties that occur during this phase are generally the result of a mechanical obstruction, but neurologic disease cannot be ruled out. For example, impaired peristalsis can arise from a brainstem infarct.

Medical Nutrition Therapy

Weight loss, anorexia, and dehydration are key concerns with dysphagia. Observation during meals allows the nurse or RDN to screen informally for signs of dysphagia and bring them to the attention of the health care team. Environmental distractions and conversations during mealtime increase the risk for aspiration and should be curtailed. Reports of coughing and unusually long mealtimes are associated with tongue, facial, and masticator muscle weakness. Changing the consistency of foods served may be beneficial while keeping the diet palatable and

nutritionally adequate also are important. A soft, blended, or pureed consistency can reduce the need for oral manipulation and conserve energy while eating.

In 2002, The Academy of Nutrition and Dietetics (formerly the American Dietetic Association) published the National Dysphagia Diet (NDD) developed through consensus from a panel of dietitians, speech pathologists and scientists. The NDD is prescribed by a speech pathologist that evaluates the individual's ability to safely swallow both food textures and liquids. Standard levels of dysphagia from severe to mild were designated with assigned diet texture modifications for each level to promote the safety of swallow (see [Figure 40-5](#)).

The levels of dysphagia (see [Box 40-1](#)) severity range from:
 Severe Dysphagia: inability to clear the pharynx, nonfunctional volitional cough and silent aspiration

Moderate Dysphagia: moderate retention in the oral cavity requiring cues and or supervision to clear

Mild Dysphagia: retention in the pharynx that is able to be cleared through spontaneous cough

Liquids

Swallowing liquids of thin consistency such as juice or water is the most difficult swallowing task because of the coordination and control required. Liquids are easily aspirated into the lungs and may pose a life-threatening event because [aspiration pneumonia](#) may ensue, even from sterile water in the lungs. Sterile water is no longer sterile once it is introduced to the bacterial load of the oral cavity.

If a patient has difficulty consuming thin liquids, meeting fluid needs can become a challenge. Dry milk powder as a thickener alters the taste and might raise protein content too high for children, especially with limited free water. Commercial thickeners now have xanthan gum or modified food starches as ingredients. Benefits of xanthan gum include: it is tasteless, holds its thickening level over time, is easy to mix, and can be used on the ketogenic diet as it does not contain any carbohydrate or calories. It is not recommended for children less than 1 year of age because it has been implicated in

Level 2: Dysphagia Mechanically Altered Diet- This is a semisolid consistency, cohesive, moist food requiring some chewing. Fork mashed, well-cooked, drained cooked vegetables and fruit.

Level 3: Dysphagia—Advanced or Soft Diet- This is soft foods that require more chewing: thin-sliced, tender chunks or ground meats, eggs, casseroles, shredded lettuce, rice. Well-moistened breads. All canned or soft, ripe peeled fresh fruit, and all tender cooked vegetables.

Regular Diet: All foods allowed.

FIGURE 40-5 Levels of National Dysphagia Diet (NDD)

BOX 40-2 Levels of Thickening Liquids

Nectar : Fluids run freely off of the spoon, but leaves a mild coating on the spoon.

Honey: Fluids slowly drips off of the end of the spoon.

Pudding: Fluids remains on the spoon and does not flow off.

(Chart created by Therese O'Flaherty MS, RD) adapted from the Dietitians Association and the Speech Pathology Association of Australia, 2007.

the development of necrotizing enterocolitis (NEC) (Beal et al., 2012). Modified food starches add calories and continue to thicken over time so it is more difficult to be accurate in the level of thickening. Modifications in fluids were also addressed in the NDD report and the four terms used to identify the viscosity level of fluids are thin, nectar-like, honey-like, and spoon-thick (McCullough, et al., 2003):

Infant cereals, pudding or yogurt blend well into fluids, provide calories and protein, and are less expensive than commercial thickeners. Stage 2 baby fruits or applesauce can be added to juice to create a nectar or honey consistency, maintain a good flavor, and add calories, and they are less expensive than commercial supplements (see [Box 40-2](#) and [Table 40-5](#)).

It is difficult to maintain adequate fluid intake with thickened liquids, especially if drinking skills are poor. Mild chronic dehydration resulting from limited water intake can cause

fatigue and malaise. Encouraging soft or blended fruits and vegetables provide a good source of free water.

The **Frazier Water Protocol**, which allows for drinking water in those who otherwise require thickened liquids is being increasingly used in long term care. This protocol is based on the following assumptions:

1. Aspiration of water poses little risk to the patient if oral bacteria associated with the development of aspiration pneumonia can be minimized.
2. Allowing free water decreases the risk of dehydration.
3. Allowing free water increases patient compliance with swallowing precautions and improves quality of life.
4. Good oral hygiene is a key ingredient of the water protocol and offers other benefits to swallowing.

Liquid intake is a concern in those with neurogenic bladder and urinary retention, a common management issue in patients with a **myelopathy** (a pathologic condition of the spinal cord) or an SCI. This predisposes the individual to urinary tract infections (UTIs). Alternately, myelopathy and SCI may result in urinary urgency, frequency, or incontinence. To minimize these problems, distributing fluids evenly throughout the waking hours and limiting them before bedtime may help. Some patients limit fluid intake severely to decrease urgency or frequent urination. This practice increases the risk of UTI and is not recommended.

One nontraumatic cause of myelopathy and neurogenic bladder is MS, an unpredictable and severe, progressive disease of the CNS. Individuals with MS have a higher incidence of UTIs.

Milk is considered a liquid with unique properties. Some people associate consumption of milk with symptoms of excess mucus production; however, research evidence does not support this belief. When the dysphasic patient reports increased phlegm after milk consumption, it may actually be a consequence of poor swallowing ability rather than mucus production.

Textures

As chronic neurologic disease progresses, cranial nerves become damaged, leading to neurologic deficits often

manifested by dysphagia or elimination of entire food groups. Nutrition intervention should be individualized according to the type and extent of dysfunction. Vitamin and mineral supplementation may be necessary. If chewable supplements are not handled safely, liquid forms may be added to acceptable foods.

Presented with small, frequent meals, the patient may eat more. Swallowing can also be improved by carefully selecting various tastes, textures, and temperatures of foods. Juices can be substituted for water and provide flavor, nutrients, and calories. A cool temperature facilitates swallowing; therefore cold food items may be better tolerated. Carbonation combined with citrus, helps with the sensory issues by “awakening” the awareness sensation in the mouth. Sauces and gravies lubricate foods for ease in swallowing and can help prevent fragmentation of foods in the oral cavity. Moist pastas, casseroles, and egg dishes are generally well tolerated. Avoid foods that crumble easily in the mouth, because they can increase choking risk. Alcoholic beverages and alcohol-containing mouth washes should be avoided because they dry out the oral membranes.

Enteral Tube Nutrition

Patients with acute and chronic neurologic diseases may benefit from nutrition support. Well-managed nutrition support helps to prevent pneumonia and sepsis, which can complicate these diseases. Enteral tube feedings may be necessary if the risk of aspiration from oral intake is high, or if the patient cannot eat or drink enough to meet his or her nutritional needs. In the latter case nocturnal tube feedings can bridge the gap between oral intake and actual nutritional or fluid requirements. This should allow the normal sensation of hunger to be generated and provide freedom from tube feeding during the day. Depending on the lifestyle of the patient, caregivers, and family, it may be preferred to offer thickened liquids at meals, then bolus additional free water through the tube at the end of the meal. Assuring good fluid intake during the daytime might avoid nighttime continuous feedings and the need for a feeding pump and supplies.

In most instances the gastrointestinal tract function remains intact, and enteral nutrition is the preferred method of administering nutrition support. One noted exception occurs after SCI, in which ileus is common for 7 to 10 days after the insult, and parenteral nutrition may be necessary. Although a nasogastric (NG) tube can be a short-term option, a percutaneous endoscopic gastrostomy (PEG) tube, commonly known as a G-tube, or gastrostomy-jejunostomy (PEG/J) commonly known as a GJ-tube, is preferred for long-term management. These should be considered for patients whose swallowing is inadequate (see Chapter 13).

Malnutrition itself can produce neuromuscular weakness that negatively affects quality of life; it is a prognostic factor for poor survival. In the acutely ill but previously well-nourished individual who is unable to resume oral nourishment within 7 days, nutrition support is used to prevent decline in nutritional health and aid in recovery until oral intake can be resumed. Conversely, in the chronically ill, nutrition support is an issue that each patient must eventually address because it may result in prolonged therapy. However, adequate nutrition can promote health and may be a welcome relief to an overburdened patient. Tube feedings can relieve stress at mealtimes, encourage oral intake, and

should be scheduled based on the lifestyle needs of the patient and family.

NEUROLOGIC DISEASES OF NUTRITIONAL ORIGIN

Dietary deficiencies of thiamin and niacin can directly result in neurologic symptoms. With **Wernicke-Korsakoff syndrome (WKS)**, the neurologic effect occurs secondary to alcoholism. Most neurologic symptoms arising from nutritional deficiencies can be corrected with increased food intake or supplements (see [Tables 40-2](#) and [Table 40-6](#)).

A new era of treating neurologic disorders with diet therapy is emerging, stemming from the effective use of ketogenic diets for epilepsy. Gluten sensitivity is yet another genetic condition with neurologic implications. Numerous reports of patients with neurologic dysfunction related to gluten sensitivity have been reported since 1966 including ataxia, headache, and seizures ([Hadjivassiliou et al, 2010](#)). Symptoms of gluten sensitivity typically are focused on gut function; however, most patients who present with neurologic manifestations of gluten sensitivity have no gastrointestinal symptoms. Celiac disease is common in people with autism with and without gastrointestinal symptoms. A case study of a child with autism who had been maintained on a gluten and casein-free diet experienced significant gains in behavior and seizure control when her diet was additionally made ketogenic ([Herbert and Buckley, 2013](#)).

NEUROLOGIC DISORDERS FROM TRAUMA

Cerebrovascular Accident (Stroke)

Stroke (cerebrovascular accident) is defined as an acute onset of focal or global neurologic deficit lasting more than 24 hours; it is attributable to diseases of the intracranial or extracranial neurovasculature. Severe strokes are often

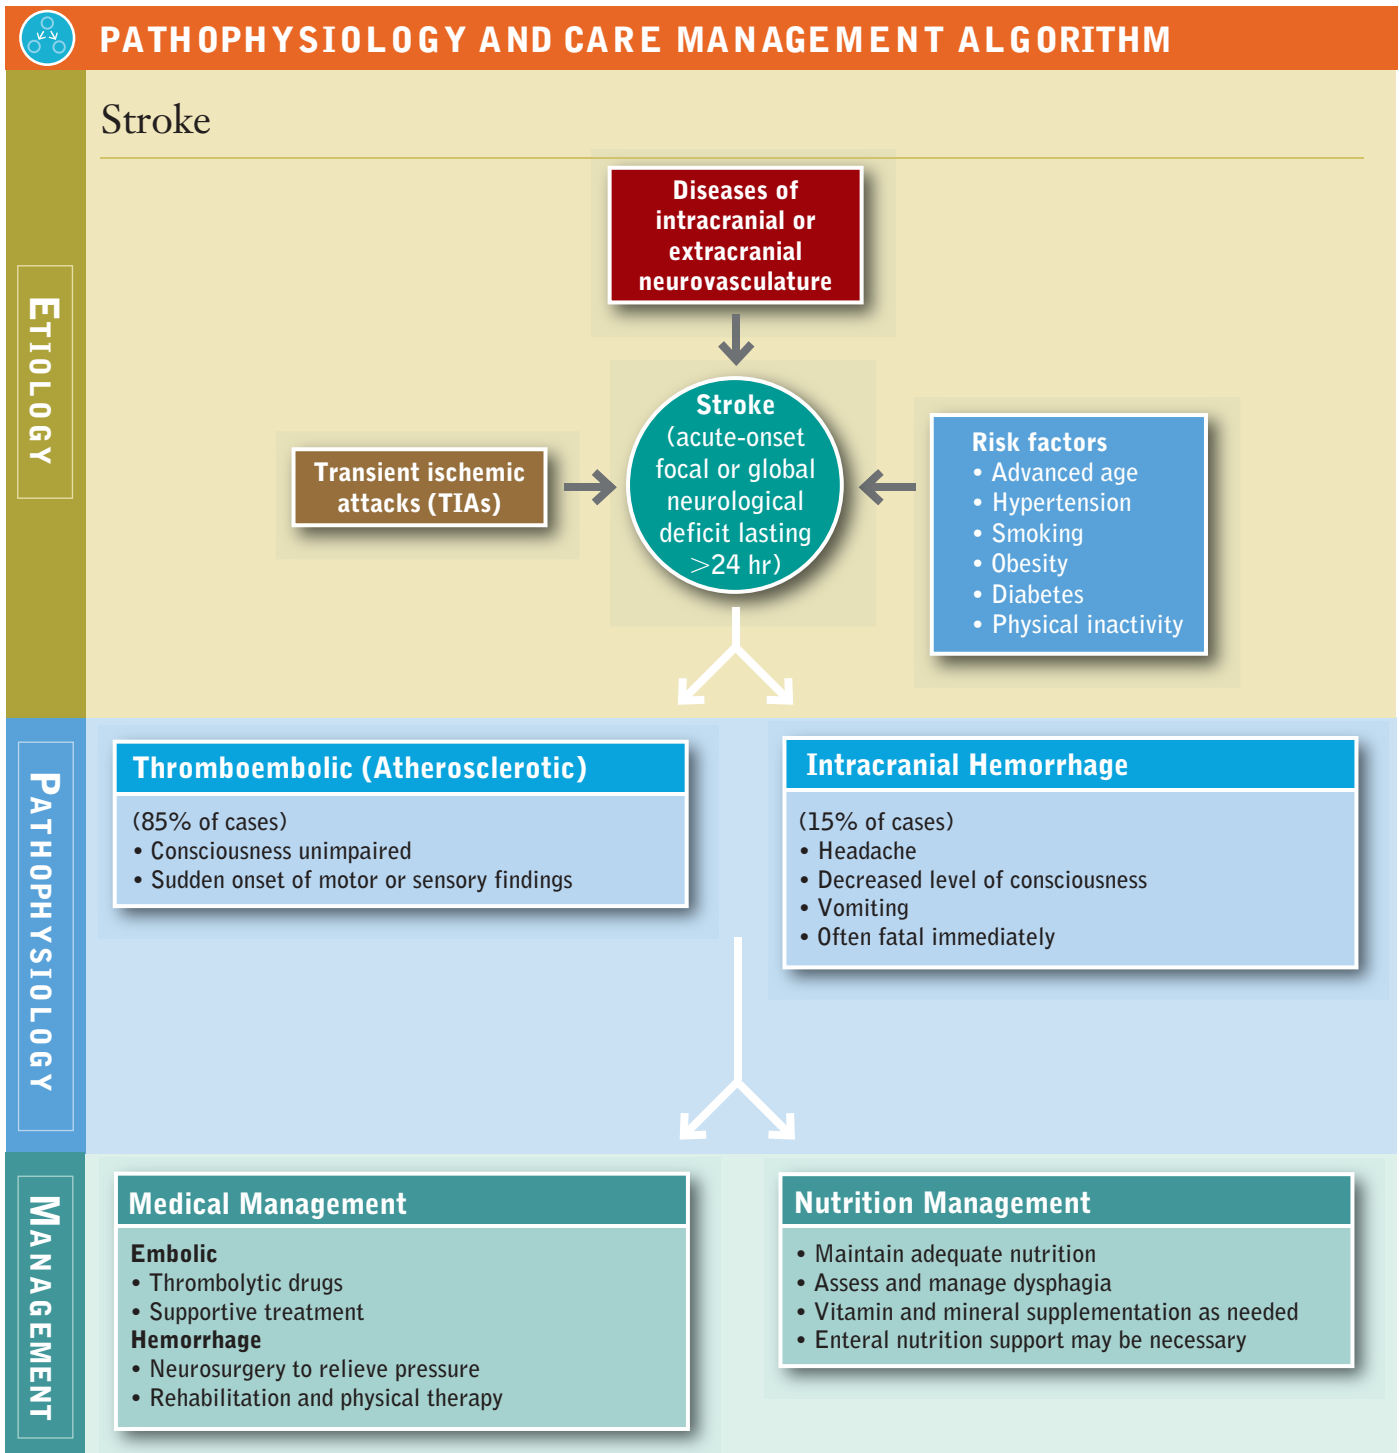

TABLE 40-6 Neurologic Diseases Arising from Nutritional Deficiencies

Disease	Nutrient	Physiologic Effect	Treatment
Wet beriberi	Thiamin	Peripheral or central neurologic dysfunction	Thiamin supplementation
Pellagra	Niacin	Memory loss, hallucinations, dementia	Niacin supplementation
Pernicious anemia	Vitamin B ₁₂	Lesions occur in myelin sheaths of optic nerves, cerebral white matter, peripheral nerves	Monthly vitamin B ₁₂ injections Oral vitamin B ₁₂ supplements
Wernicke-Korsakoff syndrome	Thiamin	Encephalopathy, involuntary eye movements, impaired movement, amnesia	Eliminate alcohol, thiamin supplementation, adequate hydration

preceded by **transient ischemic attacks (TIAs)**, brief attacks of cerebral dysfunction of vascular origin with no persistent neurologic defect. Stroke is a leading cause of death and the most common cause of disability in the United States (CDC, 2014b). Advanced age is the most significant risk factor for stroke. Among modifiable risk factors, hypertension and smoking are the major contributors (see Chapter 33). Other factors include obesity, coronary heart disease, diabetes, physical inactivity, and genetics. The high costs of stroke are attributed to the degree of disability imparted by these events.

Pathophysiology

Embolic stroke occurs when a cholesterol plaque is dislodged from a proximal vessel, travels to the brain, and blocks an artery, most commonly the middle cerebral artery (MCA). In patients with dysfunctional cardiac atria, clots may be dislodged from there and embolize. In **thrombotic stroke** a cholesterol plaque within an artery ruptures, and platelets subsequently aggregate to clog an already narrowed artery. Most strokes are incited by a **thromboembolic event**, which may be aggravated by atherosclerosis, hypertension, diabetes, and gout (see *Pathophysiology and Care Management Algorithm: Stroke*).

Intracranial hemorrhage occurs in only 15% of strokes but is often fatal immediately. Intracranial hemorrhage occurs more commonly in individuals with hypertension. In **intraparenchymal hemorrhage**, a vessel inside the brain ruptures. A variation of intraparenchymal hemorrhage is a lacunar (deep pool) infarct. These smaller infarcts occur in the deep structures of the brain such as the internal capsule, basal ganglia, pons, thalamus, and cerebellum. Even a small lacunar infarct can produce significant disability because the brain tissue in the deep structures is so densely functional. A second type of intracranial hemorrhage is **subarachnoid hemorrhage (SAH)**. SAH occurs commonly as a result of head trauma but more often as a result of a ruptured aneurysm of a vessel in the subarachnoid space.

Medical Management

Hemorrhage is suspected when the patient presents with headache, decreased level of consciousness, and vomiting, all of which occur within minutes to hours. A thromboembolic stroke is more likely to occur when the patient is fully conscious, but the onset of motor or sensory changes occurs suddenly. As with all neurologic disease, the clinical presentation depends on the location of the abnormality. An infarct of a particular cerebrovascular territory can be suspected by seeking out various neurologic deficits. An MCA occlusion produces paresis, with sensory deficits of limbs on the opposite side of the body because this artery supplies the motor and sensory strips. If the left MCA is occluded, **aphasia**, or loss of speech or expression may be present.

In the past, treatment for embolic stroke was supportive; it focused on prevention of further brain infarction and rehabilitation. Use of thrombolytic, “clot-busting” drugs reverses brain ischemia by lysing the clots. Initiation of therapy needs to occur within 6 hours of the onset of symptoms. Use of aspirin may be of some value in preventing further cerebrovascular events, but its effectiveness varies from one patient to another.

Controlling ICP while maintaining sufficient perfusion of the brain is the treatment for intracranial hemorrhage. This may include surgical evacuation of large volumes of intracranial blood, ventricular drainage, or other neurosurgical interventions. Rehabilitation is a key component. Hemorrhage, particularly SAH, has severe functional consequences and therefore has a longer period of convalescence than ischemic stroke.

Medical Nutrition Therapy

Lifestyle and behavior changes that include diet are key components to primary prevention of stroke (Meschia et al, 2014). Nutrition-related factors have been compiled from various large population-based prospective studies (see Box 40-3).

BOX 40-3 Nutrition-Related Factors and Stroke Risk

Risk Factors for Stroke

Body mass index >25 kg/m² in women
 Weight gain >11 kg in 16 years in women
 Waist-to-hip ratio >0.92 in men
 Diabetes
 Hypertension
 Elevated cholesterol in hemorrhagic stroke

Protective Factors Against Stroke

Daily consumption of fresh fruit
 Flavonoid consumption >4.7 cups green tea/daily
 Fish consumption and fish oil use by white and black women and by black men
 High HDL cholesterol in ischemic stroke

Given the prevalence of stroke and its associated burden of disease, treatment for those afflicted with this disease cannot be ignored. In the United States in 2010 stroke-related medical costs and disability were estimated at \$73.7 billion (American Heart Association, American Stroke Association, 2015).

Efforts should be directed toward maintaining the overall health of the patient. A diet high in omega-3 fatty acids has been shown in some studies to provide a protective benefit against stroke, however, omega-3 fat supplements have not shown the same benefit. Omega-3 fat supplements should be avoided by anyone taking a blood thinner such as warfarin or aspirin (NIH, NCCIH, 2013).

Eating difficulties and resulting behavioral problems are determined by the extent of the stroke and the area of the brain affected (see Table 40-7). Dysphagia, an independent predictor of mortality, commonly accompanies stroke and contributes to complications and poor outcome from malnutrition, pulmonary infections, disability, increased length of hospital stay, and institutional care. In some instances nutrition support is required to maintain nutritional health until oral alimentation can be resumed. As motor functions improve, eating and other activities of daily living are part of the patient's rehabilitation process and necessary for resuming independence. Malnutrition predicts a poor outcome and should be prevented.

HEAD TRAUMA OR NEUROTRAUMA

Traumatic brain injury (TBI) refers to any of the following, alone or in combination: brain injury, skull fractures, extraparenchymal hemorrhage—epidural, subdural, subarachnoid—or hemorrhage into the brain tissue itself, including intraparenchymal or intraventricular hemorrhage. In the United States trauma is the leading cause of death in persons up to 44 years of age, and more than one half of these deaths are the result of head injuries (CDC, 2014a). The annual incidence is estimated to be 200 per 100,000 people, with a peak frequency between 15 and 24 years of age. Motor vehicle collisions are the major source of injury.

Morbidity is high and headache is one of the most common complaints. It is difficult to accurately predict neurologic recovery. Despite intensive intervention, long-term disability occurs in a large portion of the survivors of severe head injury.

Pathophysiology

Brain injury can be categorized as three types: concussion, contusion, and diffuse axonal injury. A **concussion** is a brief loss of consciousness, less than 6 hours, with no damage found on computed tomography (CT) or magnetic resonance imaging (MRI) scans. Microscopic studies have failed to find any evidence of structural damage in areas of known concussion, although evidence of change in cellular metabolism exists. A contusion is characterized by damaged capillaries and swelling, followed by resolution of the damage. Large contusions may dramatically increase ICP and may lead to ischemia or herniation. Contusions can be detected by CT or MRI scans. **Diffuse axonal injury** results from the shearing of axons by a rotational acceleration of the brain inside the skull. Damaged areas are often found in the corpus callosum (the bridge between the two hemispheres) and the upper, outer portion of the brainstem.

Skull fractures of the calvarium and the base are described in the same manner as other fractures. Comminution refers to splintering of bone into many fragments. Displacement refers

TABLE 40-7 Practical Interventions for Eating-Related Behavioral Problems

Behavioral Problem	Intervention
Attention or concentration deficit	Verbally direct client through each step of eating process; place utensils in hand. Make food and fluids available and visible.
Combative, throws food	Identify provocative agent, remove. Dining assistant stands or sits on nondominant side. Provide nonbreakable dishes with suction holder. Give one food at a time. Reward appropriate mealtime behavior.
Chews constantly	Tell client to stop chewing after each bite. Serve soft foods to reduce the need to chew. Offer small bites.
Eats nonedible things	Remove nonedibles from reach; provide finger foods. Use edible centerpiece or table decorations.
Eats too quickly	Set utensils down between bites. Offer food items separately. Offer bulky foods that require chewing. Use a smaller spoon or cup.
Eats too slowly	Monitor eating pace and provide verbal cues: "chew," "take a bite." Serve first to allow more time. Use insulated dishes to maintain proper temperatures.
Forgetful or disoriented	Follow simple routines. Provide constant environment. Provide assigned seating. Minimize distractions and limit choices.
Forgets to swallow	Tell client to swallow. Feel for swallow before offering next bite. Stroke upward on larynx.
Inappropriate emotional expression	Engage in conversation; ignore emotional display. Provide a quiet environment.
Paces	Sit beside client at table. Change dining location. Provide aerobic exercise before meals. Offer finger foods.
Plays in food	Use cups with covers or spouts. Serve one food at a time. Fill glass or plate half full at refill. Offer finger foods.
Shows paranoia	Use cups with covers or spouts. Provide structured routine. Present food in consistent manner. Serve foods in closed containers. Do not put medicine in food.
Spits	Evaluate chewing and swallowing ability. Tell client not to spit. Place client away from others who would be offended. Provide mealtime supervision.
Will not go into dining room	Ask why; change dining location. Provide a single dining partner versus a group. Serve meals in room if needed.

Modified from National Institute on Aging (NIA) at <http://www.nia.nih.gov/nia.nih.gov/templates/ADEAR>. Accessed March 22, 2011.

to a condition in which bones are displaced from their original positions. *Open* or *closed* describes whether a fracture is exposed to air. Open fractures dramatically increase the risk of infection (osteomyelitis), and open skull fractures in particular carry an increased risk for meningitis because the dura mater is often violated.

Epidural and **subdural hematomas** are often corrected by surgical intervention. The volume of these lesions often displaces the brain tissue and may cause diffuse axonal injury and swelling. When the lesion becomes large enough, it may cause herniation of brain contents through various openings of the skull base. Consequent compression and ischemia of vital brain structures often rapidly lead to death.

Medical Management

The body's response to stress from TBI results in production of cytokines (interleukin-1, interleukin-6, interleukin-8, and tumor necrosis factor) and inflammation (see Chapter 3). These are elevated in the body after head injury and are associated with the hormonal milieu that negatively affects metabolism and organ function (see Chapter 38). Some of the metabolic events include fever, neutrophilia, muscle breakdown, altered amino acid metabolism, production of hepatic acute-phase reactants, increased endothelial permeability, and expression of endothelial adhesion molecules. Specific cytokines tend to cause organ demise; tissue damage has been observed in the gut, liver, lung, and brain. Overall, the molecular basis of functional recovery is poorly understood.

Clinical findings of brain injury often include a transient decrease in level of consciousness. Headache and dizziness are relatively common and not worrisome unless they become more intense or are accompanied by vomiting. Focal neurologic deficits, progressively decreasing level of consciousness, and penetrating brain injury demand prompt neurosurgical evaluation.

Skull fractures underneath lacerations often can be felt as a "drop off" or discontinuity on the surface of the skull and are readily identifiable by CT scan. Basilar skull fractures are manifested by **otorrhea** (fluid leaking from the ear) or **rhinorrhea** (salty fluid dripping from the nose or down the pharynx). Other signs include raccoon eyes and Battle's sign—blood behind the mastoid process. Basilar skull fractures may precipitate injuries to cranial nerves, which are essential for chewing, swallowing, taste, and smell.

Hematomas are neurosurgical emergencies because they may rapidly progress to herniation of brain contents through the skull base and to subsequent death. These lesions may present similarly, with decreased level of consciousness, contralateral hemiparesis, and pupillary dilation. These lesions damage brain tissue by gross displacement and traction. Classically the **epidural hematoma** presents with progressively decreasing consciousness after an interval of several hours during which the patient had only a brief loss of consciousness. Subdural hematoma usually features progressively decreasing consciousness from the time of injury.

Sequelae most often include epilepsy and the postconcussive syndrome, a constellation of headache, vertigo, fatigue, and memory difficulties. Treatment for these patients can be highly complex, but the two goals of any therapeutic intervention are to maintain cerebral perfusion and to regulate ICP. Perfusion and pressure control have implications for nutrition therapy.

Medical Nutrition Therapy

The goal of nutrition therapy is to oppose the hypercatabolism and hypermetabolism associated with inflammation (see Chapters 3 and 38). Hypercatabolism is manifested by protein degradation, evidenced by profound urinary urea nitrogen excretion. Nitrogen catabolism in a fasting normal human is only 3 to 5 g of nitrogen per day, whereas nitrogen excretion is 14 to 25 g of nitrogen per day in the fasting patient with severe head injury. In the absence of nutritional intake, this degree of nitrogen loss can result in a 10% decrease in lean mass within 7 days. A 30% weight loss increases mortality rate ([Brain Trauma Foundation, 2007](#)).

Hypermetabolism contributes to increased energy expenditure. Correlations between the severity of brain injury as measured by the [Glasgow Coma Scale](#) and energy requirements have been shown. The Glasgow Coma Scale is based on a 15-point scale for estimating and categorizing the outcomes of brain injury on the basis of overall social capability or dependence on others.

Replacement of 100% to 140% resting metabolism expenditure with 15% to 20% nitrogen calories reduces nitrogen loss ([Brain Trauma Foundation, 2007](#)). In patients medicated with barbiturates, metabolic expenditure may be decreased to 100% to 120% of basal metabolic rate. This decreased metabolic rate in pharmacologically paralyzed patients suggests that maintaining muscle tone is an important part of metabolic expenditure. See Chapter 38 for guidelines on care of the critically ill patient with head trauma.

An experimental dietary intervention based on a pyrazole curcumin derivative reestablishes membrane integrity and homeostasis after TBI ([Sharma et al, 2010](#)). The omega-3 fatty acids docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA) have antioxidative, antiinflammatory, and antiapoptosis effects, leading to neuron protection in the damaged brain ([Su, 2010](#)). Studies have shown that implementation of a ketogenic diet postinjury improves structural and functional outcome in TBI ([Prins, 2014](#)).

Immune enhancing nutrition formulas are available for critically ill head-injured patients that are enhanced with glutamine, arginine and omega-3 fatty acids. Data to support their use has not been consistent. One recent study did show increased prealbumin levels and some benefit of decreased infection in those patients using the immune-enhanced formula ([Painter et al, 2015](#)).

SPINE TRAUMA AND SPINAL CORD INJURY

Spine trauma encompasses many types of injuries, ranging from stable fractures of the spinal column to catastrophic transection of the spinal cord. A complete [spinal cord injury \(SCI\)](#) is defined as a lesion in which there is no preservation of motor or sensory function more than three segments below the level of the injury. With an incomplete injury there is some degree of residual motor or sensory function more than three segments below the lesion.

Pathophysiology

The spinal cord responds to insult in a manner similar to the brain. Bleeding, contusion, and shorn axons appear first, followed by a several-year remodeling process consisting of gliosis and fibrosis.

The location of the SCI and the disruption of the descending axons determines the extent of paralysis. [Tetraplegia](#) (formerly known as quadriplegia) exists when the injury to the spinal

cord affects all four extremities. When the SCI location results in only lower extremity involvement, it is called [paraplegia](#).

Medical Management

[Spinal cord injuries](#) have numerous clinical manifestations, depending on the level of the injury. Complete transection results in complete loss of function below the level of the lesion, including the bladder and sphincters. After the patient is stabilized hemodynamically, the doctor evaluates the degree of neurologic deficit. Patients with suspected SCI are usually immobilized promptly in the field. Complete radiographic evaluation of the spinal column is obligatory in multitrauma and unconscious patients.

In the awake patient, clinical evidence of spine compromise is usually sufficient to determine the need for further workup. CT and MRI are used to more accurately delineate bony damage and spinal cord compromise. A dismal 3% of patients with complete spinal cord insults recover some function after 24 hours. Failure to regain function after 24 hours predicts a poor prognosis for reestablishment of function in the future. Incomplete spinal cord syndromes may have somewhat better outcomes.

Morbidity and mortality rates associated with SCI have improved dramatically, particularly in the last two decades. Advances in acute-phase care have reduced early mortality and prevented complications frequently associated with early death, such as respiratory failure and pulmonary emboli. Today, fewer than 10% of patients with SCI die of the acute injury.

Medical Nutrition Therapy

Technologic advances in enteral and parenteral feeding techniques and formulas have played a role in maintaining nutrition status of these patients (see Chapter 13). Although the metabolic response to neurotrauma has been studied extensively, the acute metabolic response to SCI has not; but it is similar to other forms of neurotrauma during the acute phase. Initially paralytic ileus may occur but often resolves within 72 hours after injury. Because DHA and EPA have antioxidative, antiinflammatory, antiapoptosis effects, patients may benefit from fish oil supplementation ([Su, 2010](#)).

For those who survive the injury but are disabled for life, there are significant alterations in lifestyle as well as the possibility of secondary complications. In general the number and frequency of complications and the presence of constipation, pressure ulcers, obesity, and pain vary but will involve nutrition. [Box 40-4](#) describes the rehabilitation potential based on the level of injury. Evidence-based practice guidelines for SCI were released in 2010 by the Academy of Nutrition and Dietetics.

Individuals with SCI have significantly higher fat mass and lower lean mass. Loss of muscle tone caused by skeletal muscle paralysis below the level of injury contributes to decreased metabolic activity, initial weight loss, and predisposition to osteoporosis. Guidelines for accepted weights adjusted for paraplegia and tetraplegia are as follows: the paraplegic should weigh 10 to 15 lb less than the ideal body mass index (BMI) would indicate; the tetraplegic should weigh 15 to 20 lb less than ideal weight dictated by the BMI. The higher the injury, the lower the metabolic rate; a lower energy requirement occurs.

Tetraplegic patients have lower metabolic rates than paraplegic patients, proportional to the amount of denervated muscle in their arms and legs, caused in part by the loss of residual motor function. In the rehabilitation phase, tetraplegics may

BOX 40-4 Key Guidelines for Managing Spinal Cord Injury

If the patient with spinal cord injury (SCI) is in the acute phase, the registered dietitian nutritionist (RDN) should assess energy needs by indirect calorimetry (IC).

Initial weight loss during the acute phase of injury may lead to weight gain in the chronic phase because of body mass redistribution.

Patients with SCI have reduced metabolic activity because of denervated muscle. Actual energy needs are at least 10% below predicted needs.

Because of decreased energy expenditure and caloric needs, secondary to lower levels of spontaneous physical activity and a lower thermic effect of food, adults in the chronic phase of SCI are often overweight or obese and therefore at risk for diabetes and cardiovascular disease.

Persons of all ages with SCI appear to be at high risk for cardiovascular disease, atherogenesis, and undesirable blood lipid values. Modifiable risk factors such as obesity, inactivity, dietary factors, and smoking must be addressed. Physical activity, including sports, swimming, electrically stimulated exercise, and body-weight supported treadmill training, may result in improvements in blood lipid parameters. Dietary intervention using the current evidence-based guide for lipid disorders should be provided by an RDN.

Nutrition care provided by the RDN as part of a multidisciplinary team results in improved nutrition-related outcomes in the acute care, rehabilitation, and community settings. SCI patients experience improvements in nutrient deficiencies, nutrition problems associated with

social isolation and mobility issues, overweight and obesity, bowel management, swallowing, and nutrition-related chronic diseases.

Cranberry juice may be beneficial for prevention of urinary tract infections.

One cup (250 ml) three times daily can be recommended, unless the patient has diabetes.

A minimum of 1.5 L of fluid is recommended per day. Therapeutic diets of high fiber and adequate water intake alone often do not suffice for treatment of constipation; a routine bowel preparation program may be required. For chronic bowel dysfunction, 15 g of fiber seems more beneficial than higher levels (20 to 30 g).

Maintenance of nutritional health is important because poor nutrition is a risk factor for infection and pressure ulcer development. Regular assessment of nutritional status, the provision of adequate nutritional intake, and the implementation of aggressive nutritional support measures are indicated. Reduced pressure ulcer development occurs in patients who maintain a normal weight, higher activity levels, and better serum levels of total protein, albumin, prealbumin, zinc, vitamin D, and vitamin A. Thus sufficient intake of calories, protein, zinc, and vitamins C, A, and B-complex is warranted.

When pressure ulcers are present, use 30 to 40 kcal/kg of body weight/day and 1.2 g to 1.5 g of protein/kg body weight/day (see Chapter 20). Fluid requirements should be at least 1 ml fluid per kcal provided; increase if air-fluidized beds are used and when losses are increased for any reason.

Data from American Dietetic Association: *Evidence Analysis Library: Spinal Cord Injury Guidelines* (website): <http://www.adaevidencelibrary.com/topic.cfm?cat=3486&auth=1>. Accessed October 31, 2010.

require approximately 25% to 50% fewer calories than conventional equations predict. Thus, these patients have the potential to become overweight. It has been proposed that obesity may slow the eventual rehabilitation process by limiting functional outcome.

As a consequence of bone loss resulting from the loss of mineralization caused by immobilization, SCI is associated with osteopenia and osteoporosis, and the prevalence of long-bone fractures increases. Adequate intake of vitamin D and calcium should be planned without excessive daily intakes.

NEUROLOGIC DISEASES

Adrenomyeloleukodystrophy

Pathophysiology

Adrenomyeloleukodystrophy (ALD) is a rare congenital enzyme deficiency that affects the metabolism of very-long-chain fatty acids (VLCFAs) in young men. This leads to accumulation of VLCFAs, particularly hexacosanoic acid (C26:0) and tetracosanoic acid (C24:0) in the brain and adrenal glands. The incidence is 1 in 21,000 male births and 1 in 14,000 female (Hung et al, 2013). It is an X-linked recessive disorder characterized by myelopathy, peripheral neuropathy, and cerebral demyelination. The adult variant, adrenomyeloneuropathy, has chronic distal axonopathy of spinal cord and peripheral nerves marked by cerebral inflammatory demyelination; head trauma is an environmental factor that is detrimental in those people genetically at risk. The mental and physical deterioration progresses to dementia, aphasia, apraxia, dysarthria, and blindness.

Medical Management

Clinical manifestations usually occur before age 7 and may manifest as adrenal insufficiency or cerebral decompensation.

Dysarthria (impairment of the tongue or other muscles needed for speech) and dysphagia may interfere with oral alimentation. Bronzing of the skin is a late clinical sign. With

adrenal insufficiency, replacement of steroids is indicated (see Table 40-8), which may improve neurologic symptoms and prolong life. Numerous therapies have been directed at the root of the disorder but have been disappointing. The selective use of bone marrow transplant is one current therapy; gene therapy holds promise for the future.

Medical Nutrition Therapy

Nutritional therapy by dietary avoidance of VLCFAs does not lead to biochemical change because of endogenous synthesis. A specialty altered fatty acid product, Lorenzo's oil (C18:1 oleic acid and C22:1 erucic acid), lowers the VLCFA level. Although the clinical course is not significantly improved, a slower decline in function may result (Sassa et al, 2014).

Amyotrophic Lateral Sclerosis

Etiology

Amyotrophic lateral sclerosis (ALS), also known as Lou Gehrig disease, is a neurodegenerative disorder affecting the motor neurons in the central nervous system. There are 5000 people diagnosed annually in the United States (International Alliance of ALS/MND Associations, 2014). ALS involves a progressive denervation, atrophy, and weakness of muscles; hence the name amyotrophy. Men are affected more than women, and the average age of onset is the mid-50s with 90% having no family history of the disease.

The cause of ALS is not clear. Thus there is no cure, and survival is typically 3 to 5 years after disease onset. Risk factors related to occupation, trauma, diet, or socioeconomic status are not consistent, although environmental toxins have been suspected to play a role. One of the first clues that ALS may involve an environmental factor was obtained on the island of Guam in the Pacific, where an unusually high proportion of people over the past century have developed symptoms similar to ALS as they age. Studies are ongoing but thus far without proof of cause.

TABLE 40-8 Drugs Commonly Used in the Treatment of Neurologic Diseases

Disease or Condition	Drug	Basic Function	Nutrition-Related Side Effects	
Adrenomyeloleukodystrophy	Adrenal hormones		Weight gain	
Alzheimer's disease	Donepezil	Supports nerve cell communication	Anorexia, weight loss	
	Galantamine			
	Axona	MCT energy source for mitochondria function		
	Rivastigmine	Delays worsening of symptoms		
	Tacrine			
	Memantine	May help improve attention, reasoning, language		
Amyotrophic lateral sclerosis	Riluzole	Decreases motor neuron damage	Suggests decreased use of caffeine	
Epilepsy	Valproate	Anticonvulsant	Increased appetite and requirements of vitamin D	
	Phenytoin	Anticonvulsant	Increased requirements of vitamin D and K	
	Keppra	Anticonvulsant	Poor coordination	
	Carbamazepine	Anticonvulsant	Nausea, increased vitamin D requirements	
	Phenobarbital	Sedative, hypnotic	Increased requirements of vitamins D, K, and possibly folic acid	
	Topamax	Anticonvulsant	Nausea	
Guillain-Barré syndrome	Immunoglobulins or plasma-pheresis	Decreases immune attacks	Consider celiac disease	
Migraine headache	NSAIDs	Antiinflammatory		
	Sympathomimetics			
	Serotonin agonists			
	Sumatriptan	Serotonin 5-HT ₁ receptor agonist	Dehydration, anorexia	
Myasthenia gravis	Anticholinesterase inhibitors	Improve muscle contraction and strength	GI upset, increased urination	
Multiple sclerosis	Corticosteroids: oral prednisone, IV methylprednisolone	Reduce inflammation	Increased appetite, weight gain	
	Interferon: beta 1a –(Avonex, Rebif) beta 1b –(Betaseron)	Slow rate of symptom development	Anorexia, increased or decreased weight	
	Novantrone (mitoxantrone)	Immunosuppressants, anticancer antibiotics	Anorexia, harmful to heart, leukemia	
	Anthracedione			
	Natalizumab (formerly Antegran)	Monotherapy	Risk of progressive multifocal leukoencephalopathy	
	Glatiramer acetate	Immunomodulator drug for relapsing-remitting MS	Flushing, sweating	
	Symptomatic therapies: amantadine	Reduces fatigue, Reduces spasticity	Anorexia, weight loss Increased appetite, weight	
	Diazepam	Decreases paroxysmal dystonia, sensory symptoms	Anorexia, N/V, diarrhea	
	Parkinson's disease	Carbamazepine		
		Amitriptyline	Reduces pain	
Levodopa		Dopamine precursor	Anorexia	
COMT inhibitors:		Prolongs effectiveness of levodopa		
Entacapone				
Tolcapone				
Exelon		Acetylcholinesterase inhibitor	Anorexia, weight loss	
MAO-B inhibitors		Reduces breakdown of dopamine		
Stroke	Trihexyphenidyl	Anticholinergics		
	Benzotropine			
	Ethopropazine			
	Anticoagulants	Preventive	Bleeding, decreased platelets	
	Antiplatelet agents			
	Thrombolytic therapy when acute: heparin	Dissolves clots		

Data from National Institute of Neurologic Disorders and Stroke: *Disorders Index* (website): http://www.ninds.nih.gov/disorders/disorder_index.htm. COMT (catechol-O-methyltransferase); GI, gastrointestinal; IV, intravenous; MAO-B (monoamine oxidase B); MCT, medium chain triglyceride; MS, multiple sclerosis; NSAID, nonsteroidal antiinflammatory drug; N/V, nausea and vomiting.

FIGURE 40-6 The role of curcumin and resveratrol in neuroprotection. Left: Curcumin has multiple biologic effects: it chelates transition metals (iron and copper) and acts as an antioxidant and antiinflammatory molecule, protecting from oxidative stress. Right: Resveratrol favors phosphorylation in protein kinase C, activating the nonamyloidogenic pathway of A β PP cleavage, and this leads to reduction in A β formation. sA β PP α , a product of A β PP cleavage, gets translocated to the nucleus and modulates the genes. All these events favor neuronal cell survival. A β , Amyloid beta; PKC, protein kinase C; sA β PP α , secreted fragment of amyloid protein precursor beta. (From Ramesh BN et al: Neuronutrition and Alzheimer's disease, *J Alzheimers Dis* 19:1123, 2010. With permission from IOS Press.)

In 2014 the U.S. Department of Agriculture approved a randomized clinical trial of stem cell transplant in people with ALS, the most aggressive treatment attempted to date.

Pathophysiology

The pathologic basis of weakness in ALS is the selective death of motor neurons in the ventral gray matter of the spinal cord, brainstem, and in the motor cortex. Clinical manifestations are characterized by generalized skeletal muscular weakness, atrophy, and hyperreflexia (NIH, 2015).

The typical presentation is lower motor neuron (weakness, wasting, fasciculation) and upper motor neuron deficits (hyperactive tendon reflexes, Hoffman signs, Babinski signs, or clonus). Muscle weakness begins in the legs and hands and progresses to the proximal arms and oropharynx. As these motor nerves deteriorate, almost all of the voluntary skeletal muscles are at risk for atrophy and complete loss of function. The loss of spinal motor neurons causes the denervation of voluntary skeletal muscles of the neck, trunk, and limbs, resulting in muscle wasting, flaccid weakness, involuntary twitching (fasciculations), and loss of mobility.

Progressive loss of function in cortical motor neurons can lead to spasticity of jaw muscles, resulting in slurred speech and dysphagia. The onset of dysphagia is usually insidious. Swallowing difficulties usually follow speech difficulties. Although some weight loss is inevitable given the muscle atrophy, consistent or dramatic loss may be an indicator of chewing difficulties or dysphagia. Eye movement and eye blink are spared, as are the sphincter muscles of the bowel and bladder; thus incontinence is rare. Sensation remains intact and mental acuity is maintained.

Medical Management

No currently known therapy cures the disease. Treatment with a high dose of methylcobalamin (B₁₂) is being studied to preserve muscle integrity (NIH, 2014). The ketogenic diet has shown positive results in disease amelioration in mouse models (Paganoni, 2013). Although mechanical ventilation can extend the life of patients, most decline this option. Quality of life is

poor in advanced ALS and supportive comfort measures are primarily used.

Medical Nutrition Therapy

There are decreases in body fat, lean body mass, muscle power, and nitrogen balance and an increase in resting energy expenditure as death approaches. Some of the nutritional changes during the different stages of ALS are noted in Table 40-9.

Hypermetabolic status and increased resting energy expenditure measurements have been noted. The relationship between dysphagia and respiratory status is important. As ALS progresses, a progressive loss of function in bulbar and respiratory muscles contributes to oral and pharyngeal dysphagia. This results in the need for nutrition support, generally via a gastrostomy tube. In late stages, when the respiratory status is

TABLE 40-9 Nutritional and Metabolic Changes During the Progression of Amyotrophic Lateral Sclerosis

	Early Phase	Late Phase
Pathophysiology	Cycles of muscle denervation, muscle catabolism and atrophy, reinnervation, and protein synthesis	Net muscle catabolism and atrophy
Functional status	Mild functional restriction of physical activity Mild impairment of respiration	Progressive limitation of physical activity Increased work of ventilation
Nutritional and metabolic changes	Positive nitrogen balance Normal resting energy expenditure Probable neutral energy balance	Negative nitrogen balance Increased resting energy expenditure Decrease in body fat

From Kasarskis EJ et al: Nutritional status of patients with amyotrophic lateral sclerosis: relation to the proximity of death, *Am J Clin Nutr* 63:130, 1996.

impaired, feeding tube placement is associated with more risk. For that reason early feeding tube placement is recommended.

The clinician should become familiar with common clinical findings in ALS to prevent secondary complications of malnutrition and dehydration. The functional status of each patient should be monitored closely so that timely intervention with the appropriate management techniques can be started. In particular, dysphagia should be monitored closely. Oropharyngeal weakness affects survival in ALS by placing the patient at continuous risk of aspiration, pneumonia, and sepsis and by curtailing the adequate intake of energy and protein. These problems can compound the deteriorating effects of the disease. The Amyotrophic Lateral Sclerosis Severity Scale often is used to assess the functional level of swallowing, speech, and upper and lower extremities. Once the severity of deficits has been identified, appropriate interventions can be implemented (see *Focus On: Dysphagia Intervention for Amyotrophic Lateral Sclerosis*).

Epilepsy

Epilepsy is a chronic condition characterized by unprovoked, recurring seizures. **Seizures** are caused by abnormal electrical activity of a group of neurons. It is estimated that 3 million Americans have epilepsy (*Epilepsy Foundation, 2014*).

Pathophysiology

Most seizures begin in early life, but a resurgence occurs after age 60. The first occurrence of a seizure should prompt investigation into a cause. A clinical workup usually reveals no anatomic abnormalities, and the cause of the seizure may remain unknown (idiopathic). Seizures before age 2 are usually caused by fever, developmental defects, birth injuries, or a metabolic disease (see Chapters 43 and 44). The medical history is the key component for suggesting further avenues of diagnostic investigation and potential treatments, especially in children. An electroencephalogram can help to delineate seizure activity. It is most helpful in localizing partial complex seizures.

Medical Management

The dramatic **tonic-clonic (grand mal) seizure** is the most common image of a convulsive seizure, yet numerous classifications of seizures, each with a different and often less dramatic clinical presentation, exist. A generalized tonic-clonic seizure typically involves the entire brain cortex from its beginning phases. After such a seizure the patient wakes up slowly and will be groggy and disoriented for minutes to hours. This is termed the postictal phase and is characterized by deep sleep, headache, confusion, and muscle soreness.

FOCUS ON

Dysphagia Intervention for Amyotrophic Lateral Sclerosis (ALS)

Strand and colleagues (1996) outlined dysphagia intervention on a continuum of five stages that correlate to the amyotrophic lateral sclerosis (ALS) severity scale. They include the following:

Normal Eating Habits (ALS Severity Scale Rating 10-9)

Early assessment and intervention are critical for maintaining nutritional health in ALS. This is the appropriate time to begin educating the patient, before the development of speech or swallowing symptoms. Hydration and maintenance of nutritional health are critical at this stage. Fluid intake of at least 2 qts/day is important. Dehydration contributes to fatigue and thickens saliva. For patients with spinal ALS, emphasis on fluids is important because they may intentionally limit fluid intake because of difficulties with toileting. The diet history is helpful to assess patterns of normal chewing, swallowing, and the rate of ingestion. Weight loss history establishes a baseline weight. A weight loss of 10% or more is indicative of nutritional risk.

Early Eating Problems (Severity Scale Rating 8-7)

At this point patients begin to report difficulties eating; reports of coughing and unusually long mealtimes are associated with tongue, facial, and masticator muscle weakness. Dietary intervention begins to focus on modification of consistency, avoidance of thin liquids, and use of foods that are easier to chew and swallow.

Dietary Consistency Changes (Severity Scale Rating 6-5)

As symptoms progress, the oral transport of food becomes difficult as dry, crumbly foods tend to break apart and cause choking. Foods that require more chewing (e.g., raw vegetables or steak) are typically avoided. As dysphagia progresses, ingestion of thin liquids, especially water, may become more problematic. Often the patient has fatigue and malaise, which may be associated with a mild chronic dehydration resulting from a decreased fluid intake. Dietary intervention should change food consistency to mechanically soft or pureed (see Appendix 28) to reduce the need for oral manipulation and to conserve energy. Small, frequent meals also may increase intake. Thick liquids that contain a high percentage of water, as well as attempts to increase fluid intake, must be emphasized to maintain fluid balance. Popsicles, gelatin, ice, and fresh fruit are additional sources of free water. Liquids can be thickened with a modified cornstarch thickener. Swallowing can be improved by emphasizing taste, texture, and temperature. Juices can be substituted for water

to provide taste, nutrients, and calories. A cool temperature facilitates the swallowing mechanism; therefore cold food items may be better tolerated; heat does not provide the same advantage. Carbonation also may be better tolerated because of the beneficial effect of texture. Instructions for preventing aspiration should be addressed: safe swallowing includes sitting bolt upright with the head in a chin-down position. Concentrating on the swallowing process can also help reduce choking. Avoid environmental distractions and conversation during mealtime; however, families should be encouraged to maintain a normal mealtime routine. As dysphagia progresses, the limitation of food consistencies may result in the exclusion of entire food groups. Vitamin and mineral supplementation may be necessary. If chewable supplements are not handled safely, liquid forms may be added to acceptable foods. Fiber also may have to be added along with fluids for constipation problems.

Tube Feeding (Severity Scale Rating 4-3)

Dehydration will occur acutely before malnutrition, a more chronic state, is exhibited. This may be an early indication of the need for nutrition support. Weight loss from muscle wasting and dysphagia eventually leads to placement of a percutaneous endoscopic gastrostomy (PEG) tube for nutrition and protection against aspiration caused by dysphagia. Enteral nutrition support is preferred because the gastrointestinal tract should be functioning properly. Given the progressive nature of ALS, placing feeding tubes when there are signs of dysphagia and dehydration is better than initiating this therapy later, after the patient has become overtly malnourished or when respiratory status is marginal. The decision of whether to place a feeding tube for nutrition support is part of the decision-making process each patient must face. Adequate nutrition can maintain health of the individual longer and may be a welcome relief for the patient. The purpose of nutrition support should be to enhance the quality of life. Long-term access should be considered via a PEG or percutaneous endoscope jejunostomy tube (see Chapter 13).

Nothing by Mouth (Severity Scale Rating 2-1)

The final level of dysphagia is reached when the patient can neither eat orally nor manage his or her own oral secretions. Although saliva production is not increased, it tends to pool in the front of the mouth as a result of a declining swallow response. Once the swallowing mechanism is absent, mechanical ventilation is required to manage saliva flow. Tube feeding is permanent at this stage.

The **absence seizure (petit mal)** is also generalized in nature. A patient with absence seizures may appear to be daydreaming during an episode, but he or she recovers consciousness within a few seconds and has no postictal fatigue or disorientation. Partial seizures occur when there is a discrete focus of epileptogenic brain tissue. A simple partial seizure involves no loss of consciousness, whereas a complex partial seizure is characterized by a change in consciousness. Failure of partial seizure control may prompt consideration of seizure surgery. A localized focus resected from nonessential brain renders a patient seizure free in 75% of cases.

Determining the seizure type is key to implementing effective therapy. Antiepileptic drugs control seizures in 70% of people; however, these drugs can have undesirable effects. Use of just one antiseizure medication is recommended initially, resorting to combination therapies only when needed. If seizures are not well controlled after a trial of two antiseizure drugs, the likelihood of control from an additional medication or combination of medications is minimal.

Medications used in anticonvulsant therapy may alter the nutrition status of the patient (see [Table 40-8](#)) (see Chapter 8 and Appendix 31). Phenobarbital has been associated with decreased intelligence quotient when used in children ([Eddy et al, 2011](#)). It occasionally is considered for use after failure of other antiepileptic drugs. Phenobarbital, phenytoin, and valproates interfere with intestinal absorption of calcium by interfering with vitamin D metabolism in the kidneys. Long-term therapy with these drugs may lead to osteomalacia in adults or rickets in children, and vitamin D supplementation is recommended. Folic acid supplementation

interferes with phenytoin metabolism; thus it contributes to difficulties in achieving therapeutic levels.

Phenytoin, valproates, and phenobarbital are bound primarily to albumin in the bloodstream. Decreased serum albumin levels limit the amount of drug that can be bound. This results in an increased free drug concentration and possible drug toxicity even with a standard dose.

Absorption of phenobarbital is delayed by the consumption of food; therefore administration of the drug must be staggered around mealtimes if it is used. Continuous enteral feeding slows the absorption of phenytoin, thus necessitating an increase in the dose to achieve a therapeutic level. Stopping the tube feeding 1 hour before and 1 hour after the phenytoin dose was common practice in the past but is no longer recommended. The phenytoin dose should be adjusted based on the tube feeding.

Medical Nutrition Therapy

The classic **ketogenic diet**, which has been in existence since the 1920s, can be used for treatment of all types of seizures ([Zupec-Kania et al, 2013](#)). Originally designed using ratios of 4:1 or 3:1 (grams of fat to nonfat) to achieve strong and consistent ketosis, less restrictive versions are now available that can also be effective. The modified ketogenic uses lower ratios (e.g., 1:1 and 2:1), modified Atkins, and the Low Glycemic Index Treatment (LGIT) are also available for those who may benefit from a less restricted approach ([Kumada et al, 2013](#)). [Table 40-10](#) presents the classic ketogenic diet.

TABLE 40-10 Comparison of Ketogenic Diet Therapies

Questions	Ketogenic	MCT Oil	Low Glycemic Index Treatment	Modified Atkins
Is medical supervision required?	Yes	Yes	Yes	Yes
Is diet high in fat?	Yes	Yes	Yes	Yes
Is diet low in carbohydrate?	Yes	Yes	Yes	Yes
What is the ratio of fat to carbohydrate & protein?	4:1, 3:1, 2:1, 1:1	Approximately 1:1	Approximately 1:1	Approximately 1:1
How much carbohydrate is allowed on a 1000 Calorie diet?	8gm carb on a 4:1 16gm carb on a 3:1 30gm carb on a 2:1 40-60gm carb on a 1:1	40-50gm	40-60gm	10gm for 1 month 15-20gm afterwards
How are foods measured?	Weighed	Weighed or measured	Measured or estimated	Estimated
Are meal plans used?	Yes	Yes	Yes	Optional
Where is the diet started?	Hospital	Hospital	Home	Home
Are calories controlled?	Yes	Yes	Yes	No
Are vitamin and mineral supplements required?	Yes	Yes	Yes	Yes
Are liquids (fluids) restricted?	No	No	No	No
Is a pre-diet laboratory evaluation required?	Yes	Yes	Yes	Yes
Can there be side-effects?	Yes	Yes	Yes	Yes
What is the overall difference in design of these diets?	This is an individualized and structured diet that provides specific meal plans. Foods are weighed and meals should be consumed in their entirety for best results. The ratio of this diet can be adjusted to effect better seizure-control and also liberalized for better tolerance. This diet is also considered a low glycemic therapy and results in steady glucose levels.	An individualized and structured diet containing Medium Chain Triglycerides (MCT) which are highly ketogenic. This allows more carbohydrate and protein than the classic ketogenic diet. A source of essential fatty acids must be included with this diet.	This is individualized but less structured diet than the ketogenic diet. It uses exchange lists for meal planning and emphasizes complex carbohydrates. The balance of low glycemic carbohydrates in combination with fat result in steady glucose levels. It is not intended to promote ketosis.	This diet focuses on limiting the amount of carbohydrate while encouraging fat. Carbohydrate may be consumed at any time during the day as long as it is within limits and should be consumed with fat. Suggested meal plans are used as a guide. Protein is not limited but too much is discouraged.

Glucose Transporter Type I Deficiency Syndrome (Glut-1 DS) and pyruvate dehydrogenase deficiency (PDHD) are two genetically inherited disorders that typically include seizures and are treatable with ketogenic diet therapy. The diet also has been effective for other inherited disorders in which seizures are also typical: glycogen storage diseases, nonketotic hyperglycinemia, and respiratory chain defects. The common feature of each of these conditions is in the failure of the brain to derive adequate fuel from glucose. Ketones provided by ketogenic diet therapy offer an alternative fuel source which improves symptoms, preserves neurons, and can prevent further decline.

The ketogenic diet has minimal side effects, and risks of the diet are low blood sugar, upset stomach at first caused by the high amounts of fat, and constipation. The long-term risk of kidney stones is rare; elevated serum cholesterol is usually temporary and disappears with discontinuation of the diet; and growth, which is sometimes slowed while on the diet, resumes at the child's normal rate (Patel et al, 2010). Although the diet is restrictive and requires continued effort, it completely controls epilepsy in 10-15% of the children whose seizures are otherwise uncontrollable (Zupec-Kania et al, 2013). Practical guidelines for implementing the diet have been published in *Epilepsia* and are also available through The Charlie Foundation (Kossoff et al, 2009).

The diet is designed to create and maintain a state of ketosis. The beneficial effect in epilepsy may be caused by a change in neuronal metabolism; ketones may inhibit neurotransmitters, thus producing an anticonvulsant and neuroprotective effect in the brain. Initiation of the classic ketogenic diet in children typically begins under close medical supervision, while administration of the more liberal versions described earlier may

begin at home with prior instructions. Fasting before starting diet therapies is sometimes used to stimulate ketosis especially in catastrophic epilepsies and in the overweight individual; however, it should not be prescribed in those with metabolic defects (which may result in a metabolic crisis). Improvement in seizure control can take up to 3 months after diet has been implemented. Antiepileptic drugs are not stopped but may be reduced before initiation, if medication toxicity occurs, or after it has been established that the diet therapy is effective.

The classic ketogenic diet is determined in a ratio of 3:1 or 4:1, meaning that there are 3 or 4 g of fat for every 1 g of protein and carbohydrate combined in the diet. With a 4:1 ratio, the diet is calculated so that at least 90% of the kilocalories are from fat. Protein is calculated to provide appropriate intake for growth (approximately 1 g/kg/day). Carbohydrates are added to make up the remaining small portion of calories that is typically less than 20 g in children (see Table 40-11).

The majority of the diet is composed of fresh meats, eggs, cheese, fish, heavy whipping cream, butter, oils, nuts, and seeds. Vegetables and fruits are added in small amounts, within the current diet prescription (see Table 40-11). Ketosis is monitored by regular measurements of urine ketones or serum beta-hydroxybutyrate.

Goal level of ketones are patient specific; some individuals need to be in the range of 35 to 60 mg/L (4 to 7 mmol/L) for seizure control while others may achieve control with little or no ketosis, which is typical with the liberal diets (modified ketogenic of 1:1 and 2:1 ratios, and LGIT). A carbohydrate-free multiple vitamin and mineral supplement is necessary to ensure that the diet is nutritionally complete. However, additional vitamins and minerals are often necessary, including calcium, vitamin D, and selenium.

TABLE 40-11 Typical Ketogenic Diet for a Child

Menu for 1 day	Amount (g)	Fat (g)	Protein (g)	Carbohydrate (g)	Energy Kcal & Ratio
Breakfast					
Keto pancakes (made with macadamia nuts and eggs)	54	25.19	5.41	1.72	255
Blueberries	10	0.06	0.04	0.95	5
Butter	10	8.11	0.09	0.01	73
Total		33.36	5.54	2.68	333 4:1
Lunch					
Cream—36%	45	16.2	0.9	1.35	155
Celery	10	0.02	0.07	0.14	1
Chicken breast, cooked—skin removed	17	0.61	5.27	0	27
Avocado	17	2.62	0.33	0.31	26
Olive oil	14	14	0	0	126
Total		33.45	6.57	1.8	335 4:1
Snack					
Cream—36% whipped	56	20.16	1.12	1.68	193
Strawberries	35	0.11	0.23	1.99	10
Total		20.27	1.35	3.67	203 4:1
Dinner					
Cream 36%	40	14.4	0.8	1.2	138
Tomato sauce	21	0.42	0.34	1.18	10
Ground beef 85% lean cooked	17	2.38	4.19	0	38
Spaghetti squash cooked	10	0.03	0.06	0.51	3
Olive oil	16	16	0	0	144
Total		33.23	5.39	2.89	333 4:1
Totals for the day		122.99	18.85	11.04	1204 4:1

All prescription and over-the-counter medications (e.g., pain relievers, cold remedies, mouthwash, toothpaste, and lotions) must be scrutinized for sugar content to minimize carbohydrate. It is important that the diet be strictly followed; the smallest amount of extra carbohydrate can cause a breakthrough seizure. Weight and height should be monitored, because a rapid rate of weight gain can decrease ketosis and reduce effectiveness. The nutritionists should work closely with the patient throughout the course of therapy to ensure nutritional adequacy and optimal seizure control benefit.

A variation of the ketogenic diet is the modified Atkins diet in which calories are not restricted, but carbohydrates are drastically limited to 10 to 20 g/day. The ratio of fat to protein and carbohydrate is usually 1:1. It appears that the best results are achieved when the diet begins with 10 g/day of carbohydrate and is then adjusted upward, always maintaining ketosis (Porta et al, 2009; Weber et al, 2009). Another variation of the ketogenic diet is the low glycemic index treatment, which aims for 60% of calories from fat and limits carbohydrate to 28% of calories; the remaining 12% of calories are allocated to protein. Foods are estimated in household measure and meal plans are used as a guide (Zupec-Kania et al, 2013).

The **medium-chain triglyceride (MCT) oil**-based ketogenic diet is yet another therapy, used frequently in the United Kingdom and Canada, in which 60% of the fat is provided by MCTs and 12% is provided by long-chain-fats. MCT oil is an odorless, colorless, tasteless oil and was originally used as a means of improving the palatability of the diet. A greater amount of nonketogenic foods such as fruits and vegetables and small amounts of bread and other starches can be allowed because ketosis from MCT can be more readily achieved with a lower percentage of fat in the diet. MCT can be added in to the classic ketogenic diet and modified Atkins diet to increase ketosis. Coconut oil also can be used as a source of MCT to increase palatability, but it contains only 45% to 50% MCT, so more may be needed. MCT oil or coconut oils also are added if the serum triglycerides are too high with the use of the traditional ketogenic diet.

Attention to the patient's health status, growth, and development is required during the course of therapy. For the child whose epilepsy is controlled by the diet, complying with the diet is much easier than dealing with devastating seizures and injuries.

As clinical and scientific research evolves, improvements in which diet to use, how long to use it, and specific guidelines for certain epilepsies will emerge. Some patients may benefit from a simple diet initially then graduate to the more restrictive ketogenic therapy based on their seizure outcome results. Others may start off with the most restrictive ketogenic therapy and transition to a less restrictive one for long term maintenance.

Discontinuation of the diet is individual and may vary from 1 to 3 years from the initiation period. The person is "weaned" off the ketogenic diet over a period of several months to a year as small amounts of carbohydrates are added with observation for seizure recurrence. Some patients choose to stay long term on the liberal versions of the ketogenic diet such as the LGIT for improved seizure control if they have not achieved seizure freedom on the more restrictive ketogenic diets.

Guillain-Barré Syndrome and Chronic Inflammatory Demyelinating Polyneuropathy

Guillain-Barré Syndrome (GBS) and **chronic inflammatory demyelinating polyneuropathy (CIDP)** are acquired

immune-mediated inflammatory disorders of the peripheral nervous system. The incidence of GBS is approximately 2 in 100,000; the incidence of CIDP is far less prevalent (CDC, 2014).

Etiology

In 60% of GBS cases the disorder follows an infection, surgery, or an immunization. Some of the more common organisms are *Campylobacter jejuni* and *Mycoplasma* spp. Several pathologic varieties exist, and the nature of the distinction is related to the segment of the immune system that is inflicting nerve damage. The clinical course of GBS is similar regardless of subtype, although GBS after a *Campylobacter* infection tends to be more severe. Gluten sensitivity has been reported in some cases as a cause of GBS. The cause of CIDP is similar to GBS; however, the illness follows a longer course and was previously referred to as a chronic form of GBS (Eldar and Chapman, 2014).

Pathophysiology

Relatively symmetric weakness with **paresthesia** usually begins in the legs and progresses to the arms. The loss of function in affected nerves occurs because of demyelination. **Myelin** is the specialized fatty insulation that envelops the conducting part of the nerve, the axon. In GBS the immune system recognizes myelin and mounts an attack against it. Presumably myelin shares a common characteristic with the pathogen from the antecedent infection; thus the immune system cannot differentiate what is foreign (the pathogen) from what is native (myelin). When the nerve is demyelinated, its ability to conduct signals is severely impaired, resulting in neuropathy.

Medical Management

GBS reveals itself in a matter of days. The most common sequence of symptoms is **areflexia** (absence of reflexes), followed by proximal limb weakness, cranial nerve weakness, and respiratory insufficiency. These symptoms normally peak by 2 weeks but may progress up to 1 month. Medical diagnosis is ordinarily made on clinical grounds, but nerve conduction studies are also beneficial. Before the clinical course is apparent, myelopathic disorders must be considered.

Because of the precipitous progression of vital capacity and swallowing function may rapidly deteriorate such that intensive care is sometimes necessary. Intubation and respiratory support should be instituted early in respiratory decline to avoid the need for resuscitation. Plasmapheresis, the exchange of the patient's plasma for albumin, is often helpful to reduce the load of circulating antibodies. Intravenous immunoglobulin or steroids have been shown to be of benefit.

Medical Nutrition Therapy

Guillain-Barré syndrome evolves quickly; during the acute stage, the metabolic response of GBS is similar to the stress response that occurs in neurotrauma. Energy needs assessed by indirect calorimetry may be as high as 40 to 45 kcal/kg and protein needs twice the usual amount. Supportive nutritional care should be offered to attenuate muscle wasting.

For a small percentage of patients, oropharyngeal muscles may be affected, leading to dysphagia and dysarthria. In this situation, a visit by the RDN at mealtime can be a valuable way to observe difficulties the patient may have with chewing or swallowing. Specific difficulties warrant evaluation by a swallowing

specialist. The speech therapist can evaluate the degree of dysphagia and make appropriate dietary recommendations pertaining to texture. As the patient recovers, it is important to discuss safe food handling and future prevention of *C. jejuni* infection.

Myasthenia Gravis

Myasthenia Gravis (MG) is the most well-known disorder of the neuromuscular junction. The neuromuscular junction is the site on the striated muscle membrane where a spinal motor neuron connects. Here the signal from the nerve is carried to the muscle via a submicron-size gap, a synapse. The molecule that carries the signal from the nerve ending to the muscle membrane is acetylcholine (ACh), and acetylcholine receptors (AChRs) populate the muscle membrane. These receptors translate the chemical signal of ACh into an electrical signal that is required for contraction of muscle fibers. MG is one of the most well-characterized autoimmune diseases, a class of disorders in which the body's immune system raises a response to AChRs. The incidence of MG is low, approximately 20 in 100,000 people (Myasthenia Gravis Foundation, 2014).

Pathophysiology

In MG the body unwittingly makes antibodies to AChR. These antibodies are the same that fight off colds and give immunity. The AChR antibodies bind to AChR and make them unresponsive to ACh. There is no disorder of nerve conduction and no intrinsic disorder of muscle. The characteristic weakness in MG occurs because the signal of the nervous system to the muscle is garbled at the neuromuscular junction. Patients with MG commonly have an overactive thymus gland. This gland resides in the anterior thorax and plays a role in the maturation of B-lymphocytes, the cells that are charged with synthesizing antibodies.

Relapsing and remitting weakness and fatigue, varying from minutes to days, characterize MG. The most common presentation is diplopia (double vision) caused by extraocular muscle weakness, followed by dysarthria, facial muscle weakness, and dysphagia. Dysphagia or swallowing disorders (resulting from fatigue after mastication) may cause malnutrition. Less commonly, proximal limb weakness in the hips and shoulders may be present. Severe diaphragmatic weakness can result in respiratory difficulty. No involvement of sensory nerves occurs.

Medical Management

Anticholinesterases are medicines that inhibit acetylcholinesterase, thus serving to increase the amount of ACh in the neuromuscular junction. Corticosteroids are immunosuppressive. Removal of the thymus results in symptomatic improvement in most patients.

Medical Nutrition Therapy

Chewing and swallowing often are compromised in MG. Because this compromise occurs with fatigue, it is important to provide nutritionally dense foods at the beginning of meals before the patient tires. Small, frequent meals that are easy to chew and swallow are helpful. Difficulties holding a bolus on the tongue also have been observed, suggesting that foods that do not fall apart easily may be better tolerated. For patients treated with anticholinesterase drugs, it is crucial to time medication with feeding to facilitate optimal swallowing.

Physical activity should be limited before mealtime to ensure maximum strength to eat a meal. It is also important not to

encourage food consumption once the patient begins to fatigue because this may contribute to aspiration. If and when respiratory crisis occurs, it is usually temporary. Nutrition support via a tube may be implemented in the interim to assist in maintaining vital functions of the patient until the crisis subsides. Once extubated, a swallow evaluation using cinefluoroscopy is appropriate to assess the degree of **deglutitory dysfunction** (swallowing irregularity) or risk of aspiration associated with an oral diet.

Multiple Sclerosis

Multiple sclerosis (MS) is a chronic inflammatory disorder of the central nervous system (CNS) and is one of the most common causes of nontraumatic disability among young and middle-aged adults. MS-related health care costs are estimated to be more than \$10 billion annually in the United States (US). **MS** affects the CNS and is characterized by destruction of the myelin sheath, the function of which is transmission of electrical nerve impulses. Multiple areas of optic nerves, spinal cord, and brain undergo "sclerosis," whereby myelin is replaced with sclera or scar tissue. No single test can ascertain whether a patient has MS; however, diagnostic criteria (McDonald criteria) were developed for use by practicing clinicians (Polman et al, 2011).

The signs and symptoms of MS are easily distinguished, and they recur over the natural history of this disease. In the worst scenario MS can render a person unable to write, speak, or walk. Fortunately, the majority of patients are only mildly affected. MS affects approximately 400,000 people in the United States and 2.5 million worldwide. In the United States, prevalence estimates are approximately 90 per 100,000 population. MS symptoms can start anywhere between 10 and 80 years of age, but onset is usually between 20 and 40 years, with a mean of 32 years. Although MS is more frequently seen in Caucasians than African Americans, the latter group appears to accumulate disability more quickly, suggesting more destructive tissue injury in this population. The prevalence of MS varies by geographic location and generally increases the further one travels from the equator in either hemisphere. It remains unclear whether this altered incidence represents an environmental influence, genetic difference, or variable surveillance (Hersh and Fox, 2015).

Pathophysiology

The precise cause of MS remains undetermined. A familial predisposition to MS has been noted in a minority of cases. It is more common in women and in people of Northern European ancestry (National MS Society, 2015). Geographic latitude and diet are therefore implicated. Epidemiologic studies have linked the incidence of MS to geographic location and sunshine exposure. Studies have shown that people born in an area with a high risk of MS who then move—or migrate—to an area with a lower risk before the age of 15 assume the risk of their new area. Such data suggest that exposure to some environmental agent before puberty may predispose a person to develop MS later on.

There is growing evidence that vitamin D may play a role. The degree of sunlight exposure catalyzes the production of vitamin D in the skin. Vitamin D produced by the skin is eventually metabolized to vitamin D₃ which is a selective immune system regulator and may inhibit MS progression (Lee et al, 2009). Further, in cross-sectional evaluations of MS and vitamin D, an increased prevalence of clinical vitamin D deficiency was associated with decreased bone density (Mark and Carson, 2006). Given the current evidence of the potential benefits of

vitamin D, it appears to be reasonable and safe to consider vitamin D supplementation adequate to achieve normal levels in patients with MS (Solomon and Whitham, 2010).

The evidence is also growing that smoking plays an important role in MS. Studies have shown that smoking increases a person's risk of developing MS and is associated with more severe disease and more rapid disease progression. Fortunately, the evidence also suggests that stopping smoking—whether before or after the onset of MS—is associated with a slower progression of disability (National Multiple Sclerosis Society, 2015).

Medical Management

Fluctuating symptoms and spontaneous remissions make treatments difficult to evaluate. Currently no proven treatment for changing the course of MS, preventing future attacks, or preventing deterioration exists. Initially recovery from relapses is nearly complete, but over time, neurologic deficits remain. Therefore measures to maximize recovery from initial attacks or exacerbations, prevent fatigue and infection, and use all of the available rehabilitative measures to postpone the bedridden stage of disease are imperative. Physical and occupational therapies are standard for weakness, spasticity, tremor, uncoordination, and other symptoms.

Drugs for spasticity can be initiated at a low dose and cautiously increased until the patient responds. Physical therapy for gait training and range-of-motion exercises helps. Steroid therapy is used in treating exacerbations; adrenocorticotropic hormone (ACTH) and prednisolone are the drugs of choice. However, treatment is not consistently effective and tends to be more useful in cases of less than 5 years' duration. Side effects of short-term steroid treatment include increased appetite, weight gain, fluid retention, nervousness, and insomnia. Reduced cerebrospinal fluid and serum levels of vitamin B₁₂ and folate have been noted in MS patients who receive high-dose steroids. Methotrexate also may be used with ACTH, causing anorexia and nausea.

Medical Nutrition Therapy

Several dietary regimens for managing MS have been studied, all of which have yielded equivocal results. Various diets such as allergen-free, gluten-free, pectin-free, fructose-restricted, raw food diet, megadoses of micronutrients, zinc phosphates with calcium, and other combinations have not been proven effective. Restriction of saturated fat has been evaluated by several researchers but with inconclusive results. The National Multiple Sclerosis Society has published a guide to vitamin, minerals, and herbs in 2011 that can be useful when working with an MS patient (Bowling and Stewart, 2011). The RDN's evaluation of the patient to maximize nutritional intake is imperative. Vitamin D status should be assessed by measuring 25-hydroxy vitamin D, and supplementation may be warranted (see Appendix 45). There is now some evidence that an anti-inflammatory diet (see Chapter 3 and Appendix 31) can be of use in treating MS. This is an active area of research.

As the disease progresses, neurologic deficits and dysphasia may occur as the result of damaged cranial nerves. Thus diet consistency may have to be modified from solids to mechanically soft or pureed items, even progressing to thick liquids to prevent aspiration. Impaired vision, dysarthria, and poor ambulation make meal preparation into a difficult task. In this situation reliance on comfort foods or prepackaged, single-serving, or convenience foods often permits independent

preparation of meals. Given the chronic nature of this debilitating disease, patients may require enteral nutrition support.

Neurogenic bladder is common, causing urinary incontinence, urgency, and frequency. To minimize these problems, distributing fluids evenly throughout the waking hours and limiting them before bed is helpful. Some patients limit fluid intake severely to decrease frequency of urination but thereby increase the risk of urinary tract infections (UTIs). UTIs are common in patients with MS and are associated with MS relapse (Mahadeva et al, 2014).

Neurogenic bowel can cause either constipation or diarrhea, and incidence of fecal impaction is increased in MS. A diet that is high in fiber with additional prunes and adequate fluid can moderate both problems.

Parkinson's Disease

Parkinson's disease (PD) is a progressive, disabling, neurodegenerative disease, first described by James Parkinson in 1817. PD is characterized by slow and decreased movement, muscular rigidity, resting tremor, postural instability, and decreased dopamine transmission to the basal ganglia. Although the natural history of this disease can be remarkably benign in some cases, approximately 66% of patients are disabled within 5 years, and 80% are disabled after 10 years (Yao et al, 2013).

PD is one of the most common neurologic diseases in North America; it affects approximately 1% of the population older than 65 years of age. The incidence is similar across socioeconomic groups, although PD is less common in blacks and Asians in comparison with whites. It most commonly occurs between the ages of 40 and 70.

Pathophysiology

PD is caused by the progressive impairment or deterioration of neurons (nerve cells) in an area of the brain known as the substantia nigra. When functioning normally, these neurons produce the vital brain chemical known as dopamine. The cause of PD is unknown, but several factors appear to play a role. The presence of Lewy bodies, which are clumps of specific substances within brain cells, are microscopic markers of PD. Researchers believe these Lewy bodies hold an important clue to the cause of PD. Lewy bodies are proteins found in abundance in the brainstem area that deplete the neurotransmitter dopamine.

The role of endogenous toxins from cellular oxidative reactions has emerged because aging has been associated with a loss of neurons containing dopamine and an increase in monoamine oxidase. When metabolized (enzymatic oxidation and autoxidation), dopamine produces endogenous toxins (hydrogen peroxide and free radicals), causing peroxidation of membrane lipids and cell death. In the presence of an inherited or acquired predisposition, severe oxidative injury can lead to substantial loss of dopaminergic neurons similar to that observed in PD.

Several other environmental factors also have been implicated as causal factors of PD. The connection between smoking and a lowered risk for PD has been evaluated, but results are inconsistent (Ma et al, 2006). In older patients, drug-induced PD may occur as a side effect of neuroleptics or metoclopramide (see Chapter 8 and Appendix 23).

Dairy products have been linked to PD (Jiang et al, 2014). A meta-analysis of dairy intake and PD risk found a 17% increase in PD for every 200 g/day increment in milk intake. Environmental toxins in the dairy products consumed was

not ruled out. Recent epidemiologic studies have shown a link between PD and environmental factors including drinking well water, rural living, farming, diet, and exposure to agricultural chemicals (Pan-Montojo and Reichmann, 2014). PD has also been linked to the exposure to different metals and industrial compounds. Many studies performed in the 1990s identified manganese, lead, copper, iron, zinc, aluminium, or amalgam. Higher incidence of PD has been reported in manganese miners. It was shown that manganese, a component of various pesticides, also reproduces PD symptoms after long and chronic exposure (between 6 months and 16 years). Remarkably, some populations have witnessed a decreasing prevalence of certain types of neurodegenerative diseases that coincide with the disappearance of an environmental factor unique to these populations (Pan-Montojo and Reichmann, 2014).

Nutrient-related findings are biologically plausible and support the hypothesis that oxidative stress may contribute to the pathogenesis of PD (Czlonkowska et al, 2011). The relationships of folate, elevated plasma homocysteine levels, and caloric deficits are being evaluated.

Medical Management

The “classic triad” signs—tremor at rest, rigidity, and bradykinesia—remain the criterion for medical diagnosis. However, it was well over a century before L-dopa (a precursor to dopamine) was introduced for controlling symptoms. Exelon, a cholinesterase inhibitor, was approved by the FDA in 2006 for use in mild to moderate PD dementia. Pharmacotherapy agents, surgical interventions, and physical therapy are the best adjunctive therapies.

Medical Nutrition Therapy

The primary focus of nutrition intervention is to optimize dietary intake particularly to maintain muscle mass for strength and mobility. Nutrition intervention should also focus on drug-nutrient interactions, especially between dietary protein and L-dopa. Side effects of medications for PD include anorexia, nausea, reduced sense of smell, constipation, and dry mouth. To diminish the gastrointestinal side effects of L-dopa, it should be taken with meals. Foods that contain natural L-dopa such as broad beans (fava beans) should be avoided. For some patients dyskinesia may be reduced by limiting dietary protein at breakfast and lunch and including it in the evening meal. Table 40-12 presents a sample menu for this diet.

Fiber and fluid adequacy lessen constipation, a common concern for persons with PD. Pyridoxine (vitamin B₆) has a possible interaction with L-dopa. Decarboxylase, the enzyme required to convert L-dopa to dopamine, depends on pyridoxine. If excessive amounts of the vitamin are present, L-dopa may be metabolized in the periphery and not in the CNS, where its therapeutic activity occurs. Therefore vitamin preparations containing pyridoxine should not be taken with doses of L-dopa. Interactions between pyridoxine and aspartame should be considered as well. In addition, manganese should be carefully monitored to avoid excesses above DRI levels.

The high demand for molecular oxygen, the enrichment of polyunsaturated fatty acids in membrane phospholipids, and the relatively low abundance of antioxidant defense enzymes are all relevant factors (Sun et al, 2008). Antiinflammatory and neuroprotective effects come from phenolic compounds, such as resveratrol from grapes and red wine, curcumin from turmeric, apocynin from *Picrorhiza kurroa*, and epigallocatechin from

TABLE 40-12 Dietary Protein Redistribution with L-Dopa Therapy

	Amount of Protein (g)
BREAKFAST	
½ C oatmeal	2
1 orange	0.5
1 C Rice Dream beverage	0.5
Egg replacer (unlimited)	0
Low-protein bread toast	0
Margarine or butter (unlimited)	0
Jelly or jam (unlimited)	0
Sugar or sugar substitute (unlimited)	0
Coffee or tea (unlimited)	0
LUNCH	
½ C vegetable soup	2
1 C tossed salad	1
Salad dressing (unlimited)	0
1 banana	1
Low-protein pasta (unlimited)	0
Margarine or butter (unlimited)	0
Low-protein cookies (unlimited)	0
Juice, coffee, tea, or water	0
AFTERNOON SNACK	
Gum drops or hard candy (unlimited)	0
Apple or cranberry juice (unlimited)	0
TOTAL	7
DINNER	
4 oz (at least) beef, pork, veal, chicken	28 or more
1 C stuffing	4
Gravy	0
½ C peas	2
¾ C yogurt	8
1 C milk	8
EVENING SNACK	
1 oz cheese or deli meat	7
4 crackers	2
Juice, herbal tea, or water	0
DAILY TOTAL	66 or more

green tea (Sun et al, 2008). Sufficient intake of vitamin D₃ and omega-3 fatty acids should be recommended.

In a small clinical study seven volunteers with PD agreed to maintain a ketogenic diet for 1 month. Five had improvement in their postdiet test scores. Although this study did not include a control group, it has brought attention to the potential role of ketogenic diet therapy in this disease (Hashim and VanItallie, 2014).

As the disease progresses, rigidity of the extremities can interfere with the patient's ability to eat independently. Rigidity interferes with the ability to control the position of the head and trunk, necessary for eating. Eating is slowed; mealtimes can take up to an hour. Simultaneous movements such as those required to handle a knife and fork become difficult. Tremors in the arms and hands may make consuming liquids independently impossible without spilling. Perception and spatial organization can become impaired. Dysphagia is often a late complication. A large number of patients may be silent aspirators, which affects nutrition status.

Experimental treatment procedures are being tested and reported with increasing frequency. Deep brain penetration, other surgical interventions, and efforts with stem cell research continue in hopes that a “cure” is possible.

CLINICAL CASE STUDY

Clarence is a 74-year-old white man hospitalized for evaluation of dementia progression and recent hearing difficulty. He was diagnosed with Parkinson's disease 5 years ago. He has been taking L-dopa and furosemide (Lasix). He lives with his wife, who is his primary caregiver. Clarence is 5'10" and currently weighs 155 lb. His medical chart indicates that his weight was 170 lb at his last hospital visit 6 months ago, after a fall. Clarence's wife notes that his appetite and hearing seem to have changed and he shows little interest in food at meal times. They don't talk much during meals and staff have observed his wife helping him eat and suspect some problems with nutrition. His wife describes his eating as very slow, sometimes taking 2 hours for a meal. He coughs a lot after he eats. When asked about whether Clarence is losing weight his wife wasn't sure, but said his pants do seem to be getting looser.

Inadequate energy intake r/t decreased food intake as evidenced by weight loss and clothes getting looser.

Difficulty swallowing related to PD as evidenced by slow eating pace and coughing during meals.

Nutrition Care Questions

1. What dietary advice do you have for Clarence and his caregiver?
2. What changes in Clarence's diet would you recommend?
3. What other evaluations does Clarence need?
4. What possible food-drug interaction could be occurring?

MNT in Psychiatric and Cognitive Disorders

*Jacob Teitelbaum, MD; Alan Weiss, MD;
Geri Brewster, RDN, MPH, CDN;
Ruth Leyse-Wallace, PhD*

KEY TERMS

addiction	dementia	fibromyalgia syndrome (FMS)
advanced glycation end products (AGEs)	depression	glutamate
alpha-linolenic acid	dopamine	leaky gut (intestinal hyperpermeability)
alpha-lipoic acid	<i>Diagnostic and Statistical Manual of Mental Disorders (DSM-5)</i>	major depressive disorder (MDD)
alcoholism	docosahexaenoic acid (DHA)	mild cognitive impairment (MCI)
Alzheimer's disease (AD)	dysthymia	neurotransmission
anxiety	eicosapentaenoic acid (EPA)	norepinephrine
arachidonic acid	enteric nervous system (ENS)	serotonin
bipolar disorders	epinephrine	serotonin syndrome
chronic fatigue syndrome (CFS)		vascular dementia

Most illnesses reflect widespread disorders in many parts of the body and are a mix of physical and psychologic factors. For example, heart attacks are more common in those with higher levels of hostility ([Izawa et al, 2011](#)), and schizophrenia and autism have been associated with many factors, including food sensitivities ([Jackson et al, 2012](#); [Teitelbaum et al, 2011](#)). Unfortunately, conditions may be labeled as psychologic from a mindset that views the condition as “less real” than other illnesses. This is especially common until a biologic marker or laboratory test is available for an illness. For example, multiple sclerosis was previously called “hysterical paralysis,” thought to be caused by an oedipal complex; and lupus was once considered to be a neurosis, until tests for these conditions were developed. Chronic fatigue syndrome (CFS) and fibromyalgia (FMS) are now just moving beyond this same approach.

As this shift occurs, the artificial and unhealthy boundary between mental and physical illnesses is fading, being replaced with a more accurate reality that treatment in general is most effective when it treats the whole person, recognizing that physiologic underpinnings are causative in many mental health disorders. The psychologic consequences of suboptimal nutritional intake may occur before the physical signs. Suspicions may begin with a diet history indicating irregular eating habits and unhealthy food choices and progress through a nutrition-focused physical examination, to biochemical assessment and resolution of symptoms with supplementation.

The brain weighs approximately 3 lb (1.4 kg). Nerve cells (neurons) gather and transmit electrochemical signals via axons and dendrites. Neurons are the “gray matter” of the brain; dendrites and axons are the “white matter.” The cerebrum is the largest part

of the brain divided into two halves, which are divided into four lobes, in each hemisphere: (1) the frontal lobes involved with speech, thought, learning, emotion, and movement; (2) the parietal lobes, which process sensory information such as touch, temperature, and pain; (3) the occipital lobes, dealing with vision; and (4) the temporal lobes, which are involved with hearing and memory. The central nervous system consists of the brain and the spinal cord, which connect to the peripheral nervous system, which extends throughout the body (see [Figure 41-1](#)).

The brain is approximately 80% fat. The fatty acid composition of neuronal cell membrane phospholipids reflects their intake in the diet. The degree of a fatty acid's unsaturation determines its three-dimensional structure and thus membrane fluidity and function. The ratio between omega-3 and omega-6 polyunsaturated fatty acids (PUFAs) influences various aspects of serotonergic and catecholaminergic neurotransmission. Beyond their role in brain structure, essential fatty acids (EFAs) are involved in the synthesis and functions of neurotransmitters and in the molecules of the immune system. Nutrition can impact multiple functions in most parts of the brain (see [Box 41-1](#)).

Nerve cells communicate through the release of molecules of neurotransmitters from the transmitting (releasing) end of one nerve cell, through the synapse between them, to the receiving end (receptors) of a nearby neuron. There are numerous neurotransmitters, including [serotonin](#), acetylcholine, dopamine, [norepinephrine](#), [epinephrine](#), and [glutamate](#). Amino acids such as tryptophan, tyrosine, and glycine are examples of nutrients necessary to the formation of neurotransmitters (see [Table 41-1](#)).

One of the most important contributions of nutrition to mental health is maintaining the structure and function of the

FIGURE 41-1 The human brain

BOX 41-1 How Nutrients Affect Mental Health

Nutrients can affect mental health through a variety of actions:

1. Nutrients can support or interfere with normal development of the brain and central nervous system.
2. Nutrients may serve as precursors to neurotransmitters.
3. Macronutrients act as an energy source for the brain.
4. Nutrients influence genetic transcription.
5. Nutrients function differently in pharmacologic doses than at nutritional (food based) doses.
6. Nutrients contribute to mood, and sense of well-being.
7. Nutrients may enter or exit from cells related to thoughts, emotions, and stress.

Reference: Leyse-Wallace R: *Nutrition and mental health*, Boca Raton, Fla, 2013, Taylor and Francis Inc., CRC Press.

neurons and neurotransmitters in the nervous system. The production of neurotransmitters requires adequate amounts of nutrients. Among these nutrients are amino acids (tryptophan, tyrosine, and glutamine), minerals (zinc, copper, iron, selenium, magnesium), and B vitamins (B₁, B₂, B₃, B₆, B₁₂, folic acid). These neurotransmitters and nutrients coordinate communication within the body and between the body and the environment. People often ask the question “Which nutrients are important for proper nervous system functioning, including mood?” The proper response is simply, “All of them.”

Because the conditions discussed here largely reflect metabolic, biochemical and genetic derangements (e.g., nutritional deficiencies, food sensitivities, and alterations in neurotransmitter levels) rather than structural issues (e.g., cancers or heart attacks), they

NEW DIRECTIONS

Brain-Derived Neurotrophic Factor (BDNF)

Brain-derived neurotrophic factor, also known as *BDNF*, is a protein found in the brain and the peripheral nerves. It plays a role in the growth, differentiation, and maintenance of nerve cells. In the brain, BDNF binds to receptors in the synapses between neurons, increasing voltage, and improving signal strength. The synapses can change and adapt over time in response to experience, a characteristic called *synaptic plasticity*. The BDNF protein helps regulate synaptic plasticity, which is important for learning and memory.

Inside the cells, BDNF activates genes that increase production of more BDNF and other important proteins, as well as serotonin, the neurotransmitter vital for learning and self-esteem. Low levels of BDNF have been associated with depression and even suicide.

The BDNF protein is found in regions of the brain that control eating, drinking, and body weight; and likely contributes to the management of these functions.

Certain common genetic variations (polymorphisms; see Chapter 5) in the BDNF gene have been associated with an increased risk of developing psychiatric disorders such as bipolar disorder, schizophrenia, anxiety, and eating disorders.

A particular polymorphism in the *BDNF* gene alters the amino acid sequence in the protein, replacing valine with methionine at position 66 (written as Val66Met or V66M), which impairs the protein's ability to function. Many studies report an association between the Val66Met polymorphism and psychiatric disorders; however, some studies have not supported these findings. It is still unclear how changes in the *BDNF* gene are related to these disorders. See <http://ghr.nlm.nih.gov/gene/BDNF>.

TABLE 41-1 Neurotransmitters: Precursors and Urinary Metabolites

Neurotransmitter	Precursors	Required Co-Factors	Urinary Metabolite
Norepinephrine	Phenylalanine and tyrosine	Copper, SAMe, vitamin C	Vanilmandelate (VMA)
Norepinephrine to epinephrine	Phenylalanine and tyrosine	Copper, SAMe, vitamin C	Vanilmandelate (VMA)
Dopamine	Phenylalanine and tyrosine	Tetrahydrobiopterin (BH ₄), vitamin B ₆	Homovanillate (HVA)
Serotonin	Tryptophan	Tetrahydrobiopterin (BH ₄), vitamin B ₆	5-Hydroxyindoleacetate (5-HIAA)

can often be dramatically improved through optimization of the diet. An example is hypothyroidism-induced depression or **dys-thymia** that can be corrected by identification and treatment of iodine deficiency. This makes medical nutrition therapy (MNT) a very valuable component of treatment for these conditions.

THE ENTERIC NERVOUS SYSTEM (ENS)

The gut has a huge number of neurons, with the gut often being called the **enteric nervous system (ENS)** or “the second brain,” which functions autonomously (Gershon, 1999). The ENS contains about 100 million neurons—fewer than the brain, but more than the spinal cord. Acetylcholine and norepinephrine are major neurotransmitters in the ENS. Neural activity in the gut is triggered by receptors that respond to mechanical, thermal, osmotic, and chemical stimuli. Bidirectional information continually passes between the gut and CNS. Factors such as psychologic stress, gender, and reproductive status influence transit time through the gut. Neurologic and gastrointestinal conditions may have gut and brain components (Sharkey and Savidge, 2014).

The gastrointestinal tract is colonized by more than 10 trillion bacteria, more than there are cells in the body. These bacteria and their by-products influence brain function and behavior. Gastrointestinal infections with unhealthy microbiota can influence brain function by causing increased gut membrane permeability, also called “**leaky gut**,” which is discussed further in Chapters 26 and 28. Leaky gut can result from a host of bowel infections and medications and is associated with many illnesses such as Crohn’s disease, celiac disease, multiple sclerosis, and irritable bowel syndrome. Because of this, both probiotics (which must be enteric coated to survive transit through the stomach acid), and prebiotics (e.g., chicory) which support the growth of healthy gut bacteria, should be included as a routine part of treatment.

BLOOD GLUCOSE REGULATION

Excessive sugar intake can cause wide fluctuations in blood glucose that can amplify aberrant moods and behavior (Young and Benton, 2014). Both high and low blood glucose have been found to have a strong association with a myriad of psychiatric conditions, including anxiety, depression, and schizophrenia (Balhara, 2011). Rapid and abrupt increases in blood sugar (glucose) can trigger rapid and excessive release of insulin. This is followed by a rapid drop in blood sugar as insulin drives glucose into the cells. The body compensates by raising levels of the compounds epinephrine and cortisol, both of which can trigger marked emotional changes and erratic behavior. The effects of insulin persist well beyond the

presence of sugar in the gastrointestinal tract (GIT). The natural response is to consume more sugar as it provides immediate relief of the symptoms of low blood sugar; this is the beginning of an emotional “sugar roller coaster” (Gaby, 2011).

The habit of eating sweets during stress may be physiologically rewarding, as it results in an increased movement of tryptophan into the brain. This occurs as insulin selectively drives other competing amino acids into muscles, leaving more tryptophan to enter the brain. This raises the level of serotonin, causing a soothing effect, the result being people learn to reach for sugar during stress (Page et al, 2011). Over time the increased sugar consumption combined with low fiber intake will cause increasing insulin resistance, paradoxically worsening the symptoms (see Chapter 30). With the average American consuming over 130 lb of sugar yearly (Walton, 2012), this is becoming a major health problem. On the other hand adequate *complex* carbohydrate intake is important because low-carbohydrate diets may have a negative effect on mood (Brinkworth et al, 2009).

To summarize, fluctuations in blood glucose can cause marked mood shifts, which can markedly accentuate psychiatric conditions and associated behavioral disorders. Reducing sugar intake can decrease these blood glucose fluctuations considerably. Higher protein as well as healthy fat intakes can contribute to stabilization of blood sugar levels, often with dramatic clinical and emotional improvement from balancing these three macronutrients (see *Clinical Insight: Helping Your Client Consume Less Sugar*).

CLINICAL INSIGHT

Helping Your Client Consume Less Sugar

- Instruct your client to reduce sugar intake by eliminating sodas and fruit juices, both of which have about $\frac{3}{4}$ tsp of sugar per ounce; a 64-ounce soda has 48 spoons of sugar: this message may effectively hit home.
- Recommend substituting healthy beverages such as vegetable juices, coconut water, and home-brewed herbal teas, which can be sweetened with sweeteners such as stevia (a processed plant-based sweetener) or erythritol (a sugar alcohol).
- Teach your client how to divide grams of sugar listed on the label by four to figure out how many teaspoons of sugar there are per serving of a food. So, if a serving contains 20 g of sugar as stated on the label – $20/4 = 5$ tsp of sugar per serving. The American Heart Association (AHA) recommends adults consume no more than 6 to 9 teaspoons of sugar per day (AHA, 2014). This quick reality check is usually enough to change behavior.

Adapted from: Teitelbaum, J: Beat Sugar Addiction, Fair Winds Press, 2015.

FOOD ALLERGIES AND SENSITIVITIES

Adverse reactions to food (ARF), allergies, and intolerances may contribute to psychologic symptoms, as well as other neurologic issues (see Chapter 26 for a detailed discussion of ARF). Conditions associated with food intolerances include peripheral neuropathy, inflammatory myopathies (muscle dysfunction or inflammation), myelopathies (spinal cord dysfunction or inflammation), and headache, as well as anxiety, schizophrenia, epilepsy, ataxia, Attention-deficit/hyperactivity disorder (ADHD), depression, and autism spectrum disorders (Jackson et al, 2012a). Clinically, complex health conditions without known cause are often found to improve by treating food sensitivities.

THE ROLE OF NUTRIENTS IN MENTAL FUNCTION

Omega-3 Fatty Acids

Omega-3 polyunsaturated fatty acids are the preferred fatty acids in the brain and nervous system. From conception through

BOX 41-2 Some Conditions for Which EPA* and DHA Have Benefit

Anxiety	Dyspraxia
Attention-deficit/ hyperactivity disorder (ADHD)	Eating disorders
Autism	Postpartum depression
Bipolar disorder	Schizophrenia
Depression	Suicidal ideation

*DHA, docosahexanoic acid; EPA, eicosapentaenoic acid.

maturity, the essential omega-3 fatty acids eicosapentaenoic acid (EPA) and docosahexanoic acid (DHA) make unique and irreplaceable contributions to overall brain and nervous system functioning. Clinical research has shown effective and promising roles for EPA and DHA in various psychiatric conditions (see [Box 41-2](#)) (see [Focus On: Abbreviations for Fatty Acids](#)).

FOCUS ON

Abbreviations for Fatty Acids

AA	Arachidonic acid
ALA	Alpha (α) linolenic acid
CLA	Conjugated linoleic acid
DGLA	Dihomo- <i>gamma</i> (γ)-linolenic acid
DHA	Docosapentaenoic acid
EFA	Essential fatty acid
EPA	Eicosapentaenoic acid
GLA	Gamma-linolenic acid
HUFA	Highly unsaturated fatty acid
LA	Linoleic acid
LCFA	Long-chain fatty acids
MUFA	Monounsaturated fatty acids
PUFA	Polyunsaturated fatty acids

Alpha-linolenic acid (ALA), an omega-3 fat with 8 carbons and 3 double bonds (18:3), is found in the oil of some seeds and nuts (e.g., flax, chia, sunflower, soybean, and walnuts). **Eicosapentaenoic acid (EPA)** is a 20-carbon omega-3 fatty acid with 5 double bonds (20:5), and **docosahexanoic acid (DHA)** is a 22-carbon fatty acid with 6 double bonds (22:6). EPA and DHA occur naturally in fatty fish and seafood.

ALA serves as a precursor for EPA and DHA, but the conversion of ALA to EPA is approximately 5% to 10%, and conversion of ALA to DHA is even lower (<3%). Health status, other nutritional factors, and genetic variations in the production of the delta-6 desaturase enzyme may influence the conversion rate. Studies have suggested possible differences in conversion rates between vegetarians and carnivores ([Welch et al, 2010](#)). Most nutrition and mental health experts do not recommend reliance on ALA as a source of EPA or DHA.

Arachidonic acid (ARA), a 20-carbon omega-6 fatty acid with 4 double bonds (20:4) serves as a precursor to the eicosanoids prostaglandins, thromboxanes, and leukotrienes, which are involved with inflammation, vasoconstriction, and a multitude of metabolic regulations, and also influence mood (see Chapter 3).

Although specific mechanisms remain unclear, clinical research has shown the importance of sufficient EPA intake for general mental health, and particularly as an adjunctive treatment for depression ([Freeman et al, 2006](#)). In general, EPA works better when ingested with DHA. They occur together naturally in foods. DHA is preferred and selectively stored in brain and nerve cells, and makes up much of the mass of brain tissue. It is required for normal brain growth, development, and

maturation and is involved with **neurotransmission** (brain cells communicating with each other), lipid messaging, genetic expression, and cell membrane synthesis. DHA also provides vital structural contributions; DHA is concentrated in the phospholipids of brain cell membranes.

Oily fish such as salmon, sardines, and tuna are high in EPA and DHA, with the freshest fish having the highest levels. Some canned tuna also has significant amounts and may be more practical for those who cannot get fresh fish. Omega-3 levels of canned albacore tuna are higher than “chunk light” canned tuna, and the tuna should be water and not oil packed, because otherwise the omega-3 oils, which are fat soluble, will be lost when the oil is poured off (see Appendix 34).

During Pregnancy and Lactation

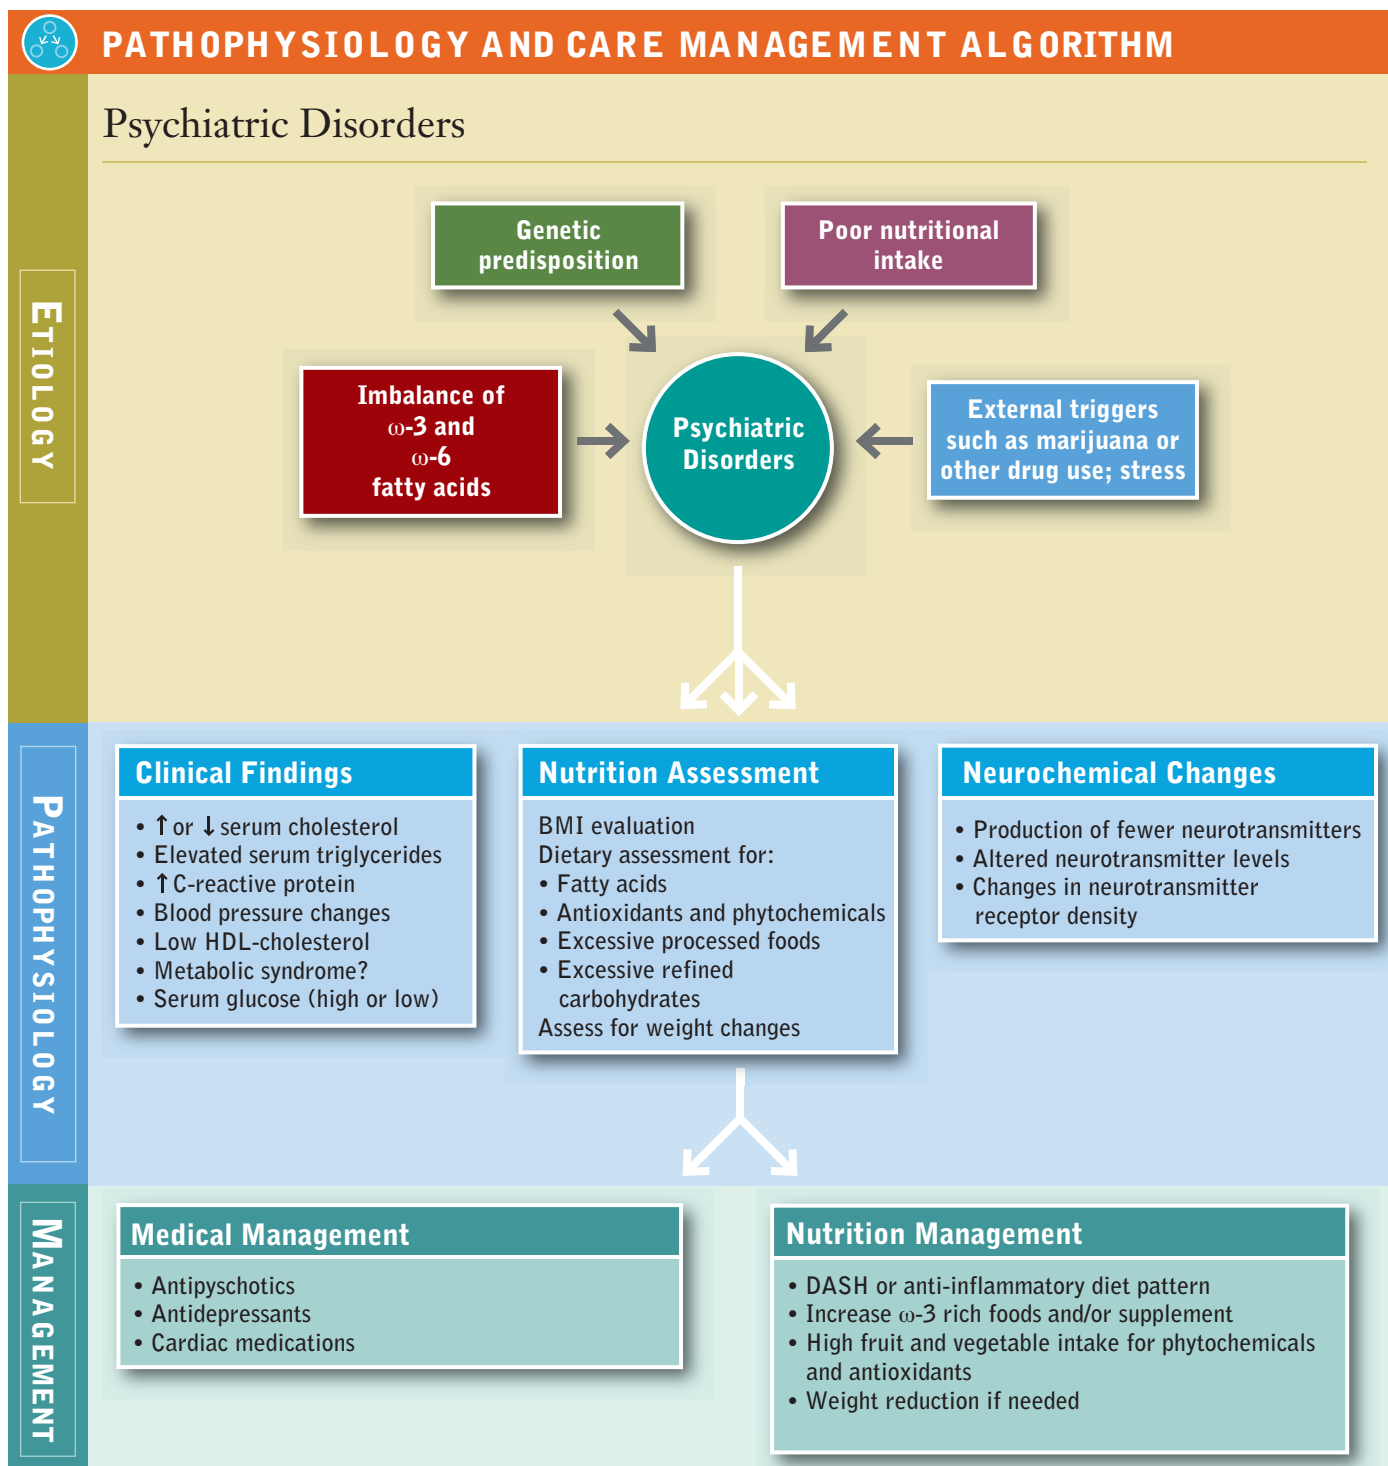

Experts recommend that pregnant women consume at least 200 to 300 mg DHA during pregnancy for proper infant development. The role of DHA and EPA in pregnancy and lactation is discussed in Chapter 15. Up to 10% of pregnant women may experience depression, and there is considerable interest in finding effective alternatives to prescription medication. Several pilot trials using EPA and DHA from fish oil have been conducted in depressed pregnant women and women with postpartum depression. One dose-ranging study reported measurable improvements in women who consumed as little as 500 mg of combined EPA and DHA. Experts have also recently suggested that a daily intake of 900 mg DHA during pregnancy may be necessary to support infant and maternal needs.

A landmark study that followed more than 9000 pregnant women and their children for 8 years reported lower intelligence quotient and social development in the children of those women who consumed less than 12 ounces of fish a week while pregnant. In other words, the children of the women who ate fish two or more times a week during their pregnancy fared better emotionally and mentally ([Hibbeln and Davis, 2009](#)). Some concern has been raised about high mercury levels in fish during pregnancy (see Chapters 15 and 17); mercury-free omega-3 fatty acid supplements which also dramatically simplify supplementation are now available (see [New Directions: Fatty Acid Vectorization](#)).

During Childhood

Depression among children is increasing. At the same time, the few studies measuring consumption of EPA and DHA in children report very low average intakes. The few clinical trials conducted in depressed children have shown significant benefit from EPA and DHA fish oil supplementation.

Some clinical trials using EPA and DHA supplements from fish oil in children with attention-deficit disorder (ADD) or attention-deficit hyperactivity disorder (ADHD) have reported benefit, but not all. The difference in findings may be due to many variables, including study design, dose, age of supplementation, the background diet, genetics, and teacher or family dynamics ([Gillies, 2012](#)). However, it has been shown that children with ADD, ADHD, behavior problems, or who are overweight, tend to have lower levels of EPA and DHA in their blood ([Antalis et al, 2006](#)). In one study, a total of 132 Australian children aged 7 to 12 years with ADHD participated in a randomized, placebo-controlled, double-blind intervention over 15 weeks, taking omega-3 fatty acids alone, omega-3 fatty acids + micronutrients, or placebo. Significant medium to strong positive treatment effects were found on parent ratings of core ADHD symptoms, inattention, hyperactivity/impulsivity, on the Conners Parent

Rating Scale (CPRS) in both omega-3 fatty acid treatment groups compared with the placebo group (Sinn and Bryan, 2007) (see Chapter 44 for further discussion of ADD and ADHD).

During Adulthood

According to the World Health Organization (WHO) major depression is a leading cause of disability around the world (WHO, 2012). The intake of seafood has been shown to be inversely related to the incidence of depression in populations around the world. Increases in homicide occurrence have been associated with less seafood consumption. When EPA, DHA,

and multivitamins were given to prison inmates, antisocial behavior, including violence, fell significantly, compared with those on placebo. In another study, teens who had previously attempted suicide made fewer suicide attempts when given EPA and DHA (Hallahan et al, 2007).

With much of the brain composed of the fatty acids found in fish oil (DHA), it is not surprising that fish oil has been shown to be helpful in many conditions. These include depression and schizophrenia unresponsive to drug treatment alone. EPA was also found to be beneficial in treating the depression associated with bipolar illness (manic depressive illness) (Gaby, 2011).

During Senior Adulthood and Aging

Not surprisingly, omega-3 fatty acids assist in maintaining cognitive function with age. Research suggests that individuals who consume more fish and seafood during their lifetimes have better cognitive function later in life. Higher blood levels of DHA have been associated with better cognitive function in middle adulthood. Omega-3 fatty acids may have substantial benefits in reducing the risk of cognitive decline in older people (Molfino et al, 2014).

Consumption of a Mediterranean-type diet has also been associated with a decreased rate of cognitive decline with age. It is not clear which aspect of this whole diet approach is responsible for this effect, although it is possible that it is not a single nutrient, but the combined effects of the overall diet that produces this benefit. The Mediterranean diet is high in antioxidants and nutrients such as choline and phosphatidylcholine, known to be important for brain function.

Long-chain omega-3 polyunsaturated fatty acids (PUFAs), along with other nutrients, have the potential of preventing and reducing comorbidities in older adults. They modulate inflammation, hyperlipidemia, platelet aggregation, and hypertension. Different mechanisms contribute to these effects, including supporting cell membrane function and composition, eicosanoid production, and gene expression.

The position of The Academy of Nutrition and Dietetics (AND) includes a recommendation for children and adults to eat fish at least twice a week. The 2004 recommendation of the International Society for the Study of Fatty Acids and Lipids is consumption of a daily minimum of 500 mg combined of EPA and DHA. With caveats inherent for ecologic, nutrient disappearance analyses, a healthy dietary allowance for omega-3 fatty acids for current U.S. diets was estimated at 3.5 g/day for a 2000-kcal diet. This recommended allowance can likely be reduced to one tenth of that amount by consuming fewer omega-6 fatty acids (Hibbeln et al, 2006). Higher intakes may be especially helpful in neurologic and psychiatric disorders because of the key roles these omega-3s play in the brain.

Omega-3 Supplements

For those who do not get optimal amounts of omega-3 fats from their diet, supplements can be useful and effective. In nature 1000 mg of fish oil contains approximately 180 mg EPA and 120 mg DHA; the remainder is other oils and fatty acids. Therapeutic amounts of EPA and DHA start with around 400 mg of each. Supplement companies sell concentrates of varying dosages, so it is important to read the label. It is also important to make sure the label indicates that the fat is free of heavy metals such as mercury and contaminants such as organophosphates. Tasting the contents of a fish oil capsule can reveal rancid oil, which should not be consumed.

Omega-3 supplements containing krill oil have the added advantage of containing phosphatidylcholine and the phytonutrient astaxanthin, a natural antioxidant that gives krill oil its red color. An algal (vegetarian) source of DHA is also available for vegetarians and vegans. For most people, using a vectorized pure omega-3 with phospholipids is best, and allows optimal supplementation with one to two tablets a day instead of 8 to 16 capsules, while also avoiding problems of contamination with chemicals or heavy metals (see [New Directions: Fatty Acid Vectorization](#)).

NEW DIRECTIONS

Fatty Acid Vectorization

A new process called “vectorization” yields a source of omega-3 fatty acids, in which the fatty acid is positioned in the center position of a glycerol (sn2) instead of position three (sn3). The COOH end of the fatty acid is phosphorylated, creating a phospholipid. Phospholipids have been shown to be a superior carrier of DHA and EPA, enhancing the absorption of the omega-3 fatty acids up to 50-fold over fish oil. One such product, “Vectomega” is available in Europe (Bourre, 2004; Parmentier et al, 2007). These products allow high levels of omega-3 fatty acid support with fewer pills or capsules.

Vitamins

Vitamins are critical for energy production as well as many other reactions, and deficiencies can cause serious cognitive and mood problems. Insufficient vitamin intake is defined as intake of an amount below the reference daily vitamin intake amounts, but vitamin deficiency means development of clinically relevant, measurable disorders or characteristic deficiency symptoms due to insufficient intake. Nonetheless, any person with insufficient vitamin intake is also at risk for development of a subclinical functional vitamin deficiency (see Chapter 7).

Mild nutritional deficiencies from poor diet can cause behavioral and cognitive dysfunction as can increased needs from altered metabolism resulting from gene mutations (see Chapter 5). Obtaining the levels of micronutrients shown in studies to change brain function often requires a pharmacologic, rather than an DRI level of supplementation, and cannot be reasonably achieved by diet alone. Described below are the function of selected vitamins and minerals involved in psychiatric conditions.

Studies have identified genetic mutations that alter the production and function of serotonin, dopamine, and other neurotransmitters. These alterations may sometimes be identified by various biochemical or deoxyribonucleic acid (DNA) tests. For example, the methylenetetrahydrofolate reductase (MTHFR) test can reveal alleles (C > T and A > C substitutions) that influence folate metabolism and can lead to a decrease in the production of serotonin and dopamine, as well as an increase in homocysteine levels resulting from a blocked metabolic pathway. People with these genetic single nucleotide polymorphisms (SNPs) (see Chapter 5) with active illness may require folate supplementation in a methylated (5-methyltetrahydrofolate -MTHF) form. Over half the adult population has an MTHFR mutation, so its presence is often not significant. An elevated homocysteine, or even a high folic acid level, should increase the index of suspicion and suggests there should be a clinical trial of giving a 2-mg (2000 mcg) dose/day of hydroxymethylcobalamin plus 200 mcg MTHF/day daily for 3 months. Elevated methylmalonic acid levels suggest the need for B₁₂ supplementation, especially in the presence of elevated serum homocysteine levels (see Chapters 7 and 32) (see Appendix 40 for food sources of folic acid and vitamin B₁₂).

Thiamin (Vitamin B₁)

Thiamin diphosphate (TDP), the most bioactive form of thiamine, is an essential coenzyme in glucose metabolism and the biosynthesis of neurotransmitters, including acetylcholine, γ -aminobutyrate, glutamate, aspartate, and serotonin. Norepinephrine, serotonin, and glutamate, as well as their receptors, are potential targets for antidepressive therapies. The degradation rate of TDP, bound to its dependent enzymes, is directly

proportional to the available amount of its main substrate, carbohydrate. Body stores of B₁ fall rapidly during fasting. Low TDP concentrations and impaired thiamin-dependent enzymatic activities have been detected in the brains of patients with Alzheimer's disease (AD), Parkinson's dementia (PD), and other neurodegenerative diseases (Zhang et al, 2013).

Wernicke encephalopathy (WE) is a potentially reversible, yet serious neurologic manifestation caused by vitamin B₁ (thiamin) deficiency. It is commonly associated with heavy alcohol consumption but is also reported with the excessive vomiting of hyperemesis gravidum, and vomiting after bariatric surgery. Most patients present with the triad of ocular signs (nystagmus), ataxia, and confusion (see Chapter 29).

Guidelines by the European Federation of Neurological Societies (EFNS) recommend that patients with alcoholism or the conditions mentioned above receive thiamin, 200 mg tid, administered IV, before starting any carbohydrate or glucose intake, and that it be continued until there is no further improvement in signs and symptoms (see Chapter 29). For nonalcoholic patients, an intravenous dose of thiamin, 100 to 200 mg once daily, may be sufficient (Galvin et al, 2010).

In a double-blind study 50 mg/day of thiamin (vs. placebo) was associated with reports of being more clearheaded, composed, and energetic. These influences took place in subjects whose thiamin status was adequate according to traditional criteria (Benton et al, 1997). Learning disorders as well as behavioral problems in young children (sometimes to the point of hospitalization) were shown to improve with a high-dose thiamin supplement (Fattal et al, 2011). People with AD were shown to have lower serum thiamin levels than those with other types of dementia (Lu'o'ng and Nguyen, 2011). Some medications may interact with thiamin (see Box 41-3).

Riboflavin (Vitamin B₂)

Biochemical signs of riboflavin depletion appear within a few days of dietary deprivation. Poor riboflavin status interferes with iron handling and contributes to the etiology of anemia when iron intakes are low. Riboflavin is involved in determining circulating concentrations of homocysteine and may exert some of its effects by reducing the metabolism of other B vitamins, notably folate and vitamin B₆, of particular interest in psychiatric disorders. In those with frequent migraines, supplementing with 400 mg of riboflavin a day decreased migraine frequency by 50% to 69% after 6 weeks of use (Markley, 2012).

BOX 41-3 Medications that May Cause Vitamin B₁ Deficiency

- Digoxin—Laboratory studies suggest that digoxin (a medication used to treat heart conditions) may reduce the ability of heart cells to absorb and use vitamin B₁; this may be particularly true when digoxin is combined with furosemide (Lasix, a loop diuretic).
- Diuretics—Diuretics (particularly furosemide, a loop diuretic) may reduce levels of vitamin B₁ in the body.
- Phenytoin (Dilantin)—Some evidence suggests people taking phenytoin have lower levels of thiamin in their blood, and that may contribute to the side effects of the drug. However, that is not true of all people who take phenytoin.

Reference: University of Maryland Medical Center: *Possible interactions with vitamin B₁ (thiamine)* (website: <http://umm.edu/health/medical/altmed/supplement-interaction/possible-interactions-with-vitamin-b1-thiamine>, 2013. Accessed January 26, 2015.

Niacin (Vitamin B₃)

Niacin is a key component of the molecule NADH, which is important for production of the neurotransmitter dopamine. One of the signs of pellagra, the niacin-deficiency disease, is dementia. Pellagra can be a cause of delirium during alcohol withdrawal (Oldham and Ivkovic, 2012). Acute pellagra resembles sunburn in its first stages. Psychiatric manifestations are fairly common, but are easily overlooked due to their nonspecific nature. Examples include irritability, poor concentration, anxiety, fatigue, restlessness, apathy, and depression (Prakash et al, 2008).

A 5½-year, prospective, population study of more than 3700 people showed that those who had the lowest niacin intake (14 mg/day) were 70% more likely to develop AD than individuals who had the highest intake (45 mg/day). A benefit was shown with an increased intake up to 17 mg/day (Morris et al, 2004; Morris et al, 2005).

Vitamin B₁₂

The symptoms of vitamin B₁₂ deficiency may include agitation, irritability, confusion, disorientation, amnesia, impaired concentration and attention, and insomnia. Mental symptoms may also include stupor, apathy, negativism, memory and judgment disorders or even psychoses, depression, and dementia (Grober et al, 2013). Catatonia is also described as a psychiatric form of vitamin B₁₂ deficiency. Psychiatric disorders that may be diagnosed in patients having B₁₂ deficiency include depression, bipolar disorder, panic disorder, psychosis, phobias, and dementia.

A vitamin B₁₂ deficiency may express itself in a wide variety of neurologic manifestations such as paresthesias, coordination disorders, and reduced nerve conduction velocity and in the elderly, with progressive brain atrophy. Cobalamin contributes to hematopoiesis, myelin synthesis, and synthesis of epithelial tissue.

Seventy-five to ninety percent of persons with a clinically relevant B₁₂ deficiency have neurologic disorders, and in about 25% of cases these are the only clinical manifestations of the B₁₂ deficiency. Levels less than 200 ng/L are sure signs of a B₁₂ deficiency, but a functional B₁₂ deficiency may also be present at levels under 450 ng/L.

Moderately elevated concentrations of homocysteine (>10 µmol/L) have been associated with an increased risk of dementia, notably AD, in many cross-sectional and prospective studies. Raised plasma concentrations of homocysteine are associated with regional and whole-brain atrophy, not only in AD but also in healthy elderly people. Determination of methylmalonic acid and homocysteine are particularly recommended in cases of diagnostically unclarified B₁₂ deficiency.

Possible nutrient-drug interactions occur with antibiotics, anticonvulsants, colchicine, metformin, and N₂O. Proton pump inhibitors reduce gastric acid secretion and thus the intestinal release of vitamin B₁₂ from foods (see Chapter 8).

Hydroxycobalamin, methylcobalamin, and cyanocobalamin are suitable for treatment. The lowest dose of oral cyanocobalamin required to normalize mild vitamin B₁₂ deficiency is more than 200 times the recommended dietary allowance of approximately 3 µg daily (i.e., >500 µg per day). For deficiency resulting from absorption disorders, doses of 500 to 2000 µg/day are required. A *Cochrane Group* review concluded that 1000 to 2000 µg/day, administered orally, was as effective as intramuscular B₁₂ in achieving hematologic and neurologic responses (Vidal-Alaball et al, 2005), though IM B₁₂ will achieve normalization more quickly and ensure compliance at the start of treatment.

In a recent randomized and double-blind interventional study (VITACOG study) involving 168 elderly persons with mild cognitive impairment (age >70 years), oral supplementation of vitamin B₁₂, folic acid, and vitamin B₆ over a period of 24 months slowed the progression of brain atrophy and the reduction of cognitive performance by 53.3% (Grober et al, 2013).

In a study of people being treated for depression, participants with higher levels of vitamin B₁₂ tended to get a greater benefit from antidepressants (Moore et al, 2012).

Folic Acid

Folate deficiency is associated with depression, cognitive decline, and dementia. The NHANES 2010 data examined relations between folate and vitamin B₁₂ status biomarkers for mental as well as physical conditions. These conditions included lead and neurobehavioral test performance, anemia and cognitive function, hypothyroidism, and gene-nutrient interactions.

Folate deficiency has been identified as a risk factor for schizophrenia through epidemiologic, biochemical, and gene association studies. Folate plus vitamin B₁₂ supplementation can improve negative symptoms of schizophrenia. Negative symptoms imply the lack of something, such as social contacts, initiative, energy, motivation or display of emotion, but treatment response is influenced by genetic variation in folate absorption. These findings support a personalized medicine approach for the treatment of negative symptoms (Roffman et al, 2013).

Folate deficiency may be the result of decreased intake, or increased needs caused by common genetic defects (see MTHFR discussion above). Causes of decreased intake include poor diet, old age, poverty, and alcoholism. Less commonly, inadequate intake can arise through inappropriate and prolonged hyperalimentation or other use of synthetic diets that may be low in folate. Consequences of inadequate intake are compounded when there is an increased folate requirement, such as during pregnancy, lactation, premature birth, and chronic hemolytic anemias, for example, sickle cell anemia and thalassemias (see Chapter 32). Conditions associated with increased cell turnover such as leukemias, aggressive lymphomas, and tumors associated with a high proliferative rate can also cause increased folate demand.

Supplementing with folic acid may help memory. In one study, 818 cognitively healthy people ages 50 to 75 years took either folic acid, 800 mcg, or placebo for 3 years. On memory tests, those who took supplements had scores comparable to people 5½ years younger (Durga et al, 2007).

In addition, low folate is associated with AD, with higher folate levels being associated with a 50% reduction in the risk of developing AD (Luchsinger et al, 2007). Not all studies have shown a protective effect, however, and one study showed a U-shaped curve, with very high folate levels being associated with higher homocysteine levels and a greater risk for developing AD (Faux et al, 2011).

Total homocysteine (tHcy), a nonspecific indicator of inadequate folate status, accumulates with folate inadequacy but is relatively stable across normal folate ranges (Yetley and Johnson, 2011). Folate biomarkers (serum, plasma, and red blood cell folate) increase in response to folic acid in a dose-response manner (Duffy et al, 2014).

Vitamin D

Vitamin D affects hundreds of genes in the human body and is recognized as an important nutrient for brain health as well as for bone and skeletal health. Clinical research has associated

vitamin D deficiency with the presence of mood disorders, with aspects of cognitive disorders, as well as increased risk for major and minor depression in older adults (Stewart and Hirani, 2010). Supplementing with vitamin D, however, has shown mixed results (Bertone-Johnson et al, 2012; Kjærgaard et al, 2012).

Vitamin D has a crucial role in proliferation, differentiation, neurotrophism, neuroprotection, neurotransmission, and neuroplasticity of cells. Vitamin D exerts its biologic function not only by influencing cellular processes directly, but also by influencing gene expression. The brain has vitamin D receptors, which help to provide protection against, and even aid in reversal of, neurocognitive decline. In a study that combined vitamin D with the AD medication memantine, the combination therapy was associated with improvement when compared to memantine or vitamin D alone (Annweiler et al, 2012).

Serum levels of vitamin D are most often tested by assessing circulating levels of 25(OH)D, which is the combined product of skin synthesis from sun exposure and dietary sources (see Chapter 7 and Appendix 45). Currently, no “official” agreement has been reached regarding blood levels of 25(OH)D that indicate deficiency, insufficiency, and sufficiency of vitamin D, especially related to brain health. For example, serum levels of 25(OH)D may be low despite a person having an adequate diet or sufficient sun exposure, because of conversion to other forms such as 1,25(OH)D. Many practitioners favor 25(OH)D serum levels of at least 30 ng/ml or 75 nmol/L, although for treatment of cancer, diabetes, autoimmune illness or depression levels of 60 to 80 ng/ml may be beneficial.

The best sources of vitamin D are (1) exposure of a large amount of skin to sunlight for at least 15 to 20 min/day without sunscreen, (2) foods such as oily fish and egg yolks, and (3) vitamin D–fortified foods, such as cow, soy, or other fortified milks, and fortified cereals. The recommended advice regarding sun exposure is to “avoid sunburn—not sunshine” (see Appendix 45).

Minerals

Iron

Iron deficiency results in poor brain myelination and impaired monoamine metabolism. Glutamate and γ -aminobutyric acid homeostasis is modified by changes in brain iron status. Such changes not only produce deficits in memory, learning capacity, and motor skills but also result in emotional and psychologic problems (Kim and Wessling-Resnick, 2014).

Iron deficiency is associated with apathy, depression, and fatigue. Iron deficiency anemia in children is associated with a significantly increased risk of psychiatric disorders, including mood disorders, autism spectrum disorder, attention-deficit hyperactivity disorder, and developmental disorders (Chen et al, 2013) (see Chapters 32 and 44). At 10 years of age, children given iron supplements from 6 months to 12 months of age smiled and laughed more and needed less prompting to complete a social stress task. However, there were no differences in behaviors such as anxiety, depression, or social problems. Benefits in affect and response to reward may improve performance at school and work, mental health, and personal relationships (Lozoff et al, 2014). Anemia is a late sign of iron deficiency, and therefore a normal blood count in no way precludes its presence. In addition, a ferritin under 60 mcg/l (ng/ml), and when anemia is present a < 100 mcg/l (ng/ml), can reflect iron deficiency, even though this level is well within the normal range. (Vaucher 2012; Wang 2009; Kis 1998)

Iron plays a critical role in dopaminergic signaling. Atypical antipsychotic medications, increasingly used in children and adolescents, modulate brain dopamine. In a study of 115 children who had taken risperidone for 2.5 ± 1.7 years, 45% had iron depletion and 14% had iron deficiency. Iron status was inversely associated with weight gain during risperidone treatment. It was also inversely associated with the antipsychotic prolactin concentration, which was nearly 50% higher in the iron-deficient group (Calarge and Ziegler, 2013). Nutrition assessment should include evaluation of iron status. Prolactinemia is a challenging side effect of risperidone therapy, especially in males, that may be improved when iron status is normalized.

Selenium

The essential trace mineral selenium is a constituent of selenoproteins, which have important structural and functional roles. Known as antioxidants, they act as a catalyst for the production of active thyroid hormone and are needed for the proper functioning of the immune system. Deficiency has been linked to adverse mood states (Rayman, 2000). One study found that low dietary selenium intake was associated with an approximate tripling of the likelihood for developing de novo Major Depressive Disorder (MDD) (Pasco et al, 2012).

Selenium is available in multivitamin/multimineral supplements and as a stand-alone supplement, often in the forms of selenomethionine or selenium-enriched yeast (grown in a high-selenium medium). An optimal dose for supplementation is ~ 55 mcg per day (Akbaraly T, 2010). Selenium poisoning from very large intakes is a concern (Nutall, 2006).

Selenium may have a moderate interaction with some medications. These include anticoagulants, aspirin, clopidogrel (Plavix), warfarin (Coumadin), and cholesterol-lowering drugs atorvastatin (Lipitor), fluvastatin (Lescol), lovastatin (Mevacor), and pravastatin (Pravachol). Selenium may decrease the clearance and excretion time of barbiturates. It may also interact with niacin, vitamins C and E, and beta-carotene (Web MD, 2009). See Chapter 8 and Appendix 23.

Zinc

Zinc imbalance can result not only from insufficient dietary intake but also from impaired activity of zinc transport proteins and zinc-dependent regulation of metabolic pathways. It is known that some neurodegenerative processes are connected with altered zinc homeostasis, and it may influence the state of AD, depression, and aging-related loss of cognitive function (Tyszka-Czochara et al, 2014). Zinc may play a role in regulating the production of dopamine in the brain. Mechanisms of action by which zinc reduces depressive symptoms include (1) decreasing dopamine reuptake (by binding to the dopamine receptor), (2) increasing the conversion of the thyroid hormone T4 to T3, and (3) the promotion of excitatory neurotransmitter function.

A study of older adults in Australia using a food-frequency questionnaire found those with the highest zinc intake had a 30% to 50% reduction of odds of developing depression. They also reported no association between the zinc-to-iron ratio and developing depression (Vashum et al, 2014).

A study of seventh graders showed that 20 mg a day of supplemental zinc improved school performance with improved memory and attention span (Teitelbaum, 2015). Children with attention-deficit hyperactivity disorder had lower blood levels of zinc, ferritin, and magnesium than children without ADHD, but had normal copper levels (Mahmoud et al, 2011).

Amino Acids

In addition to being the building blocks for the key neurotransmitters serotonin (from tryptophan), dopamine, and norepinephrine (both from tyrosine), amino acids are also critical precursors for the antioxidants glutathione (made from glutamine, glycine and N-acetyl cysteine [NAC]). Amino acid sufficiency can be measured either through plasma or urinary amino acids or by urinary organic acid testing, which measures by-products of the particular neurotransmitter pathways (see Table 41-1). As more of the neurotransmitters are found in the gut than in the brain, these tests may only be helpful but certainly are not absolute indicators of brain neurotransmitter levels or adequacy. Amino acid levels can be low due to inadequate protein intake.

The role of serotonin and dopamine in depression is widely known and it is targeted by many medications, but the role of antioxidants gets less attention, despite being important. For example, NAC has been shown to be helpful in a wide array of psychiatric conditions, including addiction, compulsive and grooming disorders, schizophrenia, and bipolar disorder (Dean et al, 2011). Doses of 500 to 2000 mg are commonly used safely and at low cost.

Phytochemicals

New research suggests that plant-based foods rich in bioactive phytochemicals make important nutritional and biochemical contributions to normal brain function and mental health. Promising phytochemicals include three subclasses of flavonoids: flavanols, anthocyanins, and flavanones (see *Focus On: Eating to Detoxify* in Chapter 19). These phytochemicals have antioxidant activity, but their more important contributions may be in protecting and preserving brain cell structure and metabolism through a complex cascade of cellular mechanisms, including signaling, transcription, phosphorylation, and gene expression (Spencer, 2010). Foods such as berries, citrus fruits, green tea, and some spices contain phytochemicals, as well as essential vitamins and minerals. Curcumin may be especially neuroprotective, being associated with lower risks of Alzheimer's and Parkinson's Disease (see Alzheimer's discussion below).

There is evidence that numerous other plant-based molecules have nutritional and possibly pharmacologic effects in the brain, and the mechanisms are sometimes unknown. These molecules appear to affect brain health through antioxidant, antiinflammatory, and nutrigenomic influences. Other mechanisms are also plausible. Examples of these foods include onion, ginger, turmeric, oregano, sage, rosemary, and garlic. This is an exciting area of research to watch in the twenty-first century. In a study on sulforaphane treatment of autism spectrum disorder (ASD) by Singh et al (2014), participants receiving sulforaphane, a broccoli seed extract, had improvement in social interaction, abnormal behavior, and verbal communication. Sulforaphane, which showed negligible toxicity, was selected because it upregulates genes that protect aerobic cells against oxidative stress, inflammation, and DNA damage, all of which are prominent and possibly mechanistic characteristics of ASD (see Chapter 44).

Nutritional Supplements

People experiencing cognitive and mood dysfunction, or psychosis, often have difficulty maintaining a healthy diet despite guidance. Levels of some nutrients may require intakes in excess of the RDA, which often cannot be obtained through diet. A multivitamin is a reasonable solution (Davison and Kaplan, 2011).

There are hundreds of psychiatric disorders, which fall into general categories as shown in Table 41-2.

TABLE 41-2 Medical Nutrition Therapy (MNT) for Psychiatric Disorders

A psychiatric diagnosis is based on symptoms observed or reported. A psychoanalytic diagnosis involves the etiology and meaning of symptoms. *The Diagnostic and Statistical Manual of Mental Disorders*, Fifth Edition (DSM-5), is used by both groups of mental health professionals.

There are hundreds of psychiatric disorders, which fall into the thirteen categories below.

MNT therapy for psychiatric disorders requires a nutritional assessment, which takes into account the following:

1. Increase or decrease in appetite
2. Increase or decrease in activity level and therefore calorie requirements
3. Use of medications which cause dry mouth, thirst, and constipation
4. Decrease in ability to concentrate, understand, and follow directions
5. Altered nutritional needs due to use of alcohol, drugs, or tobacco
6. Possible decrease in ability for self-care such as adequate income, shopping, meal preparation
7. History of food choices or comorbid conditions that result in suboptimal or deficient nutritional intake, or supplement use while restoring healthy eating habits
8. Use of food or nutrition supplements as the "Magic Answer" in therapy

Psychiatric Disorder	Description	Examples	Nutrition Strategies
Adjustment disorders	A group of symptoms, such as stress, feeling sad or hopeless, and physical symptoms that can occur after a stressful life event. Difficulty coping can result in a stronger reaction than expected for the type of event that occurred.		Small, concrete steps and goals. Assess physical symptoms and changes (fatigue, diarrhea, activity level, etc.)
Anxiety disorders	Worry and fear are constant and overwhelming and can be crippling. Anxiety can cause such distress that it interferes with a person's ability to lead a normal life.	Includes panic disorder, social anxiety disorder, and specific phobias	Reassurance and verbal reward for successes. Gradual changes. Use healthy comfort foods. Support blood sugar stability. Support healthy food choices and eating habits. Omit foods with negative associations.
Associative disorders	Escape from reality in ways that are involuntary and unhealthy, experience of disconnection and lack of continuity between thoughts, memories, surroundings, actions, and identity.	Symptoms include amnesia and not remembering previous alternate identities.	
Eating disorders	A group of serious conditions in which preoccupation with food and weight results in focus on little else Eating disorders can cause serious physical problems and can even be life-threatening. (see Chapter 22)	Includes anorexia nervosa, bulimia, and binge-eating disorders.	Support good food choices already in place. Enlist individual in goal-setting; Encourage use of multivitamin/mineral supplement. Include moderate activity level and social eating.
Impulse control disorders (ICD)	Repetitive or compulsive engagement in a specific behavior (e.g., gambling, hair-pulling) despite adverse consequences, diminished control over the problematic behavior, and tension, or urge state prior to engagement in the behavior.	Includes pathologic gambling, kleptomania, pyromania, and intermittent explosive disorder. Criteria for other ICDs (compulsive shopping, problematic Internet use, compulsive sexual behavior, and compulsive skin picking) are currently under consideration.	Steer away from over-focus on a single goal. Encourage variety in food choices. Moderate a regular schedule of meals and snacks.
Mood disorders	A general emotional state or mood that is distorted or inconsistent with the circumstances.	Includes: Major depressive disorder —prolonged and persistent periods of extreme sadness Bipolar I and II disorders —also called manic depression or bipolar affective disorders Seasonal affective disorder (SAD) —a form of depression associated with fewer hours of daylight Cyclothymic disorder —emotional ups and downs; less extreme than bipolar disorder Premenstrual dysphoric disorder —mood changes and irritability that occur during a woman's premenstrual phase and go away with the onset of menses Persistent depressive disorder (dysthymia) —a long-term (chronic) form of depression Disruptive mood dysregulation disorder —chronic, severe and persistent irritability in children, often includes frequent temper outbursts that are inconsistent with the child's developmental age	Inquire about history of weight changes. Ensure adequate folic acid (methyl folate), B ₁₂ , and omega-3 fatty acid intake. Encourage regular, simple meals and snacks Detailed planning Social eating if possible. Bipolar: Assess for consistent fluid and sodium intake. Plan designated income for food if necessary. Include plan for social exercise and activity.
Personality disorders	A class of mental disorders characterized by long-term rigid patterns of thought and behavior that deviate markedly from the expectations of the culture. They can cause serious problems and impairment of function.	Includes: behavioral pattern which causes significant distress or impairment in personal, social, or occupational situations. Similar situations do not affect most people's daily functioning to the same degree.	Flexible food choices. Variety of foods and beverages. Flexible eating times.

TABLE 41-2 Medical Nutrition Therapy (MNT) for Psychiatric Disorders—cont'd

Psychiatric Disorder	Description	Examples	Nutrition Strategies
Psychotic disorders	Serious illnesses that affect the mind and alter a person's ability to think clearly, make good judgments, respond emotionally, communicate effectively, understand reality, and behave appropriately.	Includes: Schizophrenia —symptoms such as hallucinations and difficulty staying in touch with reality. Often unable to meet the ordinary demands of daily life. Schizoaffective disorder —have symptoms of schizophrenia and a mood disorder.	Social eating. Simple meals. Give shopping guidelines and healthy snack ideas. Assess for potential metabolic syndrome. Assess for excess supplement use or water intake. Support adequate nutrition for healthy physical function.
Sexual dysfunction	Inability to fully enjoy sexual intercourse; disorders that interfere with a full sexual response cycle rarely threaten physical health, but can take a heavy psychological toll, bringing on depression, anxiety, and debilitating feelings of inadequacy.		
Sexual disorders	Disorders involving sexual functioning, desire, or performance, must cause marked distress or interpersonal difficulty to rate as disorder.	Diagnosis made only when the situation persists, caused at least in part by psychological factors; could occur occasionally or be caused by a temporary factor such as fatigue, sickness, alcohol, or drugs.	
Sleep disorders	Disorders involving changes in sleeping patterns or habits. Signs and symptoms include excessive daytime sleepiness, irregular breathing or increased movement during sleep, difficulty sleeping, and abnormal sleep behaviors.	Includes insomnia, sleep apnea, restless leg syndrome and narcolepsy.	Food record with times of eating to increase awareness and presence of night eating syndrome.
Somatoform disorders	A group of disorders characterized by thoughts, feelings, or behaviors related to somatic (physical) symptoms, and are excessive for any medical disorder that may be present.	May accompany anxiety disorders and mood disorders, which commonly produce physical symptoms. Somatic symptoms improve with successful treatment of the anxiety or mood disorder.	Review physical symptoms and changes in frequency and severity (abdominal pain, diarrhea, constipation). Eating for comfort.
Substance disorders	Distinct, independent, co-occurring mental disorders, in that all or most of the psychiatric symptoms are the direct result of substance use.	Symptoms of substance-induced disorders go from mild anxiety and depression (the most common across all substances) to full-blown manic and other psychotic reactions (much less common). Psychotic symptoms can be caused by heavy and long-term amphetamine abuse. Dementia (problems with memory, concentration, and problem solving) may result from using substances directly toxic to the brain, which commonly include alcohol, inhalants like gasoline, and amphetamines.	Calculate calories from alcohol, mg of caffeine intake; % of calories from sugar and sweets to increase client awareness and track progress. Moderate goals. Gradual changes. Encourage use of vitamin/mineral supplements. Assess history of irregular food intake and weight changes. Challenge “magic answer” thinking re: supplements, etc.

ADDICTION AND SUBSTANCE ABUSE

Addiction is defined as the persistent compulsive use of a substance known by the user to be physically, psychologically, or socially harmful. Addiction to alcohol, or **alcoholism**, and other substances results in compulsive and relapsing behavior. Addiction may be accompanied by depression or anxiety.

Successful treatment requires attention to the contribution of nutrition in the perpetuation of and recovery from addiction. Addictions may result in poor appetite, craving for sugar and sweets, constipation, and lack of motivation to prepare meals. Poor nutritional status may result from primary malnutrition from insufficient food or nutrient intake, or secondary malnutrition due to alteration in absorption, digestion, metabolism, or excretion of nutrients.

Addiction involves numerous neurotransmitters. The master “pleasure” molecule, which links and involves most forms of

addiction, is **dopamine**. Its production is triggered by use of heroin, amphetamines, marijuana, alcohol, nicotine, cocaine, and caffeine or the activities of gambling or sex. Some evidence links compulsive eating behavior to the same reward system. Other neurotransmitters demonstrated to be involved in addiction include serotonin and glutamate. Nutritional derangements associated with addiction may be severe and can perpetuate addiction, or intensify addiction-related health problems, and make recovery a more difficult process.

Screening for Alcoholism

A moderate intake is defined as no more than two drinks a day for men or one drink a day for women (CDC, 2014). Individuals with intakes larger than this should be assessed using a validated screening tool for **alcoholism**.

The CAGE questionnaire has been commonly been as a screening and evaluation tool for alcoholism (see Box 41-4).

BOX 41-4 CAGE Questionnaire for Assessing Alcohol Use

Have you ever felt you should **C**ut down on your drinking?
 Have people **A**nnoyed you by criticizing your drinking?
 Have you ever felt bad or **G**uilty about your drinking?
 Have you ever had a drink first thing in the morning to steady your nerves or to get rid of a hangover (**E**ye opener)?

Item responses on the CAGE are scored 0 or 1, with a higher score as an indication of alcohol problems. A total score of 2 or greater is considered clinically significant.

Ewing JA: Detecting alcoholism. The CAGE questionnaire, *JAMA* 252:1905, 1984.

However, the CAGE questionnaire has been largely replaced by the Alcohol Use Disorders Identification Test (AUDIT) screening instrument because of its improved sensitivity and specificity. The AUDIT tool, developed in 1982 by the World Health Organization, is a simple way to screen and identify people at risk of alcohol problems (see [Box 41-5](#)).

Pathophysiology

Alcohol can be both a tonic and a poison. Moderate drinking seems to be good for the heart and circulatory system and may protect against type 2 diabetes and gallstones. Heavy drinking is a major cause of preventable death in most countries; it is implicated in about half of fatal traffic accidents in the United States. Heavy drinking can damage the liver and heart, harm

an unborn child, increase the chances of developing breast and some other cancers, contribute to depression and violence, and interfere with relationships (<http://www.mayoclinic.org/healthy-living/nutrition-and-healthy-eating/in-depth/alcohol/art-20044551>). When alcohol begins to create problems, and especially when one denies these issues or cannot change the course of them, alcohol addiction must be considered.

Nutrient deficiencies can exacerbate these negative consequences of chronic alcohol consumption:

1. Deficiency of vitamin B₁ can trigger confusion and psychosis (called Wernicke encephalopathy; see Chapter 29)
2. Magnesium deficiency may aggravate withdrawal symptoms such as delirium tremens (DTs) and cardiac arrhythmias. Red blood cell (RBC) magnesium levels are more useful in assessment than serum magnesium levels, which may remain “normal” even with severe magnesium deficiency. Because magnesium deficiency is so common in alcoholics, deficiency should be presumed to be present.
3. Osteoporosis can be a direct influence of alcohol use or due to the commonly associated poor diet of alcoholics. Key nutrients and recommended doses to improve bone density are shown below. Vitamin D inhibits strontium absorption, so it must be taken at a different time of day ([Reginster et al, 2012](#)).
 Strontium: 340 to 680 mg/day
 Vitamin D: 1000 to 2000 IU
 Magnesium: 200 mg
 Vitamin K: 150 mcg
 Boron: 3 mg

BOX 41-5 Alcohol Use Disorders Identification Test (AUDIT) Instrument

1. How often do you have a drink containing alcohol?
 (0) Never (skip to questions 9-10)
 (1) Monthly or less
 (2) 2 to 4 times a month
 (3) 2 to 3 times a week
 (4) 4 or more times a week
2. How many drinks containing alcohol do you have on a typical day when you are drinking?
 (0) 1 or 2
 (1) 3 or 4
 (2) 5 or 6
 (3) 7, 8, or 9
 (4) 10 or more
3. How often do you have six or more drinks on one occasion?
 (0) Never
 (1) Less than monthly
 (2) Monthly
 (3) Weekly
 (4) Daily or almost daily
4. How often during the last year have you found that you were not able to stop drinking once you had started?
 (0) Never
 (1) Less than monthly
 (2) Monthly
 (3) Weekly
 (4) Daily or almost daily
5. How often during the last year have you failed to do what was normally expected from you because of drinking?
 (0) Never
 (1) Less than monthly
 (2) Monthly
 (3) Weekly
 (4) Daily or almost daily
6. How often during the last year have you been unable to remember what happened the night before because you had been drinking?
 (0) Never
 (1) Less than monthly
 (2) Monthly
 (3) Weekly
 (4) Daily or almost daily
7. How often during the last year have you needed an alcoholic drink first thing in the morning to get yourself going after a night of heavy drinking?
 (0) Never
 (1) Less than monthly
 (2) Monthly
 (3) Weekly
 (4) Daily or almost daily
8. How often during the last year have you had a feeling of guilt or remorse after drinking?
 (0) Never
 (1) Less than monthly
 (2) Monthly
 (3) Weekly
 (4) Daily or almost daily
9. Have you or someone else been injured as a result of your drinking?
 (0) No
 (2) Yes, but not in the last year
 (4) Yes, during the last year
10. Has a relative, friend, doctor, or another health professional expressed concern about your drinking or suggested you cut down?
 (0) No
 (2) Yes, but not in the last year
 (4) Yes, during the last year

Add up the points associated with answers. A total score of 8 or more indicates harmful drinking behavior.

Calcium is best obtained from food sources, such as dairy foods, sardines, dark green vegetables, and seeds.

4. Malnutrition, malabsorption, gastritis, and chronic diarrhea (see Chapter 28)
5. Hepatitis and cirrhosis (see Chapter 29)
6. Cardiomyopathy (see Chapter 33)
7. Bone marrow disorders
8. Neuropathy, which is also associated with B₁₂ deficiency, and dementias

Medical Management

The science of treating addictions has evolved considerably. Treatment has progressed from viewing it as a character flaw or sign of weakness to thinking of addiction as a chronic brain disorder that results from genetic and environmental inputs.

Any patient or client with active substance abuse issues may be presumed to have nutritional deficiencies. It may be useful to do nutritional testing, especially to document the more dangerous conditions such as thiamin deficiency (see Chapter 7). However, in an acute setting it is critical and may even be lifesaving to presume that B vitamin and magnesium deficiencies are present, and treat them rather than wait for laboratory results.

Acute alcohol withdrawal is a unique case of an addiction-related medical emergency that requires prompt nutritional treatment. Other addictions and deficiencies may be addressed over a few weeks or months.

Medical Nutrition Therapy

Medical nutritional therapy for addictions should be individualized, taking into account the current nutritional status of the patient. Some addicts may be homeless and clearly malnourished, whereas others may have less visible deficiencies. Special attention must be given to B vitamins, magnesium, and amino acid deficiencies (see Chapter 29). When possible, the best approach is to evaluate each patient for deficiencies through blood work and then replete as needed or assume poor nutritional status and provide a broad multivitamin/mineral supplement and a diet containing high-quality protein and fats. When gastritis or other intestinal problems are evident, these must be treated to allow for adequate digestion and absorption of nutrients.

Providing adequate levels of amino acids, B vitamins, minerals and omega-3 fatty acids generally stabilizes function in a patient dealing with addiction of any kind. As seen with many psychiatric disorders, magnesium and NAC are also very helpful in addiction recovery (Bondi et al, 2014; McClure et al, 2014).

BOX 41-6 Summary of Medical Nutrition Therapy for Substance Abuse

If warranted by history, assess for high risk alcohol consumption.
 Assess appetite, nausea, and potential changes in food consumption.
 Assess oral health and missing teeth, and chewing ability.
 Start multivitamin-mineral supplement; recommend use for 6 months.
 Recommend supplement of omega-3 fatty acids: 800 to 1000 mg/day.
 Recommend biochemical assessment of thiamin, iron, folic acid, Mg, Se.
 Recommend 25% to 30% of calories in diet from high quality protein.
 Liberal nutritionally adequate diet (300-450 mg caffeine, moderate use of desserts to mediate withdrawal, moderate fiber and adequate fluid intake, inclusion of dairy foods)
 Recommend attendance at nutrition education group as early as possible during withdrawal

Reference: Weiss, D: *Nutrition interventions in addiction recovery: the role of the dietitian in substance abuse treatment*. Webinar, September 25, 2013.

Addressing specific neurotransmitter issues can be very useful. Whether a patient is self-medicating to overcome neurotransmitter imbalances or has imbalances brought on as a result of the addiction, bringing balance back to neurotransmitter levels is part of management and recovery. Providing amino acid supplementation can support neurotransmitter production. Specifically, tyrosine is essential for production of dopamine, whereas tryptophan is required for serotonin production. Using tyrosine at 500 mg twice a day, or adding tyrosine-rich foods may help boost dopamine levels and reduce the risk of relapse. Tyrosine-rich foods include duck, chicken, ricotta cheese, dark chocolate, and seaweed (see Box 8-4 for more foods rich in tyrosine and its decarboxylated product tyramine).

Protein malabsorption is common among alcoholics and addicts in general. Supporting digestive function using plant-based digestive enzymes, which work across a much wider pH range than animal-sourced enzymes, may also be helpful in promoting nutritional sufficiency.

Finally, educating addicts about brain function and nutrition enhances their ability to participate successfully in a recovery program, and empowers them to make healthy choices while also understanding the mechanism of addiction (see Box 41-6).

ANXIETY

According to the Centers for Disease Control (CDC), the prevalence rates for anxiety disorder in developed countries range from 13.6% to 28.8% of the population, and is higher in developed nations than in developing nations. The underlying etiology of anxiety is not well understood. Different forms of anxiety include generalized anxiety disorder (GAD), panic disorder, obsessive compulsive disorder (OCD), posttraumatic stress disorder (PTSD), and social anxiety disorder (see Table 41-2). Common to all these disorders are heightened and poorly controlled emotional, somatic, and neurologic symptoms triggered by a specific type of circumstance or situation, or in the case of GAD, not related to any specific trigger.

Etiology

At one level, **anxiety** expressed as a heightened awareness of one's surroundings and of potential danger can be seen as an evolutionary advantage in terms of dealing with threats. However, when this mechanism becomes pervasive and debilitating, it moves into the realm of pathology.

There is a clear genetic component to anxiety. Early life stress may constitute a significant etiologic factor for anxiety. It is felt that the anxiety and panic response becomes "hard-wired" responses at an early age that create hormonal and brain patterns that become entrenched.

Pathophysiology

The structure in the brain thought to generate anxiety is the amygdala (the threat center), which processes fear-related stimuli and then signals other parts of the brain (especially the locus ceruleus) to fire and release norepinephrine; corticotropin-releasing factor (CRF), which ultimately stimulates elevated cortisol levels; and other excitatory components of the sympathetic nervous system. Glutamate is being recognized as playing an increasing role in anxiety disorders (as well as in depression) and is a target for pharmacologic and nonpharmacologic treatment (European College of Neuropsychopharmacology, 2013).

BOX 41-7 MNT for Management of Anxiety

- Assess for vitamin D, magnesium, and B vitamin status (see Chapter 7).
- Reduce caffeine intake.
Eliminating caffeine for 3 to 4 weeks is recommended to see if anxiety decreases. Warn the person about withdrawal for 7 to 10 days, including headaches. Cutting intake in half every 4 to 7 days may avoid this. Switching from coffee to green tea can also be helpful as it has less caffeine and contains theanine, a calming amino acid. Anxiety may be triggered by even low doses of caffeine (the amounts in decaffeinated coffee); a switch to caffeine-free teas may be necessary.
- Reduce intake of sucrose and other forms sugar.
- Add a multivitamin containing high doses of B vitamins and minerals including copper, chromium, zinc, and selenium plus 200 mg per day of magnesium.
- Increase high-quality protein intake throughout the day.

Complementary Therapies for Anxiety

- **Theanine:** Derived from green tea—doses of 200 mg 1 to 4× per day are helpful (Unno et al, 2013). L-theanine is involved in the formation of the calming neurotransmitter, gamma amino butyric acid (GABA), and also stimulates the release of serotonin and dopamine.
- **Passion flower extract:** Doses of 100 to 500 mg 1 to 4× per day can be helpful (Movafegh et al, 2008).
- **Magnolia:** Magnolia bark has a long history of use in traditional Chinese formulas that relieve both anxiety and depression without the feeling sedation (Talbot et al, 2013).

- **Lavender:** The smell of lavender is calming, so keeping a vase full of lavender flowers (even dried) around or using a lavender oil spray can be helpful. In addition, taking a lavender capsule can be calming and reduce the need for tranquilizers (Woelk and Schlafke, 2010).
- **Inositol:** Can be helpful in treating anxiety and panic disorders, and is very safe. In high doses may be valuable in controlling several other mental health disorders, including panic disorder, obsessive compulsive disorder, agoraphobia, and depression.
- **GABA:** Deficiency of the neurotransmitter GABA is associated with anxiety, with GABA being a primary counterbalance for the excitatory neurotransmitter glutamate (Lydiard, 2003).

- Woelk H, Schlafke S: A multi-center, double-blind, randomised study of the Lavender oil preparation Silexan in comparison to Lorazepam for generalized anxiety disorder, *Phytomedicine* 17:94, 2010.

Difficult life circumstances that provoke stress can exacerbate underlying anxiety disorders and may be helpful to address with counseling. These can include marital and relationship stress and job stress, as well as physiologic stressors such as sleep disorders, menopause, thyroid disease, and food allergies. Hormonal imbalances, including high or low thyroid, low progesterone, and high or low testosterone levels, can also trigger anxiety. Anxiety can be a presenting complaint of perimenopause and of high or low cortisol levels, reflecting adrenal gland dysfunction.

Anxiety provokes physical and emotional symptoms, including rapid heart rate, shallow breathing, diaphoresis, hypervigilance, and sleep disorders. It can be difficult at first to diagnose anxiety, because patients present with multiple somatic complaints, and only after somatic pathology is ruled out can a diagnosis of anxiety disorder be established.

Medical Management

The primary pharmacologic therapy for anxiety disorders includes benzodiazepines, selective serotonin reuptake inhibitors (SSRIs), and norepinephrine reuptake inhibitors. Medications used primarily for other conditions can be useful in the treatment of anxiety, such as gabapentin, buspirone, and antipsychotic medications. Each of these can be effective but not for everyone. Each of these treatments carries the potential for side effects.

Medical Nutritional Therapy

Nutritional therapies that target the underlying metabolic causes of anxiety can be effective. Reactive hypoglycemia can trigger anxiety and should be suspected if attacks are worse in the late morning or afternoon (i.e., after several hours without food) or 30 to 60 minutes after a sugary meal or drink. Caffeine aggravates this, causing even more severe hypoglycemic symptoms (Gaby, 2011).

Nutritional deficiencies are common, especially of vitamin D (Armstrong et al, 2007), B vitamins, and magnesium. Magnesium deficiency can cause anxiety and anxiety also can cause increased

magnesium losses. In hospitalized patients, two studies have shown that parenteral magnesium (e.g., 2 g IV over 1 hour, then 1 gm per hour for 1 to 3 days) significantly decreased severe anxiety and agitation in agitated psychiatric inpatients. A multivitamin with 100 mg magnesium and high-dose B vitamins was shown to decrease anxiety in a placebo-controlled study. Treatment with doses of B vitamins above RDA recommendations has also been shown to help a number of different types of anxiety, whether or not deficiency was present (Gaby, 2011). Box 41-7 presents MNT and herbal support for anxiety management.

Complementary therapies may also be helpful and usually carry much lower risks than medications (Aramadhan 2012).

BIPOLAR DISORDER

This is also called bipolar affective disorder, or manic depressive disorder. “Mood Disorders” in the *DSM-IV* has been replaced with separate sections for depressive disorders and bipolar disorders. Bipolar disorder is placed between the psychotic disorders and the depressive disorders in the *Diagnostic and Statistical Manual of Mental Disorders (DSM5)*, “in recognition of its place as a bridge between the two diagnostic classes in terms of symptomatology, family history and genetics” (Parker, 2014). The criteria for the major psychotic disorders and mood disorders are largely unchanged in the *Diagnostic and Statistical Manual of Mental Disorders*, fifth edition.

Bipolar disorder is a disorder in which people experience episodes of an elevated or agitated mood known as mania alternating with episodes of depression. The National Institute of Mental Health (NIMH) reports the 12-month prevalence of bipolar disorder in the U.S. adult population is approximately 2.6% and the lifetime prevalence is about 4%. The average age of onset is 25 years (National Institute of Mental Health, 2015). There is a genetic component, but other factors, including hormones, neurotransmitter abnormalities, and stress, are likely to be factors in triggering this illness.

Pathophysiology

Symptoms occur with different levels of severity. At milder levels of mania, known as hypomania, individuals appear energetic, excitable, and may be highly productive. As mania becomes more severe, individuals begin to behave erratically and impulsively, and may have great difficulty with sleep. Behavior may include alcohol abuse, sexual indiscretion, and excessive spending. Eating disorders are a potential comorbidity. The manic phase may result in difficulty in planning and preparing food.

During the depressed phase, 25% to 50% of patients attempt suicide. At the most severe level, individuals can experience psychosis. **Bipolar disorder** has recently been subdivided into Bipolar I (involving cycles of severe mood episodes from mania to depression) and Bipolar II (in which milder episodes of mania are mixed with bouts of severe depression) (see [Table 41-2](#)). Some individuals experience a mixed state in which features of mania and depression are present at the same time. Manic and depressive episodes last from a few days to several months.

Medical Management

A number of medications are used with varying degrees of success. Medical treatment of bipolar disease is complex and requires frequent monitoring by skilled clinicians. Lithium, a classic treatment, is considered benign when used as lithium orotate at low doses (e.g., 5 mg a day), but when used at high doses as lithium carbonate, can cause marked toxicity, including hypothyroidism, renal toxicity, and tremor. Lithium carbonate has a narrow therapeutic index; there is not a large difference between a toxic and therapeutic dose, and blood levels must be closely observed. Other medications used to treat bipolar disorder are mood stabilizers, benzodiazepines, and antipsychotic medications.

The presence of MTHFR reductase genetic mutations should be determined. Some genetic mutations associated with a higher risk of bipolar disorder respond to nutritional treatments of methyl folate (5-MTHF) and methylated B₁₂.

Medical Nutritional Therapy

Lithium and sodium are similar in chemical binding; therefore a stable, moderate, intake of salt and sodium is necessary to help stabilize lithium levels. A diet low in sugar and caffeine may also be helpful and is worth exploring with individual patients.

Many people starting a course of lithium experience significant dose-dependent weight gain, often resulting in noncompliance with medication. Other side effects that may affect nutritional status include increased thirst, nausea, vomiting, and diarrhea.

Studies have shown that areas with lower levels of lithium in the tap water have higher suicide rates. The usual daily intake of lithium from the diet is 0.65 to 3.1 mg/day. ([Kapusta et al, 2011](#)).

New information relates bipolar disorder to mitochondrial dysfunction, which opens the door to treating bipolar disease with mitochondrial modulators such as coenzyme Q10, n-acetylcysteine (NAC), acetyl-L-carnitine (ALCAR), S-adenosylmethionine (SAME), alpha lipoic acid, creatine monohydrate, and melatonin ([Nierenberg et al, 2013](#)). This suggests disruption of brain energy metabolism and its relationship to mood disorders and psychiatric disease.

Potentially useful supplements include the following:
Fish oil: high doses of 9.3 g a day of omega-3 oils have been helpful ([Gaby, 2011](#)).

NAC (N-acetylcysteine): 1000 mg twice per day. This significantly improved symptoms relative to placebo in 24 weeks ([Berk et al, 2008](#)).

Magnesium: 300 to 600 mg a day. Magnesium has effects that are similar to lithium, but without the toxicity ([Gaby, 2011](#)). Iron excess is also associated with an increased risk of bipolar disorder, so a screening serum ferritin level is warranted to ensure that it is within normal range ([Serata et al, 2012](#)).

Evaluation for mineral and trace element deficiencies is warranted and empiric therapy with a multiminerals is likely to have limited risk and may indeed be helpful ([Kaplan et al, 2001](#)).

As with other mood and psychiatric disorders, evaluating for the presence of celiac disease or gluten sensitivity is warranted ([Dickerson et al, 2011](#)). In nonceliac gluten sensitivity (NCGS), serum and intestinal signs may be absent, but clinical symptoms are reported, and clear within a few days of starting a gluten-free diet. Emerging scientific literature contains several reports linking gluten sensitivity states with neuropsychiatric manifestations including autism, schizophrenia, and ataxia ([Genius and Lobo, 2014](#)).

DEMENTIA AND ALZHEIMER'S DISEASE (AD)

Mild cognitive impairment (MCI) is an intermediate stage between the expected cognitive decline of normal aging and the more serious decline of dementia. It can involve problems with memory, language, thinking and judgment that are greater than normal age-related changes.

Dementia represents a serious loss of cognitive ability. It may be stable and nonprogressive, as may occur after brain injuries, or it may be progressive, resulting in long-term decline due to damage or disease in the body. Two of the most common causes are Alzheimer's disease (AD) and vascular disease (called multi-infarct dementia). Other less frequent causes are Parkinson's dementia and Lewy body dementia.

Three and a half million Americans have **vascular dementia** caused by poor circulation to the brain and multiple mini-strokes. This syndrome can result from (1) atherosclerotic vascular disease, (2) an embolism usually from the heart due to vascular or arrhythmic disease, (3) poorly controlled hypertension, or (4) an increased tendency to clotting for reasons either inherited or acquired. Recognition of vascular dementia with AD is often delayed until the syndrome is far into its course. Vascular dementia should be considered if the progression of the cognitive dysfunction has progressed in discrete steps, each representing another ministroke.

AD affects almost 5.3 million Americans ([Alzheimer's Association, 2015](#)). The most proven risk factor for AD is advanced age. Other factors that have been shown to be associated with higher risk of AD include a positive family history of AD, suboptimal folate intake or metabolism, the presence of APOE-4 alleles, female gender, cardiovascular disease, head injury, Down's syndrome, and low educational level. Recent research also links the oxidative stress of air pollution to AD risk ([Zhao and Zhao, 2013](#)). Diabetes mellitus is also a risk factor for the development of AD.

Pathophysiology

Alzheimer's disease is associated with loss of neurons, characterized by microscopic changes in the brain, which include deposition of amyloid plaques, tau proteins, and neurofibrillary tangles. The only definitive test for diagnosing AD is a brain biopsy, which, appropriately, is not done. For evaluating dementia the American Academy of Neurology recommends structural neuroimaging, which may include CT or MRI, and screening for depression, vitamin B₁₂ deficiency, and hypothyroidism. A recent study demonstrated potential use of a blood test for 10 lipids (eight phosphatidylcholines and two acetyl-carnitines) as the

best combination lipid blood test panel. A sample of peripheral blood predicted with more than 90% accuracy the development of either amnesic mild cognitive impairment or AD within a 2- or 3-year time frame (Mapstone et al, 2014).

Medical Management

Only half of people with dementia seen by physicians in general practice receive even the basic workup discussed earlier. In only 35% is the correct cause of the dementia determined, and these workups are generally conducted in higher level (secondary care) hospital settings.

A study of autopsies showed that in half the people who had been diagnosed with AD, AD was not seen on their brain biopsy. Rather, they had other causes of dementia that were missed (White, 2011). Although problematic, this also suggests that by looking for and treating nutritional and other issues, function may be improved—sometimes markedly.

Even small changes in brain function can make the difference between being able to care for oneself versus not recognizing one's children. People with dementia can have marked day-to-day fluctuations in cognition. Several types of treatment, including nutritional support and attention to adequate hydration, may significantly improve cognitive function.

It is critical that the practitioner always consider the possible presence of a treatable condition when evaluating a patient for dementia. Examples of treatable and even reversible causes of cognitive decline and memory loss include hormonal imbalances, brain tumors, infections, nutritional deficiencies (e.g., folate and vitamin B₁₂), and the side effects of numerous medications (see *Focus On: Polypharmacy in Older Adults* in Chapter 8).

It is also important to distinguish between normal fluctuations in mental function and dementia. AD is not when one keeps forgetting where one left the keys. It's when one forgets how to USE the keys. In addition, the stress of hospitalization, with poor sleep, loss of routine and familiar surroundings, being restrained and given strong psychoactive medications to treat agitation, and poor diet (e.g., being kept repeatedly NPO for tests, or dietary restrictions from acute illness) may trigger disorientation that may be confused with dementia, and which, if addressed, may be reversible. Sometimes it is the hospitalization itself that triggers a self-perpetuating (and potentially entirely reversible) chain of events that leaves the patient delirious or cognitively impaired, which then comes to be labeled as dementia. Getting the person into familiar surroundings as early as possible, off potent psychoactive medications, out of restraints, and eating a nutritious diet are important keys to treatment, management, and potentially improvement. Other factors may also optimize cognitive function (see *Box 41-8*).

The medical management of vascular dementia involves decreasing or eliminating further vascular insults to the brain. Treatment may include using aspirin, cholesterol, and blood pressure-lowering agents, and medically managing heart disease when present.

The medical therapies available for AD are currently limited to (1) acetylcholinesterase inhibitors such as donepezil (Aricept), aimed at maintaining levels of acetylcholine in the brain, and (2) memantine (Nemanda), an N-methyl-D-aspartate (NMDA) receptor antagonist aimed at reducing glutamate activity, which is excitatory and destructive of brain tissue. Some benefit can be gained from combining these two classes of drugs. Although these medications are generally well tolerated and can modestly slow progression, they often do little to improve symptoms day to day.

BOX 41-8 Optimizing Cognition in DEMENTIA

Drugs: Wean the person off drugs that are not essential. Being on 10-15 drugs (polypharmacy) is not uncommon in the elderly and can result in abnormal behavior. Anticholinergic medications are especially problematic.

Emotional: Rule out depression and make sure the person gets adequate sleep. Nutritional support with theanine, herbals, and even the smell of lavender can help sleep without increasing the risk of falling and injury.

Metabolic: Hormonal deficiencies, especially thyroid and testosterone, dramatically increase the risk of Alzheimer's disease. Levels of these hormones must be optimized. Making sure that the person is getting at least the 150 µg RDA of iodine a day is important for maintaining optimal thyroid function (Carcaillon, 2013; Tan et al, 2008) (see Chapter 31).

Ears and eyes: Hearing and vision loss can mimic dementia.

Nutrition: Optimize nutritional intake.

Tumors and other brain lesions: An MRI or CT scan is appropriate if one is diagnosed with dementia.

Infections: Silent urine and sinus infections can impair mental function.

Anemia, diabetes, and other overt medical problems should be assessed for and treated.

Carcaillon L et al: Low testosterone and the risk of dementia in elderly men: impact of age and education, *Alzheimers Dement* 10(Suppl 5): S306, 2014.

Tan ZS et al: Thyroid function and the risk of Alzheimer disease: the Framingham study, *Arch Intern Med* 168:1514, 2008.

Medically managing diabetes and insulin resistance is critical to delaying progression of dementia of any type. Hyper- and hypoglycemia as well as unchecked insulin resistance can cause damage to brain structures (Northam and Cameron, 2013) (see *New Directions: Insulin Resistance and AD and the SNIFF Study* [Schlöth et al, 2012]).

NEW DIRECTIONS

Insulin Resistance in AD and The SNIFF Study

Severe insulin resistance in some areas of the brain is present in AD. Brain tissue is one of the few tissues outside of the pancreas that produces insulin, and glucose is the fuel brain cells commonly use. If insulin resistance is present, glucose cannot enter brain cells and the cells essentially starve and cannot function, unless they switch to using ketones for fuel. This suggests that treatment of insulin resistance and metabolic syndrome may be useful in the prevention of or slowing the progression of AD (Willette et al, 2014).

This makes exercise, avoiding excess sugar and saturated fats, and increasing fiber intake especially important. Even just 4 weeks of cutting back on sugar and saturated fats was associated with increased insulin sensitivity and decreased amyloid (Hanson, 2013). Intranasal insulin at 10 or 20 IU 2×/day is currently being tested in an Alzheimer's Randomized Controlled Trial (the SNIFF (Study of Nasal Insulin to Fight Forgetfulness) study) (Claxton et al, 2015; Morris JK et al, 2014; Reger et al, 2008). See http://www.alz.org/research/video/alzheimers_videos_and_media_insulin.asp.

Another dietary goal may be to increase the level of ketones in the blood and brain. The brain can use ketones as fuel, and their metabolism does not require insulin (Paoli et al, 2014). Ketones can be increased by adding approximately 7 tsp a day of coconut oil to the diet, or even more effectively by using medium-chain triglyceride (MCT) oils. The role of ketones and ketogenic agents in prevention and management of AD continues to be researched (Sharma et al, 2014).

The "4 As" of AD point to the sequential changes in brain function, behavior, and performance that impair the individual

BOX 41-9 The 4 As of Alzheimer's Dementia

Amnesia: The inability to use or retain memory, including short-term and long-term memory.

The person may constantly repeat questions such as “Where am I?” and “Who are you?” and “When are we going to eat?” or accuse the caregiver of stealing or being an imposter. This type of behavior can continue for hours at a time. This occurs due to damage to the frontal lobes and the hippocampus. This is usually the first area of change noticed by others. At this level of amnesia, the person with dementia does not look ill, so the confusion and inability to remember can appear to be purposeful and is often interpreted as just “annoying” behavior.

NUTRITIONAL IMPACT: May forget to eat, or not trust the caretaker involved in meal preparation or service.

Aphasia: The inability to use or understand language.

The loss of the ability to speak and write is called *expressive aphasia*. An individual may forget words he has learned and will provide a lengthy description of an item because he or she cannot find the right word. He may call family members by the wrong names. With *receptive aphasia*, an individual may be unable to understand spoken or written words or may read and not understand a word of what is read. Sometimes an individual pretends to understand and even nods in agreement; this is to cover up aphasia. Although individuals may not understand words and grammar, they may still understand nonverbal behavior (i.e., smiling).

NUTRITIONAL IMPACT: May not articulate wants, needs, or requests when it comes to eating.

Apraxia: The inability to use or coordinate purposeful muscle movement or coordination.

In the early stages the person may reach for an item and miss it. He or she may have difficulty catching a ball or clapping his or her hands. The floor may appear to be moving to this person and balance becomes affected, increasing the risk for falls and injury. In time, this loss of ability to move affects the Activities of Daily Living (sleeping, ambulating, toileting, grooming, hygiene, dressing, and eating). In the end stage, the person is not able to properly chew or swallow food, increasing the risk of choking or aspiration. This is linked to damage to parietal lobes (pain, touch, temperature and pressure, sensory perception) and the cortex (skilled movement) and the Occipital lobes.

NUTRITIONAL IMPACT: Physically unable to eat, chew, or swallow.

Agnosia: The inability to recognize people, or use common objects.

The person may become lost in a familiar place because he or she doesn't recognize the items that alert us to our surroundings. He or she may confuse a fork with a spoon, a toothbrush with a hairbrush, or toothpaste with denture cream. Eventually the ability to recognize objects is lost completely. The person may also confuse a son with a husband or a father or an uncle, or a daughter may be confused with a mother or an aunt or a grandmother. This process is associated with increased damage to the frontal lobes, the occipital lobes (visual association, distance and depth perception), and the temporal lobes.

NUTRITIONAL IMPACT: May not be able to use normal eating utensils or may even forget how to feed him or herself.

Reference: *Alzheimer's Foundation of America: About Alzheimer's.* <http://www.alzfdn.org/AboutAlzheimers/symptoms.html>, 2014. Accessed January 30, 2015.

and ultimately can make adequate nutritional intake difficult to maintain (see **Box 41-9**). Specific techniques that take into account the brain deficits must be implemented to improve the ability to eat and enjoy food. An occupational therapist can offer assistance in a dining needs assessment.

Medical Nutritional Therapy

Recent evidence has emerged supporting the connection between dietary intake and cognitive health, particularly in regard to the ageing population. A healthier diet during middle-age years (adequate amounts of B vitamins, antioxidants, polyunsaturated fatty acids, phytonutrients [*Valls-Pedret et al, 2012*],

and nitrites and nitric oxide [*Justice et al, 2015*]) has been associated with better cognitive function later in life. The MIND (Mediterranean-Dietary Approach to Systolic Hypertension (Dash) diet intervention for neurodegenerative delay) diet has been found to substantially slow cognitive decline with aging. [*Morris et al, 2015*] See Appendices 26 and 31.

Three parameters of cognition (delayed recall, learning ability, and memory) were significantly associated with Hb A_{1c} levels in the range of 4.3% to 6.5%, illustrating the effect of even moderate blood glucose levels [*American Academy of Neurology, 2015; Kerti et al, 2013*].

The metabolic consequences of a high fructose intake and a deficiency of omega-3 fatty acids on cognitive abilities was associated with insulin action, signaling mediators, and lower cognitive scores. Insulin is a vasodilator. This vasodilator function is blunted in insulin-resistant individuals, and decreases cerebral circulation [*Agrawal and Gomez-Pinilla, 2012; Barrett et al, 2009*]. Insulin resistance and impairment of the insulin receptor signaling cascade in the hippocampus may be accompanied by decreasing regional blood flow and reduced memory. Vasoprotective effects that include improved cerebral bloodflow have been shown to be associated with a whole-food-based diet [*Presley et al, 2011*].

One of the most important nutrients for the prevention of AD is folic acid. A long-term study using data from the Baltimore Longitudinal Study of Aging, which was begun in 1958 and included more than 1400 participants, found that the participants who had intakes at or above the 400 mcg RDA for folate had a 55% reduction in the risk of developing AD [*Corrada et al, 2005*]. Most people who reached that level did so by taking folic acid supplements, which suggests that many people do not get the recommended amounts of folate in their diets. In another study adding folate at 1 mg a day to the anticholinesterase medications used in AD resulted in improved functional status [*Connelly et al, 2008*]. Overall, multivitamins were shown to result in improvement in immediate free recall memory [*Grima et al, 2012*]. A multivitamin, preferably with higher than RDA doses of vitamin B₁ and 400 to 1000 mcg/day of folate, is recommended.

Inadequate levels of vitamin B₁₂ can affect the risk for developing AD and dementia. Low vitamin D levels and function have also been implicated as playing a major role in AD [*Gezen-Ak et al, 2014*]. Vitamin E may help slow progression, but only if a mixed natural tocopherol containing gamma tocopherol is used. Most vitamin E supplements are synthetic alpha tocopherols, which not only increase risk of vitamin E deficiency, but do not help AD. The high levels of alpha tocopherol (more than 100 IUs/day) can induce a relative deficiency of the other tocopherols. Because of this, supplementation with vitamin E at doses more than 100 IU is not recommended, unless a natural mixed tocopherol is used [*Usoro and Mousa, 2010*].

Proper probiotic and prebiotic support is also important. There is growing evidence in the literature that the microbiome composition, species, identity and combinations, density, and distribution of these bacteria may influence how well we age. As innate immunity predominates over time certain bacteria proliferate, triggering an inflammatory response such as from tumor necrosis factor-alpha (TNF-alpha).

The integrity of the blood-brain barrier (BBB) becomes more difficult to maintain as the bacterial load and sustained TNF-alpha response occurs. In conditions such as AD, genetic polymorphisms that favor jawbone resorption during inflammation result in increased periodontal pocket depth. This provides the

perfect environment for oral anaerobes most closely associated with AD. These conditions in combination with predisposing genetic polymorphisms may increase the propensity for bacteria or endotoxins to gain access to the brain, triggering neuropathology and altering brain function (Shoemark and Allen, 2014).

Advanced glycation end products (AGEs) are implicated in the initiation and progression of Alzheimer-type dementia (Cai et al, 2014). Advanced glycation end products, also known as glycotoxins, are a diverse group of highly oxidant compounds created through a nonenzymatic reaction between reducing sugars and free amino groups of proteins, lipids, or nucleic acids. The formation of AGEs is a part of normal metabolism, but excessively high levels of AGEs in tissues and the circulation can become pathogenic. AGEs promote oxidative stress and inflammation by binding with cell surface receptors or cross-linking with body proteins, altering their structure and function. In addition to AGEs that form within the body, AGEs also exist in foods. AGEs in foods are formed during dry cooking of food, particularly baking, roasting, and frying. AGEs are absorbed and contribute significantly to the body's AGE pool (Uribarri et al, 2010).

Low levels of the omega-3 essential fatty acids DHA are present in those with dementia. Increasing omega-3 fat or fish oil intake is more likely to be helpful in those with mild cognitive defects than in those with severe AD (Freund et al, 2014). Krill oil is another substitute for fish oil in treating cognitive decline.

AD is 70% less common in India than in the United States, and this is thought to be due to a diet high in turmeric (curcumin—the spice that makes Indian curries yellow) (Rigacci and Stefani, 2015). A double-blind study, supplementing curcumin in the diets of people with AD is currently underway. Curcumin is poorly absorbed, however, so it is important to use a highly absorbed form such as BCM-95, whose absorption is 693% higher than 95% pure curcumin (Antony et al, 2008; Benny and Antony, 2006), and more than 35,000% higher than an equivalent weight of turmeric (Cuomo et al, 2011). Supplementing AD patients with BCM 95 curcumin resulted in blood amyloid changes suggestive of amyloid breakdown (Baum et al, 2008). Combining curcumin and vitamin D was also associated with increased amyloid clearance by macrophages (Masoumi et al, 2009; see Box 41-10). Curcumin may be generally neuroprotective, also showing benefit in Parkinson's disease (Pan 2012).

Other natural therapies that support brain and cognitive function include huperzine, acetylcholine, and **alpha-lipoic acid**,

BOX 41-10 MNT for Alzheimer's Disease

A multivitamin supplement containing at least 400 mcg of folate, 1000 IU of vitamin D, and 500 µg of B₁₂. If the serum vitamin B₁₂ level is under 300 pg/ml or serum homocysteine or methylmalonic acid are elevated, a trial of vitamin B₁₂ injections is reasonable.

Iron deficiency may be present despite technically normal ferritin (a key laboratory measure for iron) levels. Especially if anemia, cognitive dysfunction, or restless leg syndrome are present, it is reasonable to keep the ferritin level at least 60 mcg/l (ng/ml) or higher. Using the standard ferritin cutoffs of 12 and 20 mcg/l (ng/ml) (in females and males respectively) to diagnose iron deficiency is ill advised, as ferritin levels can be higher than this in as many as 92% of people with severe iron deficiency based on bone marrow biopsy.

Add 750 to 3000 mg a day of a highly absorbed BCM-95 curcumin product (Baum, 2008).

Manage blood glucose, lipid, and insulin levels to achieve normal levels.

Baum L et al: Six-month randomized placebo-controlled, double-blind, pilot clinical trial of curcumin in patients with Alzheimer's disease, *J Clin Psychopharmacol* 28:110, 2008.

all of which are natural agonists of acetylcholine receptors (see *New Directions: Something New in AD Management?*)

NEW DIRECTIONS

Something New in AD Management?

Phosphatidylserine may offer neuroprotection by inhibiting the formation of beta amyloid fragments. Early studies using bovine phosphatidylserine showed positive results in those with cognitive decline, but the compound was replaced with a soy-based phosphatidylserine because of fears of mad cow disease. However, the evidence supporting the improvement in age-related memory impairment associated with the soy-based compound is weaker; overall results are inconclusive and more research is needed (Wollen, 2010).

Phosphatidylcholine is a component in nerve cell membranes and may offer protection from degeneration. Cytidinediphosphocholine (CDP-choline), a precursor, has shown the most promise (Fioravanti and Yanagi, 2010). Research studies investigating the benefits of CDP-choline have been short but indicate possible positive effects on memory and behavior in patients with various forms of dementia, including AD. Longer-term studies are needed to investigate full benefits.

DEPRESSION

Major depressive disorder (MDD) is a common and costly disorder that is usually associated with severe and persistent symptoms, leading to social role impairment and increased mortality. Major depressive disorder is one of the most important causes of disability worldwide (WHO, 2012). There are multiple factors contributing to the development of **depression**, including genetics, nutrition, environmental stressors, hormonal disruption especially in the hypothalamic pituitary adrenal (HPA) axis, and alterations in neurotransmitter biology and function (the monoamine deficiency theory).

This range of factors and the relative contribution of each to the development of depression in an individual is likely an important reason for the variability of individual response to specific therapies. Thus viewing depression as a heterogeneous condition is useful and demands that the health care provider consider each patient's individuality (see Table 41-2 and Box 41-11).

BOX 41-11 Diagnostic Criteria for Major Depression

- Depressed mood or a loss of interest or pleasure in daily activities for more than 2 weeks.
- Mood representing a change from the person's baseline.
- Impaired function: social, occupational, educational.
- Specific symptoms, at least 5 of these 9, present nearly every day:
 1. Depressed mood or irritable most of the day, nearly every day, as indicated by subjective report (e.g., feels sad or empty) or observation made by others (e.g., appears tearful)
 2. Decreased interest or pleasure in most activities, most of each day
 3. Significant weight change (5%), or change in appetite
 4. Change in sleep: insomnia or hypersomnia
 5. Change in activity: psychomotor agitation or retardation
 6. Fatigue or loss of energy
 7. Guilt/worthlessness: feelings of worthlessness or excessive or inappropriate guilt
 8. Concentration: diminished ability to think or concentrate, or more indecisiveness
 9. Suicidality: Thoughts of death or suicide, or has suicide plan

American Psychiatric Association (APA): *Diagnostic and Statistical Manual of Mental Disorders*, ed 5, Arlington, Va, 2013, American Psychiatric Association.

Pathophysiology

The monoamine deficiency theory of depression suggests that a deficiency of the monoamines serotonin, dopamine, and norepinephrine, or altered monoamine receptor function in the central nervous system is the main pathophysiologic factor in depression. This theory has provided a target for the most common pharmacologic methods of treating depression.

In addition to the dietary decrease in fish oils and omega-3 fatty acids already discussed, other factors contribute to depression, including nutritional and hormonal deficiencies. In depression not responsive to antidepressants, a good response is seen using the T3 thyroid hormone despite normal thyroid tests. No significant improvement was seen with T4, the thyroid hormone most often used (Posternak et al, 2008). T3 has also been shown to be helpful in resistant bipolar depression (Kelly and Lieberman, 2009). Testosterone deficiency in men causes depression. Symptoms suggestive of depression can arise in the perimenopausal state and appropriate therapy including bioidentical hormone therapy can be a useful in addressing this (Joffe, 2011).

As discussed earlier, epidemiologic research has identified associations between lower seafood consumption and increased rates of depression around the world. Dozens of clinical studies using EPA and DHA omega-3 supplements for depression have been conducted, and results are mixed but generally positive (Martins, 2009).

Medical Management

Standard treatment of major depression includes pharmacotherapy as outlined in Box 41-12. Current pharmacologic therapy of depression is inconsistently effective (Garland, 2004).

Although a variable moderate percentage of depressed patients receive some benefit from pharmacologic therapy, a majority will not achieve full remission (see *New Directions: Can Genes Help Determine Psychopharmacologic Therapy?*)

There are pros and cons regarding whether antidepressant therapy surpasses the effect of placebo for mild to moderate depression (Insel, 2011; Kirsch et al, 2008). A thorough and instructive comparison of methods, assumptions, and the effect of media coverage written by Adrien Preda, MD, can be found at <http://blogs.plos.org/mindthebrain/2012/12/26/the-antidepressant-wars-a-sequel-how-the-media-distort-findings-and-do-harm-to-patients/> (Coyne, 2012). Other therapies include cognitive behavioral therapy (CBT), light therapy, and transcranial magnetic stimulation.

NEW DIRECTIONS

Can Genes Help Determine Psychopharmacologic Therapy?

Saliva-based genetic tests for genetic and biological markers can indicate the potential response to different psychiatric drugs. Analysis by a psychopharmacologist can help clinicians more quickly find effective treatment for patients with a range of psychiatric conditions, including depression, bipolar disorder, schizophrenia, anxiety disorders, obsessive compulsive disorders (OCD), and attention-deficit hyperactivity disorders (ADHD).

BOX 41-12 Common Medications Used to Treat Depression

- Selective serotonin reuptake inhibitors (SSRIs), such as fluoxetine, paroxetine, and sertraline among others
- Serotonin norepinephrine reuptake inhibitors, such as duloxetine and venlafaxine
- Norepinephrine-dopamine reuptake inhibitor-bupropion
- Older therapies including monoamine oxidase inhibitors and tricyclic antidepressants can be useful but are generally second-line therapies

Medical Nutritional Therapy

Fish oil supplements for treating depression are most effective with a composition of 60% EPA and 40% DHA. Supplements of fish oil with 60% EPA, using a dose of 200 to 2200 mg/day of EPA were effective against primary depression (Sublette and Ellis, 2011).

Curcumin appears to be a promising treatment for depression. A recent study showed a special highly absorbed form of curcumin (BCM 95 or CuraMed 500 mg 2×/day) to be effective for treating major depression after 8 weeks of use (Lopresti et al, 2014). Research has also shown this special, highly absorbed BCM 95 form of curcumin to be as effective as Prozac (Sanmukhani et al, 2014). Effectiveness of common curcumin is decreased because of poor absorption; the BCM 95 form used in these studies is needed for curcumin to be effective (Antony et al, 2008; Benny and Antony, 2006).

Vitamin B and magnesium deficiencies have also been linked to depression. Patients treated with 0.8 mg of folic acid/day or 0.4 mg of vitamin B₁₂/day show significant improvement (Young, 2007).

Several case reports also found that depressed patients treated with 125 to 300 mg of magnesium (as glycinate or taurinate) with each meal and at bedtime often had rapid improvement in cases of major depression in under a week (Eby and Eby, 2006).

For those with atypical depression, supplementation with chromium picolinate at 600 mcg/day was found helpful in decreasing cravings, but those treated with chromium and those receiving placebo demonstrated no difference in depression scores (Docherty et al, 2005). Key effects of chromium were on carbohydrate craving and appetite regulation.

Low serum zinc levels predispose people to treatment-resistance in depression. Repletion of zinc levels may augment otherwise ineffective therapies (Ranjbar and Shams, 2014). Mechanisms of action by zinc in reducing depressive symptoms include (1) decreasing dopamine reuptake (by binding to the dopamine receptor), (2) increasing the conversion of T4 to T3, and (3) the promotion of excitatory neurotransmitter function.

Nutritional approaches to augmenting serotonin and serotonin receptor response include the use of St John's Wort (see Chapter 12), 5-hydroxy-tryptophan (5-HTP), tryptophan, and vitamin D. S-adenosylmethionine (SAME) can be an effective additive therapy to treat major depressive disorders. Caution must be used in treating depression with St. John's Wort, tryptophan, and 5-HTP in patients being treated with serotonergic drugs, such as SSRIs, SNRIs, or tramadol to avoid triggering the **serotonin syndrome** (see *Focus On: Serotonin Syndrome*).

FOCUS ON

Serotonin Syndrome

If brain serotonin levels go too high, the result is **serotonin syndrome**. Serotonin syndrome encompasses a wide range of clinical findings.

- Mild symptoms may consist of increased heart rate, anxiety, and sweating, along with dilated pupils, tremor or twitching, and hyper-responsive reflexes.
- Symptoms of moderate elevation include hyperactive bowel sounds, high blood pressure, and fever.
- Severe symptoms include increases in heart rate and blood pressure that may lead to shock.
- Most often, excess serotonin occurs from combining serotonin raising medications (typically selective serotonin reuptake inhibitors, SSRIs). It may also come from adding 5 HTP, tryptophan, or herbs (e.g., St. John's Wort, Panax, Ginseng, nutmeg, or yohimbe) to high doses of medications which raise serotonin. Treatment is to cut back or stop these adjunctive treatments. Abruptly stopping antidepressants can cause severe withdrawal, so, except in severe situations, dosing is usually lowered rather than stopped completely (Undurraga and Baldessarini, 2012).

Although many clinicians are trained to think that the only presentation of serotonin syndrome is a febrile rigid state requiring emergency medical care, in milder forms patients are simply agitated and have muscle spasms. There is no way to diagnose this other than by clinical suspicion and altering the therapy to reduce serotonin levels and note if symptoms resolve.

In those with vitamin B₁₂ or folic acid deficiency and especially coexisting with a MTHFR (5-methyltetrahydrofolate reductase) methylation mutation or elevated homocysteine levels, optimizing B₁₂ and folic acid levels can significantly improve depression by using 5-methyltetrahydrofolate (5-MTHF) to bypass the inefficient folate metabolism and activation. 5-MTHF crosses the blood-brain barrier more readily than does standard folic acid. It is important to evaluate all patients with longstanding mood disorders, especially those with a family history of mood disorders, for a genetic methylation mutation of either COMT (catechol-O-methyl transferase) or MTHFR (methylene-tetrahydrofolate reductase) (see Chapter 5). These mutations are involved in inactivation of catecholamine neurotransmitters and are implicated in schizophrenia, OCD, ADHD, and depression as well as vascular disease, thrombotic stroke, homocystinuria, and homocystinemia.

FATIGUE, CHRONIC FATIGUE SYNDROME (CFS), AND FIBROMYALGIA SYNDROME (FMS)

Although research has shown that fatigue, **chronic fatigue syndrome (CFS)**, and **fibromyalgia syndrome (FMS)** are physical conditions, discussion of them here is included because cognitive dysfunction (often called “brain fog”) is a frequent symptom, and CFS and FMS are often poorly understood. Disorders such as CFS and FMS have a confusing array of diverse symptoms. Some experts believe that CFS and fibromyalgia are variations of the same process; they are discussed here as a single condition (CFS/FMS). Overt fibromyalgia affects approximately 2% of the population (Wolfe et al, 2013), and another approximately 2% have a milder intermediate form.

Women are affected twice as often as men. CFS and FMS can be caused by, and have overlapping symptoms with, autoimmune disorders such as systemic lupus erythematosus (SLE)

BOX 41-13 Effects of Insufficient, High-Quality Sleep

Alteration in moods: irritability, anger, greater risk for depression
 Lessened ability to cope with stress
 Decreased ability to learn
 Decreased memory
 Poor insight
 Impaired judgment
 Increased pain
 Immune dysfunction

Source: <http://www.webmd.com/sleep-disorders/excessive-sleepiness-10/emotions-cognitive>

or hypothyroidism. Viral pathogens, immune dysregulation, central nervous system dysfunction, musculoskeletal disorders, mitochondrial dysfunction, nutrient deficiencies, and other systemic abnormalities and allergies have been proposed as contributing factors in CSF/FMS.

Pathophysiology

Research suggests mitochondrial and hypothalamic dysfunction are common denominators in the syndromes of CFS/FMS (Cordero et al, 2010). Dysfunction of hormonal, sleep, and autonomic control (all centered in the hypothalamus), and energy production can explain the large number of symptoms and why most patients have a similar set of complaints.

Because the hypothalamus controls sleep, the hormonal and autonomic systems, and temperature regulation, it has very high energy needs for its size, so it malfunctions early in a shortage of energy. Similar to the circuit breaker in a house: if energy demands are too high, the body “blows a fuse.” It is protective but must be reset. In addition, inadequate energy stores in a muscle results in muscle shortening (think of writer’s cramp) and pain, which is further accentuated by the loss of deep sleep (see Box 41-13). The paradox of severe fatigue combined with insomnia, lasting more than 6 months, indicates the likelihood of a CFS-related process. If he or she also has widespread pain, fibromyalgia is probably present as well (see *Focus On: Fibromyalgia Diagnostic Criteria*).

FOCUS ON

Fibromyalgia Diagnostic Criteria

- Widespread pain index (WPI) ≥ 7 and symptom severity (SS) scale score ≥ 5 , or WPI 3 to 6 and SS scale score ≥ 9 .
- Symptoms have been present at a similar level for at least 3 months.
- The patient does not have a disorder that would otherwise explain the pain.

WPI (Widespread Pain Index)

Check each area below that you’ve had pain in over the last week. Score 1 point for each you check and enter the total score in the blank space provided.

- | | | |
|--------------------------|------------------------------------|--------------|
| • Shoulder girdle, left | • Hip (buttock, trochanter), left | • Jaw, left |
| • Shoulder girdle, right | • Hip (buttock, trochanter), right | • Jaw, right |
| • Upper arm, left | • Upper leg, left | • Chest |
| • Upper arm, right | • Upper leg, right | • Abdomen |
| • Lower arm, left | • Lower leg, left | • Upper back |
| • Lower arm, right | • Lower leg, right | • Lower back |
| | | • Neck |

_____ **Total WPI** (score 1 point for each item checked above)

FOCUS ON—cont'd

Fibromyalgia Diagnostic Criteria

SS (Symptom Severity)

- a. Rate each of the three symptoms below according to their severity you've experienced over the past week using the scale shown.
- 0 = No problem
 1 = Slight or mild problems, generally intermittent
 2 = Moderate, considerable problems, often present and/or at a moderate level
 3 = Severe: pervasive, continuous, life-disturbing problems
- ___ Fatigue
 ___ Waking unrefreshed
 ___ Cognitive symptoms ("brain fog")
- b. Rate each symptom below that you've experienced during the previous 6 months. Score 1 point for each you check.
- 0 = No problem
 1 = Slight or mild problems, generally intermittent
 2 = Moderate, considerable problems, often present and/or at a moderate level
 3 = Severe: pervasive, continuous, life-disturbing problems
- ___ Fatigue
 ___ Waking unrefreshed
 ___ Cognitive symptoms ("brain fog")
- b. Check each symptom below that you've experienced during the previous 6 months. Score 1 point for each you check.
- Headaches
 - Pain or cramps in lower abdomen
 - Depression
- ___ **Total SS** (add the scores you entered in step "a" plus 1 point for each symptom you checked in step "b")

American College of Rheumatology (ACR), 2010; Wolfe et al, 2011.

Diagnosis is based on the combination of chronic widespread pain and a symptom severity score based on the amount of fatigue, sleep disturbances, cognitive dysfunction, and other somatic symptoms. The diagnosis of fibromyalgia often overlaps with other chronic pain syndromes, including irritable bowel syndrome, temporomandibular disorders, and idiopathic low back pain. In CFS, chronic fatigue is the major symptom. It lasts 6 months or longer and is accompanied by hypotension, sore throat, multiple joint pains, headaches, postexertional fatigue, muscle pain, and impaired concentration (Avellaneda Fernández et al, 2009).

Medical Management

Standard medical therapy is aimed at addressing symptomatology but does not address the underlying metabolic, nutritional, and hormonal derangements. Medications such as low-dose Neurontin, Ambien, Flexeril, or Desyrel are used to initiate and deepen sleep. Neurontin can also be helpful in reducing pain and restless leg syndrome. Three medications are approved by the Food and Drug Administration (FDA) for treatment of fibromyalgia: duloxetine (Cymbalta), milnacipran (Savella), and the anticonvulsant pregabalin (Lyrica). These can be helpful in some patients suffering from FMS but can have significant side effects.

There are no FDA-approved medications for CFS, and clinicians generally attempt to improve sleep quality in these patients and may attempt a trial of stimulants such as modafinil or amphetamines to improve daytime function. Antiviral therapy targeted at addressing a possible viral etiology of CFS is sometimes attempted in a subset of patients, and this area is being actively researched (Johnson, 2014).

BOX 41-14 SHINE Protocol for Treating Chronic Fatigue and Fibromyalgia

Sleep support
Hormonal support
Infection treatment
Nutritional support
Exercise as able

Teitelbaum JE: Effective treatment of chronic fatigue syndrome, *Integr Med* 10:44, 2012.

Although there is still much to learn, effective treatment is now available for the majority of these patients. Restoring adequate energy production through nutritional, hormonal, and sleep support, and eliminating the stresses that overuse energy (e.g., infections, situational stresses) restores function in the hypothalamic "circuit breaker" and also allows muscles to release, thus allowing pain to resolve. A placebo-controlled study showed that with these measures, 91% of patients improve, with an average 90% improvement in quality of life, and the majority of patients no longer qualified as having FMS by the end of 3 months ($p < 0.0001$ vs. placebo) (Teitelbaum, 2012a).

The acronym *SHINE*, based on the integrated protocol used in the study, is a helpful way to structure treatment recommendations (see Box 41-14).

Disordered Sleep

A common element of CFS/FMS is a sleep disorder. Many patients sleep solidly for only 3 to 5 hours a night with multiple awakenings. Even more problematic is the loss of deep stage three and four "restorative" sleep. Besides the standard medications for sleep improvement, natural sleep remedies can also be very helpful (see Box 41-15).

Other sleep disturbances must be ruled out. Sleep apnea is suspected if the patient snores, is overweight, is hypertensive, and has a shirt collar size more than 17 inches. Restless leg syndrome (RLS), more accurately called periodic limb movement disorder of sleep (PLMD), is also fairly common in CFS/FMS. In addition to gabapentin, RLS is treated with supplemental iron, keeping ferritin levels more than 60 mcg/l (ng/ml) (Wang et al, 2009), and magnesium (Burke and Faulkner, 2012).

BOX 41-15 Natural Sleep Remedies and Recommended Dosages

1. Herbal: Use singly or in combination, once a day at HS (see Chapter 12 for possible interactions).
 Valerian (200-800 mg/day)
 Passion flower (90-360 mg)
 L-Theanine (50-200 mg)
 Hops (30-120 mg)
 Wild lettuce (18-64 mg)
 Lemon Balm Extract (20-80 mg)
 These are all combined in a product called the Revitalizing Sleep Formula (1-4 capsules at bedtime)
2. Melatonin: 0.5 - 5 mg at bedtime (0.5 mg is usually optimal for sleep, but higher doses may also decrease nighttime acid reflux).
3. Two to three spritzes or sprays of lavender on the pillow at bedtime helps sleep. Lavender is also available in capsule form.

Source: Teitelbaum JE: Effective treatment of chronic fatigue syndrome, *Integrative Medicine* 10:44, 2012.

Evaluation and Treatment of Associated Thyroid Hormonal Dysfunction

Hormonal dysfunctions are common in CFS/FMS. Sources of this dysfunction include hypothalamic and pituitary dysfunction and autoimmune conditions such as Hashimoto's thyroiditis (see Chapter 31).

If the thyroid is underactive because the hypothalamus is suppressed, as in CFS/FMS, the TSH test, which depends on normal hypothalamic function to be reliable, may appear to be normal or even suggest an overactive thyroid. Blood tests commonly use two standard deviations to define norms, making only the lowest or highest 2.5% of the population "abnormal" (i.e., viewed as requiring treatment). It is estimated that as many as 20% of women over 60 have positive antithyroperoxidase (TPO) antibodies and may be hypothyroid (see Chapter 31), showing the problem of relying on the normal range to determine the need for treatment.

In two studies by Dr. G.R. Skinner (Skinner, 1997) and his associates in the United Kingdom, patients thought to have hypothyroidism had technically normal thyroid blood tests. Yet, when treated with thyroid hormone, the large majority of patients with symptoms of low thyroid and yet normal testing, improved when given thyroid hormone (levothyroxine—T₄) at an average dosage of 100 to 120 mcg/day. This is equivalent to the use of 1 to 1¼ grains of porcine or desiccated thyroid hormone (Teitelbaum, 2007).

The goal in CFS/FMS management is to restore optimal function while keeping laboratory values in the normal or reference range for safety. The optimal range may be different than the "normal range." Because the hypothalamus controls virtually the entire hormonal system, thyroid, adrenal, and ovarian and testicular support may be needed, with the decision to treat and adjust dosages is based on a mix of signs, symptoms, and laboratory results.

As noted earlier, treating with T₃ (but not T₄) hormone in major depression, even when thyroid tests are normal, also significantly improved depression (Teitelbaum, 2007).

Immune Dysfunction and Infections

Immune dysfunction is an integral part of CFS/FMS. Dozens of infections have been implicated in CFS/FMS, including viral, parasitic, *Candida albicans*, and antibiotic-sensitive infections. Most of these infections are known as "opportunistic infections," which means they will not survive in the presence of a healthy immune system. Many of them resolve on their own as the immune system recovers with the SHINE protocol (see Box 41-13).

Exercise

Because of decreased energy production, too much exercise may result in "postexertional fatigue," leaving the person bedridden for a day or two. After 2 to 3 months on the SHINE protocol, patients can usually begin conditioning. Water aerobics can be helpful for those too weak to walk.

General Pain Relief

Pain often resolves within 3 months of simply treating with the SHINE protocol (Teitelbaum, 2007). Nonsteroidal antiinflammatory drugs (NSAIDs) have been shown to be ineffective in fibromyalgia pain and can contribute to bleeding ulcers, and increased risk of heart attacks and strokes (Bhala et al, 2013; Trelle et al, 2010). Chronic use of acetaminophen depletes glutathione, a key antioxidant. The glutathione depletion from acetaminophen may be prevented by supplementing with N-acetylcysteine (NAC 500 to 1000 mg/d) (Woodhead et al, 2012).

Besides being effective in treatment of depression as already discussed, a unique form of curcumin (BCM 95) has been shown to be very helpful for pain (Antony et al, 2008; Benny and Antony, 2006).

Medical Nutritional Therapy

It is recommended that B₁₂, iron, total iron-binding capacity (TIBC), and ferritin levels be assessed, keeping in mind that elevated serum B₁₂ may be a sign of an MTHFR mutation and inadequate utilization of B₁₂. Measurement of erythrocyte magnesium and zinc may be helpful, although the laboratory tests are not reliable indicators of nutritional status. Due to a probably low-nutrient-density diet and possible increased nutrient needs, other possible nutrient deficiencies are likely and must be treated with a healthy diet and nutritional supplements.

Healthy foods may not necessarily be the foods patients crave, but a routine of high protein, low-carbohydrate meals and snacks, along with avoidance of sugar, excessive caffeine, and alcohol are reasonable goals.

These patients often need to increase salt and water intake, especially in the presence of low blood pressure or orthostatic dizziness. Salt restriction is generally ill advised in these patients because of the adrenal dysfunction and orthostatic intolerance. Gluten avoidance may be helpful in a subset as well (Isasi et al, 2014; see Chapter 28).

Nutritional Supplements in Management of CFS and FMS

In addition to a healthy diet the following nutritional supplementation program may be helpful.

- 1. A high-potency multivitamin.** A good broad-spectrum, high-potency, powdered multivitamin/multimineral is generally better tolerated, better absorbed, and less expensive than tablets. This supplement should include at least 40 mg of each of the B vitamins 400 mcg folate (with at least 200 mcg as the MTHF form) 500 mcg of B₁₂ 1000 IU of vitamin D 200 mg of magnesium glycinate 15 mg of zinc (Teitelbaum, 2015).
- 2. D-Ribose.** Because CFS/FMS represents an energy crisis, it is critical that patients have what is needed for optimal mitochondrial function. D-Ribose is natural sugar produced by the body in the pentose phosphate shunt to produce ATP, NADH, FADH, DNA, and RNA, and is a potentially critical rate-limiting nutrient in the production of energy. The key energy molecules ATP, FADH, and NADH are predominantly ribose plus B vitamins and phosphate. Two studies with a total of 298 CFS/FMS patients taking 5 g of D-ribose 3 x day for 3 weeks showed an average of 60% increase in energy at 3 weeks (Teitelbaum et al, 2006; Teitelbaum, 2012b). Improvement is usually seen within 1 month. Recommended dosing is 5 g three times per day for 3 weeks and then bid. It is well tolerated, although occasionally it can cause a mild drop in blood glucose.
- 3. Iron.** If the iron percent saturation is under 22%, or serum ferritin is under 60 mcg/l (ng/ml), iron supplementation is recommended (Vaucher et al, 2012). It should not be taken within 6 hours of thyroid hormone, because iron blocks thyroid absorption. Treatment should be continued until the ferritin level is over 60 mcg/l (ng/ml).
- 4. B₁₂.** If serum B₁₂ is under 540 pg/ml, it is reasonable to consider a series of 10 weekly B₁₂ injections, or prescribing

5 mg sublingual B₁₂ daily. Studies on CFS show absent or near-absent spinal fluid B₁₂ levels despite normal serum B₁₂ levels.

5. **Coenzyme Q10.** Supplement with CoQ10 at 200 mg/day for 3 to 6 months, because blood levels of CoQ10 are often low in CFS/FMS (Maes et al, 2009). Side effects are rare.
6. **Acetyl L-carnitine (ALCAR).** Supplement with 1500 to 2000 mg daily for 4 months. Low carnitine levels are routinely seen in CFS/FMS. Supplementation to replace the deficits routinely present in CFS/FMS is limited to 4 months because of some concern about elevated carnitine levels being associated with increased risk of myocardial infarction (Teitelbaum, 2007).

SCHIZOPHRENIA

Schizophrenia is a severe mental disorder that presents as psychosis, often with paranoia and delusions. Diagnosis requires at least one of the symptoms to be delusions, hallucinations, or disorganized speech. A diagnosis of **schizoaffective disorder** requires that a person meet all of the criteria for schizophrenia and all of the criteria for an episode of bipolar disorder or depression, with the exception of impaired function (Parker, 2014).

Pathophysiology

The origins and causes of schizophrenia are not completely understood. Ultimately it may be understood as a heterogeneous disorder generated by a combination of biochemical, genetic, structural, nutritional, and environmental factors, including infections and toxins (Altamura et al, 2013). Schizophrenia is 83% inheritable (Cannon, 1998). Symptoms commonly begin to appear in males during their late teens and early twenties and appear in females in their twenties or early thirties.

In an ecological study higher sugar intake is associated with higher risk of developing schizophrenia (Peet, 2004).

A study of schizophrenic patients found that plasma copper was significantly higher than in the control group. Manganese and iron concentrations were significantly lower. These observations suggest that alterations in essential trace elements Mn, Cu, and Fe may play a role in the pathogenesis of schizophrenia. Variety in results of analysis are difficult to interpret (Yanik et al, 2004).

Medical Management

Pharmaceutical therapy revolves around the use of a combination of dopamine-blocking antipsychotic medications, antidepressants, and tranquilizers. Atypical antipsychotics, the newer, second-generation medications are generally preferred because they pose a lower risk of serious side effects than do conventional medications.

Conventional, or typical, first-generation antipsychotic medications have frequent and potentially significant neurologic side effects, including the possibility of developing a movement disorder (tardive dyskinesia) that may or may not be reversible. Other treatments include psychosocial interventions such as the following:

- Individual therapy
- Social skills training
- Family therapy
- Vocational rehabilitation and supported employment.

Side effects of antipsychotics may include dry mouth, constipation, and increased appetite. Some antipsychotics should not be

used with grapefruit and some other citrus fruits (see Chapter 8). Use of alcohol is contraindicated.

Medical Nutritional Therapy

People with severe mental illnesses (SMI) are more likely than other groups to be overweight, to smoke, and to have hyperglycemia and diabetes, hypertension, and dyslipidemia. Metabolic syndrome and other cardiovascular risk factors, as well as a reduced life expectancy, are common in people with schizophrenia. (Vidovic et al, 2013.)

Schizophrenia appears to be associated with altered metabolism. A computed tomography study showed that with equal total body fat and equal subcutaneous fat, there was three times the amount of visceral fat stored by schizophrenic patients. Reduced energy needs have been found in this population. The energy needs of males taking clozapine, a potent anti-psychotic drug, was overestimated by 15% using the Harris-Benedict formula (Sharpe et al, 2005).

Weight gain after the start of antipsychotic medications is a common reason for patients to discontinue medication. Weight gains of 25 to 60 lb over the course of several years have been reported. Clinically meaningful weight gain was defined as a gain of 7% above baseline and may be the trigger for a nutrition consult (Alvarez-Jimenez et al, 2006). Many patients are willing, able, and successful with weight management programs when they are offered. The most frequently used interventions included regular visits with a dietitian, a self-directed diet, and a stated treatment goal of weight loss (O'Keefe et al, 2003). Behavioral group treatment has been shown successful in preventing weight gain and achieving weight loss.

Dietary factors that affect schizophrenia and depression are similar to those that predict illnesses such as coronary heart disease and diabetes. Low levels of membrane and erythrocyte essential fatty acids have been observed, but do not appear to be related to dietary intake, but rather related to phospholipid metabolism. Supplements have been shown effective in raising the levels of essential fatty acids in cell membranes and erythrocytes. A high intake of fish oil is also associated with a better prognosis, with the EPA fraction being more helpful than the DHA (Marano et al, 2013).

Evaluating for the presence of MTHFR mutations may also contribute to treatment (Zhang et al, 2013a). MTHFR and COMT polymorphisms may increase the predilection for schizophrenia, although the exact mechanism is currently unclear (Roffman et al, 2013). MTHFR defects and elevated plasma homocysteine concentration have been suggested as risk factors for schizophrenia, but the results of epidemiologic studies have been inconsistent (Nishi et al, 2014).

The role of gluten and casein in schizophrenia has been suspected for more than 40 years, with an early blinded, controlled study showing that patients with schizophrenia on a gluten- and casein-free diet were released from the hospital significantly earlier (Niebuhr et al, 2011). See *New Directions: A1/A2 Milk Theory* for a theory on how milk protein, casein, may be a problem. New research has also investigated the role of gluten. Studies of individuals in the Clinical Antipsychotic Trials of Intervention Effectiveness (CATIE) show that 5.5% of the those with schizophrenia have a high level of anti-tTG (transglutaminase) antibodies, a measure of gluten intolerance, compared with 1.1% of the healthy control sample (Jackson et al, 2012). Twenty-three percent of those with schizophrenia (age-adjusted) had antigliadin antibodies (AGA) compared with 3.1% in the

comparison sample (Cascella et al, 2011). It is strongly recommended that those with schizophrenia have blood levels checked for IgA and IgG transglutaminase antibodies to screen for celiac disease or gluten sensitivity even in the absence of gastrointestinal symptoms (Jackson, 2012a). Antigliadin antibody levels, although not as specific, are also recommended for adequate assessment. A gluten-free trial is critical if these are positive, and reasonable even if the tests are negative (see Chapter 28).

NEW DIRECTIONS

The A1/A2 Milk Theory

A1 and A2 variants are variants of beta casein that differ at amino acid position 67 with histidine (CAT) in A1 and proline (CCT) in A2 milk as a result of single nucleotide polymorphism which leads to a conformational change. Absorption by infants and adults may differ related to the maturity of the gastrointestinal system. The bioactive peptide, beta casomorphin 7, BCM-7, is estimated to be 4-fold higher in Type A1 milk (Cade, 2000; Sodhi et al, 2010), is suggested as a risk factor for human health as it can potentially affect numerous opioid receptors in the nervous, endocrine, and immune system. A1 milk has been suggested as a risk factor for Type 1 diabetes, coronary heart disease, arteriosclerosis, sudden infant death syndrome, autism, and schizophrenia. Some investigations have shown reduction in autistic and schizophrenic symptoms with decrease in A1 milk intake. A1 is the most frequent in Holstein-Friesian, Ayrshire, and Red cattle while A2 is more frequent in Jersey and Guernsey cows. Much more research is needed in this field (Kaminski et al, 2007).

Interactions between nutrition and medications may be unique in persons with schizophrenia. Plasma and red-cell selenium concentrations were measured in random venous blood samples from four groups: mood disorder ($n = 36$), schizophrenics treated with clozapine ($n = 54$), schizophrenics not treated with clozapine ($n = 41$), and a healthy control group ($n = 56$). Selenium concentrations in plasma and red cells were found to be significantly lower in schizophrenic patients treated with clozapine compared with all other groups (Vaddadi et al, 2003).

Schizophrenic patients who smoke have been found to have lower erythrocyte DHA and EPA compared with nonsmokers. Smoking status must be taken into account when studying essential fatty acids in this population (see Box 41-16).

BOX 41-16 MNT for Schizophrenia

Caution against use of grapefruit and/or grapefruit juice (can alter medication blood levels) and use of alcohol (see Chapter 8).

Assessment of blood levels for IgA and IgG transglutaminase antibodies to screen for celiac disease or gluten sensitivity even in the absence of gastrointestinal symptoms.

A gluten-free trial is critical if these are positive, and reasonable even if the tests are negative.

A milk-free trial period with assessment for symptom changes.

Monitor weight: a 7% weight gain should trigger assessment for metabolic syndrome.

Refer to a behavioral weight management program as needed. In addition to nutrition-related material, program should include education regarding smoking, exercise, and alcohol consumption.

Assess diet for quality of fat intake; recommend supplement of essential fatty acids EPA and DHA to replenish or maintain cell membrane and erythrocyte fatty acid status.

Relevant mineral status includes possible excess plasma copper and low plasma selenium.

Relevant vitamin status includes genetic polymorphism of MTHFR and adequacy of folic acid intake.

Pediatric Specialties

The unique, special roles of nutrition in the pediatric population cannot be underestimated. Pediatricians, nurses, and dietitian nutritionists all recognize that unusual feeding problems or disorders can negatively influence growth and health, especially in the very young. This section addresses the categories affecting the nutritional intake and growth velocity of infants and children. In some cases, adolescents are mentioned if relevant, but most of this section considers younger patients.

Whether in neonatal units, in hospital pediatric units, in out-patient clinics, in long-term care units, or in home care, children need to grow as well as cope with genetic or acquired disorders. More than ever, nutrition care in this specialty arena requires an understanding of the biochemical, physiological, social, and economic challenges that our youngest citizens face.

Medical Nutrition Therapy for Low-Birth-Weight Infants

Diane M. Anderson, PhD, RDN, FADA

KEY TERMS

apnea of prematurity
appropriate for gestational age (AGA)
bronchopulmonary dysplasia (BPD)
carnitine
extrauterine growth restriction (EUGR)
extremely low birthweight (ELBW)
gastric gavage
gestational age
glucose load

hemolytic anemia
human milk fortifiers
infancy
infant mortality rate
intrauterine growth restriction (IUGR)
kangaroo care
large for gestational age (LGA)
low birthweight (LBW)
necrotizing enterocolitis (NEC)

neonatal period
neutral thermal environment
osteopenia of prematurity
perinatal period
premature (preterm) infant
respiratory distress syndrome (RDS)
small for gestational age (SGA)
surfactant
term infant
very low birthweight (VLBW)

The management of low birthweight (LBW) infants requiring intensive care is continually improving. With new technologies, enhanced understanding of pathophysiologic conditions of the **perinatal period** (from 20 weeks of gestation to 28 days after birth), current nutrition management principles, and regionalization of perinatal care, the mortality rate during **infancy**—that period from birth to 1 year of age—has decreased in the United States. In particular, the development and use of **surfactant**—a mixture of lipoproteins secreted by alveolar cells into the alveoli and respiratory air passages that contributes to the elastic properties of pulmonary tissue—has increased the survival of preterm infants, as has the use of antepartum corticosteroids. Most premature infants have the potential for long and productive lives (Hack, 2013).

Nutrition can be provided to LBW infants in many ways, each of which has certain benefits and limitations. The infant's size, age, and clinical condition dictate the nutrition requirements and the way they can be met. Because of the complexities involved in the neonatal intensive care setting, a team that includes a registered dietitian nutritionist trained in neonatal nutrition should make the decisions necessary to facilitate optimal nutrition (Ehrenkranz, 2014). Neonatal nutritionists monitor compliance with standardized feeding guidelines; ensure that early, intense nutritional support is initiated; facilitate the smooth transition from parenteral to enteral nutrition; and monitor growth and individualized nutrition support to maintain steady infant growth. In regionalized perinatal care systems, the neonatal nutritionist also may consult with health care providers in community hospitals and public health settings.

INFANT MORTALITY AND STATISTICS

In 2011 the **infant mortality rate** in the United States decreased to 6.05 infant deaths per 1000 live births (MacDorman et al,

2013). More than 56% of these deaths occur in the neonatal period, with the leading causes being birth defects, prematurity, and LBW. The preterm birth rate was 11.7%, and the incidence of LBW was 8.1% (Hamilton et al, 2013). Both rates are decreased from the 2006 rate and mark a change from the previous 20-year increase in premature and LBW infants.

The US infant mortality rate still remains higher than that for many industrialized countries (Hamilton et al, 2013). This discrepancy may be attributable to the inconsistent collection of mortality data among nations, which may falsely lower mortality rates in other countries. However, the high incidence of premature and LBW infants born in the United States contributes to this high infant mortality rate (Hamilton et al, 2013; MacDorman et al, 2013).

PHYSIOLOGIC DEVELOPMENT

Gestational Age and Size

At birth an infant who weighs less than 2500 g (5½ lb) is classified as having a **low birthweight (LBW)**; an infant weighing less than 1500 g (3⅓ lb) has a **very low birthweight (VLBW)**; and an infant weighing less than 1000 g (2¼ lb) has an **extremely low birthweight (ELBW)**. LBW may be attributable to a shortened period of gestation, prematurity, or a restricted intrauterine growth rate, which makes the infant small for gestational age (SGA).

The **term infant** is born between the 37th and 42nd weeks of gestation. A **premature (preterm) infant** is born before 37 weeks of gestation, whereas a postterm infant is born after 42 weeks of gestation.

Antenatally, an estimate of the infant's **gestational age** is based on the date of the mother's last menstrual period, clinical parameters of uterine fundal height, the presence of quickening (the first movements of the fetus that can be felt by the mother),

fetal heart tones, or ultrasound evaluations. After birth, gestational age is determined by clinical assessment. Clinical parameters fall into two groups: (1) a series of neurologic signs, which depend primarily on postures and tone and (2) a series of external characteristics that reflect the physical maturity of the infant. The New Ballard Score examination is a frequently used clinical assessment tool (Ballard et al, 1991). An accurate assessment of gestational age is important for establishing nutritional goals for individual infants and differentiating the premature infant from the term SGA infant.

An infant who is **small for gestational age (SGA)** has a birth weight that is lower than the 10th percentile of the standard weight for that gestational age. An SGA infant whose intrauterine weight gain is poor, but whose linear and head growth are between the 10th and 90th percentiles on the intrauterine growth grid, has experienced asymmetric **intrauterine growth restriction (IUGR)**. An SGA infant whose length and occipital frontal circumference are also below the 10th percentile of the standards has symmetric IUGR. Symmetric IUGR, which usually reflects early and prolonged intrauterine deficit, is apparently more detrimental to later growth and development. Some infants can be SGA because they are genetically small, and these infants usually do well.

An infant whose size is **appropriate for gestational age (AGA)** has a birth weight between the 10th and 90th percentiles on the intrauterine growth chart. The obstetrician diagnoses IUGR when the fetal growth rate decreases. Serial ultrasound measurements document this reduction in fetal anthropometric measurements, which may be caused by maternal, placental, or fetal abnormalities. The future growth and development of infants who have had IUGR is diverse, depending on the specific cause of the IUGR and treatment. Some infants who suffered from IUGR are SGA, but many may plot as AGA infants at birth. Decreased fetal growth does not always result in an infant who is SGA.

An infant whose birth weight is above the 90th percentile on the intrauterine growth chart is **large for gestational age (LGA)**. **Box 42-1** summarizes the weight classifications. **Figure 42-1** shows the classification of neonates based on maturity and intrauterine growth.

Characteristics of Immaturity

The premature or LBW infant has not had the chance to develop fully in utero and is physiologically different from the term infant (see **Figure 42-2**). Because of this, LBW infants have various clinical problems in the early **neonatal period**, depending on their intrauterine environment, degree of prematurity, birth-related trauma, and function of immature or

FIGURE 42-1 Classification of neonates based on maturity and intrauterine growth (small for gestational age [SGA], appropriate for gestational age [AGA], or large for gestational age [LGA]). (From Battaglia FC, Lubchenco LO: A practical classification of newborn infants by weight and gestational age, *J Pediatr* 71:159, 1967.)

FIGURE 42-2 A.R., born at 27 weeks of gestation; birth weight of 870 g (1 lb, 14 oz).

BOX 42-1 Classification of Birth Weight and Intrauterine Growth

Low birth weight <2500 g
Very low birth weight <1500 g
Extremely low birth weight <1000 g
Small for gestational age = Birth weight <10th percentile of standard for gestational age
Appropriate for gestational age = Birth weight between the 10th and 90th percentile of standard for gestational age
Large for gestational age = Birth weight >90th percentile of standard for gestational age

stressed organ systems. Certain problems occur with such frequency that they are considered typical of prematurity (see **Table 42-1**). Premature infants are at high risk for poor nutrition status because of poor nutrient stores, physiologic immaturity, illness (which may interfere with nutritional

TABLE 42-1 Common Problems Among Premature Infants

System	Problem
Respiratory	Respiratory distress syndrome, chronic lung disease (bronchopulmonary dysplasia)
Cardiovascular	Patent ductus arteriosus
Renal	Fluid and electrolyte imbalance
Neurologic	Intraventricular hemorrhage, periventricular leukomalacia (cerebral necrosis)
Metabolic	Hypoglycemia, hyperglycemia, hypocalcemia, metabolic acidosis
Gastrointestinal	Hyperbilirubinemia, feeding intolerance, necrotizing enterocolitis
Hematologic	Anemia
Immunologic	Sepsis, pneumonia, meningitis
Other	Apnea, bradycardia, cyanosis, osteopenia

management and needs), and the nutrient demands required for growth.

Most fetal nutrient stores are deposited during the last 3 months of gestation; therefore, the premature infant begins life in a compromised nutritional state. Because metabolic (i.e., energy) stores are limited, nutrition support in the form of parenteral nutrition (PN), enteral nutrition (EN), or both should be initiated as soon as possible. In the preterm infant weighing 1000 g, fat constitutes only 1% of total body weight; by contrast the term infant (3500 g) has a fat percentage of approximately 16%. For example, a 1000-g AGA premature infant has a glycogen and fat reserve equivalent to approximately 110 kcal/kg of body weight. With basal metabolic needs of approximately 50 kcal/kg/day, it is obvious that this infant will rapidly run out of fat and carbohydrate fuel unless adequate nutrition support is established. The depletion time is even shorter for preterm infants weighing less than 1000 g at birth. Nutrient reserves also are depleted most quickly by tiny infants who have IUGR as a result of their decreased nutrient stores.

Theoretic estimates of survival time of starved and semi-starved infants are shown in Table 42-2. These estimates assume depletion of all glycogen and fat and approximately one third of body protein tissue at a rate of 50 kcal/kg/day. The effects of fluids such as intravenously provided water (which has no exogenous calories) and 10% dextrose solution (D₁₀W) are shown. Currently, PN fluids are started on the day of birth to provide energy and protein for the VLBW infant. Early protein intake promotes positive nitrogen balance, normal plasma amino acid levels, and glucose tolerance.

TABLE 42-2 Expected Survival Time of Starved (H₂O Only) and Semistarved (D₁₀W) Infants

Birth Weight (g)	ESTIMATED SURVIVAL TIME (Days)	
	H ₂ O	D ₁₀ W
1000	4	11
2000	12	30
3500	32	80

D₁₀W, Dextrose 10% in water; H₂O, water.

The small premature infant is particularly vulnerable to undernutrition. Malnutrition in premature infants may increase the risk of infection, prolong chronic illness, and adversely affect brain growth and function. Premature infants fed premature infant formula or human milk demonstrate better growth and development than premature infants fed standard infant formula. Milk from the infant's own mother fed the first month of life has been linked to improved growth and development. Premature infants fed their own mother's milk have improved neurodevelopment at 30 months of age and higher intelligence test scores at 8 years of age and have brains larger and more developed at 15 years of age ([American Academy of Pediatrics \[AAP\], Section on Breastfeeding, 2012](#); [Issacs et al, 2010](#)).

NUTRITION REQUIREMENTS: PARENTERAL FEEDING

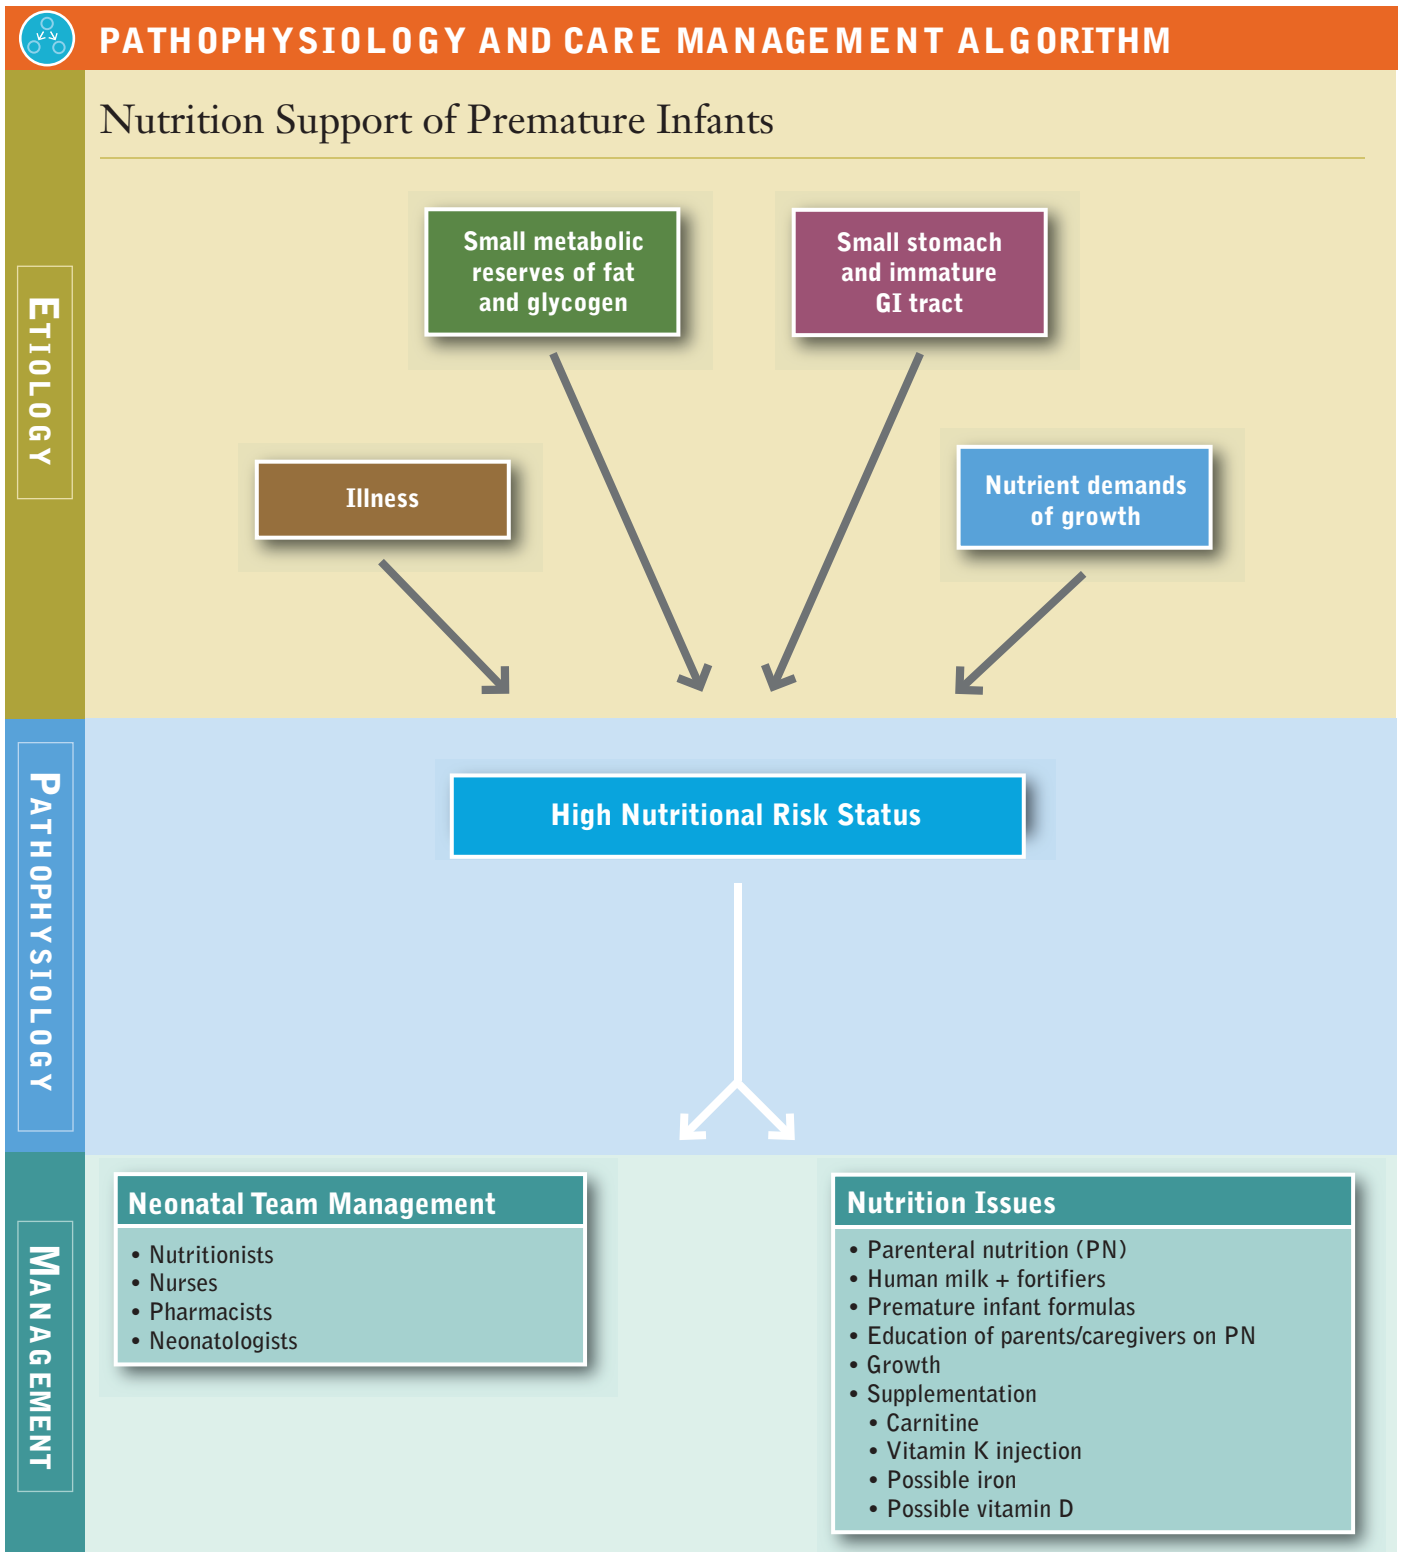

Many critically ill preterm infants have difficulty progressing to full enteral feedings in the first several days or even weeks of life. The infant's small stomach capacity, immature gastrointestinal tract, and illness make the progression to full enteral feedings difficult (see [Pathophysiology and Care Management Algorithm: Nutrition Support of Premature Infants](#)). PN becomes essential for nutrition support, either as a supplement to enteral feedings or as the total source of nutrition. Chapter 13 offers a complete discussion of PN; only aspects related to feeding of the preterm infant are presented here.

Fluid

Because fluid needs vary widely for preterm infants, fluid balance must be monitored. Inadequate intake can lead to dehydration, electrolyte imbalances, and hypotension; excessive intake can lead to edema, congestive heart failure, and possible opening of the ductus arteriosus. Additional neonatal clinical complications reported with high fluid intakes include necrotizing enterocolitis (NEC) and bronchopulmonary dysplasia (BPD) (see Chapter 34).

The premature infant has a greater percentage of body water (especially extracellular water) than the term infant (see Chapter 6). The amount of extracellular water should decrease in all infants during the first few days of life. This reduction is accompanied by a normal loss of 10% to 15% of body weight and improved renal function. Failure of this transition in fluid dynamics and lack of diuresis may complicate the course of preterm infants with respiratory disease.

Water requirements are estimated by the sum of the predicted losses from the lungs and skin, urine, and stool, and the water needed for growth. A major route of water loss in preterm infants is evaporation through the skin and respiratory tract. This insensible water loss is highest in the smallest and least mature infants because of their larger body surface area relative to body weight, increased permeability of the skin epidermis to water, and greater skin blood flow relative to metabolic rate. Insensible water loss is increased by radiant warmers and phototherapy lights and decreased by humidified incubators, heat shields and thermal blankets. Insensible water loss can vary from 50 to 100 ml/kg/day on the first day of life and increase up to 150 ml/kg/day, depending on the infant's size, gestational age, day of life, and environment. The use of humidified incubators can decrease insensible water losses and thereby reduce fluid requirements.

Excretion of urine, the other major route of water loss, varies from 1 to 3 ml/kg/hr (Doherty, 2012). This loss depends on the fluid volume and solute load presented to the kidneys. The infant's ability to concentrate urine increases with maturity. Stool water loss is generally 5 to 10 ml/kg/day, and 10 to 15 ml/kg/day is suggested as optimal for growth (Dell, 2011).

Because of the many variables affecting neonatal fluid losses, fluid needs must be determined on an individual basis. Usually fluid is administered at a rate of 60 to 100 ml/kg/day the first day of life to meet insensible losses and urine output. Fluid needs then are evaluated by assessing fluid intake and comparing it with the clinical parameters of urine output

volume and serum electrolyte, creatinine, and urea nitrogen levels. Assessments of weight, blood pressure, peripheral perfusion, skin turgor, and mucous membrane moisture are performed daily. Daily fluid administration generally increases by 10 to 20 ml/kg/day. By the end of the second week of life, preterm infants may receive fluids at a rate of 140 to 160 ml/kg/day. Fluid restriction may be necessary in preterm infants with patent ductus arteriosus, congestive heart failure, renal failure, or cerebral edema. However, more fluids are needed by preterm infants who are placed under phototherapy lights or a radiant warmer or when the environmental or body temperature is elevated.

Energy

The energy needs of preterm infants fed parenterally are less than those of enterally fed infants because absorption loss does not occur when nutritional intake bypasses the intestinal tract. Enterally fed preterm infants usually require 105 to 130 kcal/kg/day to grow, whereas parenterally fed premature neonates can grow well if they receive 90 to 100 kcal/kg/day (AAP, 2014). Minimum maintenance energy needs and adequate protein should be provided as soon as possible to prevent tissue catabolism. Providing VLBW infants with 1.5 g of protein and 40 to 60 kcal/kg/day promotes nitrogen balance during the first 3 days of life (AAP, 2014; Rigo and Senterre, 2013). Two to 3 g/kg/day of protein should be started within a few hours of birth to maximize nitrogen balance and blood amino acid levels (AAP, 2014).

Energy and protein intake should be increased as the infant's condition stabilizes and growth becomes the goal (see Table 42-3). Many VLBW infants are born AGA but at discharge from the hospital weigh less than the 10th percentile for their postmenstrual age. This new SGA status is called **extrauterine growth restriction (EUGR)**. EUGR may occur as a result of poor energy and protein intakes and the decreased growth associated with illness (Lapillonne and Griffin, 2013).

Glucose

Glucose or dextrose is the principal energy source (3.4 kcal/g). However, glucose tolerance is limited in premature infants, especially in VLBW infants, because of inadequate insulin production, insulin resistance, and continued hepatic glucose release while intravenous glucose is infusing. Hyperglycemia is less likely when glucose is administered with amino acids than when it is infused alone. Amino acids exert a stimulatory effect on insulin release. Prevention of hyperglycemia is important because it can lead to diuresis and dehydration.

TABLE 42-3 Comparison of Parenteral and Enteral Energy Needs of Premature Infants

	Parenteral	Enteral
MAINTENANCE		
Gradually increase intake to meet energy needs by the end of the first week	30-50 kcal/kg/day	50 kcal/kg/day
GROWTH		
Meet energy needs as soon as the infant's condition is stable	90-100 kcal/kg/day	105-130 kcal/kg/day

TABLE 42-4 Guidelines for Glucose Load in Premature Infants

Initial Load (mg/kg/min)*	Daily Increments (mg/kg/min)	Maximum Load (mg/kg/min)
4-6	1-2	11-12

*Use the following formula to calculate glucose load: (% Glucose × ml/kg/day) × (1000 mg/g glucose) ÷ (1440 min/day). For example, (0.10 × 150 ml/kg/day) × (1000 mg/g glucose) ÷ (1440 min/day) = 10.4 mg/kg/min.

To prevent hyperglycemia in VLBW infants, glucose should be administered in small amounts. The **glucose load** is a function of the concentration of the dextrose infusion and the rate at which it is administered (see Table 42-4). The administration of intravenous amino acids stimulates insulin production and the tolerance of intravenous glucose (Thureen et al, 2003). The administration of exogenous insulin is avoided with premature infants (AAP, 2014). Insulin adheres to the intravenous tubing, which results in blood glucose fluctuations as a result of nonsteady insulin concentrations. Additional problems for the infant include hypoglycemia, decreased linear growth, the association of hypoglycemia with poor neurodevelopment, and death (Alsweiler et al, 2012). In general, preterm infants should receive an initial glucose load of 4.5 to 6 mg/kg/min, with a gradual increase to 11 to 12 mg/kg/min. The glucose load can be advanced by 1 to 2 mg/kg/min/day. Hypoglycemia is not as common a problem as hyperglycemia, but it may occur if the glucose infusion is decreased abruptly or interrupted.

Amino Acids

Protein guidelines range from 2.7 to 4.0 g/kg/day (AAP, 2014). Protein in excess of these parenteral requirements should not be administered because additional protein offers no apparent advantage, and increases the risk of metabolic problems. In practice preterm infants are usually given 2 to 3 g/kg/day of protein for the first few days of life, and then protein is provided as tolerated. Many nurseries stock starter PN, which is water, glucose, protein, and perhaps calcium and is available 24 hours a day. Infants then can be provided with protein immediately on admission to the nursery.

In the United States several pediatric PN solutions are available. The use of pediatric PN solutions results in plasma amino acid profiles similar to those of fetal and cord blood or to those of healthy infants fed breastmilk (van Goudoever et al, 2014). These solutions promote adequate weight gain and nitrogen retention. Standard amino acid solutions are not designed to meet the particular needs of immature infants and may provoke imbalances in plasma amino acid levels. For example, cysteine, tyrosine, and taurine levels in these solutions are low relative to the needs of the preterm infant, but the methionine and glycine levels are relatively high. Because premature infants do not effectively synthesize cysteine from methionine because of decreased concentrations of the hepatic enzyme cystathionase, a cysteine supplement has been suggested. Cysteine is insoluble and unstable in solution; thus it is added as cysteine hydrochloride when the PN solution is prepared.

In addition to plasma amino acid imbalances, other metabolic problems associated with amino acid infusions in preterm infants include metabolic acidosis, hyperammonemia, and azotemia. These problems can be minimized by using the crystalline

TABLE 42-5 Guidelines for Administration of Parenteral Amino Acids for Premature Infants

Initial Rate (g/kg/day)*	Increments (g/kg/day)	Maximum Rate (g/kg/day)
2-3	Advance to meet needs	4

Data from American Academy of Pediatrics, Committee on Nutrition: Nutritional needs of preterm infants. In Kleinman RE, Greer FR, editors: *Pediatric nutrition handbook*, ed 7, Elk Grove, Ill, 2014, American Academy of Pediatrics.

*Use the following formula to calculate protein load: % Protein \times ml/kg/day = Protein g/kg/day.

For example: 2% amino acid parenteral solution provided at 150 ml/kg/day is 0.02×150 ml/kg/day = 3 g/kg/day.

amino acid products that are available and by keeping the protein load within the recommended guidelines (see Table 42-5).

Lipids

Intravenous fat emulsions are used for two reasons: (1) to meet essential fatty acid (EFA) requirements and (2) to provide a concentrated source of energy. EFA needs can be met by providing 0.5 g/kg/day of lipids. Biochemical evidence of EFA deficiency has been noted during the first week of life in VLBW infants fed parenterally without fat. The clinical consequences of EFA deficiency may include coagulation abnormalities, abnormal pulmonary surfactant, and adverse effects on lung metabolism.

Lipids can be initiated at 1 to 2 g/kg/day and should be provided over 24 hours (AAP, 2014). Lipids can be advanced by 1 to 2 g/kg/day until a rate of 3 g/kg/day is reached (see Table 42-6). Plasma triglycerides should be monitored because elevated triglyceride levels may develop in infants with a decreased ability to hydrolyze triglycerides. These infants usually have lower gestational age, SGA status, infection, surgical stress, or liver disease. Monitoring of serum triglyceride levels is indicated, and a rate of less than 3 g/kg/day of fat may be required to keep serum triglyceride levels under 200 mg/dl (AAP, 2014). Once the infant is medically stable and additional energy is needed for growth, lipid loads can be increased slowly. Intralipids can be given to the infant with hyperbilirubinemia. At the present recommendation of 3 g/kg/day, given over 24 hours, the displacement of bilirubin from albumin-binding sites does not occur (AAP, 2014).

The total lipid load is usually 25% to 40% of nonprotein calories (AAP, 2014). (The lipid emulsions currently in use are described in Chapter 13.) In preterm infants 20% solutions providing 2 kcal/ml are recommended because plasma triglyceride, cholesterol, and phospholipid levels are generally lower

TABLE 42-6 Guidelines for Administration of Parenteral Lipids for Premature Infants

Initial Rate (g/kg/day)*	Increments (g/kg/day)	Maximum Rate (g/kg/day)
1-2	1	3

Data from American Academy of Pediatrics, Committee on Nutrition: Nutritional needs of preterm infants. In Kleinman RE, Greer FR, editors: *Pediatric nutrition handbook*, ed 7, Elk Grove, Ill, 2014, American Academy of Pediatrics.

*Use the following formula to calculate lipid load: % Lipid \times ml/kg/day = Lipid g/kg/day. For example, 0.20×15 ml/kg = 3 g/kg/day.

with these than with the 10% emulsions. The 10% emulsions contain more of the phospholipid emulsifier per gram of lipid and this emulsifier decreases the breakdown of triglycerides.

Intravenous fat emulsions are made from soybean oil and contain omega-6 fatty acids, linoleic acid, and arachidonic acid (ARA). These EFAs increase the production of inflammatory mediators and increase the infant's inflammatory state (Premkumar et al, 2014) (see Chapter 3 and *Focus On: Biochemistry of Inflammation* in Chapter 39). There is a fish-oil base intravenous fat and it contains omega-3 fatty acids: eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA). These omega-3 fatty acids are antiinflammatory and are helpful in the treatment of parenteral nutrition-associated liver disease (Premkumar et al, 2014). This fish-oil product is produced in Europe and requires approval for compassionate use by the Food and Drug Administration (FDA) for patients in the United States.

Clinical experience with the fish-oil base intravenous fat is positive with resolution of PN-associated liver disease in most premature infants (Premkumar et al, 2014). Investigations are needed to determine whether this product can be used to prevent PN-associated liver disease, which presents with an elevated conjugated bilirubin. Another European fat emulsion, SMOF (soy oil, medium-chain triglyceride, olive oil, and fish oil) has just become available in the United States and requires approval by the FDA for compassionate use. This blend of fat oils may also offer antiinflammatory properties (Vanek et al, 2012).

Carnitine is frequently added to PN solutions for premature infants. Carnitine facilitates the mechanism by which fatty acids are transported across the mitochondrial membrane, allowing their oxidation to provide energy. Because intravenous lipid does not contain carnitine and premature infants have limited ability to produce carnitine, carnitine supplementation may be helpful for preterm infants who are receiving only PN for 2 to 3 weeks (Hay et al, 2014).

Electrolytes

After the first few days of life, sodium, potassium, and chloride are added to parenteral solutions to compensate for the loss of extracellular fluid. To prevent hyperkalemia and cardiac arrhythmia, potassium should be withheld until renal flow is demonstrated. In general, the preterm infant has the same electrolyte requirements as the term infant, but actual requirements vary, depending on factors such as renal function, state of hydration, and the use of diuretics (see Table 42-7). Very immature infants may have a limited ability to conserve sodium and thus may require increased amounts of sodium to maintain a normal serum sodium concentration. Serum electrolyte levels should be monitored periodically.

TABLE 42-7 Guidelines for Administration of Parenteral Electrolytes for Premature Infants

Electrolyte	Amount (mEq/kg/day)
Sodium	2-4
Chloride	2-4
Potassium	1.5-2

Data from American Academy of Pediatrics, Committee on Nutrition: Nutritional needs of preterm infants. In Kleinman RE, Greer FR, editors: *Pediatric nutrition handbook*, ed 7, Elk Grove, Ill, 2014, American Academy of Pediatrics.

Minerals

Calcium and phosphorus are important components of the PN solution. Premature infants who receive PN with low calcium and phosphorus concentrations are at risk for developing **osteopenia of prematurity**. This poor bone mineralization is most likely to develop in VLBW infants who receive PN for prolonged periods. Calcium and phosphorus status should be monitored using serum calcium, phosphorus, and alkaline phosphatase activity levels (see Appendix 22). Alkaline phosphatase activity levels in premature infants are greater than the levels seen with adults. It is common to see levels up to 600 IU/L, which may reflect rapid bone growth (Abrams, 2012). When alkaline phosphatase activity levels of 800 IU/L or more persist, knee or wrist radiographs should be examined for rickets (Abrams, 2012). Elevation in alkaline phosphatase activity also may be seen with liver disease.

Preterm infants have higher calcium and phosphorus needs than term infants. However, it is difficult to add enough calcium and phosphorus to parenteral solutions to meet these higher requirements without causing precipitation of the minerals. Calcium and phosphorus should be provided simultaneously in PN solutions. Alternate-day infusions are not recommended because abnormal serum mineral levels and decreased mineral retention develop.

Current recommendations for parenteral administration of additional calcium, phosphorus, and magnesium are presented in Table 42-8. The intakes are expressed at a volume intake of 120 to 150 ml/kg/day, with 2.5 g/100 ml of amino acids or protein. Lower fluid volumes or lower protein concentrations may cause the minerals to precipitate out of solution. The addition of cysteine hydrochloride increases the acidity of the fluid, which inhibits precipitation of calcium and phosphorus.

Trace Elements

Zinc should be given to all preterm infants receiving PN. If enteral feedings cannot be started by 2 weeks of age, additional trace elements should be added. However, the amount of manganese should be reduced for infants with obstructive jaundice; and the amounts of selenium, and chromium should be reduced in infants with renal dysfunction. Copper can be concentrated in the liver with cholestasis, and it is recommended to determine copper status by plasma copper levels or plasma ceruloplasmin levels (AAP, 2014). Parenteral iron is not routinely provided because infants often receive blood transfusions soon after birth, and enteral feedings, which provide a source of iron, often can be initiated. If necessary, the dosage for parenteral iron is approximately 10% of the enteral dosage; guidelines range from 0.2 to 0.25 mg/kg/day (Domellof, 2014). Table 42-9 provides guidelines for trace minerals.

TABLE 42-8 Guidelines for Administration of Parenteral Minerals for Premature Infants

Minerals	Amount (mg/kg/day)*
Calcium	60-80
Phosphorus	39-67
Magnesium	4.3-7.2

From American Academy of Pediatrics, Committee on Nutrition: Nutritional needs of preterm infants. In Kleinman RE, Greer FR, editors: *Pediatric nutrition handbook*, ed 7, Elk Grove, Ill, 2014, American Academy of Pediatrics.

*These recommendations assume an average fluid intake of 120 to 150 ml/kg/day with 2.5 g of amino acids per 100 ml. The amino acid concentration prevents the precipitation of these minerals.

TABLE 42-9 Guidelines for Administration of Parenteral Trace Elements for Premature Infants

Trace Elements	Amount (mcg/kg/day)
Zinc	400
Copper	20*
Manganese	1*
Selenium	1.5 – 4.5 [†]
Chromium	0.05-0.3 [†]
Molybdenum	0.25
Iodine	1

From American Academy of Pediatrics, Committee on Nutrition: Parenteral nutrition. In Kleinman RE, Greer FR, editors: *Pediatric nutrition handbook*, ed 7, Elk Grove, Ill, 2014, American Academy of Pediatrics.

*Reduced or not provided for infants with obstructive jaundice. Copper may have to be provided based on the infant's blood copper levels.

[†]Reduced or not provided for infants with renal dysfunction.

Vitamins

Shortly after birth all newborn infants receive an intramuscular (IM) injection of 0.3 to 1 mg of vitamin K to prevent hemorrhagic disease of the newborn from vitamin K deficiency. Stores of vitamin K are low in newborn infants, and there is little intestinal bacterial production of vitamin K until bacterial colonization takes place. Because initial dietary intake of vitamin K is limited, neonates are at nutritional risk if they do not receive this IM supplement.

Only intravenous multivitamin preparations currently approved and designed for use in infants should be given to provide the appropriate vitamin intake and prevent toxicity from additives used in adult multivitamin injections. The American Academy of Pediatrics recommends 40% of the infusion multivitamin (MVI)-pediatric 5-ml vial per kilogram of weight (AAP, 2014). The maximum dose of 5 ml is given to an infant with a weight of 2.5 kg (see Table 42-10).

Respiratory distress syndrome (RDS) is a disease that occurs in premature infants shortly after birth because these infants are deficient in the lung substance surfactant. **Surfactant** is responsible for keeping the lung elastic while breathing; thus surfactant supplements are given to the infant to prevent RDS or to lessen the illness. Lipids and proteins are components of surfactant, and phospholipids are the major lipid. Choline is required for phospholipid synthesis, but choline supplementation does not increase the production of phospholipids (van Aerde and Narvey, 2006). Choline is a conditionally essential nutrient because the

MVI, multivitamin for infusion.

Maximum volume intake is 5 ml/day, which is achieved at 2.5 kg body weight.

Data from American Academy of Pediatrics, Committee on Nutrition: Nutritional needs of preterm infants. In Kleinman RE, Greer FR, editors: *Pediatric nutrition handbook*, ed 7, Elk Grove, Ill, 2014, American Academy of Pediatrics.

*MVI-Pediatric/INFUVITE (5 ml) contains the following vitamins: 80 mg of ascorbic acid, 2300 USP units of vitamin A, 400 USP units of vitamin D, 1.2 mg of thiamin, 1.4 mg of riboflavin, 1 mg of vitamin B₆, 17 mg of niacin, 5 mg of pantothenic acid, 7 USP units of vitamin E, 20 mcg of biotin, 140 mcg of folic acid, 1 mcg of vitamin B₁₂, and 200 mcg of vitamin K.

infant can synthesize choline (see Chapter 15 for a discussion of requirement for choline in pregnancy). Choline is added to premature infant formulas at the level contained in human milk. The upper level is extrapolated from the adult safe level of intake (Klein, 2002).

Bronchopulmonary dysplasia (BPD) is a chronic lung disease that commonly develops in the premature infant as a result of RDS and the mechanical ventilation and oxygen used to treat it. Because of the role of vitamin A in facilitating tissue repair, and because of reports of preterm infants having low vitamin A stores, large supplemental doses of vitamin A have been suggested for the prevention of BPD. One report suggests that providing ELBW premature infants with IM injections of vitamin A at 5000 units/day three times per week during the first month of life decreases the incidence of BPD (Tyson et al, 1999). Physicians may or may not use this supplementation. The decision will be based on the incidence of BPD in their nursery, the lack of proven additional benefits, the acceptability of using IM injections, and the availability of parenteral vitamin A (Darlow and Graham, 2011). See Chapter 34 for a discussion of BPD.

Apnea of prematurity is when the infant stops breathing for 20 seconds or longer. Apnea can be due to the infant's immature response to breathing. Bradycardia, slowness of the heart rate, and poor blood oxygenation may be associated with apnea. The medication, caffeine, can be given daily to prevent apnea of prematurity. Caffeine stimulates the infant to breathe by increasing the brain's sensitivity to carbon dioxide, stimulating the central respiratory drive, and improving skeletal muscle contraction of the diaphragm. Apnea also can be caused by a lack of oxygen, cold or hot environmental temperatures, medications, or illness. The cause of apnea must be determined to provide the correct treatment to the premature infant.

Oral sucrose is given to infants for pain management during procedures such as blood draws by heel stick or venipuncture. The taste of sucrose may release endorphins, but how sucrose aids in pain management is not clear.

TRANSITION FROM PARENTERAL TO ENTERAL FEEDING

It is beneficial to begin enteral feedings for preterm infants as early as possible because the feedings stimulate gastrointestinal enzymatic development and activity, promote bile flow, increase villous growth in the small intestine, and promote mature gastrointestinal motility. These initial enteral feedings also can decrease the incidence of cholestatic jaundice and the duration of physiologic jaundice and can improve subsequent feeding tolerance in preterm infants. At times small, initial feedings are used only to prime the gut and are not intended to optimize enteral nutrient intake until the infant demonstrates feeding tolerance or is clinically stable.

When making the transition from parenteral to enteral feeding, clinicians should maintain parenteral feeding until enteral feeding is well established to maintain adequate net intake of fluid and nutrients. In VLBW infants it may take 7 to 14 days to provide full enteral feeding, and it may take longer for infants with feeding intolerances or illness. The smallest, sickest infants usually receive increments of only 10 to 20 ml/kg/day. Larger, more stable preterm infants may tolerate increments of 20 to 30 ml/kg/day (see Chapter 13 for a more detailed discussion of transitional feeding).

NUTRITION REQUIREMENTS: ENTERAL FEEDING

Enteral alimentation is preferred for preterm infants because it is more physiologic than parenteral alimentation and is nutritionally superior. Initiating a tiny amount of an appropriate breastmilk feeding whenever possible is beneficial (Ahrabi and Schanler, 2013). However, determining when and how to provide enteral feedings is often difficult and involves consideration of the degree of prematurity, history of perinatal insults, current medical condition, function of the gastrointestinal tract, respiratory status, and several other individual concerns (see Table 42-11).

Preterm infants should be fed enough to promote growth similar to that of a fetus at the same gestational age, but not so much that nutrient toxicity develops. Although the exact nutrient requirements are unknown for preterm infants, several useful guidelines exist. In general the requirements of premature infants are higher than those of term infants because the preterm infant has smaller nutrient stores, decreased digestion and absorption capabilities, and a rapid growth rate. Stress, illness, and certain therapies for illness may further influence nutrient requirements. It is also important to remember that, in general, enteral nutrient requirements are different from parenteral requirements.

Energy

The energy requirements of premature infants vary with individual biologic and environmental factors. It is estimated that an intake of 50 kcal/kg/day is required to meet maintenance energy needs, compared with 105 to 130 kcal/kg/day for growth (see Table 42-12). However, energy needs may be increased by stress, illness, and rapid growth. Likewise, energy needs may be decreased if the infant is placed in a **neutral thermal environment** (the environmental temperature at which an infant expends the least amount of energy to maintain body temperature). It is important to consider the infant's rate of growth in relation to average energy intakes. Some premature infants may need greater than 130 kcal/kg/day to sustain an appropriate rate of growth. ELBW infants or those with BPD often require such increased amounts. To provide such a large number of calories to infants with a limited ability to tolerate large fluid volumes, it may be necessary to concentrate the feedings to a level of more than 24 kcal/oz (see Box 42-2).

TABLE 42-11 Factors to Consider Before Initiating or Increasing the Volume of Enteral Feedings

Category	Factors
Perinatal	Cardiorespiratory depression
Respiratory	Stability of ventilation, blood gases, apnea, bradycardia, cyanosis
Medical	Vital signs (heart rate, respiratory rate, blood pressure, temperature), lethargy
Gastrointestinal	Anomalies (gastroschisis, omphalocele), patency, gastrointestinal tract function (bowel sounds present, passage of stool), abdominal distension, risk of necrotizing enterocolitis
Infection	Sepsis or suspect sepsis

BOX 42-2 Recipes for Preparing 90 ml (3 oz) of Concentrated Premature Infant Formula

Kcal/oz RTF*	Ratio 24/30 kcal oz RTF Formula	Volume (ml) RTF* Prema-ture 24	Volume RTF* (ml) Prema-ture 30
24	1/0	90	0
26	2/1	60	30
27	1/1	45	45
28	1/2	30	60
30	0/1	0	90

RTF, Ready-to-feed formula.

*RTF (at 24 and 30 kcal/oz).

Example: Recipe for making a 26 kcal/oz formula:

Goal = 90 ml (3 oz) of formula

2 parts of 24 kcal/oz formula + 1 part of 30 kcal/oz formula = 3 parts of formula

90 ml ÷ 3 parts = 30 ml per part

30 ml × 2 parts = 60 ml of RTF Premature 24 kcal/oz formula + 30 ml

× 1 part = 30 ml of Premature 30 kcal/oz = 90 ml (3 parts) of 26 kcal/oz formula

Protein

The amount and quality of protein must be considered when establishing protein requirements for the preterm infant. Amino acids should be provided at a level that meets demands without inducing amino acid or protein toxicity.

A reference fetus model has been used to determine the amount of protein that has to be ingested to match the quantity of protein deposited into newly formed fetal tissue (Ziegler, 2011). To achieve these fetal accretion rates, additional protein must be supplied to compensate for intestinal losses and obligatory losses in the urine and skin. Based on this method for determining protein needs, the advisable protein intake is 3.5 to 4 g/kg/day. This amount of protein is well tolerated. For the ELBW infant, up to 4.5 g/kg/day of protein has been recommended for milk feedings (Agostoni et al, 2010; Koletzko et al, 2014; Tudehope et al, 2013).

The quality or type of protein is an important consideration because premature infants have different amino acid needs than term infants because of immature hepatic enzyme pathways. The amino acid composition of whey protein, which differs

from that of casein, is more appropriate for premature infants. The essential amino acid cysteine is more highly concentrated in whey protein, and premature infants do not synthesize cysteine well. In addition, the amino acids phenylalanine and tyrosine are lower, and the preterm infant has difficulty oxidizing them. Furthermore, metabolic acidosis decreases with consumption of whey-predominant formulas. Because of the advantages of whey protein for premature infants, breastmilk or formulas containing predominately whey proteins should be chosen whenever possible.

Taurine is a sulfonic amino acid that may be important for preterm infants. Human milk is a rich source of taurine, and taurine is added to most infant formulas. Term and preterm infants develop low plasma and urine concentrations of taurine without a dietary supply. The premature infant may have difficulty with synthesizing taurine from cysteine. Although no overt disease has been reported in infants fed low taurine formulas, low taurine may affect the development of vision and hearing (Klein, 2002).

Energy must be provided at sufficient levels to allow protein to be used for growth and not merely for energy expenditure. A range of 2.5 to 3.6 gms of protein per 100 kcal is recommended. Inadequate protein intake is growth limiting, whereas excessive intake causes elevated plasma amino acid levels, azotemia, and acidosis.

Lipids

The growing preterm infant needs an adequate intake of well-absorbed dietary fat to help meet the high energy needs of growth, provide EFAs, and facilitate absorption of other important nutrients such as the fat-soluble vitamins and calcium. However, neonates in general, and premature and SGA infants in particular, digest and absorb lipids inefficiently.

Fat should constitute 40% to 50% of total calories. Furthermore, a diet that is high in fat and low in protein may yield more fat deposition than is desirable for the growing preterm infant. To meet EFA needs, linoleic acid should compose 3% of the total calories, and alpha-linolenic acid should be added in small amounts (AAP, 2014). Additional longer-chain fatty acids—ARA and DHA—are present in human milk and are added to infant formulas for term and premature infants to meet federal guidelines.

The premature infant has a greater need than the term infant for ARA and DHA supplementation. These fatty acids accumulate in fatty tissue and the brain during the last 3 months of gestation; thus the premature infant has decreased stores. Premature infants fed formulas supplemented with ARA and DHA frequently demonstrate greater gain in weight and length and higher psychomotor development scores than premature infants not receiving the fatty acid supplementation (Lapillonne et al, 2013). The DHA and ARA content of human milk is variable, and the premature infant may require supplements of ARA and DHA. However, research is needed to document supplementation use for the premature infants provided human milk (AAP, 2014).

Preterm infants have low levels of pancreatic lipase and bile salts, and this decreases their ability to digest and absorb fat. Lipases are needed for triglyceride breakdown, and bile salts solubilize fat for ease of digestion and absorption. Because medium-chain triglycerides (MCTs) do not require pancreatic lipase and bile acids for digestion and absorption, they have been added to the fat mixture in premature infant formulas.

Human milk and vegetable oils contain the EFA linoleic acid, but MCT oil does not. Premature infant formulas must contain vegetable oil and MCT oil to provide the essential long-chain fatty acids.

The composition of dietary fat also plays a role in the digestion and absorption of lipid. In general, infants absorb vegetable oils more efficiently than saturated animal fats, although one exception is the saturated fat in human milk. Infants digest and absorb human milk fat better than the saturated fat in cow's milk or the vegetable oil in standard infant formulas. Human milk contains two lipases that facilitate fat digestion and has a special fatty acid composition that aids absorption.

Carbohydrates

Carbohydrates are an important source of energy, and the enzymes for endogenous production of glucose from carbohydrate and protein are present in preterm infants. Approximately 40% of the total calories in human milk and standard infant formulas are derived from carbohydrates. Too little carbohydrate may lead to hypoglycemia, whereas too much may provoke osmotic diuresis or loose stools. The recommended range for carbohydrate intake is 40% to 50% of total calories.

Lactose, a disaccharide composed of glucose and galactose, is the predominant carbohydrate in almost all mammalian milks and may be important to the neonate for glucose homeostasis, perhaps because galactose can be used for either glucose production or glycogen storage. Generally galactose is used for glycogen formation first, and then it becomes available for glucose production as blood glucose levels decrease. Because infants born before 28 to 34 weeks of gestation have low lactase activity, the premature infant's ability to digest lactose may be marginal. In practice, malabsorption is not a clinical problem because lactose is hydrolyzed in the intestine or fermented in the colon and absorbed. Sucrose is another disaccharide that is found in commercial infant formula products. Because sucrase activity early in the third trimester is at 70% of newborn levels, sucrose is well tolerated by most premature infants. Sucrase and lactase are sensitive to changes in the intestinal milieu. Infants who have diarrhea, are undergoing antibiotic therapy, or are undernourished, may develop temporary intolerances to lactose and sucrose.

Glucose polymers are common carbohydrates in the preterm infant's diet. These polymers, consisting mainly of chains of five to nine glucose units linked together, are used to achieve the isoosmolality of certain specialized formulas. Glucosidase enzymes for digesting glucose polymers are active in small preterm infants.

Minerals and Vitamins

Premature infants require greater amounts of vitamins and minerals than term infants because they have poor body stores, are physiologically immature, are frequently ill, and will grow rapidly. Formulas and **human milk fortifiers** that are developed especially for preterm infants contain higher vitamin and mineral concentrations to meet the needs of the infant, obviating the need for additional supplementation in most cases (see [Table 42-13](#)). One major exception is infants receiving human milk with a fortifier that does not contain iron. An iron supplement of 2 mg/kg/day should be sufficient to meet their needs ([AAP, 2014](#)). The other exception is the use of donor human milk fortifier, which requires the addition of a multiple vitamin and an iron supplement.

TABLE 42-13 Recommendations for Enteral Administration of Vitamins for the Premature Infant

Vitamin	Amount (kg/day)
Vitamin A	700-1500 IU
Vitamin D	150-400 IU*
Vitamin E	6-12 IU
Vitamin K	8-10 mcg
Ascorbic acid	18-24 mg
Thiamin	180-240 mcg
Riboflavin	250-360 mcg
Pyridoxine	150-210 mcg
Niacin	3.6-4.8 mg
Pantothenate	1.2-1.7 mg
Biotin	3.6-6 mcg
Folate	25-50 mcg
Vitamin B ₁₂	0.3 mcg

Data from American Academy of Pediatrics, Committee on Nutrition: Nutritional needs of preterm infants. In Kleinman RE, Greer FR, editors: *Pediatric nutrition handbook*, ed 7, Elk Grove, Ill, 2014, American Academy of Pediatrics.

*Maximum of 400 IU/day.

Calcium and Phosphorus

Calcium and phosphorus are just two of many nutrients that growing premature infants require for optimal bone mineralization. Intake guidelines have been established at levels that promote the bone mineralization rate that occurs in the fetus. An intake of 150 to 220 mg/kg/day of calcium and 75 to 140 mg/kg/day of phosphorus is recommended ([Abrams, AAP, 2013](#)). Two thirds of the calcium and phosphorus body content of the term neonate is accumulated through active transport mechanisms during the last trimester of pregnancy. Infants who are born prematurely are deprived of this important intrauterine mineral deposition. With poor mineral stores and low dietary intake, preterm infants can develop **osteopenia of prematurity**, a disease characterized by demineralization of growing bones and documented by radiologic evidence of "washed-out" or thin bones. Very immature babies are particularly susceptible to osteopenia and may develop bone fractures or florid rickets with a prolonged dietary deficiency. Osteopenia of prematurity is most likely to develop in preterm infants who are (1) fed infant formula that is not specifically formulated for preterm infants, (2) fed human milk that is not supplemented with calcium and phosphorus, or (3) receiving long-term PN without enteral feedings.

Vitamin D

Human milk with human milk fortifier or infant formula for preterm infants provides adequate vitamin D when infants consume the entire calorie intake suggested. The current recommendations for intake range from 200 to 400 IU/day for preterm infants ([Abrams, AAP, 2013](#)).

Vitamin E

Preterm infants require more vitamin E than term infants because of their limited tissue stores, decreased absorption of fat-soluble vitamins, and rapid growth. Vitamin E protects biologic membranes against oxidative lipid breakdown. Because iron is a biologic oxidant, a diet high in either iron or polyunsaturated fatty acids (PUFAs) increases the risk of vitamin E deficiency. The PUFAs are incorporated into the red blood cell membranes and are more susceptible to oxidative damage than when saturated fatty acids compose the membranes.

A premature infant with vitamin E deficiency may experience **hemolytic anemia** (oxidative destruction of red blood cells). However, this anemia is now uncommon today because of improvements in human milk fortifiers and infant formula composition. The human milk fortifiers and premature infant formulas now contain appropriate vitamin E/PUFA ratios for preventing hemolytic anemia.

Because the dietary requirement for vitamin E depends on the PUFA content of the diet, the recommended intake of vitamin E is expressed commonly as a ratio of vitamin E to PUFA. The recommendation for vitamin E is 0.7 IU (0.5 mg of d-alpha-tocopherol) per 100 kcal, and at least 1 IU of vitamin E per gram of linoleic acid.

Pharmacologic dosing of vitamin E (50-100 mg/kg/day) has not proven to be helpful in preventing BPD or retinopathy of prematurity by reducing the toxic effects of oxygen. Furthermore, high doses of vitamin E have been associated with intraventricular hemorrhage, sepsis, NEC, liver and renal failure, and death.

Iron

Preterm infants are at risk for iron deficiency anemia because of the reduced iron stores associated with early birth. At birth most of the available iron is in the circulating hemoglobin. Thus frequent blood sampling further depletes the amount of iron available for erythropoiesis. Transfusions of red blood cells often are needed to treat the early physiologic anemia of prematurity. Recombinant erythropoietin (EPO) therapy has been used to prevent anemia. Iron supplementation is indicated to facilitate red blood cell production, and a dosage of 6 mg/kg/day of enteral iron has been used (AAP, 2014). This therapy has not consistently prevented anemia and the need for blood transfusions (AAP, 2014).

In general the recommendation for iron intake is 2 to 4 mg/kg/day (AAP, 2014). Infants fed human milk should be given ferrous sulfate drops beginning at 2 weeks of age (AAP, 2014). Formulas fortified with iron usually contain sufficient iron for preterm infants (AAP, 2014).

Folic Acid

Premature infants seem to have higher folic acid needs than infants born at term. Although serum folate levels are high at birth, they decrease dramatically, probably as a result of high folic acid use by the premature infant for deoxyribonucleic acid (DNA) and tissue synthesis needed for rapid growth.

A mild form of folic acid deficiency causing low serum folate concentrations and hypersegmentation of neutrophils is not unusual in premature infants. Megaloblastic anemia is much less common. A daily folic acid intake of 25 to 50 mcg/kg effectively maintains normal serum folate concentrations. Fortified human milk and formulas for premature infants meet these guidelines when full enteral feedings are established.

Sodium

Preterm infants, especially those with VLBW, are susceptible to hyponatremia during the neonatal period. These infants may have excessive urinary sodium losses because of renal immaturity and an inability to conserve adequate sodium. Furthermore, their sodium needs are high because of their rapid growth rate.

Daily sodium intakes of 2 to 3 mEq/kg meet the needs of most premature infants, but 4 to 5 mEq/kg or more may be

required by some infants to prevent hyponatremia (Dell, 2011). Routine sodium supplementation of fortified human milk and infant formulas is not necessary. However, it is important to consider the possibility of hyponatremia and monitor infants by assessing serum sodium until the blood level is normal. Milk can be supplemented with sodium if repletion is necessary.

FEEDING METHODS

Decisions about breastfeeding, bottle feeding, or tube feeding depend on the gestational age and the clinical condition of the preterm infant. The goal is to feed the infant via the most physiologic method possible and supply nutrients for growth without creating clinical complications.

Gastric Gavage

Gastric gavage by the oral route often is chosen for infants who are unable to suck because of immaturity or problems with the central nervous system. Infants less than 32 to 34 weeks of gestational age, regardless of birthweight have poorly coordinated sucking, swallowing, and breathing abilities because of their developmental immaturity. Consequently they have difficulty with nipple feeding.

With the oral **gastric gavage** method, a soft feeding tube is inserted through the infant's mouth and into the stomach. The major risks of this technique include aspiration and gastric distention. Because of weak or absent cough reflexes and poorly developed respiratory muscles, the tiny infant may not be able to dislodge milk from the upper airway, which can cause reflex bradycardia or airway obstruction. However, electronic monitoring of vital functions and proper positioning of the infant during feeding minimize the risk of aspiration from regurgitation of stomach contents. Tiny, immature infants whose small gastric capacity and slow intestinal motility can impede the tolerance of large-volume bolus feeds may need bolus feedings provided with a pump for a 30 to 60 minute infusion to aid in feeding tolerance.

Occasionally, elimination of the distention and vagal bradycardia requires the use of an indwelling tube for continuous gastric gavage feedings rather than intermittent administration of boluses. Continuous feedings may lead to loss of milk fat, calcium, and phosphorus, which deposit in the feeding tubing so that the infant does not receive the total amount of nutrition provided. Bolus feedings provided with the use of the pump infusion can decrease nutrient loss and promote better weight gain (Rogers et al, 2010; Senterre, 2014).

Nasal gastric gavage is sometimes better tolerated than oral tube feeding. However, because neonates must breathe through the nose, this technique may compromise the nasal airway in preterm infants and cause an associated deterioration in respiratory function. This method is helpful for infants who are learning to nipple feed. An infant with a nasal gastric tube can still form a tight seal on the bottle nipple, but it can be difficult if an oral feeding tube is in place during feedings (see Chapter 13).

Transpyloric Feeding

Transpyloric tube feeding is indicated for infants who are at risk for aspirating milk into the lungs or who have slow gastric emptying. The goal of this method is to circumvent the often slow gastric emptying of the immature infant by passing the feeding tube through the stomach and pylorus and placing its tip within the duodenum or jejunum. Infants with severe gastrointestinal

reflux do well with this method, which prevents aspiration of feedings into the lungs. This method also is used for infants whose respiratory function is compromised and who are at risk for milk aspiration. The possible disadvantages of transpyloric feedings include decreased fat absorption, diarrhea, dumping syndrome, alterations of the intestinal microflora, intestinal perforation, and bilious fluid in the stomach. In addition, the placement of transpyloric tubes also requires considerable expertise and radiographic confirmation of the catheter tip location. Although associated with many possible complications, transpyloric feedings are used when gastric feeding is not successful.

Nipple Feeding

Nipple feeding may be attempted with infants whose gestational age is greater than 32 weeks and whose ability to feed from a nipple is indicated by evidence of an established sucking reflex and sucking motion. Before this time they are unable to coordinate sucking, swallowing, and breathing. Because sucking requires effort by the infant, any stress from other causes such as hypothermia or hypoxemia diminishes the sucking ability. Therefore nipple feeding should be initiated only when the infant is under minimum stress and is sufficiently mature and strong to sustain the sucking effort. Initial oral feedings may be limited to one to three times per day to prevent undue fatigue or too much energy expenditure, either of which can slow the infant's rate of weight gain. Before oral feedings begin, a standardized oral stimulation program can help infants successfully nipple feed more quickly (Fucile et al, 2011).

Breastfeeding

When the mother of a premature infant chooses to breastfeed, nursing at the breast should begin as soon as the infant is ready. Before this time the mother must express her milk so that it can be tube-fed to her infant. These mothers need emotional and educational support for successful lactation. Studies report that premature breast-fed infants have better sucking, swallowing, and breathing coordination and fewer breathing disruptions than bottle-fed infants (Abrams and Hurst, 2014). **Kangaroo care**—allowing the mother to maintain skin-to-skin contact while holding her infant—facilitates her lactation. In addition, this type of contact promotes continuation of breastfeeding and enhances the mother's confidence in caring for her high-risk infant. The latter benefit also may apply to fathers who engage in kangaroo care with their infants (Kassity-Krich and Jones, 2014).

Feeding infants with cups instead of bottles to supplement breastfeeding has been suggested for preterm infants based on the rationale that it may prevent infant "nipple confusion" (i.e., confusion between nursing at the breast and from a bottle). Complications such as milk aspiration and low volume intakes have to be monitored. Cup feeding has been associated with successful breastfeeding at discharge, but increased length of stay in the hospital for the premature infant (AAP, American College of Obstetricians and Gynecologists [ACOG], 2014).

Tolerance of Feedings

All preterm babies receiving EN should be monitored for signs of feeding intolerance. Vomiting of feedings usually signals the infant's inability to retain the provided amount of milk. When not associated with other signs of a systemic illness, vomiting may indicate that feeding volumes were increased too quickly or are excessive for the infant's size and maturity. Simply reducing the feeding volume may resolve the problem. If not, or if the

infant has signs of a systemic illness, feedings may have to be interrupted until the infant's condition has stabilized.

Abdominal distention may be caused by excessive feeding, organic obstruction, excessive swallowing of air, resuscitation, sepsis (i.e., systemic infection), or NEC. Observing infants for abdominal distention should be a routine practice for nurses. Abdominal distention often indicates the need to interrupt feeding until its cause is determined and resolved.

Gastric residuals, measured by aspiration of the stomach contents, may be determined routinely before each bolus gavage feeding and intermittently in all continuous drip feedings. Whether a residual amount is significant depends partly on its volume in relation to the total volume of the feeding. For example, a residual volume of more than 50% of a bolus feeding or equal to the continuous infusion rate may be a sign of feeding intolerance. However, when interpreting the significance of a gastric residual measurement, clinicians must consider other concurrent signs of feeding intolerance and the previous pattern of residual volumes established for a particular infant. Residuals are frequently present before feedings are initiated and as small volume feedings are started. As long as no signs of illness are present, feedings should not be withheld.

Bile-stained emesis or residuals frequently may be due to overdistention of the stomach with reflux of bile from the intestine, or to a feeding tube that has slipped into the intestine, or may indicate that the infant has an intestinal blockage and needs additional evaluation (Schanler, 2014). Bloody or bilious gastric residuals are more alarming than those that seem to be undigested milk.

The frequency and consistency of bowel movements should be monitored constantly when feeding preterm infants. Simple inspections can detect the presence of gross blood. All feeding methods for preterm infants have associated complications. Unless close attention is paid to symptoms that indicate poor feeding tolerance, serious complications may ensue. Certain diseases can be recognized by recognizing signs of feeding intolerance. For example, **necrotizing enterocolitis (NEC)** is a serious and potentially fatal disease associated with specific symptoms such as abdominal distention and tenderness, abnormal gastric residuals, and grossly bloody stools.

SELECTION OF ENTERAL FEEDING

During the initial feeding period, premature infants often require additional time to adjust to EN and may experience concurrent stress, weight loss, and diuresis. The primary goal of enteral feeding during this initial period is to establish tolerance to the milk. Infants seem to need a period of adjustment to be able to assimilate a large volume and concentration of nutrients. Thus parenteral fluids may be necessary until infants can tolerate adequate amounts of feedings by mouth.

After the initial period of adjustment, the goal of enteral feeding changes from establishing milk tolerance to providing complete nutrition support for growth and rapid organ development. All essential nutrients should be provided in quantities that support sustained growth. The following feeding choices are appropriate: (1) human milk supplemented with human milk fortifier and iron and vitamins as indicated by fortifier used, (2) iron-fortified premature infant formula for infants who weigh less than 2 kg, or (3) iron-fortified standard infant formula for infants who weigh more than 2 kg.

Premature infants who are discharged from the hospital can be given a transitional formula. Additional vitamin D may be

indicated to provide 400 IU per day (Abrams, AAP, 2013). Breast-fed infants may be provided with two to three bottles of transitional formula daily to meet needs. The breast-fed premature infant also should receive 2 mg/kg/day of iron and a multiple vitamin for the first year of life (AAP, 2014). Premature infants discharged home on standard formula should receive a multivitamin until the infant reaches 3 kg in weight and then only vitamin D may be needed to provide 400 IU per day (AAP, 2014).

Human Milk

Human milk is the ideal food for healthy term infants and premature infants. Although human milk requires nutrient supplementation to meet the needs of premature infants, its benefits for the infant are numerous. During the first month of lactation, the composition of milk from mothers of premature infants differs from that of mothers who have given birth to term infants; the protein and sodium concentrations of breastmilk are higher in mothers with preterm infants (Klein, 2002). When premature infants are fed their own mother's milk, they grow more rapidly than infants fed banked, mature breastmilk (Ahrabi and Schanler, 2013).

In addition to its nutrient concentration, human milk offers nutritional benefits because of its unique mix of amino acids and long-chain fatty acids. The zinc and iron in human milk are more readily absorbed, and fat is more easily digested because of the presence of lipases. Moreover, human milk contains factors that are not present in formulas. These components include

(1) macrophages and T and B lymphocytes; (2) antimicrobial factors such as secretory immunoglobulin A, lactoferrin, and others; (3) hormones; (4) enzymes; and (5) growth factors. It has been reported that human milk compared with premature infant formula fed to preterm infants reduces the incidence of NEC and sepsis, improves neurodevelopment, facilitates a more rapid advancement of enteral feedings, and leads to an earlier discharge (AAP, ACOG, 2014). The use of mother's own milk for her infant supplemented with liquid donor human milk fortifier and donor human milk is linked to decreased incidence of NEC (Sullivan et al, 2010). The use of donor milk and liquid donor human milk fortifier compared with premature infant formula decreases the incidence of NEC treated by surgery and decreases the days of parenteral nutrition (Cristofalo et al, 2013).

However, one well-documented problem is associated with feeding human milk to preterm infants. Whether it is preterm, term, or mature, human milk does not meet the calcium and phosphorus needs for normal bone mineralization in premature infants. Therefore calcium and phosphorus supplements are recommended for rapidly growing preterm infants who are fed predominantly human milk. Currently three human milk fortifiers are available: powder bovine milk base, liquid bovine milk base, and liquid donor human milk base. The bovine products contain calcium and phosphorus, as well as protein, carbohydrates, fat, vitamins, and minerals, and are designed to be added to expressed breastmilk fed to premature infants (see Table 42-14). Vitamin supplements are not

needed. One bovine fortifier is iron fortified and the other requires the addition of iron. The human-milk base product is made from donor human milk that has been pasteurized, concentrated, and supplemented with calcium, phosphorous, zinc, and electrolytes. A multivitamin and an iron supplement is needed with the use of the human-milk base fortifier. The human-milk base fortifier comes as additives to make the milk 24, 26, 28 or 30 kcal/oz milk. The higher concentrations are used for infants who are volume restricted or not growing on lower caloric-dense milk (Hair et al, 2013). The calories and protein are higher with the increased concentrations, but the concentrations of calcium, phosphorous, and zinc remain the same with the donor human milk fortifier. Often the infant needs more energy and protein, but not increased mineral intake. A donor human milk cream supplement is available that is pasteurized human milk fat and can be added to human milk.

Providing human milk to a premature infant can be a very positive experience for the mother, one that promotes involvement and interaction. Because many preterm infants are neither strong enough nor mature enough to nurse at their

mother's breast in the early neonatal period, their mothers usually express their milk for several days (and occasionally for several weeks) before nursing can be established. The proper technique of expression, storage, and transport of milk should be reviewed with the mother (see Table 15-19 in Chapter 15). Many summaries of the special considerations for nursing a preterm infant have been published (AAP, ACOG, 2014).

Donor Human Milk

Pasteurized donor human milk (DM) is recommended for the premature infant when the mother's own milk (MOM) is not available or is contraindicated (AAP, 2012; see *Focus On: What Is a Human Milk Bank?*). NICUs that use donor milk may have guidelines to ensure that the infants most at risk for NEC receive donor milk. For example, an infant with a birthweight less than 1500 g and a gestational age less than 34 weeks would qualify to receive donor milk. The risk for NEC is highest at 32 weeks' gestation (Yee et al, 2012). At 34 weeks, the infant can transfer to a discharge diet of mom's milk and supplementation with transitional formula if needed. Donor milk would not be used after discharge to home.

FOCUS ON

What Is a Human Milk Bank?

By DeeAnna Wales VanReken, MS, RDN, CD

Human milk banks are nonprofit and for-profit establishments around the globe that work to pasteurize milk safely from healthy donor mothers and make it available to infants who need it most (PATH, 2013). Donors are screened carefully for medication and any supplement use, must be non-smokers, and will not be approved if they drink alcoholic beverages within defined exclusion periods.

For high-risk infants who are premature, immune compromised, or unable to breastfeed because of HIV-positive mothers, donor breastmilk is a life-saving resource when mother's own milk, the best choice, is not available (Arslanoglu et al, 2013). Because of its optimal nutrition profile and unique immunologic properties, no other source of nourishment compares when providing these vulnerable infants with the nutrition needed to get a healthy start in life. This precious commodity has saved lives and improved infant morbidity so greatly in Brazil, that the World Health Organization (WHO) has now asked that all nations advocate for the safe use of donor milk through human milk banking (WHO, 2000).

Hospitals with milk-banking systems are usually nonprofit and each have their own guidelines around distributing the milk so that it remains as a safe and altruistic option for all who need it. Recent research also has shown that unpasteurized sources of human milk can be purchased over the Internet and have a high probability for microbial contamination (Keim et al, 2013). Occasionally, mothers of healthy babies may seek out peer-to-peer sharing to avoid the cost, inconvenience, and depletion of resources for vulnerable babies who need pasteurized donor milk the most. If a mother expresses interest in these options, she should receive guidance to understand and mitigate the risks of sharing unpasteurized human milk (Gribble and Hausman, 2012).

Effective human milk banks protect, promote, and support breastfeeding at every level, and are cradled by governmental support (Arnold, 2006). The Human Milk Banking Association of North America (HMBANA) is the premier resource for information on the start up and management of this precious commodity in every community as a means to improve global health (HMBANA, 2014). Email info@hmbana.org for more information.

The use of donor milk has been linked with earlier initiation of feedings, less formula use and no change in the percentage of MOM use. DM frequently is used with the initiation of feedings before the mother's milk can be expressed. Neonatologists were concerned that the use of DM would lead to mothers not providing milk for their infant, but there was no change in mothers providing milk for their own infants (Marinelli et al, 2014).

Premature Infant Formulas

Formula preparations have been developed to meet the unique nutritional and physiologic needs of growing preterm infants. The quantity and quality of nutrients in these products promote growth at intrauterine rates. These formulas, which have caloric densities of 20, 24, and 30 kcal/oz, are available only in a ready-to-feed form. These premature formulas differ in many respects from standard cow's milk-based formulas (see Table 42-14). The types of carbohydrate, protein, and fat differ to facilitate digestion and absorption of nutrients. These for-

mulas also have higher concentrations of protein, minerals, and vitamins.

Transitional Infant Formulas

Formulas containing 22 kcal/oz have been designed as transition formulas for the premature infant. Their nutrient content is less than that of the nutrient-dense premature infant formulas and more than that of the standard infant formula (see Table 42-14). These formulas can be introduced when the infant reaches a weight of 2000 g, and they can be used throughout the first year of life. Not all premature infants need these formulas to grow appropriately. It is not clear which premature infants need this specialized formula, because studies have not always demonstrated improved growth with the use of transitional formula (Young et al, 2012). Gain of weight, length, and head circumference for age and weight for length should be monitored on the World Health Organization growth curves (Lapillonne,

2014). Transitional formulas are available in powder form and in ready-to-feed form.

Formula Adjustments

Occasionally it may be necessary to increase the energy content of the formulas fed to small infants. This may be appropriate when the infant is not growing quickly enough and already is consuming as much as possible during feedings.

Concentration

One approach to providing hypercaloric formula is to prepare the formula with less water, thus concentrating all its nutrients, including energy. Concentrated infant formulas with energy contents of 24 kcal/oz are available to hospitals as ready-to-feed nursettes. However, when using these concentrated formulas, clinicians must consider the infant's fluid intake and losses in relation to the renal solute load of the concentrated feeding to ensure that a positive water balance is maintained. This method of increasing formula density often is preferred because the nutrient balance remains the same; infants who need more energy also need additional nutrients. As mentioned, the transitional formulas are available in ready-to-feed and powder form and can be concentrated from 24 to 30 kcal/oz. However, this formula is still inadequate for infants who need additional calcium (e.g., infants with osteopenia).

A ready-to-feed 30 kcal/oz premature infant formula is available. It meets the nutritional needs for premature infants who must be fluid restricted because of illness. This 30 kcal/oz formula can be diluted with premature infant formula (24 kcal/oz) to make 26, 27, or 28 kcal/oz milks (see [Box 42-2](#)). These milks are sterile and are the preferred source of providing concentrated milks to premature infants in the neonatal intensive care unit (NICU). Infant formula powder is not sterile and is not to be used with high-risk infants when a nutritionally adequate liquid, sterile product is available ([Robbins and Meyers, 2011](#)).

Caloric Supplements

Another approach to increasing the energy content of a formula involves the use of caloric supplements such as vegetable oil, MCT oil, or glucose polymers. These supplements increase the caloric density of the formula without markedly altering solute load or osmolality. However, they do alter the relative distribution of total calories derived from protein, carbohydrate, and fat. Because even small amounts of oil or carbohydrate dilute the percentage of calories derived from protein, adding these supplements to human milk or standard (20 kcal/oz) formulas is not advised. Caloric supplements should be used only when a formula already meets all nutrient requirements other than energy or when the renal solute load is a concern.

When a high-energy formula is needed, glucose polymers can be added to a base that has a concentration of 24 kcal/oz or greater (either full-strength premature formula or a concentrated standard formula), with a maximum of 50% of total calories from fat and a minimum of 10% of total calories from protein. Vegetable oil should be added to a feeding at the time or given as an oral medication. Vegetable oil added to a day's supply of formula that is chilled will separate out from the milk and cling to the milk storage container and will not be in the feeding to the infant.

NUTRITION ASSESSMENT AND GROWTH

Dietary Intake

Dietary intake must be evaluated to ensure that the nutrition provided meets the infant's needs. Parenteral fluids and milk feedings are advanced as tolerated, and the nutrient intakes must be reviewed to ensure that they are within the guidelines for premature infants and that the infant is thriving on the nutrition provided. Appropriate growth and growth charts are reviewed in the following paragraphs.

Laboratory Indices

Laboratory assessments usually involve measuring the following parameters: (1) fluid and electrolyte balance, (2) PN or EN tolerance, (3) bone mineralization status, and (4) hematologic status (see [Table 42-15](#)). Hemoglobin and hematocrit are monitored as medically indicated. The early decrease in hematocrit reflects the physiologic drop in hemoglobin after birth and blood drawings for laboratory assessments. Early low hemoglobins are treated with blood transfusions if needed. Dietary supplementation does not change this early physiologic drop in hemoglobin.

Growth Rates and Growth Charts

All neonates typically lose some weight after birth. Preterm infants are born with more extracellular water than term infants and thus tend to lose more weight than term infants. However, the postnatal weight loss should not be excessive. Preterm infants who lose more than 15% of their birth weight may become dehydrated from the inadequate fluid intake or experience tissue wasting from poor energy intake. An infant's birth weight should be regained by the second or third week of life. The smallest and sickest infants take the longest time to regain their birth weights.

	Serum alkaline phosphatase activity	Serum alkaline phosphatase activity
Parenteral nutrition toxicity	Cholestasis: conjugated bilirubin	Not indicated
	Liver function: ALT	

ALT, Alanine aminotransferase; BUN, blood urea nitrogen.

Intrauterine growth curves have been developed using birth weight, birth length, and birth head circumference data of infants born at several successive weeks of gestation. The intrauterine growth curves are the standard of growth recommended for premature infants. During the first week of life premature infants fall away from their birth weight percentile, which reflects the normal postnatal weight loss of newborn infants. After an infant's condition stabilizes and the infant begins consuming all needed nutrients, the infant may be able to grow at a rate that parallels these curves. An intrauterine weight gain of 15 to 20 g/kg/day can be achieved.

Although weight is an important anthropometric parameter, measurements of length and head circumference also can be helpful. Premature infants should grow between 0.7 to 1 cm per week in body length and head circumference. A growth curve based on gender can be used to evaluate the adequacy of growth in all three areas (see Figures 42-3 and 42-4). This chart has a built-in correction factor for prematurity; the infant's growth can be followed from 22 to 50 weeks of gestation and it represents cross-sectional data from Canada, Australia, Germany, Italy, Scotland, and the United States (Fenton and Kim, 2013). The intrauterine curves are smooth into the World Health Organization Charts.

FIGURE 42-3 Example of a growth record of weight, length, and head circumference for female infants from 22 to 50 weeks of gestation. This chart has a built-in correction factor for prematurity. <http://ucalgary.ca/fenton> (From Fenton TR and Kim JH: A systematic review and meta-analysis to revise the Fenton growth chart for preterm infants, *BMC Pediatr* 13:59, 2013.)

FIGURE 42-4 Example of a growth record of weight, length, and head circumference for male infants from 22 to 50 weeks of gestation. This chart has a built-in correction factor for prematurity. <http://ucalgary.ca/fenton> (From Fenton TR, Kim JH: A systematic review and meta-analysis to revise the Fenton growth chart for preterm infants, *BMC Pediatr* 13:59, 2013.)

Additional intrauterine growth charts based on the birth-weight, birth length, and head circumferences of infants born in the United States have been developed (Olsen et al, 2010). Separate charts for male and female infants are available and infants can be plotted from 23 to 41 weeks' gestation.

The 2006 World Health Organization Growth Charts designed for children from birth to 2 years of age also should be used for preterm infants once they reach 40 weeks' gestation, as long as the age is adjusted (see *Focus On: Long-Term Outcome for Premature Infants*). For example, an infant born at 28 weeks of gestation is 12 weeks premature (40 weeks of term gestation minus 28 weeks of birth gestational age). Four months after birth, the growth parameters of a premature infant born at 28 weeks of gestation can be compared with those of a 1-month-old infant born at term (see Box 42-3). When using growth grids, age should be adjusted for prematurity until at least 2½ to 3 years of corrected age. In Figure 42-5 A.R.'s pattern of growth is shown through 18 years of age. These charts are based on term, healthy infants who were breast fed the first year of life (Grummer-Strawn et al, 2010). By using this chart, the infant's growth can be compared with the term infant to assess catch-up growth.

FOCUS ON

Long-Term Outcome for Premature Infants

As the survival of premature infants continues to improve, their physical growth, cognitive development, health, and quality of life are being evaluated and investigated. Previously it was believed that, if premature infants experienced catch-up growth, it would occur only during the first few years of life. However, catch-up growth for weight and length can continue throughout childhood. Head circumference catch up growth is limited to 6 to 12 months corrected age (Hack, 2013). Brain development occurs during the first year of life. As adults, ELBW infants tend to be shorter and weigh the same as infants born at term (Roberts et al, 2013a). The parents of the premature infants are often shorter than the parents of term infants, and this could contribute to the infant's adult height.

Growth in the NICU for ELBW infants is linked to growth and development at 18 to 22 months corrected age (Ehrenkranz, 2014). Infants with weight gains greater than 18 grams/kg/day or head circumference growth of 0.9 cm/week had better neurodevelopment and physical growth than infants with slower growth.

Premature infants and very low birthweight infants often develop adult-onset type 2 diabetes. Premature infants have decreased glucose regulation compared with infants born at term. Higher fasting insulin levels, impaired glucose tolerance, and increased insulin resistance may occur (Kajantie and Hovi, 2014). Premature infants or very low birthweight infants have been reported to have higher blood pressures than infants born at term and normal weight (Lapillonne and Griffin, 2013).

More research is needed. What is the optimal rate of growth for premature infants in the NICU and postdischarge to maximize cognitive/developmental outcomes and decrease their risk of adult cardiovascular and metabolic diseases (Lapillonne and Griffin, 2013)? How fast should the premature infant grow? What should the body composition be? When should catch-up growth occur?

Tools have been developed and validated that assess how adults report their health status and quality of life. The evaluations may be conducted by interviews or completion of written questionnaires (Saigal, 2014). As adults, premature and very low birthweight infants rate their quality of life to be similar to adults who were born at term. Roberts and colleagues (2013b) reported on 194 ELBW infants and 148 term infants who completed written evaluations at 18 years. Both groups were the same in their reported quality of life, health status, and self-esteem. Quality of life did not differ for the adults with the smallest birth weight or youngest gestational age. Premature infants not completing the evaluation at 18 years were more likely to have a neurosensory disability at 8 years of age, such as cystic periventricular leukomalacia, blindness, cerebral palsy, and a lower intelligent quotient.

Therefore not only are more premature infants surviving, but they also are growing into adults who are enjoying and living productive lives (Hack, 2013; Saigal, 2013). The medical and nutrition care in the hospital nursery continues to progress, which improves outcome in the nursery and sets the stage for later development.

BOX 42-3 Steps for Adjusting Age for Prematurity on Growth Charts

Calculate the number of weeks the infant was premature:

- 40 weeks (term) – Weeks of birth gestational age = Number of weeks premature
- The resulting number of weeks is the correction factor.
- Calculate the adjusted age for prematurity:
- Chronologic age – Correction factor = Adjusted age for prematurity

For example:

- 40 weeks – 28 weeks of gestation = 12 weeks premature
- Therefore 12 weeks (3 months) is the correction factor.
- 4 months (chronologic age) – 3 months (correction factor) = 1 month adjusted age

Commonly used PES (problem, etiology, signs and symptom) statements for infants are provided in Box 42-4. Assessment of nutrient intakes and infant growth are reviewed.

DISCHARGE CARE

Establishment of successful feeding is a pivotal factor determining whether a preterm infant can be discharged from the hospital nursery. Preterm infants must be able to (1) tolerate their feedings and usually obtain all of their feedings from the breast or bottle, (2) grow adequately on a modified-demand feeding schedule (usually every 3-4 hours during the day for bottle-fed infants or every 2-3 hours for breast-fed infants), and (3) maintain their body temperature without the help of an incubator. Medically stable premature infants who have delayed feeding development go home on gavage feedings for a short period. In addition, it is important that any ongoing chronic illnesses, including nutrition problems, be manageable at home.

Most important, the parents must be ready to care for their infant. In hospitals that allow parents to visit their infants in the nursery 24 hours a day, staff can help parents develop their caregiving skills and learn to care for their infant at home. Often, parents are permitted to “room in” with their infant (i.e., stay with the infant all day and night) before discharge, which helps build confidence in their ability to care for a high-risk infant (see Figure 42-6).

Many preterm infants who are discharged from the hospital weigh less than 5½ lb. Although these infants must meet certain discharge criteria before they can go home, the stress of a new environment may lead to setbacks. Small preterm infants should be followed very closely during the first month after discharge, and parents should be given as much information and support as possible. Within the first week of discharge, a home visit by a nurse, dietitian, or both and a visit to the pediatrician can be extremely helpful educationally; and they can provide opportunity for early intervention for developing problems.

Factors that affect the feeding skills and behavior of preterm infants are particularly important after the infants have been discharged. Physical factors such as a variable heart rate, a rapid respiratory rate, and tremulousness are examples of physiologic events that interfere with feeding. In addition, infants weighing less than 5½ lb have poor muscle tone. Although muscle tone gradually improves as an infant becomes larger and more mature, it can deteriorate quickly in infants who are tired or weak. Feeding is often difficult for infants who have limited muscle flexion and strength and poor head and neck control, which are needed to maintain a good feeding posture. Positioning these infants in a manner that supports normal body flexion and ensures proper alignment of the head and neck during feedings is helpful. Premature infants may also need their chin and cheeks supported while bottle feeding.

Small infants tend to sleep more than larger and term infants. It is much easier for preterm infants to feed effectively if they are fully awake. To awaken a preterm infant, the caregiver should provide one type of gentle stimulation for a few minutes and then change to a different type, repeating this pattern until the infant is fully awake. Lightly swaddling of the infant and then placing him or her in a semi upright position also may help.

The feeding environment should be as quiet as possible. Preterm infants are easily distracted and have difficulty focusing on feeding when noises or movements interrupt their attention. They also tire quickly and are easily overstimulated. When they are overstimulated, they may show only subtle signs of distress. It is important to teach parents of premature infants to

FIGURE 42-5 A, Graphs showing how A.R. (from Figure 42-2), who was born at 27 weeks of gestation, grew after leaving the neonatal unit 1 day before her due date at a weight of 4½ lb. Heights and weights until age of 24 months are plotted on the grid at “corrected age” points. A.R. experienced catch-up growth during the first 12 months. **B**, A.R.’s growth pattern from the age of 2 to 18 years. During the first 10 years she grew at the 5th percentile for weight and the 10th percentile for height. She followed her channel of growth but did not experience catch-up growth. However, between the ages of 10 and 13 she began to change growth channels and moved to the 25th percentile for weight and the 25th percentile for height (catch-up growth). At 18 years she crossed the 25th percentile for height and fell slightly below the 25th percentile for weight.

BOX 42-4 PES Statements Commonly Used for Infants

- Increased nutrient (multinutrient) needs related to increased metabolic demand as evidenced by weight gain <15 g/kg/day despite intake meeting estimated needs
- Suboptimal growth rate related to nutrient provision not meeting estimated needs as evidenced by weight gain <20 g/day
- Suboptimal mineral (iron) intake related to low iron-fortified human milk intake as evidenced by iron intake less than estimated needs for premature infants (guideline is 2-4 mg/kg/day)
- No nutrition diagnosis at this time as enteral nutrition meeting estimated needs and weight gain/growth appropriate overall

Data taken from commonly used PES Statements used by Neonatal Dietitians at Texas Children’s Hospital, Houston, Texas, December, 2014.

recognize the subtle cues that indicate the need for rest or comfort and to respond to them appropriately.

The premature infant may be able to breastfeed all feedings to meet nutritional needs. Infants with a birthweight less than 1500 g may need formula supplementation of human milk to meet their nutritional needs for adequate growth. Two to three feedings of the transitional formula can be provided, and the mother can breastfeed the other feedings or provide expressed human milk in bottles. Transitional formula is available as a liquid ready-to-feed formula. The use of powder formula as a supplement can be avoided. Infant formula powders are not sterile and have been linked with *Cronobacter sakazakii* infections. The use of two or three bottles of ready-to-feed formula provides more protein and minerals than provided when human milk is fortified with infant formula powder (AAP, 2014). A multivitamin and iron

FIGURE 42-6 Family in the nursery with their premature infant.

supplementation should be provided to meet the infant's vitamin D and increased iron demands.

After discharge, most preterm infants need approximately 180 ml/kg/day ($2\frac{3}{4}$ oz/lb/day) of breastmilk or standard infant formula containing 20 kcal/oz. This amount of milk provides 120 kcal/kg/day (55 kcal/lb/day). Alternatively, transitional formula with a concentration of 22 kcal/oz can be provided at a rate of 160 ml/kg/day (or 2.5 oz/lb/day). The best way to determine whether these amounts are adequate for individual infants is to compare their intake with their growth progress over time. Some infants may need a formula that provides 24 kcal/oz. As mentioned previously, powdered transitional formula can be readily altered to a concentration of 24 kcal/oz.

It is important to evaluate needs based on the three growth parameters: weight, length, and head circumference. Patterns of

growth should be assessed to determine whether (1) individual growth rate curves at least parallel reference curves, (2) growth curves are shifting inappropriately across growth percentiles, (3) weight is appropriate for length, and (4) growth is proportionate in all three areas.

NEURODEVELOPMENTAL OUTCOME

It is possible to meet the metabolic and nutritional needs of premature infants sufficiently to sustain life and promote growth and development. In fact, more tiny premature infants are surviving than ever before because of adequate nutrition support and the recent advances in neonatal intensive care technology. There is concern that the ELBW infant is often smaller at discharge than the infant of the same postmenstrual age who was not born prematurely. One report suggests that providing appropriate protein intake during week 1 of life to ELBW infants leads to improved growth of weight, length, and head circumference at 36 weeks' gestation, and improved head circumference in male infants at 18 months' corrected age (Poindexter, 2014). Improved neurodevelopment and growth at 18 months has been reported with ELBW infants who gained more weight and had greater head circumference growth during their stay in the nursery (Ehrenkranz, 2014). The developmental outcome scores for ELBW infants have been higher as the intakes of mother's own milk increase (Ahrabi and Schanler, 2013). Research on the neurodevelopment of premature infants who receive fortified donor human milk is needed (Arslanoglu et al, 2013).

The increased survival rate of ELBW infants has increased concerns about their short- and long-term neurodevelopmental outcomes. Many questions have been raised about the quality of life awaiting infants who receive neonatal intensive care. As a rule, VLBW infants should be referred to a follow-up clinic to evaluate their development and growth and begin early interventions (Hack, 2013). The survival of ELBW infants has increased, with an increase in the number of children who are developmentally normal who attend school and live independent lives as adults (Hack, 2013). Many of these premature infants reach adulthood with no evidence of any disability (see Figure 42-7).

CLINICAL CASE STUDY 1

Heather, an infant born at 26 weeks of gestation, was admitted to the neonatal intensive care unit. Her birth weight was 850 g (appropriate for gestational age). Heather had respiratory distress syndrome and had to receive a tube for mechanical ventilation. During the first few hours of her life, she was given surfactant, and her ventilator settings were lowered. She was also placed in a humidified incubator and given 100 ml/kg/day of starter parenteral nutrition (dextrose 10% in water with amino acids) intravenously.

On the second day after her birth, she had gained 20 g, and her serum sodium concentration and urine volume output were low. She was diagnosed with excessive fluid intake. Her blood pressure was low and the drug dopamine was provided to increase her urine output.

On the fourth day after birth, her body weight had decreased 50 g—6% of her birth weight—and her serum electrolyte levels were normal. The protein concentration of her parenteral fluids was increased, as was the volume of intravenous fat being provided.

By the fifth day, Heather was clinically stable. She began receiving feedings of milk from her mother—1.0 ml every 3 hours (10 ml/kg of her birth weight)—via bolus oral gastric tube. The feedings were tolerated well. She then began receiving daily a larger volume of her mother's breastmilk and less parenteral fluids.

On day eleven, full enteral feedings were established, and after extubation Heather was successfully breathing on her own.

Nutrition Diagnostic Statement, Day 2

Excessive fluid intake related to intravenous fluids administered as evidenced by gain of 20 g and low serum sodium level.

Nutrition Diagnostic Statement, Day 11

Inadequate intake of protein and minerals related to increased needs due to prematurity as evidenced by unfortified human milk not meeting established nutritional needs of premature infants.

Nutrition Care Questions

1. On the second day after birth, should Heather's intravenous fluid volume have been (1) increased because she needed more calories, (2) decreased because she was overhydrated, or (3) changed to enteral feedings because she was clinically stable?
2. How should the intravenous fat that was given to Heather have been administered?
3. The breastmilk from Heather's mother may have inadequate amounts of which nutrients? What do you recommend to resolve this?

FIGURE 42-7 The premature infant A.R. (see Figures 42-2 and 42-6) as she grows up. **A**, 3½ years. **B**, 10 years. **C**, 14 years. **D**, 18 years. (D, Courtesy Yuen Lui Studio, Seattle, Wash.)

CLINICAL CASE STUDY 2

Baby Le was born at 29 weeks of gestation, and his birthweight was 1400 g. He is now 1 week old or 30 weeks' postmenstrual age and weighs 1375 g. He is receiving parenteral nutrition at 130 ml/kg/day that contains 12.5% dextrose and 3.5% amino acids and a 20% intravenous fat emulsion at 15 ml/kg per day. The registered dietitian nutritionist (RDN) assesses the nutrient intake, and calculations are given in the following table. The patient's intakes are compared with the parenteral guidelines of the American Academy of Pediatrics (AAP, 2014) for premature infants.

Nutrient	Nutrient (kg/day)	Guidelines (kg/day)
Kilocalories kcal/kg/day	103	90-100
Glucose mg/kg/min	11.3	11-12
Protein g/kg	4.6	2.7-4.0
Fat g/kg	3	1-3

Nutrition Diagnostic Statement

Excessive protein intake related to excessive provision in parenteral nutrition as evidenced by protein intake greater than recommendation of 4.0 g of protein per kilogram established by the AAP in 2014.

Nutrition Care Questions

1. The RDN chooses the nutrition diagnosis and writes the problem-etiology-signs and symptoms statement. Interventions include decreasing the amino acid concentration to 3%, which will provide 4.0 g of protein per kilogram per day.
2. In how many days would you monitor and evaluate Baby Le's nutrition status?
3. What guidance is needed for the staff to evaluate him for signs of dehydration?

Medical Nutrition Therapy for Genetic Metabolic Disorders

Beth N. Ogata, MS, RDN, CD, CSP,
Cristine M. Trahms, MS, RDN, FADA

KEY TERMS

argininosuccinic aciduria (ASA)

autosomal-recessive

branched-chain ketoaciduria

carbonyl-phosphate synthetase (CPS)
deficiency

citrullinemia

fatty acid oxidation disorders

galactokinase deficiency

galactosemia

galactose-1-phosphate uridylyltransferase (GALT) deficiency

genetic metabolic disorders

gluconeogenesis

glycogen storage diseases
(GSDs)

glycogenolysis

hereditary fructose intolerance

ketone utilization disorder

L-carnitine

long-chain 3-hydroxyacyl-CoA
dehydrogenase (LCHAD)
deficiency

maple syrup urine disease
(MSUD)

medium-chain acyl-CoA dehydrogenase (MCAD) deficiency

methylmalonic acidemia

ornithine transcarbamylase (OTC)
deficiency

phenylketonuria (PKU)

propionic acidemia

urea cycle disorders (UCDs)

Genetic metabolic disorders are inherited traits that result in the absence or reduced activity of a specific enzyme or cofactor necessary for optimal metabolism. Most genetic metabolic disorders are inherited as **autosomal-recessive** traits; autosomal means that the gene is located on a chromosome other than the X or Y chromosomes (see Chapter 5). The treatment for many metabolic disorders is medical nutrition therapy (MNT), with intervention specific to the disorder. The goals of MNT are to maintain biochemical equilibrium for the affected pathway, provide adequate nutrients to support typical growth and development, and support social and emotional development. Nutrition interventions are designed to circumvent the missing or inactive enzyme by (1) restricting the amount of substrate available, (2) supplementing the amount of product, (3) supplementing the enzymatic cofactor, or (4) combining any or all of these approaches. The primary conditions commonly found in the United States are discussed here, and [Table 43-1](#) outlines other disorders by the enzymatic defects, distinctive clinical and biochemical features, and current approaches to dietary therapy.

In some instances, when treatment is initiated early in the newborn period and meticulously continued for a lifetime, the affected individual can be cognitively and physically normal. For other conditions, cognitive and physical damage can occur despite early and meticulous treatment. Biochemical disorders range from variations in enzyme activity that are benign, to severe manifestations that are incompatible with life. For many, significant questions related to diagnosis and treatment remain.

NEWBORN SCREENING

Most inherited metabolic disorders are associated with severe clinical illness that often appears soon after birth. Intellectual disability and severe neurologic involvement may be immediately apparent. Diagnosis of a specific disorder may be difficult, and appropriate treatment measures may be uncertain. Prenatal diagnosis is available for many metabolic disorders, but it usually requires the identification of a family at risk, which can be done only after the birth of an affected child. Effective newborn screening programs, as well as advanced diagnostic techniques and treatment modalities have improved the outcome for many of these infants.

Infants suspected of having a metabolic disorder should be afforded access to care offered by centers with expertise in treating these disorders. Infants who are afebrile for no apparent reason, lethargic, vomiting, in respiratory distress, or having seizures should be evaluated for an undiagnosed metabolic disorder. The initial assessment should include blood gas measurements, electrolyte values, glucose and ammonia tests, and a urine test for ketones.

Advances in newborn screening technology offer opportunities for earlier diagnosis, prevention of neurologic crisis, and improved intellectual and physical outcomes. When tandem mass spectrometry techniques are used in newborn screening laboratories, infants with a broader range of metabolic disorders can be detected, and the disorder can be identified earlier (see [Focus On: Newborn Screening](#) and [Figure 43-1](#)).

TABLE 43-1 Selected Genetic Metabolic Disorders That Respond To Dietary Treatment

Disorder	Affected Enzyme	Prevalence	Clinical and Biochemical Features	Medical Nutrition Therapy	Adjunct Treatment
Urea Cycle Disorders (UCDs)					
Carbamyl-phosphate synthetase deficiency	Carbamyl-phosphate synthetase	1:30,000 (all UCDs)	Vomiting, seizures, sometimes coma → death Survivors usually have ID ↑ plasma ammonia and glutamine	Food: low protein Formula: without nonessential amino acids	L-carnitine, phenylbutyrate,* L-citrulline, L-arginine Hemodialysis or peritoneal dialysis during acute episodes
Ornithine trans-carbamylase deficiency	Ornithine trans-carbamylase (x-linked)	1:30,000 (all UCDs)	Vomiting, seizures, coma → death as a newborn ↑ plasma ammonia, glutamine, glutamic acid and alanine	Food: low protein Formula: without nonessential amino acids	L-carnitine, phenylbutyrate,* L-citrulline, L-arginine
Citrullinemia	Argininosuccinate synthetase	1:30,000 (all UCDs)	<i>Neonatal:</i> vomiting, seizures, coma → death <i>Infantile:</i> vomiting, seizures, progressive developmental delay ↑ plasma citrulline and ammonia, alanine	Food: low protein Formula: without nonessential amino acids	L-carnitine, phenylbutyrate,* L-arginine
Argininosuccinic aciduria	Argininosuccinate lyase	1:30,000 (all UCDs)	<i>Neonatal:</i> hypotonia, seizures <i>Subacute:</i> vomiting, FTT, progressive developmental delay ↑ plasma argininosuccinic acid, citrulline and ammonia	Food: low protein Formula: lower protein SF (without nonessential amino acids)	L-carnitine, phenylbutyrate*
Argininemia	Arginase	1:30,000 (all UCDs)	Periodic vomiting, seizures, coma Progressive spastic diplegia, developmental delay ↑ arginine and ammonia related to protein intake	Food: low protein Formula: lower protein SF (without nonessential amino acids)	L-carnitine, phenylbutyrate*
Organic Acidemias					
Methylmalonic acidemia	Methylmalonyl-CoA mutase or similar	1:80,000	Metabolic acidosis, vomiting, seizures, coma, often death ↑ organic urine acid and plasma ammonia levels	Food: low protein Formula: lower protein SF (without isoleucine, methionine, threonine, valine)	L-carnitine, vitamin B ₁₂ IV fluids, bicarbonate during acute episodes
Propionic acidemia	Propionyl-CoA carboxylase or similar	1:80,000	Metabolic acidosis, ↑ plasma ammonia and propionic acid, ↑ urine methylcitric acid	Food: low protein Formula: lower protein SF (without isoleucine, methionine, threonine, valine)	L-carnitine, biotin IV fluids, bicarbonate during acute episodes
Isovaleric acidemia	Isovaleryl-CoA dehydrogenase	1:80,000	Poor feeding, lethargy, seizures, metabolic ketoacidosis, hyperammonemia	Food: low protein Formula: SF (without leucine)	L-carnitine, L-glycine
Ketone utilization disorder	2-methylacetoacetyl-CoA-thiolase or similar	Unknown	Vomiting, dehydration, metabolic ketoacidosis	Food: low protein Formula: SF (without isoleucine) Avoid fasting, high complex carbohydrates	L-carnitine, Bicitra

Continued

TABLE 43-1 Selected Genetic Metabolic Disorders That Respond To Dietary Treatment—cont'd

Disorder	Affected Enzyme	Prevalence	Clinical and Biochemical Features	Medical Nutrition Therapy	Adjunct Treatment
Biotinidase deficiency	Biotinidase or similar	1:60,000	In <i>infancy</i> , seizures, hypotonia, rash, stridor, apnea; in <i>older children</i> , also see alopecia, ataxia, developmental delay, hearing loss		Supplemental oral biotin
Carbohydrate Disorders					
Galactosemia	Galactose-1-phosphate uridylyltransferase	1:50,000	Vomiting, hepatomegaly, FTT, cataracts, ID, often early sepsis ↑ urine and blood galactose	Eliminate lactose, low galactose, use soy protein isolate formula	
Hereditary fructose intolerance	Fructose-1-phosphate aldolase	1:20,000	Vomiting; hepatomegaly; hypoglycemia, FTT, renal tubular defects after fructose introduction ↑ blood and urine fructose after fructose feeding	No sucrose, fructose	
Fructose 1,6-diphosphatase deficiency	Fructose 1,6-diphosphatase	Unknown	Hypoglycemia, hepatomegaly, hypotonia, metabolic acidosis upon fructose introduction No ↑ blood/urine fructose	No sucrose, fructose	
Glycogen storage disease, type Ia	Glucose-6-phosphatase	1:60,000	Profound hypoglycemia, hepatomegaly	Low lactose, fructose, sucrose; low fat; high complex carbohydrate; avoid fasting	Raw cornstarch, iron supplements
Amino Acid Disorders					
Hyperphenylalaninemias					
Phenylketonuria	Phenylalanine hydroxylase	1:15,000		Food: low protein Formula: SF (without Phe, supplemented with tyrosine)	
Mild phenylketonuria	Phenylalanine hydroxylase	1:24,000	↑ blood Phe	Food: low protein Formula: SF (without Phe, supplemented with tyrosine)	
Dihydropteridine reductase deficiency	Dihydropteridine reductase	Rare	↑ blood Phe, irritability, developmental delay, seizures	Food: low protein Formula: SF (without Phe, supplemented with tyrosine)	Biopterin, 5-hydroxytryptophan, L-dopa, folic acid
Biopterin synthase defect	Biopterin synthase	Rare	Mild ↑ blood Phe, irritability, developmental delay, seizures	None	L-dopa, tetrahydrobiopterin, 5-hydroxytryptophan Nitisinone [†]
Tyrosinemia, type I	Fumarylacetoacetate hydrolase	<1:120,000	Vomiting, acidosis, diarrhea, FTT, hepatomegaly, rickets ↑ blood and urine tyrosine, methionine; ↑ urine parahydroxy derivatives of tyrosine; liver cancer	Food: low protein Formula: SF (without tyrosine, Phe, methionine)	
Maple Syrup Urine Disease					
MSUD	Branched-chain ketoacid decarboxylase complex (<2% activity)	1:200,000	Seizures, acidosis Plasma leucine, isoleucine, valine 10× normal	Food: low protein Formula: SF (without leucine, isoleucine, valine)	Thiamin [†]

TABLE 43-1 Selected Genetic Metabolic Disorders That Respond To Dietary Treatment—cont'd

Disorder	Affected Enzyme	Prevalence	Clinical and Biochemical Features	Medical Nutrition Therapy	Adjunct Treatment
Intermittent MSUD	Branched-chain ketoacid decarboxylase complex (<20% activity between episodes)	Rare	Intermittent symptoms Plasma leucine, isoleucine, valine 10× normal during illness	Food: low protein Formula: SF (without leucine, isoleucine, valine)	
Homocystinuria	Cystathionine synthase or similar	1:200,000	Detached retinas; thromboembolic and cardiac disease; mild to moderate ID; bony abnormalities; fair hair and skin; ↑ methionine, homocysteine	Food: low protein Formula: SF (without methionine, supplemented with L-cystine)	Betaine, folate, vitamin B ₁₂ , vitamin B ₆ [†] if folate levels are normal
Fatty Acid Oxidation Disorders					
Long chain acyl-CoA dehydrogenase deficiency	Long-chain acyl-CoA dehydrogenase	Rare	Vomiting, lethargy, hypoglycemia	Low fat, low long-chain fatty acids; avoid fasting	MCT oil, L-carnitine [§]
Long-chain 3-hydroxy-acyl-CoA dehydrogenase deficiency	Long-chain 3-hydroxy-acyl-CoA dehydrogenase	Rare	Vomiting, lethargy, hypoglycemia	Low fat, low long-chain fatty acids; avoid fasting	MCT oil, L-carnitine [§]
Medium chain acyl-CoA dehydrogenase deficiency	Medium-chain acyl-CoA dehydrogenase	1:20,000	Vomiting, lethargy, hypoglycemia	Low fat, low medium-chain fatty acids, avoid fasting	L-carnitine [§]
Short chain acyl-CoA dehydrogenase deficiency	Short-chain acyl-CoA dehydrogenase	Rare	Vomiting, lethargy, hypoglycemia	Low fat, low short-chain fatty acids, avoid fasting	L-carnitine [§]

[§]Patient may or may not respond to the compound.

[§]Use depends on clinic.

FOCUS ON

Newborn Screening (NBS)

Since the 1960s, states across the United States have adopted mandatory newborn screening (NBS) as law (Waisbren, 2006). These programs were developed as a result of the efficacy of the Guthrie bacterial inhibition assay, in which dried blood spots were used to identify PKU. This simple, sensitive, and inexpensive screening test became the basis for population-based screening systems for newborns. Hemoglobinopathies, endocrine disorders, metabolic disorders, and some infectious diseases can be identified effectively with the use of dried blood spots.

Tandem mass spectrometry was first used in the 1990s and is now used across the United States. This technology makes it possible to identify multiple disorders from a single dried blood spot. The number of disorders screened for varies by state, and expanded screening also is offered by private, for-profit companies. Follow-up programs also vary; some states have single, organized programs, whereas follow-up in other states is less centralized. Conditions successfully screened for by early NBS programs include congenital hypothyroidism, phenylketonuria, congenital adrenal hyperplasia, galactosemia, sickle cell disease, and maple syrup urine disease (Broscio et al, 2006).

The Maternal and Child Health Bureau (MCHB) of the US Health Resources and Services Administration commissioned a report from the American College of Medical Genetics (ACMG). This expert panel identified 29 conditions for which newborn screening should be mandated and

25 secondary conditions that may be detected incidentally (MCHB, 2007). The ACMG developed a series of ACTION (ACT) sheets and confirmatory algorithms for disorders that are identified by NBS screening. The ACT sheets describe the steps health professionals should follow in communicating with the family and determining follow-up. They are available at <http://www.ncbi.nlm.nih.gov/books/NBK55827/>.

Other groups, including the World Health Organization, March of Dimes, and Massachusetts Newborn Screening Advisory Committee, also have issued recommendations.

Providers who may be involved in the care and follow-up of families identified by NBS should have a good understanding of their state's system, as well as the confounding factors that may affect results. Communication among families, primary health care providers, and tertiary clinics is critical to timely identification and treatment. Follow-up, including referral to the appropriate specialists, is important for any family who receives positive NBS results. NBS fact sheets from the Committee on Genetics of the American Academy of Pediatrics describe (1) newborn screening; (2) follow-up of abnormal screening results to facilitate timely diagnostic testing and management; (3) diagnostic testing; (4) disease management, which requires coordination with the medical home and genetic counseling; and (5) continuous evaluation and improvement of the NBS system (Kaye et al, 2006).

FIGURE 43-1 Blood spots are collected from a newborn for newborn screening. (Courtesy Kelly McKean.)

DISORDERS OF AMINO ACID METABOLISM

Nutrition therapy for amino acid disorders most commonly consists of substrate restriction, which involves limiting one or more essential amino acids to the minimum requirement while providing adequate energy and nutrients to promote typical growth and development (e.g., restricting phenylalanine [Phe] in phenylketonuria). An inadequate intake of an essential amino acid is often as detrimental as excess. Supplementation of the product of the specific enzymatic reaction usually is required in nutrition therapy for amino acid

disorders; for example, tyrosine (Tyr) is supplemented in formulas for treatment of PKU.

Requirements for individual amino acids are difficult to determine because typical growth and development can be achieved over a wide range of intake. The data of Holt and Snyderman (1967) often are used as the basis for prescribing amino acid intakes (see Table 43-2). Careful and frequent monitoring is required to ensure the adequacy of the nutritional prescription. Although nitrogen studies are the most precise, weight gain in infants is a sensitive and easily monitored index of well-being and nutritional adequacy.

PHENYLKETONURIA

Etiology

Phenylketonuria (PKU) is the most common of the hyperphenylalaninemias. In this disorder phenylalanine (Phe) is not metabolized to tyrosine (Tyr) because of a deficiency or inactivity of phenylalanine hydroxylase (PAH) as shown in Figure 43-2. Of the amino acid disorders, PKU provides a reasonable model for detailed discussion because it (1) occurs relatively frequently and most neonates are screened for it; (2) has a successful MNT treatment; and (3) has a predictable course, with available documentation of “natural” and “intervention” history (see *Focus On: Time Line of Events in the Diagnosis and Treatment of Phenylketonuria*).

Nutritional treatment involves restricting the substrate (Phe) and supplementing the product (Tyr) (see *Pathophysiology and Care Management Algorithm: Phenylketonuria*). Most affected infants exhibit PAH deficiency; the remainder (less than 3%) have defects in associated pathways. Low-Phe nutrition therapy does not prevent the neurologic deterioration present in the disorders of these other associated pathways.

TABLE 43-2 Approximate Daily Requirements for Selected Dietary Components and Amino Acids in Infancy and Childhood

Dietary Component or Amino Acid	AGE AND REQUIREMENT		Dietary Component or Amino Acid	AGE AND REQUIREMENT	
	Birth to 12 mo (mg/kg)	1-10 yr (mg/day)		Birth to 12 mo (mg/kg)	1-10 yr (mg/day)
Phenylalanine	1-5 mo: 47-90 6-12 mo: 25-47	200-500*	Lysine	90-120	1200-1600
Histidine	16-34		Threonine	45-87	800-1000
Tyrosine [†]	1-5 mo: 60-80 6-12 mo: 40-60	25-85 (mg/kg)	Tryptophan	13-22	60-120
Leucine	76-150	1000	Energy	1-5 mo: 108 kcal/kg 6-12 mo: 98 kcal/kg	70-102 kcal/kg
Isoleucine	1-5 mo: 79-110 6-12 mo: 50-75	1000	Water	100 mL/kg	1000 mL
Valine	1-5 mo: 65-105 6-12 mo: 50-80	400-600	Carbohydrate	kcal × 0.5 ÷ 4 = g/ day	kcal × 0.5 ÷ 4 = g/day
Methionine [‡]	20-45	400-800	Total protein	1-5 mo: 2.2 g/kg 6-12 mo: 1.6 g/kg	16-18
Cyst(e)ine [§]	15-50	400-800	Fat	kcal × 0.35 ÷ 9 = g/ day	kcal × 0.35 ÷ 9 = g/ day

Modified from American Academy of Pediatrics, Committee on Nutrition: Special diets for infants with inborn errors of metabolism, *Pediatrics* 57:783, 1976.

Compiled from amino acid data of Holt and Snyderman. Information on amino acid requirements of infants and children at different ages is limited; the figures given here are in excess of minimum requirements. Consequently, this table should be used only as a guide and should not be regarded as an authoritative statement to which individual patients must conform.

*More phenylalanine (>800 mg) is required in the absence of tyrosine.

†Total phenylalanine plus tyrosine should be considered in the prescription because most phenylalanine is converted to tyrosine.

‡More methionine is required in the absence of cyst(e)ine.

§More cyst(e)ine is required in presence of a blocked *trans*-sulfuration outflow pathway for methionine metabolism.

FIGURE 43-2 Hyperphenylalaninemias. **1**, Phenylalanine hydroxylase deficiency; **2**, Dihydropteridine reductase deficiency; **3**, Biopterin synthetase deficiency. *NADPH*, Nicotinamide-adenine dinucleotide phosphate (reduced form); *NADP*⁺, nicotinamide-adenine dinucleotide phosphate (oxidized form).

FOCUS ON

Time Line of Events in the Diagnosis and Treatment of Phenylketonuria

- 1934:** A. Folling identifies phenylpyruvic acid in the urine of mentally retarded siblings.
- 1950s:** G. Jervis demonstrates a deficiency of phenylalanine oxidation in the liver tissue of an affected patient. H. Bickel demonstrates that dietary phenylalanine restrictions lower the blood concentration of phenylalanine.
- 1960s:** R. Guthrie develops a bacterial inhibition assay for measuring blood phenylalanine levels.
- Mid-1960s:** Semisynthetic formulas restricted in phenylalanine content become commercially available.
- 1965-1970:** States adopt newborn screening programs to detect phenylketonuria (PKU).
- 1967-1980:** Collaborative Study of Children Treated for Phenylketonuria is conducted. Data from this study form the basis for treatment protocols for PKU clinics in the United States.
- Late-1970s:** Detrimental effects of maternal PKU are recognized as a significant public health problem.
- 1980s:** Lifelong restriction of phenylalanine intake becomes the standard of care in PKU clinics in the United States.

- 1983:** The Maternal PKU Collaborative Study begins to study the effects of treatment on the pregnancy outcome of women with phenylketonuria.
- 1987:** Techniques for carrier detection and prenatal diagnosis of PKU are developed.
- Late-1980s:** The gene for phenylalanine hydroxylase deficiency (MIM No. 261600) is located on chromosome 12q22-q24.1. DNA mutation analysis is accomplished with peripheral leukocytes.
- 1990s:** Phenylalanine level of 2-6 mg/dl (120-360 μmol/L), lower than the previous level of less than 10 mg/dL (600 μmol/L), becomes the new standard of care for treatment of PKU.
- 2000s:** Tetrahydrobiopterin-responsive forms of PKU are recognized, especially those with mild mutations.
- 2010:** Research into alternative and adjunct therapies such as the use of large neutral amino acids, BH₄ supplementation, enzyme substitution, and somatic gene therapy.
- 2014:** Clinical trials for enzyme replacement therapy using pegylated phenylalanine ammonia lyase (PEG-PAL) injections are underway.

Data from Maternal Child Health Bureau: Newborn screening: toward a uniform screening panel and system, *Genet Med* 8(Suppl 1):1S, 2006; Saugstad LF: From genetics to epigenetics, *Nutr Health* 18:285, 2006; Mitchell JJ, Scriver CR: Phenylalanine hydroxylase deficiency. In Pagon RA et al, editors: GeneReviews [Internet]. Seattle, 1993-2000, University of Washington, Seattle [updated January 31, 2013].

Medical Treatment

All states have newborn screening programs for PKU and other metabolic disorders. Diagnostic criteria for PKU include an elevated blood concentration of Phe and an elevated (i.e., greater than 3) Phe:Tyr ratio. The diagnostic process also should include evaluation for hyperphenylalaninemia that results from the deficiency of enzymes other than PAH, including defects in tetrahydrobiopterin (BH₄) synthesis or regeneration

(Vockley et al, 2014). An effective newborn screening program and access to an organized follow-up program are critical to early identification and treatment of infants with PKU.

The advantage of rigorous nutrition therapy has been demonstrated by measurements of intellectual function. Individuals who do not receive diet therapy have severe intellectual disability, whereas individuals who are on therapy from the early neonatal period have normal intellectual function (McPheeters et al,

PATHOPHYSIOLOGY AND CARE MANAGEMENT ALGORITHM

Phenylketonuria

ETIOLOGY

PATHOPHYSIOLOGY

Increased phenylalanine and abnormal phenylalanine/tyrosine ratio in blood

If left untreated or inadequate treatment – intellectual disability

Clinical Findings

- Blood phenylalanine >6-10 mg/dL (360-600 $\mu\text{mol/L}$)
- Blood tyrosine <3 mg/dL (165 $\mu\text{mol/L}$)

MANAGEMENT

Medical Management

Regular monitoring of blood phenylalanine to maintain at 1-6 mg/dL (60-360 $\mu\text{mol/L}$)

Nutrition Care

- Phenylalanine-free formula/medical food
- Low phenylalanine foods
- Supplement with tyrosine
- Education of family and child about formula/medical food preparation
- Adequate nutritional intake
- Regular monitoring of growth
- Education on label reading and food choices

2012). Outcome, measured as intellectual function, depends on the age of the infant at diagnosis and start of nutrition therapy, as well as the individual's biochemical control over time.

BH_4 has been studied to evaluate its effectiveness as an alternative treatment to severe dietary Phe restriction, since

BH_4 is a cofactor needed for proper activity of the enzyme. Treatment with sapropterin (a synthetic form of BH_4) is used as an adjunct therapy for some milder mutations; observations on long-term outcome are needed (Lindgren et al, 2013). Those individuals who respond have what is called

BH₄-responsive PKU. However, even for BH₄-responsive individuals, ongoing intervention and nutrition monitoring is needed (Singh et al, 2010).

Other studies have examined the possibility of enzyme substitution with phenylalanine ammonia lyase (PAL) to degrade Phe, or gene therapy to restore PAH activity (Blau et al, 2010).

Blood Phenylalanine Control. Blood Phe concentration must be checked regularly, depending on the age and health status of the child, to be sure it remains within the range of 2 to 6 mg/dl or 120 to 360 μ mol/L (McPheeters et al, 2012). Phe-containing foods are offered as tolerated as long as the blood concentration of Phe remains in the range of good biochemical control. The child's rate of growth and mental development must be monitored carefully.

Effective management requires a team approach in which the child, parents, registered dietitian nutritionist, pediatrician, psychologist, social worker, and nurse work together to achieve and maintain biochemical control in an atmosphere promoting normal mental and emotional development. An essential management tool for parents, children, and clinicians is the food diary used to monitor Phe intake. Daily record keeping supports compliance with treatment and builds self-management skills. An accurate record of food and formula intake (see Figure 4-6) for at least the 3 days before a laboratory specimen is obtained is critical for accurate interpretation of the results and subsequent adjustment of the Phe prescription.

Elevations in blood Phe concentration generally are caused by either excessive Phe intake or tissue catabolism. Intake of Phe in excess of the amount required for growth accumulates in the blood. Deficient energy intake or the stress of illness or infection can result in protein breakdown and the release of amino acids, including Phe, into the blood. In general, the anorexia of illness limits energy intake. Preventing tissue catabolism by maintaining intake of the formula/medical food as much as possible is essential. Although it occasionally may be necessary to offer only clear liquids during an illness, the Phe-free formula/medical food should be reintroduced as soon as it is feasible. Tube-feeding is an option if oral intake is not possible.

Continuing the restricted-Phe dietary therapy throughout childhood, adolescence, and beyond is recommended (McPheeters et al, 2012; Vockley et al, 2014). Progressively decreasing IQs, learning difficulties, poor attention span, and behavioral difficulties have been reported in children who have discontinued the dietary regimen. Children who maintain well-controlled blood Phe levels demonstrate comparatively higher intellectual achievement than those who do not. Good dietary control of blood Phe concentrations is the best predictor of IQ, whereas "off-diet" blood Phe concentrations of greater than 20 mg/dl (1200 μ mol/L) are the best predictors of IQ loss. Subtle deficits in higher-level cognitive function may persist even at blood Phe levels of 6 to 10 mg/dl (360 to 600 μ mol/L). Thus most clinics recommend treatment blood levels of 2 to 6 mg/dl (120 to 360 μ mol/L). *Restricted-Phe therapy should be continued for life to maintain normal cognitive function.*

Medical Nutrition Therapy

Nutrition management guidelines for PKU have been published (Singh et al, 2014).

Formula. For PKU, dietary therapy is planned around the use of a formula/medical food with Phe removed from the

protein. Formulas or medical foods provide a major portion of the daily protein and energy needs for affected infants, children, and adults. In general, the protein source in the formula/medical food is L-amino acids, with the critical amino acid (i.e., Phe) omitted. Glycomacropeptide (GMP), a whey protein with very little Phe, is used in a few medical foods as an alternative to L-amino acids (van Calcar and Ney, 2012). Carbohydrate sources are corn syrup solids, modified tapioca starch, sucrose, and hydrolyzed cornstarch. Fat is provided by a variety of oils.

Some formula/medical foods contain no fat or carbohydrate, so these components must be provided from other sources. If using formulas without fat, clinicians must provide sources of essential fatty acids. Essential fatty acid deficiencies have been noted among individuals consuming fat-free formulas (Camp et al, 2014; Singh et al, 2014). Most formulas and medical foods contain calcium, iron, and all other necessary vitamins and minerals and are a reliable source of these nutrients. When others are devoid of these nutrients, supplementation is needed to ensure nutritional adequacy.

Phe-free formula is supplemented with regular infant formula or breastmilk during infancy and cow's milk in early childhood to provide high-biologic value protein, nonessential amino acids, and sufficient Phe to meet the individualized requirements of the growing child. The optimal amount of protein substitute depends on the individual's age (and thus requirements for growth) and enzyme activity; thus it must be prescribed individually. Because the protein in specialized formulas is synthetic, it is provided in amounts greater than the Dietary Reference Intake (DRI) (Singh et al, 2014).

The Phe-free formula and milk mixture often provides approximately 90% of the protein and 80% of the energy needed by infants and toddlers. A method for calculating the appropriate quantities of a low-Phe food pattern is shown in Table 43-3. Calculations should provide adequate but not excessive energy for the infant, as well as appropriate fluid to maintain hydration. To support metabolic control effectively, formula/medical foods must be consumed in three or four nearly equal portions throughout the day.

Low-Phenylalanine Foods. Foods of moderate- or low-Phe content are used as a supplement to the formula or medical food mixture. These foods are offered at the appropriate ages to support developmental readiness and to meet energy needs. Puréed foods from a spoon may be introduced at 5 to 6 months of age, finger foods at 7 to 8 months, and the cup at 8 to 9 months, using the same timing and progression of texture recommended for typical children (see Chapters 16 and 17). Table 43-4 lists typical low-Phe food patterns for young children.

Low-protein pastas, breads, and baked goods made from wheat starch add variety to the food pattern and allow children to eat some foods "to appetite." A variety of low-protein pastas, rice, baked goods, egg replacers, and other foods are available. Wheat starch and a variety of low-protein baking mixes for breads, cakes, and cookies are also available. Table 43-5 compares low-protein and regular food items.

In many cases parents create recipes or adapt family favorites to meet the needs of their children. These recipes offer the children a variety of textures and food choices, allowing them to participate in family meals. Families are also able to meet the energy and Phe needs of their children without resorting to excessive intakes of sugars and concentrated sweets.

TABLE 43-3 Guidelines for Low-Phenylalanine Food Pattern Calculations

Step 1: Calculate the child's needs for phenylalanine, protein, and energy (kcal).

Phenylalanine

$$7.7 \text{ kg} \times 40^* \text{ mg phenylalanine} = 308 \text{ mg phe/kg/d}$$

Protein

$$7.7 \text{ kg} \times 2.5\text{-}3^\dagger \text{ g pro} = 19\text{-}25 \text{ g pro/kg/d}$$

Energy

$$7.7 \text{ kg} \times 100^\ddagger \text{ kcal} = 770 \text{ kcal/kg/d}$$

Step 2: Estimate the amount of phenylalanine, protein, and energy to be obtained from foods other than the formula mixture.

APPROXIMATE NEEDS

	Phenylalanine (mg/d)	Protein (g/d)	Energy (kcal/d)
Foods	30	1-2	100
Formula	~288	18-24	670
Total	318	19-25	770

Step 3: Confirm that a reasonable food pattern is provided with the estimated phenylalanine from food guideline. A sample food pattern:

	Phenylalanine (mg)	Protein (g)	Energy (kcal)
Green beans, strained, 2 Tbsp	15	0.4	8
Banana, mashed, 2 Tbsp	10	0.3	28
Carrots, strained, 2 Tbsp	6	0.2	7
Total	30	0.9	33

Step 4: Determine the amount of standard infant formula to be included in the formula. This information is determined from the infant's estimated phenylalanine needs.

Step 5: Determine the amount of phenylalanine-free formula required per day. This information is determined from the infant's estimated protein and energy needs.

Step 6: Determine the amount of water to mix with the formula. The consistency of the formula will vary according to the infant's age and fluid requirements. For example, for the infant described in the case study, add water to make a total volume of 32 oz.

Step 7: Determine the amounts of phenylalanine, protein, and energy provided by formulas and foods.

	Phenylalanine (mg/d)	Protein (g/d)	Energy (kcal/d)
Phenex-1 powder (70 g)	0	10.5	325
Enfamil powder (70 g)	294	7.4	350
Food	30	1-2	100
Total	324	18.9-19.9	775

Step 8: Determine the actual amounts of phenylalanine, protein, and energy per kilogram body weight.

Phenylalanine

$$324 \div 7.7 \text{ kg} = 42 \text{ mg phe/kg/d}$$

Protein

$$19.4 \div 7.7 \text{ kg} = 2.5 \text{ g pro/kg/d}$$

Energy

$$774 \div 7.7 \text{ kg} = 101 \text{ kcal/kg/d}$$

TABLE 43-4 Typical Menus for a 3-Year-Old with Phenylketonuria

Tolerance: 300 mg phenylalanine/day

Formula/medical food for 24 hours: 120 g Phenyl-Free-2, 100 g 2% milk, water to 24 oz

This formula mixture provides 30 g protein, 460 kcal, 170 mg phenylalanine.

Tolerance: 400 mg phenylalanine/day

Formula/medical food for 24 hours: 120 g Phenyl-Free-2, 100 g 2% milk, water to 24 oz

This formula mixture provides 30 g protein, 460 kcal, 170 mg phenylalanine.

Menu for 100 mg

Phenylalanine from Food (mg)

Breakfast	
Formula mixture, 6 oz	
Kix cereal, 1/4 cup	22
Peaches, canned, 60 g (1/4 cup)	9
Lunch	
Formula mixture, 6 oz	
Low protein bread, 1/2 slice	6
Jelly, 1 tsp	0
Carrots, cooked, 40 g (1/4 cup)	14
Apricots, canned, 25 g (1/2 cup)	32
Snack	
Apple slice, peeled, 1/2 cup	3
Goldfish crackers, 10	18 mg
Formula mixture, 6 oz	
Dinner	
Formula mixture, 6 oz	
Low-protein pasta, 1/2 C, cooked	5
Tomato sauce, 2 Tbsp	12
Green beans, cooked, 17 g (2 Tbsp)	9
Total phenylalanine from food	130 mg

Menu for 200 mg

Phenylalanine from Food (mg)

Breakfast	
Formula mixture, 6 oz	
Rice Krispies, 20 g (1/4 cup)	25
Nondairy creamer, 2 Tbsp	9
Lunch	
Formula mixture, 6 oz	
Vegetable soup, 1/2 cup	82
Grapes, 50 g (10)	9
Low-protein crackers, 5	3
Low-protein cookie, 2	8
Snack	
Rice cakes, 6 g (2 mini)	25
Jelly, 1 tsp	0
Formula mixture, 6 oz	
Dinner	
Formula mixture, 6 oz	
Potato, diced, 50 g (5 Tbsp)	39
Dairy-free margarine, 1 tsp	0 mg
Zucchini, sauteed, 1/4 cup (45 g)	10
Total phenylalanine from food	180

*A phenylalanine intake of 40 mg/kg/day is chosen as a moderate intake level. The prescription for phenylalanine must be adapted to individual needs as judged by growth and blood levels.

†Although these intakes are higher than the recommended dietary allowance, they are the intakes found by the Collaborative Study to promote normal growth with consumption of protein hydrolysate-based formula.

‡Total energy intake must be adjusted to meet individual needs, and an excess must be avoided.

Acosta PB: Recommendations for protein and energy intakes by patients with phenylketonuria, *Eur J Pediatr* 155(Suppl 1):S121, 1996 and Singh RH et al: Recommendations for the nutrition management of phenylalanine hydroxylase deficiency, *Genet Med* 16:121, 2014.

A formula or medical food that is free of Phe and has a more appropriate amino acid, vitamin, and mineral composition for an older child is generally introduced in the toddler or preschool period. The criteria for introduction of these "next-step" formulas are that the child accept the food pattern and formula well and reliably consume a wide variety of foods from the low-Phe food list. Successful management with consistently low blood Phe levels is based on habit (i.e., the formula/medical food is offered and consumed without negotiation or threat). Children respond favorably to the regularity

TABLE 43-5 Comparison of Protein and Energy Content of Foods Used in Low-Protein Diets

Food Item	Energy (kcal)	Protein (g)
Pasta, ½ cup, cooked		
Low-protein	107	0.15
Regular	72	2.4
Bread, 1 slice		
Low-protein	135	0.2
Regular	74	2.4
Cereal, ½ cup, cooked		
Low-protein	45	0.0
Regular	80	1.0
Egg, 1		
Low-protein egg replacer	30	0.0
Regular	67	5.6

of the time of ingestion of the formula/medical food and the familiarity of its taste and presentation. Table 43-6 compares a restricted Phe food pattern with a typical food pattern for a child of the same age.

Education About Therapy Management. The energy needs and amino acid requirements of children with PKU do not differ appreciably from those of children in general. With proper management, typical growth can be expected (see Figure 43-3). However, parents may tend to offer excessive energy as sweets because they feel their child is being deprived of food experiences. Health care providers should support families in recognizing that children with PKU are healthy children who must make careful food choices for themselves, not chronically ill children who require food indulgences.

Appropriate clinical interaction with family members provides them with the information and skills to differentiate between food behaviors that are typical for the age and developmental level of the child and those related specifically to PKU. To avoid power struggles and conflicts over food, it is advisable to involve the child in choosing appropriate foods at an early age. Children who are 2 to 3 years old can master the concept of appropriate choices when foods are categorized as “yes foods”

FIGURE 43-3 Two young children, both with phenylketonuria, who were identified by a newborn screening program and started on treatment by 7 days of age, demonstrate typical growth and development. (Courtesy Beth Ogata, Seattle.)

and “no foods.” The concept of an appropriate quantity of a food can be introduced to a 3- or 4-year-old child in terms of “how many” by counting crackers or raisins and then in terms of “how much” by weighing or measuring foods such as cereal or fruit. The child then moves to more complex tasks

TABLE 43-6 Comparison of Menus Appropriate for Children with and without Phenylketonuria

Meal	Menu for PKU	Phenylalanine (mg)	Regular menu	Phenylalanine (mg)
Breakfast	Phenylalanine-free formula	0	Milk	450
	Puffed rice cereal	19	Puffed rice cereal	19
	Orange juice	11	Orange juice	11

TABLE 43-7 Tasks Expected of Children with Phenylketonuria by Age Level

Age (yr)	School Level	Task
2-3	Preschool	Distinguishing between "yes" and "no" foods
3-4	Preschool	Counting: how many?
4-5	Preschool	Measuring: how much?
5-6	Kindergarten	Preparing own formula; using scale
6-7	Grade 1-2	Writing basic notes in food diary
7-8	Grade 2	Making some decisions on after-school snack
8-9	Grade 3	Preparing breakfast
9-10	Grade 4	Packing lunches
10-14	Middle school	Managing food choices with increasing independence
14-18	High school	Independently managing phenylketonuria

(e.g., formula and food preparation) and planning of meals (e.g., breakfast or a packed lunch). Responsibility for planning a full day's menu by calculating the quantity of Phe in portions of food and compiling the daily total is the ultimate goal. These age-related tasks are shown in [Table 43-7](#).

Psychosocial Development. The necessity of carefully controlling food intake may prompt parents to overprotect their children and perhaps to restrict their social activities. The children, in turn, may react negatively to their parents and to their nutrition therapy. The ability of the family to respond to the stresses of PKU, as reflected by adaptability and cohesion scores, is demonstrated by improved blood Phe concentrations and the positive coping behaviors of older children with PKU. Thus continuing nutrition therapy beyond early childhood requires that children become knowledgeable about and responsible for managing their own food choices. The health care team becomes responsible for working with families and children to provide strategies that enable children and adolescents to participate in social and school activities, interact with peers, and progress through the typical developmental stages with self-confidence and self-esteem.

Children require parental and professional support as they assume responsibility for their food management. Self-management of food choices is a strategy to prevent the child using dietary non-compliance as a wedge against parental restrictions. Normal intellectual development is a laudable goal of management of PKU, but to be entirely successful children with PKU concomitantly need to develop self-assurance and a strong self-image. This can be achieved in part by fostering self-management, problem-solving skills, independence, and a typical lifestyle.

Maternal PKU

A pregnant woman with elevated blood Phe concentrations endangers her fetus because of the active transport of amino acids across the placenta. The fetus is exposed to approximately twice the Phe level contained in normal maternal blood. Babies whose mothers have elevated blood Phe concentrations have an increased occurrence of cardiac defects, retarded growth, microcephaly, and intellectual disability, as presented in [Table 43-8](#). The fetus appears to be at risk of damage even with minor elevations in maternal

TABLE 43-8 Frequency of Abnormalities in Children Born to Mothers with Phenylketonuria

Complication (% of Offspring)	MATERNAL PHENYLALANINE LEVELS (mg/dl)				Non-PKU Mother
	20	16-19	11-15	3-10	
Mental retardation	92	73	22	21	5.0
Microcephaly	73	68	35	24	4.8

Low birth weight	40	52	56	13	9.6

Modified from Lenke RR, Levy HL: Maternal phenylketonuria and hyperphenylalaninemia: an international survey of the outcome of untreated and treated pregnancies. *N Engl J Med* 303:1202, 1980.
PKU, Phenylketonuria.

blood Phe levels, and the higher the level, the more severe the effect. Strict control of maternal Phe levels before conception and throughout pregnancy offers the best opportunity for normal fetal development ([Koch et al, 2010](#); [Martino et al, 2013](#)).

Nutrition management for pregnant women with hyperphenylalaninemia is complex. The changing physiology of pregnancy and fluctuating nutritional needs are difficult to monitor with the precision required to maintain appropriately low blood-Phe concentrations. Even with meticulous attention to Phe intake, blood concentrations, and the nutrient requirements of pregnancy, a woman cannot be ensured a normal infant ([Lee et al, 2005](#)). The risks of abnormal development of the fetus, even with therapeutic dietary management and maintenance of blood Phe concentrations at 1 to 5 mg/dl (60-300 μ mol/L), are an important consideration for young women with PKU considering pregnancy ([Waisbren and Azen, 2003](#)).

Nutritional management during pregnancy is challenging, even for women who have consistently followed a low-Phe dietary regimen since infancy. Women who have discontinued Phe dietary treatment find that reinstating medical food consumption and limiting food choices can be difficult and overwhelming. Inadequate maternal nourishment (i.e., inadequate intakes of total protein, fat, and energy) may contribute to poor fetal development and should be prevented. Adherence to nutrition therapy during pregnancy for even the well-motivated woman requires family and professional support, as well as frequent monitoring of biochemical and nutritional aspects of pregnancy and PKU.

Adults Living with Phenylketonuria

Many adults with PKU have had the benefits of early diagnosis and treatment and are less likely to be affected by neurologic damage. However, among those who have had some degree of intellectual disability, hyperactivity and self-abuse are often major concerns. Not all patients respond to late initiation of treatment with improved behavioral or intellectual function. For the difficult-to-manage older patient, a trial of a low-Phe food pattern is recommended. If successful, continued Phe restriction therapy may facilitate behavioral management.

Reinstating a Phe-restricted food pattern is difficult after the eating pattern has been liberalized. However, the current recommendation of most clinics is effective management of blood Phe concentration throughout a lifetime. This recommendation is based on reports of declining intellectual capabilities and changes in the brain after prolonged, significant elevation of Phe concentrations (Camp et al, 2014). The efficacy of continued treatment throughout adulthood has been documented by reports of improved intellectual performance and problem-solving abilities when blood Phe levels are kept low. Dietary management of PKU throughout the life span is similar to that of other chronic disorders, and prudent MNT results in a normal quality of life.

Maple Syrup Urine Disease

Maple syrup urine disease (MSUD), or **branched-chain ketoaciduria**, results from a defect in enzymatic activity, specifically the branched-chain alpha-ketoacid dehydrogenase complex. It is an autosomal-recessive disorder. Infants appear normal at birth, but by 4 or 5 days of age they demonstrate poor feeding, vomiting, lethargy, and periodic hypertonia. A characteristic sweet, malty odor from the urine and perspiration can be noted toward the end of the first week of life.

Pathophysiology

The decarboxylation defect of MSUD prevents metabolism of the branched-chain amino acids (BCAAs) leucine, isoleucine, and valine (see Figure 43-4). Leucine tends to be more problematic than the others. The precise mechanism for the com-

plete decarboxylase reaction and the resultant neurologic damage is not known. Neither is the reason why leucine metabolism is significantly more abnormal than that of the other two BCAAs (Strauss et al, 2013).

Medical Treatment

Failure to treat this condition leads to acidosis, neurologic deterioration, seizures, and coma, proceeding eventually to death. Management of acute disease often requires peritoneal dialysis and hydration (see Chapter 35).

Depending on the severity of the enzyme defect, early intervention and meticulous biochemical control can provide a more hopeful prognosis for infants and children with MSUD. Reasonable growth and intellectual development in the normal-to-low-normal range have been described. Diagnosis before 7 days of age and long-term metabolic control are critical factors in long-term normalization of intellectual development. Maintenance of plasma leucine concentrations in infants and preschool children should be as close to physiologically normal as possible. Concentrations greater than 10 mg/dl (760 $\mu\text{mol/L}$) often are associated with alpha-ketoacidemia and neurologic symptoms.

Because the liver is the central site of metabolic control for amino acids and other compounds that cause acute degeneration of the brain during illness, therapeutic liver transplantation has been proposed as an option in MSUD. Studies are underway to assess the long-term effects of this procedure on stabilization of biochemical and neurologic status (Mazariegos et al, 2012).

FIGURE 43-4 Organic acidemias and maple syrup urine disease (MSUD). **1**, Branched-chain ketoacid decarboxylase (MSUD); **2**, Valine aminotransferase; **3**, Leucine-isoleucine aminotransferase; **4**, Propionyl-CoA carboxylase (propionic acidemia); **5**, Methylmalonyl-CoA racemase (methylmalonic aciduria); **6**, Methylmalonyl-CoA mutase (methylmalonic aciduria); **7**, Isovaleryl-CoA dehydrogenase (isovaleric acidemia); **8**, Beta-methylcrotonyl-CoA carboxylase (biotin-responsive multiple carboxylase deficiency). **CoA**, Coenzyme A.

Medical Nutrition Therapy

Nutrition therapy requires very careful monitoring of blood concentrations of leucine, isoleucine, and valine as well as growth and general nutritional adequacy. Several formulas specifically designed for the treatment of this disorder are available to provide a reasonable amino acid and vitamin mixture. These generally are supplemented with a small quantity of standard infant formula or cow's milk to provide the BCAAs needed to support growth and development. Some infants and children may require additional supplementation with L-valine or L-isoleucine to maintain biochemical balance.

BCAAs may be introduced gradually into the diet when plasma leucine concentrations are decreased sufficiently (Chuang and Shih, 2010; Frazier et al, 2014). Clinical relapse is related most often to the degree of elevation of leucine concentrations, and these relapses often are related to infection. Acute infections represent life-threatening medical emergencies in this group of children. If the plasma leucine concentration increases rapidly during illness, BCAAs should be removed from the diet immediately and intravenous therapy can be started.

DISORDERS OF ORGANIC ACID METABOLISM

The organic acid disorders are a group of disorders characterized by the accumulation in the blood of non-amino acid organic acids. Usually most of the organic acids are excreted efficiently in the urine. Diagnosis is based on excretion of compounds not normally present or the presence of abnormally high amounts of other compounds in the urine. The clinical course can vary but is generally marked by vomiting, lethargy, hypotonia, dehydration, seizures, and coma. Survivors often have permanent neurologic damage.

Pathophysiology

Propionic acidemia is a defect of propionyl-coenzyme A (CoA) carboxylase in the pathway of propionyl-CoA to methylmalonyl-CoA, as illustrated in Figure 43-4. Metabolic acidosis with a marked anion gap and hyperammonemia is characteristic, and long-chain ketonuria also may be present.

At least five separate enzyme deficiencies have been identified that result in **methylmalonic acidemia** or aciduria. The defect of methylmalonyl-CoA mutase apoenzyme is the most frequently identified. In methylmalonic acidemia, the clinical features are similar to those of propionic acidemia. Acidosis is common, and diagnosis is confirmed by the presence of large amounts of methylmalonic acid in blood and urine. Other findings include hypoglycemia, ketonuria, and elevation of plasma ammonia and lactate levels.

Ketone utilization disorders (mitochondrial 2-methylacetoacetyl-CoA thiolase deficiency or similar enzyme defect) are disorders of isoleucine and ketone body metabolism. Affected individuals are usually older infants or toddlers who present with ketoacidosis, vomiting, and lethargy with secondary dehydration and sometimes coma. This event often is preceded by febrile illness or fasting.

Medical Treatment

Some patients with propionic acidemia may respond to pharmacologic doses of biotin. Long-term outcome in propionic acidemia is variable; hypotonia and cognitive delay may result even in children who are diagnosed early and who receive

rigorous treatment. Liver damage and cardiomyopathy are possible sequelae. Liver transplantation may limit intellectual disability and cardiac changes (Sutton et al, 2012).

Individuals with methylmalonic acidemia may respond to pharmacologic doses of vitamin B₁₂. Responsiveness should be determined as part of the diagnostic process (Manoli and Venditti, 2010). Progressive renal insufficiency is often a long-term outcome. Developmental delay is often caused by early and/or prolonged hyperammonemia.

For ketone use disorders, the treatment is dietary protein restriction (usually 1.5 g/kg of body weight per day); supplementation with **L-carnitine**, a carrier of fatty acids across the mitochondrial membranes; avoidance of fasting by providing small, frequent meals that consist primarily of complex carbohydrates; and the use of Bicitra (sodium citrate-citric acid) to treat ketoacidosis.

Medical Nutrition Therapy

The goals of managing acute episodes of propionic acidemia and methylmalonic acidemia are to achieve and maintain normal nutrient intake and biochemical balance. Maintenance of energy and fluid intake is important to prevent tissue catabolism and dehydration. Intravenous fluids correct electrolyte imbalances, and abnormal metabolites are removed through urinary excretion, promoted by a high fluid intake. Relapses of metabolic acidosis may result from excessive protein intake, infection, constipation, or unidentified factors. Treatment for these episodes must be rapid because coma and death can occur quickly. Parents become skilled at identifying early signs of illness.

Restricted protein intake is an essential component of the treatment of organic acid disorders. A daily protein intake of 1 to 1.5 g/kg of body weight is often an effective treatment modality for infants who have a mild form of the disorder. This can be supplied by diluting standard infant formula to decrease the protein content and adding a protein-free formula to meet other nutrient needs. Specialized formulas that limit threonine and isoleucine and omit methionine and valine are used, as clinically indicated, to support an adequate protein intake and growth.

Requirements for the limited amino acids may vary widely. Growth rate, state of health, residual enzyme activity, and overall protein and energy intakes must be monitored carefully and correlated with plasma amino acid levels. Adequate hydration is critical to maintain metabolic equilibrium. Food refusal and lack of appetite may complicate nutrition therapy, which compromises medical management.

DISORDERS OF UREA CYCLE METABOLISM

All **urea cycle disorders (USDs)** result in an accumulation of ammonia in the blood. The clinical signs of elevated ammonia are vomiting and lethargy, which may progress to seizures, coma, and ultimately death. In infants the adverse effects of elevated ammonia levels are rapid and devastating. In older children symptoms of elevated ammonia may be preceded by hyperactivity and irritability. Neurologic damage may result from frequent and severe episodes of hyperammonemia. The severity and variation of the clinical courses of some urea cycle defects may be related to the degree of residual enzyme activity. The common urea cycle defects are discussed in a progression that proceeds around the urea cycle, as shown in Figure 43-5.

FIGURE 43-5 Urea cycle disorders. **1**, Carbamyl-phosphate synthetase deficiency; **2**, Ornithine carbamyl transferase deficiency; **3**, Argininosuccinic acid synthetase (citrullinemia); **4**, Argininosuccinic acid lyase (argininosuccinic aciduria); **5**, Arginase deficiency (arginemia); **6**, Adenosine triphosphate.

Pathophysiology

Ornithine transcarbamylase (OTC) deficiency is an X-linked disorder marked by blockage in the conversion of ornithine and carbamyl phosphate to citrulline. OTC deficiency is identified by hyperammonemia and increased urinary orotic acid, with normal levels of citrulline, argininosuccinic acid, and arginine. Severe OTC deficiency is usually lethal in males. Heterozygous females with various degrees of enzyme activity may not demonstrate symptoms until they are induced by stress, as from an infection, or a significant increase in protein intake.

Citrullinemia is the result of a deficiency of argininosuccinic acid synthetase in the metabolism of citrulline to argininosuccinic acid. Citrullinemia is identified by markedly elevated citrulline levels in the urine and blood. Symptoms may be present in the neonatal period, or they may develop gradually in early infancy. Poor feeding and recurrent vomiting occur which, without immediate treatment, progress to seizures, neurologic abnormalities, and coma.

Argininosuccinic aciduria (ASA) results from deficiency of argininosuccinic lyase, which is involved in the metabolism of argininosuccinic acid to arginine. ASA is identified by the presence of argininosuccinic acid in urine and blood. L-arginine must be supplemented to provide an alternative pathway for waste nitrogen excretion.

Carbamyl-phosphate synthetase (CPS) deficiency is the result of deficient activity of CPS. The onset is usually in the early neonatal period, with vomiting, irritability, marked hyperammonemia, respiratory distress, altered muscle tone, lethargy, and often coma. Specific laboratory findings usually include low plasma levels of citrulline and arginine and normal orotic acid levels in urine.

Medical Treatment

Acute episodes of illness are managed by discontinuing protein intake and administering intravenous fluids and glucose to correct dehydration and provide energy. If hyperammonemia is severe, peritoneal dialysis, hemodialysis, or exchange transfusion may be required. Intravenous sodium benzoate or other alternative pathway compounds have been beneficial in reducing the hyperammonemia.

Neurologic outcome and intellectual development in individuals with urea cycle disorders vary, with a range from normal IQ and motor function to severe intellectual disability and cerebral palsy. Although information on long-term follow-up is limited, the use of alternative pathways for waste nitrogen excretion and a protein-restricted food pattern may improve the outcome.

Medical Nutrition Therapy

Nutritional management of patients who have urea cycle disorders is a challenging task. The aim of therapy for the urea cycle disorders is to prevent or decrease hyperammonemia and the detrimental neurologic consequences associated with it. Treatment is similar for all of the disorders. For mildly affected infants a standard infant formula can be diluted to provide protein at 1 to 1.5 g/kg body weight per day. The energy, vitamin, and mineral concentrations can be brought up to recommended intake levels with the addition of a protein-free formula that contains these nutrients. However, for most individuals, specialized formulas are needed to adjust protein composition in an effort to limit ammonia production.

The amount of protein tolerated is affected by variables such as the specific enzyme defect, age-related growth rate,

BOX 43-1 Steps in Designing a Low-Protein Eating Plan

1. Determine the protein tolerance of the individual based on (1) diagnosis, (2) age, and (3) growth. Consider the metabolic stability and total protein intake required for the infant's or child's weight.
2. Calculate the protein and energy needs of the individual based on age, activity, and weight.
3. Provide at least 70% of total protein as high-biologic value protein from formula for infants, and from milk or dairy foods for older children. Use a specialized formula if the infant or child cannot tolerate the entire protein intake from intact protein.
4. Provide energy and nutrient sources to meet basic needs.
5. Add water to meet fluid requirements and maintain appropriate concentration of formula mixture.
6. For the older infant and child, provide foods to meet food variety, texture, and energy needs.
7. Provide adequate intake of calcium, iron, zinc, and all other vitamins and minerals for age.

health status, level of physical activity, amount of free amino acids administered, energy needs, residual enzyme function, and the use of nitrogen-scavenging medications. Recommendations must take family lifestyle and the individual's eating behaviors into consideration. Long-term therapy consists of restricting dietary protein to 1 to 2 g/kg/day, depending on individual tolerance. For most infants and children with these disorders, L-arginine supplements are required to prevent arginine deficiency and assist in waste nitrogen excretion. L-arginine is supplemented based on individual needs, except in the case of arginase deficiency (Brusilow and Horwich, 2010). Phenylbutyrate or other compounds that enhance alternative metabolic pathways usually are required to normalize ammonia levels.

Protein-Restricted Diets

Infants and children with urea cycle defects or organic acidemias generally require restricted-protein intakes and specialized formulas. The amount of protein prescribed is based on the individual's tolerance or residual enzyme activity, age, and projected growth rate. The highest protein level tolerated should be given to ensure adequate growth and a margin of nutritional safety. The steps for effective planning of a low-protein food pattern are shown in Box 43-1.

In general, low-protein or restricted-protein food patterns can be formulated from readily available, lower-protein infant, toddler, and table foods. Special low-protein foods (see Table 43-5) can be used to provide energy, texture, and variety in the food pattern without appreciably increasing the protein load. The prescribed protein level can be met by adding a protein-free or specialized formula product to standard infant formula. Supplementing carbohydrate and fat makes up the resultant energy deficit.

Specialty formulas are available when needed. The appropriate choice depends on the level of protein restriction, age, and condition of the child. The usual recommendations for energy density and vitamin and mineral composition are generally appropriate to support growth for the infant or child. Osmolarity of the formula and the individual's ability to tolerate hyperosmolar solutions must be considered.

DISORDERS OF CARBOHYDRATE METABOLISM

Disorders of carbohydrate metabolism vary in presentation, clinical course, and outcome. Galactosemia may present in the early newborn period as life-threatening seizures and sepsis. Hereditary fructose intolerance may present during mid-infancy when solids that contain offending ingredients are introduced. Glycogen storage diseases (GSDs) may present at the time when feedings are spaced and subsequent hypoglycemia appears. All of these disorders require early and aggressive nutritional therapy.

Hereditary Fructose Intolerance

Hereditary fructose intolerance (HFI) results from a deficiency of the liver enzyme aldolase B. The disorder typically presents in infancy and toddlerhood, when dietary sources of sucrose and fructose are introduced. Initial symptoms include nausea, bloating, and vomiting. Untreated, liver and kidney damage can occur, along with growth restriction.

Medical Nutrition Therapy

Current management for HFI is restriction of dietary sources of fructose (including disaccharides composed of fructose) and some sugar alcohols, such as sorbitol. HFI (incidence of about 1 in 20,000 to 30,000 in Europe) is different than the more common fructose malabsorption, in which individuals experience gastrointestinal symptoms after ingesting large amounts of fructose (Ali et al, 1998; Bouteldja and Timson, 2010; see Chapter 28).

Galactosemia

Galactosemia, an elevated level of plasma galactose-1-phosphate combined with galactosuria, is found in two autosomal-recessive metabolic disorders: **galactokinase deficiency** and **galactose-1-phosphate uridylyltransferase (GALT) deficiency**, which is also called "classic galactosemia." Illness generally occurs within the first 2 weeks of life. Symptoms are vomiting, diarrhea, lethargy, failure to thrive, jaundice, hepatomegaly, and cataracts. Infants with galactosemia may be hypoglycemic and susceptible to infection from gram-negative organisms. If the condition is not treated, death frequently ensues secondarily to septicemia.

Pathophysiology

Galactosemia results from a disturbance in the conversion of galactose to glucose because of the absence or inactivity of one of the enzymes shown in Figure 43-6. The enzyme deficiency causes an accumulation of galactose, or galactose and galactose-1-phosphate, in body tissues. In addition, expanded newborn screening programs have identified many newborns with Duarte galactosemia. These infants have one allele for galactosemia and one for Duarte galactosemia and are often said to have "D/G galactosemia." The Duarte allele produces approximately 5% to 20% of the GALT enzyme. Little is known about the natural history of D/G galactosemia; apparently infants and children develop normally without medical complications.

Medical Treatment

When diagnosis and therapy are delayed, intellectual disability can result (Waisbren, 2006). With early diagnosis and treatment,

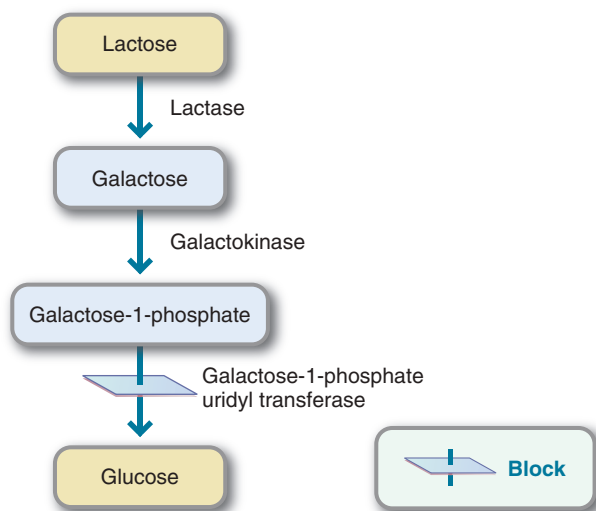

FIGURE 43-6 Schematic diagram of the metabolism of galactose in galactosemia.

physical and motor development should proceed normally. However, intellectual achievement may be depressed. Patients often have IQs of 85 to 100, visual-perceptual and speech difficulties, and problems with executive function (Doyle et al, 2010; Kaufman et al, 1995). Ovarian failure affects approximately 75% to 95% of women with galactosemia (Forges et al, 2006).

Medical Nutrition Therapy

Galactosemia is treated with lifelong galactose restriction. Although galactose is required for the production of galactolipids and cerebrosides, it can be produced by an alternative pathway if galactose is omitted from the diet. Galactose restriction mandates strict avoidance of all milk and milk products and lactose-containing foods because lactose is hydrolyzed into galactose and glucose. Effective galactose restriction requires careful reading of food product labels (see Box 26-9). Milk is added to many products, and lactose often appears in the coating of the tablet form of medications. Infants with galactosemia are fed soy-based formula (see Box 26-9). Some fruits and vegetables contain significant amounts of galactose. Whether these sources of galactose contribute to the pathophysiology characteristics of the disorder is unclear. Table 43-9 presents a low-galactose food pattern.

Medical opinions differ about the intensity and duration of treatment for Duarte galactosemia (Berry, 2012). Many centers eliminate galactose from the diets of these children for the first year of life; other centers do not.

Glycogen Storage Diseases

Glycogen storage diseases (GSDs) reflect an inability to metabolize glycogen to glucose. There are a number of possible enzyme defects along the pathway. The most common of the GSDs are types I and III. Their symptoms are poor physical growth, hypoglycemia, hepatomegaly, and abnormal biochemical parameters, especially for cholesterol and triglycerides. Advances in the treatment of GSDs may improve the quality of life for affected children (Bali et al, 2013).

TABLE 43-9 Food Lists for Low-Galactose Food Pattern

Allowable Foods	Galactose-Containing Foods to be Avoided*
<p>Milk and Milk Substitutes Similac Sensitive Isomil Soy Enfamil Prosoabee Gerber Good Start Soy Plus</p>	All forms of animal milk Imitation or filled milk Cream, butter, some margarines Cottage cheese, cream cheese Hard cheeses Yogurt Ice cream, ice milk, sherbet Breastmilk
<p>Fruits All fresh, frozen, canned, or dried fruits except those processed with unsafe ingredients[†]</p>	
<p>Vegetables All fresh, frozen, canned, or dried vegetables except those processed with unsafe ingredients,[†] seasoned with butter or margarine, breaded, or creamed</p>	
<p>Meat, Poultry, Fish, Eggs, Nuts Plain beef, lamb, veal, pork, ham, fish, turkey, chicken, game, fowl, Kosher frankfurters, eggs, nut butters, nuts</p>	
<p>Breads and Cereals Cooked and dry cereals, bread or crackers without milk or unsafe ingredients,[†] macaroni, spaghetti, noodles, rice, tortillas</p>	
<p>Fats All vegetable oils; all shortening, lard, margarines, and salad dressings except those made with unsafe ingredients[†]; mayonnaise; olives</p>	

*Lactose is often used as a pharmaceutical bulking agent, filler, or excipient; thus tablets, tinctures, and vitamin and mineral mixtures should be evaluated carefully for galactose content. The *Physician's Desk Reference* now lists active and inactive ingredients in medications, as well as manufacturers' telephone numbers.

[†]Unsafe ingredients include milk, buttermilk, cream, lactose, galactose, casein, caseinate, whey, dry milk solids, or curds. Labels should be checked regularly and carefully because formulations of products change often (see Box 26-9).

Pathophysiology

GSD type Ia (25% of GSDs) is a defect in the enzyme glucose-1-6-phosphatase, which impairs the formation of new glucose (**gluconeogenesis**) and the breakdown of glycogen from storage (**glycogenolysis**). The affected person is unable to metabolize glycogen stored in the liver. Severe hypoglycemia can result and cause irreparable damage.

Amylo-1, 6-glucosidase deficiency (GSD III or debrancher enzyme deficiency) prevents glycogen breakdown beyond

branch points. This disorder is similar to GSD Ia in that glycogenolysis is inefficient but gluconeogenesis is amplified to help maintain glucose production. The symptoms of GSD III are usually less severe and range from hepatomegaly to severe hypoglycemia (Dagli et al, 2012).

Medical Treatment

The outcome of treatment has been good. The hazard of severe hypoglycemic episodes is diminished, physical growth is improved, and liver size is decreased. The risk of progressive renal dysfunction is not entirely eliminated by current treatment, but liver transplantation for some types of GSD (e.g., type Ib) is sometimes an option. Treatment protocols for the GSDs are still evolving. The protocols include various kinds of carbohydrates at various doses during the day and night. Individual tolerance, body weight, state of health, ambient temperature, and physical activity are important considerations when designing the specific pattern of carbohydrate administration. The goal for all of the protocols remains the same: normalization of blood glucose levels.

Medical Nutrition Therapy

The rationale for intervention is to maintain plasma glucose in a normal range and prevent hypoglycemia by providing a constant supply of exogenous glucose. Administration of raw cornstarch (e.g., a slurry of cornstarch mixed with cold water) at regular intervals and a high-complex carbohydrate, low-fat dietary pattern are advocated to prevent hypoglycemia. Some infants and children do very well with oral cornstarch administration, whereas others require glucose polymers administered via continuous-drip gastric feedings to prevent hypoglycemic episodes during the night (Bali et al, 2013; Dagli et al, 2012). The dose of cornstarch should be individualized; doses of 1.6 to 2.5 g/kg at 4- to 6-hour intervals are generally effective for young children with GSD I (Bali et al, 2013). Iron supplementation is required to maintain adequate hematologic status because cornstarch interferes with iron absorption.

DISORDERS OF FATTY ACID OXIDATION

Recent laboratory advancements have enabled identification of **fatty acid oxidation disorders** such as **medium-chain acyl-CoA dehydrogenase (MCAD) deficiency** and **long-chain 3-hydroxyacyl-CoA dehydrogenase (LCHAD) deficiency** (see Figure 43-7). Children who are not identified by newborn screening usually present during periods of fasting or illness with symptoms of variable severity, including failure to thrive, episodic vomiting, and hypotonia.

Pathophysiology

Children with MCAD deficiency who present clinically typically have hypoglycemia without urine ketones, lethargy, seizures, and coma. Children with LCHAD deficiency become hypoglycemic and demonstrate abnormal liver function, reduced or absent ketones in the urine, and often secondary carnitine deficiency. They also may have hepatomegaly and acute liver disease. Hypoglycemia can progress quickly and be fatal (Matern and Rinaldo, 2012; Roe and Ding, 2010). Both disorders are included in the newborn screening panels in all U.S. states.

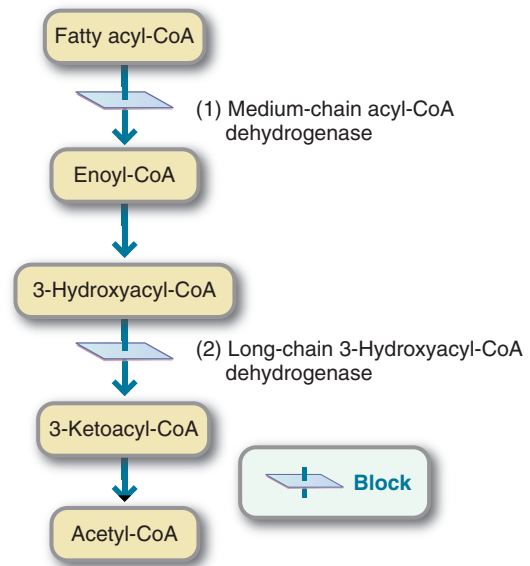

FIGURE 43-7 Mitochondrial fatty acid oxidation disorders: **1**, Medium-chain acyl-Coenzyme A dehydrogenase deficiency, the most common fatty acid oxidation disorder. **2**, Long-chain 3-hydroxyacyl-CoA dehydrogenase deficiency.

Medical Nutrition Therapy

The concept underlying effective treatment for fatty acid oxidation disorders is straightforward: avoidance of fasting. This is accomplished by the regularly spaced intake of foods that provide an adequate energy intake and are high in carbohydrates. A low-fat diet is advocated because fats are not effectively metabolized. Consumption of not more than 30% of energy as fat has been recommended; some individuals require more restriction. Supplementation with **L-carnitine**, a substance that functions as a carrier of fatty acids across the mitochondrial membranes, is recommended by some clinics.

Children often do very well with three meals and three snacks offered at regular intervals. Most children may require additional carbohydrate before bed, based on individual ability to maintain blood glucose levels throughout the night (Matern and Rinaldo, 2012). Depending on the disorder, supplementation with specific fatty acids (e.g., medium-chain fats for disorders that involve blocks of long-chain metabolism) may be indicated.

ROLE OF THE NUTRITIONIST IN GENETIC METABOLIC DISORDERS

The role of the pediatric nutrition specialist in the treatment of metabolic disorders is a complex one that requires expertise in MNT for the specific disorder. Preparation and competency requires access to detailed information about the disorders and treatment modalities. A family-centered approach, knowledge of feeding-skill development, and understanding of behavior modification techniques, as well as the support and counsel of a team of health care providers involved in the care of the patient, are also required. Nutrition intervention is often a lifelong consideration. Specific objectives of nutrition care are shown in Box 43-2.

BOX 43-2 Intervention Objectives for the Nutritionist Involved in the Treatment of Genetic Metabolic Disorders

In the clinic the registered dietitian nutritionist (RDN) has a major role in ongoing therapy and planning for each child. These responsibilities include gathering of objective food intake data from the family, assessing the adequacy of the child's intake, and working with the family to incorporate appropriate ways to monitor the restricted food intake pattern. The child with a metabolic disorder often presents with a wide range of concerns, which may include unstable biochemical markers, failure to gain weight, excessive weight gain, difficulty adhering to the diet, and behaviors that cause an adverse feeding situation. Thus managing a child with a metabolic disorder requires input from the entire health care team. The nutritionist uses skills and knowledge of foods as sources of nutrients, parent-child relationships, growth, development, and interviewing to obtain the necessary information for assessing and planning for the child with a genetic metabolic disorder.

- I. The RDN functions as an effective interdisciplinary team member by doing the following:
 - A. Becoming familiar with the background and current status of the child by reviewing the medical record
 - B. Recognizing and accepting the responsibility as the nutritionist by doing the following:
 1. Identifying appropriate intake of nutrients for growth, activity, and biochemical balance
 2. Identifying developmental stages of feeding behavior
 3. Understanding the concept of food as a support of developmental progress
 4. Identifying behavior as it affects nutrient intake
 - C. Understanding, respecting, and using the expertise of the team disciplines in providing care for the child
- II. The RDN provides adequate and supportive patient services by doing the following:
 - A. Establishing a positive, cooperative working relationship with the parent, child, and other family members
 - B. Interviewing the family about dietary intake and the feeding situation in a nonjudgmental manner
 - C. Assessing the parent-child relationship as it relates to dietary management and control of the disorder
 - D. Developing a plan for appropriate dietary management based on growth, biochemical levels, nutrient needs, developmental progress and nutrition diagnosis, such as:
 - Excessive protein intake
 - Altered nutrition-related laboratory values
 - Intake of inappropriate amino acids
 - Inadequate vitamin intake
 - Inadequate mineral intake
 - Food medication interaction
 - Food- and nutrition-related knowledge deficit
 - Limited adherence to nutrition-related recommendations
 - E. Developing a plan that includes appropriate foods and recognizes the family's skills in food preparation, as well as family routines
 - F. Working with the family to establish a method to deal effectively with negative feeding behaviors, if necessary
 - G. Contacting the family after receiving laboratory results and calculating food records to make necessary and appropriate changes in diet prescription
- III. Supporting families in their efforts at effective dietary and behavior management
- IV. The RDN develops a professional knowledge base by doing the following:
 - A. Being familiar with the current literature on the treatment of metabolic disorders
 - B. Understanding the genetic basis of metabolic disorders
- V. The RDN works with team members to understand the long-term patient care and create a written care plan for the patient.

CLINICAL CASE STUDY

Adelaide was born weighing 6-lb, 7 oz and her 1-day newborn screening test result for phenylalanine was 3.7 mg/dl (222 $\mu\text{mol/L}$). She was breastfed with no supplemental formula. A repeat sample was requested to further document the phenylalanine concentration in her blood. The result from this sample, collected on day 4 of life, was 6.2 mg/dl (372 $\mu\text{mol/L}$). To confirm the diagnosis for this child, which was considered to be "presumptive positive," a quantitative sample was obtained, and phenylalanine and tyrosine levels were both measured. On day of life 9 the serum phenylalanine concentration was 16.6 mg/dl (1328 $\mu\text{mol/L}$), and the tyrosine level was 1.1 mg/dl (60.5 $\mu\text{mol/L}$); the phenylalanine to tyrosine ratio was 22.0:1. Blood and urine were collected for bipterin screening; results were later found to be normal.

To provide adequate protein and energy intake and at the same time decrease the serum phenylalanine concentration, a phenylalanine-free formula was introduced at standard dilution without a phenylalanine supplement. Within 24 hours Adelaide's serum phenylalanine concentration had decreased to 8.3 mg/dl (498 $\mu\text{mol/L}$) while she was being provided an intake of 12 to 14 oz of the Phe-free formula. Breastfeedings were reintroduced; she was offered 3 breastfeedings and Phe-free formula ad lib. Within 48 hours the level was 6.6 mg/dl (396 $\mu\text{mol/L}$), with an intake of 4 oz of the formula.

Adelaide's phenylalanine concentrations were measured every 4 days, and the levels were 3.6 mg/dl (216 $\mu\text{mol/L}$) and 2.2 mg/dl (132 $\mu\text{mol/L}$). In subsequent weeks growth and serum phenylalanine concentrations continued to be monitored carefully, and energy and phenylalanine intakes

were adjusted as necessary to maintain blood phenylalanine concentrations between 2 and 6 mg/dl (120 to 360 $\mu\text{mol/L}$) and to maintain growth in appropriate channels.

By age 2 months, Adelaide's intake had increased to approximately 12 oz formula along with three breastfeedings daily (alternating breastmilk and formula feedings), and her feeding pattern was fairly consistent. Blood phenylalanine was measured at 8.7 mg/dl (522 $\mu\text{mol/L}$), which is outside the desired range. Her Phe-free formula was increased to 14 oz/d to effectively decrease the amount of phenylalanine provided by breastmilk.

Nutrition Diagnostic Statement

Altered nutrition-related laboratory values (phenylalanine) related to phenylketonuria and dietary phe intake, as evidenced by blood phenylalanine outside desired range.

Nutrition Care Questions

1. What is the expected energy requirement for Adelaide?
2. What are the baseline expectations for intake for a 6-lb, 7-oz neonate? If breastmilk is expected to provide about half of this amount, how much phenylalanine-free formula would you use to provide protein and energy intakes at recommended levels?
3. What are the growth expectations for Adelaide?
4. What steps would you take if Adelaide's plasma phenylalanine concentration exceeded 6 mg/dl (360 $\mu\text{mol/L}$) on subsequent measurements?

Medical Nutrition Therapy for Intellectual and Developmental Disabilities

Harriet Cloud, MS, RDN, FAND

KEY TERMS

alcohol-related birth defects (ARBD)
alcohol-related neurodevelopmental disorders (ARND)
Arnold Chiari malformation of the brain
Asperger syndrome
attention-deficit/hyperactivity disorder (ADHD)
autism spectrum disorders (ASD)
cerebral palsy (CP)

cleft lip and cleft palate (CL/CP)
developmental disability
Down's syndrome (DS)
fetal alcohol spectrum disorders (FASD)
hypotonia
individualized education plan (IEP)
individualized family plan
intellectual disability
midfacial hypoplasia

mosaicism
myelomeningocele (MM)
nondysjunction
oral-motor problems
pervasive developmental disorder (PDD)
Prader-Willi syndrome (PWS)
spina bifida
translocation

Individuals with developmental disabilities were generally housed in institutions for the first half of the 20th century. Little attention was paid to their education, or medical or nutritional care. In 1963 the Developmental Disabilities Assistance and Bill of Rights Act was passed. Through this Act federal funds supported the development and operation of state councils, protection and advocacy systems, university centers, and projects of national significance. This Act provided the structure to assist people with developmental disabilities to pursue meaningful and productive lives. The institutions that housed these individuals gradually were closed or reduced in size. By 1975 these individuals were cared for at home, in schools, or in small residential facilities. In 1975 Public Law (P.L.) 94-142 was passed, opening public schools to children with developmental disabilities. In 1985 P.L. 99-487 (102-119 in 1992), the Early Intervention Act, was passed, bringing services to children from birth to school age.

A **developmental disability** is defined as a severe chronic disability that is attributable to a mental or physical impairment or combination of mental and physical impairments. It is manifested before the person attains age 22; is likely to continue indefinitely; results in substantial functional limitations in three or more areas of major life activity (self-care, receptive and expressive language, learning, mobility, self-direction, capacity for independent living, and economic self-sufficiency); and reflects the person's need for a combination of generic or specialized interdisciplinary care, treatments, or other services that are lifelong or of extended duration and individually planned and coordinated. Developmental disabilities affect individuals of all ages and are not a disease state. They are conditions that are caused by fetal abnormalities, birth defects, and metabolic and chromosomal disorders.

Intellectual disability replaced the term *mental retardation* in the 11th edition of the *Definition Manual of the American*

Association on Intellectual and Developmental Disabilities (AAIDD, 2013). **Intellectual disability** is the most common developmental disability, characterized by significantly below-average intellectual functioning along with related limitations in areas such as communication, self-care, functional academics, home living, self-direction, health and safety, leisure, or work and social skills. An estimated 1% to 3% of the population have this diagnosis.

Developmental disabilities have been traced to many causes: chromosomal aberrations, congenital anomalies, specific syndromes, neuromuscular dysfunction, neurologic disorders, prematurity, cerebral palsy (CP), untreated inborn errors of metabolism, toxins in the environment, and nutrient deficiencies. The Centers for Disease Control and Prevention (CDC) reports that 3% of all live births have a birth defect (CDC, 2014), and there are 4.5 million Americans living with developmental disabilities (Van Riper et al, 2010).

MEDICAL NUTRITION THERAPY

Medical nutrition therapy (MNT) services vary depending on the individual's physical or mental problem, and much has been learned about the role of nutrition in the prevention of disabilities and intervention. The role of the registered dietitian nutritionist (RDN) is essential. Because there is an abundance of information that parents and caretakers use from support groups and websites that are untested scientifically, RDNs often are providing evidence-based counseling to counteract misinformation.

Numerous nutrition problems have been identified in the individual with developmental disabilities. Growth retardation, obesity, failure to thrive, feeding problems, metabolic disorders, gastrointestinal disorders, medication-nutrient interactions,

constipation, and cardiac and renal problems may be present. Other health problems exist, depending on the disorder. Table 44-1 lists the most common developmental disabilities and their associated nutrition problems.

The Academy of Nutrition and Dietetics confirms that nutrition services provided by RDNs are essential components of

comprehensive care for infants, children, and adults with intellectual and developmental disabilities. Nutrition services should be provided throughout the life cycle. Educational and vocational programs should provide MNT in a manner that is interdisciplinary, family centered, community based, and culturally competent (Van Riper et al, 2010).

TABLE 44-1 Selected Syndromes and Developmental Disabilities: Frequent Nutrition Diagnoses

Syndrome or Disability	Underweight or Overweight/Obesity	Altered Energy Requirements	Altered GI function	Feeding Problems	Other Issues
<p>Cerebral Palsy A disorder of muscle control or coordination resulting from injury to the brain during its early (fetal, perinatal, and early childhood) development; there may be associated problems with intellectual, visual, or other functions.</p>	Growth problems	Failure to thrive	Constipation	Oral/motor problems	Central nervous system involvement; orthopedic problems; medication-nutrient interactions related to seizure disorder treatment
<p>Down's Syndrome (Genetic Disorder) Results from an extra chromosome 21, causing developmental problems such as congenital heart disease, intellectual disability, small stature, and decreased muscle tone</p>	Risk for obesity	Related to short stature and limited activity	Constipation	Poor suck in infancy	Gum disease; increased risk of heart disease; osteoporosis; Alzheimer's disease risk
<p>Prader-Willi Syndrome (Genetic Disorder) A disorder characterized by uncontrollable eating habits, inability to distinguish hunger from appetite; severe obesity; poorly developed genitalia; and moderate to severe intellectual disability</p>	Risk for obesity	Failure to thrive in infancy	N/A	Weak suck in infancy; abnormal food-related activities	Risk of diabetes mellitus
<p>Autism Classified as a type of pervasive developmental disorder; diagnostic criteria include communication problems, ritualistic behaviors, and inappropriate social interactions</p>	N/A	N/A	Possible dysfunction	Limited food selections; strong food dislikes	Pica; medication-nutrient interactions
<p>Spina Bifida (Myelomeningocele) Results from a midline defect of the skin, spinal column, and spinal cord; characterized by hydrocephalus, intellectual disability, and lack of muscular control</p>	Risk for obesity	Altered energy needs based on short stature and limited mobility	Constipation	Swallowing problems caused by Arnold Chiari malformation of the brain	Urinary tract infections

Nutrition Assessment

Anthropometric Measures

Anthropometric measures are altered when an individual is unable to stand, suffers from contractions, or has other gross motor problems. Measuring body weight may require special equipment such as chair scales or bucket scales. Wheelchair scales are used in some clinics but require that the wheelchair weight be known. Obtaining height for the nonambulatory individual requires a recumbent board that can be purchased or constructed. Other measures of height include arm span, knee-to-ankle height, or sitting height (see Figure 44-1 and Appendix 15).

Although growth charts for children with various syndromes do exist, most clinicians recommend using the general CDC charts (see Appendices 4 through 11) because the information in the specialized charts is often based on small numbers, mixed populations, and old data (CDC, 2014). For the infant with a developmental disability, the WHO growth charts are recommended from birth to 24 months.

Other measures that can be used to explore weight issues include arm circumference, triceps skinfold measures, and body mass index (BMI). BMI is a part of the CDC growth charts and can also be found in Appendices 7, 11, and 18. Using the BMI for age can be controversial. For example, BMI is limited for

identifying overweight in children with developmental disabilities who are overly fat because of decreased muscle mass and short stature.

Biochemical Measures

Laboratory assessment for the child and adult with developmental disabilities is generally the same as that discussed in Chapter 7 and Appendix 22. Additional tests may be indicated for the individual with epilepsy or seizures who is receiving an anticonvulsant medication such as phenytoin, divalproex sodium, topiramate, or carbamazepine. Use of these medications can lead to low blood levels of folic acid, carnitine, ascorbic acid, calcium, vitamin D, alkaline phosphatase, phosphorus, and pyridoxine (see Chapter 8 and Appendix 23).

Assessment of thyroid status is part of the protocol for children with Down's syndrome (DS), and a glucose tolerance test is recommended for evaluation of the child with Prader-Willi syndrome (PWS). As appropriate, genetic testing may be encouraged for affected individuals and their biological family members.

Dietary Intake and Feeding Problems

Dietary information should be obtained for the child with a developmental disability through a diet history or a food frequency

FIGURE 44-1 A, Knee height measure. B, Sitting height measure. C, Arm span measure. (Courtesy Cristine M. Trahms, 2002.)

questionnaire (see Chapter 4). However, obtaining an accurate recall is difficult when the child is in a day care center. Written diaries are also difficult to obtain when the child has multiple caretakers or when he or she is in school. When working with an adult with developmental disabilities, it is often difficult to obtain accurate information unless the individual has supervision, such as in special residential housing. Use of pictures and food models often can help in obtaining an estimate of the individual's intake (see *Focus On: Does Your App Know What You Are Eating?* in Chapter 4).

Many children and adults with developmental disabilities display feeding problems that seriously decrease their ability to eat an adequate diet. Feeding problems are defined as the inability or refusal to eat certain foods because of neuromotor dysfunction, obstructive lesions such as strictures, and psychosocial factors. Other causes of feeding problems in this population include oral-motor difficulties, dysphagia, positioning problems, conflict in parent-child relationships, sensory issues, and tactile resistance from previous intubation (Heiss et al, 2010). The nutritional consequences of feeding problems include inadequate weight gain, poor growth in length, lowered immunity, anemia, vitamin and mineral deficiencies, dental caries, and psychosocial problems. Feeding problems should be assessed with an understanding of the normal development of feeding and the physical makeup of the mouth and pharynx (see Chapters 16 through 18 and Chapter 40).

Estimates are that feeding problems are found in 40% to 70% of children with special health care needs and 80% of children with developmental delays. Feeding problems are classified as oral motor, positioning, behavioral, and self-feeding. **Oral-motor problems** include difficulty with suckling, sucking, swallowing, and chewing. They also include sensory motor integration and problems with self-feeding and are described as exaggerations of normal neuromotor mechanisms that disrupt the rhythm and organization of oral-motor function and interfere with the feeding process (see Box 44-1).

Children with developmental disabilities such as Down's syndrome (DS), cerebral palsy (CP), or cleft lip and palate (CL/CP) often have oral-motor feeding problems that may be related to the cleft, muscle tone, and inability to accept texture changes. The oral-motor problem also can be related to the developmental level, which may be delayed.

BOX 44-1 Oral-Motor Problems

Problem	Description
Tonic bite reflex	Strong jaw closure when teeth and gums are stimulated
Tongue thrust	Forceful and often repetitive protrusion of an often bunched or thick tongue in response to oral stimulation
Jaw thrust	Forceful opening of the jaw to the maximum extent during eating, drinking, attempting to speak, or general excitement
Tongue retraction	Pulling back the tongue within the oral cavity at the presentation of food, spoon, or cup
Lip retraction	Pulling back the lips in a very tight smile-like pattern at the approach of the spoon or cup toward the face
Sensory defensiveness	A strong adverse reaction to sensory input (touch, sound, light)

Positioning a child for feeding relates to his or her motor development, head control, trunk stability, and ability to have hips and legs at a right angle (see Figures 44-2 and 44-3). This is frequently a problem for individuals with CP, spina bifida, and DS. Without proper positioning, oral-motor problems are difficult to correct.

The ability to self-feed may be delayed in the child with developmental disabilities and requires training by a feeding specialist. A feeding evaluation is best completed with actual

FIGURE 44-2 Proper feeding position for the infant. (From Cloud H: *Team approach to pediatric feeding problems*, Chicago, 1987, American Dietetic Association. © American Dietetic Association. Reprinted with permission.)

FIGURE 44-3 Good feeding position for a child ages 6 to 24 months, showing hip flexion, trunk in midline, and head in midline. Good foot support with a stool should continue throughout childhood. (From Cloud H: *Team approach to pediatric feeding problems*, Chicago, 1987, American Dietetic Association. © American Dietetic Association. Reprinted with permission.)

observation by a team composed of a speech therapist, a dentist, a physical therapist, an occupational therapist, and an RDN. An excellent interdisciplinary feeding evaluation form is the Developmental Feeding Tool shown in Figure 44-4. Frequently, adaptive feeding equipment is needed.

Behavioral issues may result from oral-motor or sensory problems, medical problems, certain medications, and the amount of emphasis placed on feeding. Issues such as control of the feeding process along with lack of autonomy in the child may create negative behavior. Environmental factors also

influence the eating behavior of the child (see Chapter 17). Examples include where the child is fed, distractibility, serving sizes, delayed weaning, and frequency of feeding.

Nutrition Diagnosis

Once the nutrition assessment has been completed, problems should be identified related to growth. Excessive or inadequate weights; inadequate dietary intake; excessive or inadequate fluid intake; altered gastrointestinal problems such as constipation, vomiting, and diarrhea; intake of foods that are unsafe because of contamination or food allergies; food-medication interactions; chewing and swallowing difficulties; and problems with self-feeding may be issues. The nutrition diagnoses should be

listed and priorities established. When possible, this information is shared with the parent, caregiver, or the adult client before the intervention process begins.

Interventions

Once the nutrition diagnoses are identified and prioritized, short- and long-term goals should be set. Consideration must be given to the motivational level of the parent or client, his or her cultural background, and how the therapy can be community based and family centered. This means that consideration must be given to where the client will be served so that it becomes a part of the **individualized education plan (IEP)** or the **individualized family plan**.

Intervention plans should include all aspects of an individual's treatment program to avoid issuing an isolated set of instructions relevant to only one treatment goal. In some cases MNT may not be the family's first priority in the care of the child or adult, making it important for the RDN to recognize the family's cues (see Chapter 14). Even when the family is ready for an intervention, such as weight management for a child with spina bifida, many factors require consideration. The parent or caregiver's educational level and income, language barriers, access to safe and appropriate food, and family coping strategies always should be identified (see Chapter 14).

Monitoring and Evaluation

Once MNT has been initiated, the need for follow-up evaluation and monitoring by either the RDN or another health care professional is important. Giving information in writing, followed by a phone call, gives the chance to repeat some of the discussion and to answer any questions not asked during the initial session. Clarification of suggestions often is needed when monitoring nutrition changes that affect growth and development; a follow-up visit also may be needed.

A case manager may be involved who communicates with the adult with the disability. The RDN may need to find appropriate resources to pay for supplemental nutrition products, tube feedings, and special food products as a part of the follow-up process. Community and agency resources are discussed.

CHROMOSOMAL ABERRATIONS

Down's Syndrome

Down's syndrome (DS) is a chromosomal aberration of chromosome 21 (trisomy 21). It has an incidence of 1 in 600 to 800 live births and results from the presence of an extra chromosome in each cell of the body. This anomaly causes the physical and developmental features of short stature; congenital heart disease; mental retardation; decreased muscle tone; hyperflexibility of joints; speckling of the iris (Brushfield spots); upward slant of the eyes; epicanthal folds; small oral cavity; short, broad hands with the single palmar crease; and a wide gap between the first and second toes (Bull and Committee on Genetics, 2011; see Figure 44-5).

FIGURE 44-5 Child with Down's syndrome.

Pathophysiology

Normally every cell of the human body except for the gametes (sperm or ova) contains 46 chromosomes, which are arranged in pairs (see Chapter 5). With DS there is one extra chromosome for a total of 47. This anomaly can occur by one of these three processes: nondysjunction, translocation, and mosaicism. In **nondysjunction**, chromosome 21 fails to separate before conception and the abnormal gamete joins with a normal gamete at conception to form a fertilized egg with three of chromosome 21. This also may occur during the first cell division after conception. This type of DS is usually sporadic and has a recurrence rate of 0.5% to 1%. In **translocation**, the extra chromosome is attached to another chromosome (usually 14, 15, or 22). Approximately half the time, this type of DS is inherited from a parent who is a carrier; it has a much higher risk of recurrence in another pregnancy. In **mosaicism** the abnormal separation of chromosome 21 occurs sometime after conception. All future divisions of the affected cell result in cells with an extra chromosome. Therefore the child has some cells with the normal number of chromosomes and other cells with an extra chromosome. Frequently the child with this type of DS lacks some of the more distinctive features of the syndrome (Bull and Committee on Genetics, 2011) (see *Pathophysiology and Care Management Algorithm: Down's Syndrome*).

Medical Treatment

The National Down Syndrome Congress has published a listing of the health concerns for individuals with DS; many have nutrition implications (see Table 44-2).

Health Concern	Implications	Treatment
Congenital heart disease	40%-50% of population	Medication or surgical repair
Hypotonia	Reduced muscle tone, increased range of joints	
Motor function problem	Poor physical function	Early intervention for physical therapy, occupational therapy
Delayed growth	Short stature	In some cases growth hormone
Developmental delays	Poor physical, emotional function	Early intervention
Hearing concerns	Small ear canals, otitis media, conductive impairment	Early intervention
Dental problems	Decreased saliva, reflux, and vomiting	Low sucrose intake
Ocular problems	Refractive errors, strabismus, cataracts	Corrective glasses
Cervical spine abnormality		None
Thyroid disease	Hypothyroidism	Thyroid supplement, tests repeated annually
Overweight	Excessive weight gain, inactivity	Decrease energy intake, increase activity
Seizure disorders	Variable nutrient intake	Medications
Emotional disorders	May occur late in childhood	Medication, counseling

Updated from Saenz RB: Primary care of infants and young children with Down syndrome, *Am Fam Phys* 59:381, 1999.

PATHOPHYSIOLOGY AND CARE MANAGEMENT ALGORITHM

Down's Syndrome

ETIOLOGY

PATHOPHYSIOLOGY

Clinical Findings

- Hypotonia
- Hyperflexibility/mobility of the joints
- Hip subluxation or dislocation
- Scoliosis
- Foot deformity
- Microbrachycephaly
- Short neck
- Depressed nasal bridge and small nose
- Upward slanting eyes
- Abnormally shaped ear
- Enlarged, protruding tongue
- Single simian crease in center of the palm
- Excessive space between large and second toe
- Mental retardation
- Speech and motor delay
- Cardiac anomalies
- GI atresia or stenosis
- Hearing loss
- Hypothyroidism
- Dental problems
- Cataracts

MANAGEMENT

Nutrition Assessment

- Feeding problems
- Nutritional intake
- Fluid intake
- BMI compared with Down's syndrome standards
- Weight changes
- Dysphagia
- Hemoglobin concentration

Medical Management

- Monitor for leukemia
- Management of infections
- Management of respiratory problems
- Signs of Alzheimer's disease later
- Annual monitoring of hypothyroidism

Nutrition Care

- Feeding management
- Feeding environment
- Use of adaptive feeding utensils
- Monitor weight changes
- Monitor for signs of nutrient deficiencies

Medical Nutrition Therapy

Anthropometric Measures. Height, weight, head circumference, triceps skinfold, and arm circumference are obtained for the child with DS with the usual measurements (see Chapter 7). BMI can be taken but may be higher than normal because of short stature. Growth measures are an important part of the assessment and ongoing nutrition therapy because these individuals tend to be short. Muscle tone is low and gross motor ability is often delayed, leading to the possibility of the individual becoming overweight. Monitoring should be frequent, and growth is plotted on the CDC charts or the WHO charts for the younger child (see Appendices 4 through 11).

Biochemical Measures. Numerous studies have shown biochemical and metabolic abnormalities in individuals with DS; however, many have involve small samples and were difficult to interpret (Bull and Committee on Genetics, 2011). Although serum concentrations of albumin have been found to be low, the guidelines from the Down Syndrome Medical Congress do not list serum albumin assessment as routine. Increased glucose levels have been reported, with an increased incidence of diabetes mellitus.

Current guidelines for the treatment of infants and children with DS include evaluation of thyroid function at birth and thereafter annually. A number of studies have looked at zinc, copper, and selenium as possible deficiencies but concluded that they do not usually exist in children with Down's syndrome (Lima et al, 2010).

Dietary Intake. During infancy the food intake of the infant with DS may differ from that of the normal infant. Although human breastmilk is recommended, many infants with DS are formula fed. Infant illnesses, admission to the neonatal unit, frustration, depression, perceived milk insufficiency, and difficulty in suckling by the infant are reasons why formula feeding is used.

Progression to solid food has been found to be delayed in children with DS, mostly as a result of delays in feeding and motor development. Introduction of solid food may not be offered at 6 months if the infant has poor head control or is not yet sitting. Low tone and sucking problems also delay weaning from the breast or bottle to the cup. IEPs include feeding and feeding progression instruction and practice.

An important part of evaluating the dietary intake is determining energy and fluid needs, because children with DS have a high prevalence of obesity. Studies have indicated that the resting energy expenditure (REE) of the child with DS is lower than for children without DS—and may be as much as 10% lower than the dietary reference intake (DRI) for energy. For the child older than the age of 5, calculations for energy requirements may have to be based on height rather than weight (see Table 44-3 and Chapter 2).

Feeding Skills. Feeding skills are delayed in the infant and child with DS. Some parents find difficulty in initiating oral motor skills such as suckling and sucking. The infant with DS often has difficulty in coordinating sucking, swallowing, and breathing, which are the foundations for early feeding. When the infant has a congenital heart defect, which occurs in 40% to 60% of DS infants, sucking is weakened, and fatigue interferes with the feeding process. Gastrointestinal anomalies are found in 8% to 12% of infants with DS, and these infants often require nasogastric or gastrostomy feedings.

Other physical factors that make feeding difficult in the first years of life include a **midfacial hypoplasia** (a craniofacial deformity common in cleft palate), a small oral cavity, a small mandible, delayed or abnormal dentition, malocclusion, nasal congestion,

TABLE 44-3 Estimated Caloric Needs for Special Conditions

Condition	kcal/cmhgt	Comments
Normal child	Average 16	
Prader-Willi	Maintain growth: 10-11 Promote weight loss: 8.5	For all children and adolescents
Cerebral palsy		
Mild	14	For children ages 5-11 yr
Severe, limited mobility	11	For children ages 5-11 yr
Down's syndrome	Girls: 14.3 Boys: 16.1	For children ages 5-11 yr
Motor dysfunction		
Nonambulatory	7-11	For children ages 5-12 yr
Ambulatory	14	For children ages 5-12 yr
Spina bifida	Maintain weight: 9-11 Promote weight loss: 7	For all children older than 8 years of age and minimally active

Modified from Weston S, Murray P: Alternative methods of estimating daily energy requirements based on health condition. In Devore J, Shotton A, editors: *Pocket guide to children with special health care and nutritional needs*, Chicago, 2012, Academy of Nutrition and Dietetics.

facial hypotonia, small hands and short fingers. Weaning and self-feeding are usually late compared with the normal infant and frequently do not emerge until 15 to 18 months of age. The DS infant strives for independence and autonomy approximately 6 months later than the child without DS.

Intervention Strategies

Overweight. The most effective intervention for the overweight child with DS is to design a calorie-controlled eating plan based on kilocalories per centimeter of height as shown in Table 44-3 (Murray and Ryan-Krause, 2010). Dietary management includes assessing the feeding developmental level of the child, working with a physical therapist related to gross motor skills and physical activity levels, and making environmental changes. Environmental changes should include following a regular eating schedule that includes three meals at regular times with the child sitting either in a high chair or at the table. Planned snacks should be low in fat and sugar. Soft drinks should be eliminated, and milk should be low fat (after age 2). Physical activity should be encouraged.

Counseling in which the parent helps determine a realistic plan should focus on serving sizes and food preparation and decreasing the number of times meals are purchased in fast-food restaurants. If the child or adolescent is school age, a prescription for a special meal at school can be obtained by using the school food service prescription (to be discussed later in the chapter). Recent studies involving adolescents and young adults have addressed the success of exercise and healthy lifestyles for obese participants with Down's syndrome. Successful programs include parent training in behavioral intervention, and nutrition and activity education over multiple sessions (Curtin et al, 2013).

Eating Skills. Often parents wrongly expect different eating development for the child with DS. Behavioral problems related to feeding may develop based on what happens between the parent and child at mealtime. An example of this is the unnecessary

delay of weaning to a cup or progression of food textures because of inadequate effort or education. During intervention programs the feeding team can guide the parent in positioning the child and working toward attainable feeding skills related to the developmental level of the child.

Constipation. This is a frequent problem for the child with DS because of overall low tone followed by lack of fiber and fluid in the diet. Treatment should involve increasing fiber and fluid, with water consumption emphasized. Fiber content of the diet for children after age 3, is 5 to 6 g per year of age per day. For adults the recommendation is for 25 to 30 g of dietary fiber daily (see Chapter 28).

Prader-Willi Syndrome

Prader-Willi syndrome (PWS) was first described in 1956 by Prader, Willi, and Lambert. It is a genetic condition caused by the absence of chromosomal material. PWS occurs with a frequency of 1 in 10,000 to 1 in 25,000 live births. Characteristics of the syndrome include developmental delays, poor muscle tone, short stature, small hands and feet, incomplete sexual development, and unique facial features. Insatiable appetite leading to obesity is the classic feature of PWS; however, in infancy the problem of **hypotonia** (low muscle tone) interferes with feeding and leads to failure to thrive (Miller et al, 2011; see Figure 44-6). Developmental delays (affecting 50% of the population), learning disabilities, and mental retardation (affecting 10%) are associated with PWS.

The genetic basis of PWS is complex. Individuals with PWS have a portion of genetic material deleted from chromosome 15 received from the father. Of the cases of PWS, 70% are caused from the paternal deletion, occurring in a specific region on the q arm of the chromosome. PWS also can develop if a child receives both chromosome 15s from the mother. This is seen in approximately 25% of the cases of PWS and is called maternal uniparental disomy. Early detection of PWS is now possible because of the use of DNA methylation analysis, which correctly diagnoses 99% of the cases (Miller et al, 2011). This is an important development in the early identification and subsequent treatment of these children to prevent obesity and growth retardation, and is used to identify the infant born with features and characteristics described previously.

FIGURE 44-6 Child with Prader Willi syndrome.

Pathophysiology

Metabolic Abnormalities. Short stature in the individual with PWS has been attributed to growth hormone deficiency. In addition to decreased growth hormone release, children have low serum insulin-like growth factor (IGF)-1, low IGF-binding protein-1, and low insulin compared with normal obese children. Growth hormone (GH) therapy was approved by the Food and Drug Administration in 2000, and in one 5-year study in Japan 37 patients from age 3 to 21 years experienced significant increase in height gain velocity when given growth hormone (Obata et al, 2003). A more recent study found that GH therapy of infants and toddlers for 12 months significantly improved body composition and mobility skill acquisition (Carrel et al, 2010).

In addition to the growth hormone deficiency, individuals have a deficiency in the hypothalamic-pituitary-gonadal axis, causing delayed and incomplete sexual development. Finally there is a decreased insulin response to a glucose load in children with PWS compared with age-matched non-PWS obese children (Haqq et al, 2011).

Appetite and Obesity. Appetite control and obesity are common problems for individuals with PWS. After the initial period of failure to thrive, children begin to gain excessively between the ages of 1 and 4, and appetite slowly becomes excessive. Based on longitudinal study, Miller et al describe this gradual and complex progression in terms of seven nutritional phases based on levels of appetite, metabolic changes, and growth. In fact, some adults with PWS may progress to the last phase, with no insatiable appetite, and the person is able to feel full (Miller et al, 2011).

This uncontrollable appetite, a classic feature of PWS, when combined with overeating, a low basal metabolic rate, and decreased activity, leads to the characteristic obesity. The cause of the uncontrollable appetite is suspected to involve the hypothalamus and altered levels of satiety hormones and peptides such as ghrelin (Scerif et al, 2011).

Body composition is an important consideration in the evaluation of individuals with PWS. They have decreased lean body mass and increased body fat, even in infancy (Reus et al, 2011). Body fat generally is deposited in the thighs, buttocks, and abdominal area. The lowered energy expenditure is found in young children, adolescents, and adults with PWS, with one study showing adolescents with PWS having a total energy expenditure (TEE) 53% of that of normal obese adolescents (McCune and Driscoll, 2005). The low muscle tone contributes greatly to the lack of interest in physical activity.

Nutrition Assessment

Anthropometric Measures. Height measurements tend to be lower in PWS infants and young children, with the rate of height gain tapering off between the ages of 1 and 4. The usual measurements of length or height, weight, and head circumference should be taken and plotted on the CDC growth curves. Other measures of interest include arm circumference and triceps skinfold measures. BMI may be distorted for the individual with PWS because of the short stature; however, plotting the BMI over time is useful in determining unusual changes (see Appendices 7 and 11). It is important that anthropometric measures be taken frequently and reported to the parents or caregiver.

Biochemical Measures. Biochemical studies are generally the same for the PWS individual, with the exception of either fasting blood glucose tests or glucose tolerance tests. These are added because of the risk for diabetes mellitus, possibly related

to the decreased insulin response and obesity that usually accompany PWS.

Dietary Intake. Dietary information varies for individuals with PWS, depending on their age. In infancy the dietary information should be obtained with a careful dietary history and analyzed for energy and nutrient intake. Infants are commonly difficult to feed because of their hypotonia, poor suck, and delayed motor skills. Generally their feeding development is slower than in the normal infant, and transitioning to food at 4 to 6 months of age may be difficult. Many of these infants have gastroesophageal reflux, requiring medication or thickening of their formula.

During the toddler years, weight gain may increase rapidly as dietary intake increases. This requires careful assessment of portion sizes, frequency of feeding, and types of foods served. Although some parents may report that the child with PWS does not eat more than other children in the family, they have to be educated that the energy needs of the child are lower because of the reduced lean muscle mass and slow development of motor skills and activity. As the child gets older, interest in food increases; and, starting around ages 5 through 12, the child may be hungry all the time and display difficult behaviors such as tantrums, stubbornness, and food stealing. Information gathered during the dietary interview should include asking about environmental control techniques.

Determination of energy needs for the infant with PWS is the same as for a normal infant. However, as the child enters the toddler years, he or she will need fewer calories to maintain weight gain along the growth curve. This will apply in adulthood when fewer calories are needed to maintain weight. Energy needs have been calculated according to centimeters of height from 2 years on. It has been recommended that the macronutrient intake of the diet be 25% protein, 50% carbohydrate, and 25% fat (see Table 44-3).

Feeding Skills. The infant with PWS often presents with weak oral skills and poor sucking skills in the first year of life. As the child matures, feeding skills are not a problem, but they may be delayed. Chewing and swallowing problems usually are not seen, although they may be associated with the low muscle tone. Behavioral feeding issues are associated with an insatiable appetite and not being provided with food. This can bring about tantrums.

Intervention Strategies

Intervention for PWS should occur at each developmental stage: infancy, toddler, preschool age, school age, and adult.

Infancy. Providing adequate nutrition as established by the American Academy of Pediatrics (AAP) related to breastfeeding or formula feeding is recommended. Because feeding may be difficult related to sucking, concentrating the formula or breastmilk may be necessary to promote adequate weight gain. Feeding intervention will assist in improving the sucking problems caused by hypotonia. As the infant matures, a concentrated formula is not necessary, and foods can be added when head control and trunk stability are achieved, usually at approximately ages 4 to 6 months.

Toddler and Preschool Age. Most children begin to gain excessive weight between 1 and 4 years of age. Beginning a structured dietary protocol for the child and the family is important so that the toddler learns that meals are provided at specified times so that a pattern of grazing doesn't develop. Parents should be taught to provide small servings of meats,

vegetables, grains, and fruits and limited amounts of sweets. Early intervention for these children in the preschool years is very important in working with feeding issues and intake control as they grow older. Weight, height, and nutrient intake should be monitored monthly and energy needs adjusted if weight gain becomes excessive. Concurrently physical activity must be encouraged as a part of the IEP, and physical therapy services made available if necessary.

School Age. For the school-age child, collaboration with the school food service program becomes important. Energy needs should be calculated per centimeter of height (see Table 44-3) and are generally 50% to 75% of the energy needs of unaffected children. This may require using the prescription for special meals through the school food service program.

At home environmental controls may be required, with cupboards and even kitchens being locked, because the child and adolescent have limited satiety, and will search for food away from mealtime. Some parents report that growth hormone therapy for their child helps, but it doesn't seem to change the child's lack of satiety. Appetite-suppressing medications have been used but are largely unsuccessful.

Adulthood. Prevention of obesity is truly the key for successful treatment of PWS; however, many adults who are not identified early become very obese. Weight management programs providing a very low 6 to 8 kcal per centimeter of height may be required. Nutrient values should be calculated, and vitamin-mineral supplements added, as well as essential fatty acids (EFAs) if indicated. Many dietary treatments have been tried such as the ketogenic diet (see Chapter 40) and the protein-sparing modified-fast diets. However, with any approach strict supervision is usually required, and great emphasis must be placed on physical activity. A behavior management approach also has been recommended to implement the dietary management and physical activity plans. In many states there are group homes for adults with PWS, in which supervised independent living is possible and meals can be very structured and exercise programs implemented.

MNT of children and adults with PWS requires follow-up with many health care providers and schools. Fortunately parents of the individual with PWS now have access to a number of support groups and organizations dedicated to education, research, and establishing treatment programs.

NEUROLOGIC DISORDERS

Spina Bifida

Spina bifida is a neurologic tube defect that presents in a number of ways: meningocele, **myelomeningocele (MM)**, and spina bifida occulta. MM is the most common derangement in the formation of the spinal cord and generally occurs between 26 to 30 days of gestation, with the date of occurrence affecting the location of the lesion. The lesion may occur in the thoracic, lumbar, or sacral area and influences the amount of paralysis. The higher the lesion, the greater is the paralysis. Manifestations range from weakness in the lower extremities to complete paralysis and loss of sensation. Other manifestations include incontinence and hydrocephalus. The incidence of spina bifida is about 2.7 to 3.8 per 10,000 live births in the US per year, with Hispanics having the highest incidence (Canfield et al, 2014).

Prevention of spina bifida is now possible. In the 1980s, studies reported a positive effect from supplementation of mothers with folic acid plus multivitamins (Smithells et al, 1983). This reduced the risk of a second pregnancy with spina

bifida as an outcome. As a result of numerous studies showing folic acid supplementation before conception to be effective, the national recommendation is 400 mcg/day for all women of childbearing age. Through their Public Health Program, the World Health Organization advocates globally for folic acid supplementation. Folic acid has been added to many flours and other cereal and grain products in the food supply since 1996 (CDC, 2010). These public health measures have resulted in increased folic acid blood levels in U.S. women of childbearing age and a decrease of 20% in the national rate of spina bifida (Das et al, 2013; see Chapter 15).

Pathophysiology

The spinal lesion may be open and can be repaired surgically shortly after birth, usually within 24 hours, to prevent infection. Although the spinal opening can be repaired surgically, the nerve damage is permanent, resulting in the varying degrees of paralysis of the lower limbs. In addition to physical and mobility issues, most individuals have some form of learning disability.

The spinal lesion affects many systems of the body and can result in weakness in the lower extremities, paralysis, and non-ambulation; poor skin condition caused by pressure sores; loss of sensation and bladder incontinence; hydrocephalus; urinary tract infections; constipation; and obesity. Seizures also occur in approximately 20% of children with MM and may require medication. If medication fails, a ketogenic diet can be tried (see Chapter 40). Chronic medication is required for prevention and treatment of urinary tract infections and for bladder control. The resultant nutrition problems include obesity, feeding problems, constipation, and drug-nutrient interaction problems. Children with spina bifida may be allergic to latex. It has been recommended that they avoid certain foods such as bananas, kiwi, and avocados. Mild reactions can occur from apples, carrots, celery, tomatoes, papaya, and melons (Blumchen et al, 2010; see Box 26-5).

Nutrition Assessment

Anthropometric Measures. Infants and children with neural tube defects are usually shorter because of reduced length and atrophy of the lower extremities, although other problems such as hydrocephalus, scoliosis, renal disease, and malnutrition may contribute. The level of the lesions also can affect the length and height of the individual.

Obtaining accurate length and height measures can be difficult, especially as the child grows older. An alternate measure for determining height, the arm span/height ratio, is used and modified, depending on leg muscle mass. Arm span can be used directly as a height measure ($\text{arm span} \times 1$) if there is no leg muscle mass loss, as in a sacral lesion. $\text{arm span} \times 0.95$ can be used to determine height if there is partial leg muscle loss, and $\text{arm span} \times 0.90$ is used for a height measurement when there is complete leg muscle loss, such as with a thoracic spinal lesion (Kreutzer et al, 2013; see Figure 44-1 and Appendix 15).

Weight measures can be obtained for the child unable to stand by using chair scales, bucket scales, and wheelchair scales. To monitor the weight accurately, it should be obtained in a consistent manner, with the person in light clothing or undressed. Triceps skinfold measures can also be used, along with subscapular measures and abdominal and thorax measures, to determine the amount of body fat. They may be used as adjuncts to stature and weight measurements (Krick et al 2012).

Head circumference should be measured in infants and toddlers up to age 3. A high percentage of children with spina bifida have head shunts as a result of their hydrocephalus. Unusual changes in the size of the head may indicate a problem with the shunt.

Biochemical Measures. Most protocols in the treatment of spina bifida include iron status tests, measurements of vitamin C and zinc levels, and other tests related to the nutritional consequences of medications needed for seizures and urinary tract infection control (see Chapters 7 and 8 and Appendices 30 and 31).

Dietary Intake. Many children with spina bifida eat a limited variety of foods, and they are frequently described as “picky eaters” by the parents. When doing a dietary history, it is important to ask about the variety of foods, particularly of high-fiber foods. The school-age child may be prone to skipping breakfast because early morning preparations for school require more time than for the nonaffected child.

Energy needs are lower for the child with spina bifida (see Table 44-3), and calorie requirements must be determined carefully to prevent the obesity to which many are prone. Ekvall and Cerniglia (2005) found that for MM children 8 years or older, the caloric need is 7 cal/cm of height for weight loss and 9 to 11 cal/cm of height to maintain weight. It is important to evaluate how the mother or caretaker perceives food for the child because it represents sympathy and love for many parents.

It is important to evaluate fluid intake because so many children have urinary tract infections and may be drinking inadequate amounts of water and excessive amounts of soft drinks or tea. Cranberry juice can be offered. Physical activity also must be evaluated and may be found to be very limited, particularly when the child is nonambulatory. Ambulatory individuals with a shunt may be restricted from contact sports but can be involved in walking and running.

Feeding skills need to be evaluated, along with oral motor function in particular. Many children with spina bifida are born with **Arnold Chiari malformation of the brain**, which affects the brainstem and swallowing (see Chapter 40 and Appendix 28 for dietary recommendations for dysphagia). Difficulty in swallowing may contribute to the child avoiding certain foods later in life. Because of this there may be delays in weaning from the breast or bottle to the cup, but there should be no delays in gaining self-feeding skills.

Clinical Evaluation. Evaluation should include looking for pressure sores and signs of dehydration, along with asking about the amount and type of fluids consumed. Constipation may be caused by the neurogenic bowel combined with a diet low in fiber and fluids. The evaluation should include a review of food intake, fiber content, and fluids.

Intervention Strategies

Many children with spina bifida are overweight. It usually occurs when ambulation is a problem leading to decreased energy needs. Refusal to accept a wide variety of foods is common. Frequent feeding is an oral-motor and a behavioral problem. Counseling should include introducing foods around age 6 months, limiting the intake of high-sucrose infant jar foods, and training the child to accept a wide variety of flavors and textures.

Obesity prevention should include addressing the problems of limited physical activity, increasing fluids and fiber, and calculating the appropriate amount of calories. Once the child is in school, the food service manager should be provided with a

prescription for a low-calorie breakfast and lunch, and weight management program should be listed as a part of the IEP. Enrollment in a group weight management program has been used successfully with modification of the accompanying physical exercise. The ideal program uses a team approach with involvement of the RD, nurse, occupational therapist, physical therapist, educator, and psychologist (see Chapter 21).

In many clinics the child or adult with spina bifida is seen on a semiannual or annual basis. This frequent follow-up is necessary and should include monitoring of growth, particularly weight; food and fluid intake; and medication use. School programs and IEPs are excellent follow-up tools; however, the school often lacks appropriate scales for weighing a nonambulatory student. In this situation the parent should be encouraged to bring the child to the clinic for weight checks or, if distance is a problem, find a long-term care facility that will permit use of its scales. Follow-up by phone contact or e-mail can be done for evaluating dietary intake and fluid management.

Cerebral Palsy

Cerebral palsy (CP) is a group of disorders of motor control or coordination resulting from injury to the brain during its early development. Among the causative agents of CP are prematurity; blood-type incompatibility; placental insufficiency; maternal infection that includes German measles; other viral diseases; neonatal jaundice; anoxia at birth; and other bacterial infections of the mother, fetus, or infant that affect the central nervous system.

The problem in CP lies in the inability of the brain to control the muscles, even though the muscles themselves and the nerves connecting them to the spinal cord are normal. The extent and location of the brain injury determine the type and distribution of CP. The incidence of CP varies with different studies, but the most commonly used rate is 1.5 to 4 in 1000 live births. The prevalence of premature births has contributed to maintenance of this figure despite electronic fetal monitoring (see Figure 44-7).

Pathophysiology

There are various types of CP, which are classified according to the neurologic signs involving muscle tone and abnormal motor patterns and postures. The diagnosis of CP is generally made between 9 to 12 months of age and as late as 2 years with some types (see Box 44-2).

Poor nutrition status and growth failure, often related to feeding problems, are common in children with CP. Meeting energy and nutrient needs is particularly difficult in children and adults with more severe forms of CP such as spastic quadriplegia and athetoid CP. For example, bone mineral density of children and adolescents with moderate to severe CP is reduced in those with gross motor function and feeding difficulties (Andrew and Sullivan, 2010).

Other health problems include constipation, usually caused by inactivity and lack of fiber and fluids, often connected to feeding problems. Dental problems occur and often are related to malocclusion, dental irregularities, and fractured teeth. Lengthy and prolonged bottle-feedings of milk and juice promote the decay of the primary upper front teeth and molars (see Chapter 25). Hearing problems and especially visual impairments, mental retardation, respiratory problems, and seizures affect nutrition status. Seizures are controlled with anticonvulsants, and a number of drug-nutrient interaction problems occur (see Chapter 8).

FIGURE 44-7 Child with cerebral palsy.

BOX 44-2 Different Types of Cerebral Palsy

Spastic CP: Increased muscle tone, persistent infant reflexes, increased deep tendon reflexes in one of three patterns: hemiplegia (arm and leg on one side of the body), diplegia (involving the lower extremities), and quadriplegia (all four extremities and may include the trunk, head, and neck)

Dyskinetic CP: Abnormalities in muscle tone that affect the entire body; includes athetoid CP, which includes uncontrolled and continuous involuntary movements

Mixed CP: A condition in which both athetosis and spasticity are present

Ataxic CP: Abnormalities of voluntary movement and balance such as unsteady gait

Athetoid dyskinetic CP: Normal intelligence but difficulty walking, sitting, speaking clearly

CP, Cerebral palsy.

Data from MYCHILD: Types of Cerebral Palsy (website): <http://www.cerebralpalsy.org/types-of-cerebral-palsy/>, 2015. Accessed January 7, 2015.

Nutrition Assessment

Anthropometric Measures. This is an important area of assessment because of the growth failure of the more severely involved child or adult with CP. Children with CP are often shorter, and, depending on the level of severity, some children with CP may have to be measured for length using recumbent length boards or standing boards even as they grow older (see Appendix 15). However, some of the measuring devices are inappropriate for the child with contractures and inability to be stretched out full length. Arm span can be used when the individual's arms are stretchable, as well as upper arm and

lower leg length. Stevenson (2005) has recommended lower leg length or knee height as a possible measure for determining height for children and adults with lower-leg CP (see [Figure 44-1](#)). The CDC recommends using the CDC/WHO curves designed for nonaffected children, plotting sequentially for indications of malnutrition rather than using the disease-specific curves.

Weight measures should be collected over time. Scales may require modifications, with positioning devices for the individual with CP who has developed scoliosis, contractures, and spasticity. Working with a physical therapist to find a positioning device that can be placed in a chair scale or using a bucket scale often works well. Mid-upper arm circumference and triceps skinfold measures are recommended reliable ways to screen for fat stores in children with CP. Head circumference should be measured regularly from birth to 36 months and plotted on the CDC growth curves.

Biochemical Measures. Although no specific laboratory tests are indicated for the child with CP, a complete blood count, including hemoglobin and hematocrit, should be done when food intake is limited and malnutrition is a possibility. Because bone fractures are a significant problem for many children and adults with spastic quadriplegia, bone mineral density may require evaluating. Medications for seizures may be given; many have nutrition interaction problems (see [Appendix 23](#)). Evaluation of vitamin D, calcium, carnitine, and vitamin K levels is recommended.

Dietary Intake. Feeding methods can result in limiting the intake of food and fluid; caretakers may not provide sufficient food to meet nutritional needs. The energy needs of the individual with CP vary according to the type of CP. Studies show that the REE and TEE are lower in those with spastic quadriplegic CP than in normal controls (see [Table 44-3](#)).

Intervention Strategies

A high percentage of children with CP have feeding problems that are largely the result of oral-motor, positioning, and behavioral factors. As infants they have difficulty swallowing and coordinating swallowing and chewing, so the normal progression to solid foods is later than usual. All this may lead to inadequate intake and growth limitations. For those infants and children with IEPs, the team of dietitian nutritionist, speech therapist, occupational therapist, and physical therapist should evaluate the problem and work together in planning therapy.

Gastroesophageal reflux frequently is seen in these infants and toddlers. A tube feeding may be required if a modified barium swallow reveals aspiration. Alternative techniques in feeding should be considered, which could include thickening all beverages or placing a gastrostomy tube ([Mahant et al, 2011](#)). RDNs should evaluate gastrostomy feedings for caloric and nutritional value, volume required, and osmolality and offer directions for inclusion of solid foods in addition to the formula if possible.

Usual problems identified in the evaluation will be altered growth, inadequate energy or fluid intakes, drug-nutrient interaction problems, constipation, and feeding problems. Working out an intervention plan is most successful when it involves the parent as part of the team, addresses cultural issues, and recognizes the importance of the feeding problem. Children with CP have complex problems that require continuing follow-up with the family in the community and will take time to correct. State agencies provide tube-feeding formulas and special wheelchairs

TABLE 44-4 Pervasive Developmental Disorders (PDD)

Disorder	Characteristics
Autistic disorder	Impairment in social interaction Poor communication skills Repetitive and stereotypical behavior
Rett syndrome	Normal until 6-18 months Loss of motor skill abilities Loss of social interaction Deceleration of head growth between 5 and 48 months
Childhood disintegrative disorder	Before age 10 years Loss of expressive language, social skills, bowel or bladder control, play motor skills
Asperger syndrome	Impairment in social interaction Restricted repetitive or stereotypical behavior Normal language development Normal cognitive development
Pervasive developmental disorder not otherwise specified	Deficits in social behavior Impairment in understanding speech and in speech development Does not meet the criteria for the other four disorders

and equipment to assist with feeding problems. These agencies vary from state to state.

Autism

Autism is one of five disorders under the category **pervasive developmental disorder (PDD)**. PDD was first used in the 1980s to describe a class of disorders as shown in [Table 44-4](#). All types of PDD are neurologic disorders that are usually evident by age 3. In general, children who have a type of PDD have difficulty in talking, playing with other children, and relating to others, including their families. In a recent report CDC estimated that 1 in 68 children has been identified with autism spectrum disorder. This estimate is roughly 30% higher than a previous estimate in 2012 (www.cdc.gov/mmwr, CDC, 2015).

Pathophysiology

Autism spectrum disorders (ASD) are diagnosed by the presence of qualitatively impaired reciprocal social interaction; impaired communication skills; and restricted, repetitive, stereotypical interests and behaviors. Many children with autism also have intellectual compromise. ASD is four times more common in boys than in girls.

Asperger syndrome describes children with the problems of ASD but who have normal to high cognitive levels. These children have a difficult time socializing but may otherwise be able to attend school successfully.

ASD may occur with other developmental or physical disabilities. They have been associated with tuberous sclerosis and maternal rubella. Macrocephaly has been a common finding in large surveys of individuals with autism and also among their relatives. Overall growth is usually normal, and medical problems nonexistent. However, with the limited variety of foods usually eaten by these children, phytonutrient, vitamin and mineral intake could be inadequate.

Efforts to find the cause of ASD have led to many studies looking at a possible toxic environment or food, a nutritionally deficient diet, immune system problems, oxidative stress, and

pesticide exposure as important factors. Other studies have studied neurotransmitters such as elevated serotonin levels and disturbances in gamma-amino butyric acid (GABA) receptors, glutamate transmitters, and cholinergic activity. A number of prenatal causes have been evaluated, including pesticides. In one California study women in the first 8 weeks of pregnancy who lived near farm fields sprayed with dicofol and endosulfan were several times more likely to give birth to children with autism (Roberts et al, 2007). More research is needed with greater numbers of mothers included.

Some treatment and research programs are using genomic panels to identify specific intervention protocols. The genomic panel identifies single-nucleotide polymorphisms (SNPs), which are identified from blood samples or cell cultures (see Chapter 5). This work has revealed that the child with autism may need additional omega-3 or EFAs; nutrients with antioxidant qualities such as vitamins A, C, E, and selenium; mineral supplementation with zinc, calcium, and magnesium; a mercury-free diet; or an allergy-elimination diet (see Chapter 26).

Interest in a neurochemical cause of ASD has noted gluten and casein as the suspected sources. Intestinal inflammation has been reported in children with ASD and has improved with dietary restriction of gluten and casein (Elder, 2008; Whiteley et al, 2013). Antibodies to casein, gluten, and soy have been noted in some children with ASD.

Nutrition Assessment

Anthropometric Measures. Height and weight are determined for the child and adult with ASD using the equipment and growth charts for nonaffected individuals. Head circumference has been found to be larger than that of the non-ASD individual.

Biochemical Measures. There is no standard pattern of tests that should be given other than the regular blood work for health monitoring. However, amino acid screening shortly after birth, thyroid testing, and allergy testing may be indicated (see Chapter 26).

Dietary Intake. Dietary evaluations are sometimes difficult to complete for the child with a very limited intake. An effective measure may be provided by having the parents and caregivers keep a food diary for several days to determine the macronutrient intake in addition to the vitamin and mineral intake (see Chapter 4). Obtaining information related to when food is presented and the amount eaten is important, along with fluid consumption. Often excessive fluids are provided to compensate for limited food consumption.

Evaluations should include an observation of the child during mealtime. Some children are slow in arriving at developmental milestones for self-feeding, and require feeding. Others finger feed or insist on self-feeding. The texture of the food presented should be recorded because sensory integration is difficult for children with ASD, and they may be very resistant to texture progression or variety. This is reflected in their fixation on one food (e.g., crackers, dry cereal, or chips). Food jags and picky eating are common. Evaluation should include a description of the feeding environment, whether there is a high chair or age-appropriate toddler chair, the timing of meals, and the location for meals.

Medical Nutrition Therapy

No one therapy or method works for all individuals with ASD. Many professionals and families use a range of treatments

simultaneously, including behavior modification, structured educational approaches, medication, speech therapy, occupational therapy, and counseling. Popular nutrition interventions include mineral and vitamin therapy and elimination diets such as a gluten-free (see Chapter 28), casein-free diet (see Chapter 26); allergy diets (see Chapter 26); supplementation with essential fatty acids (EFAs) and megavitamins. A recent double-blind, placebo-controlled, randomized study involved the use of sulforaphane, a phytochemical found in broccoli seed extract, to treat 29 males with ASD, aged 13 to 27 yrs. The results showed its use improved social interaction and verbal communication, and reduced abnormal behavior based on three widely accepted behavioral measures. Dietary sulforaphane was selected because it upregulates genes that protect cells against oxidative stress, inflammation and DNA-damage, all of which are prominent and possibly mechanistic characteristics of ASD (Singh et al, 2014).

There are anecdotal reports of success. The exclusion diets are now used in some treatment centers and are publicized on various websites (<http://www.autismndi.com>). Table 44-5 describes some exclusion diets. It is important for the RDN to understand these various forms of therapy in order to counsel the parent effectively. Because of the increasing prevalence of ASD, research on potential MNT should be promoted. One of the problems with the gluten-, casein-free diet is cost, because special foods needed to provide sufficient food choices are expensive and sometimes difficult to find (see Chapters 26 and 28).

When MNT is used, taking a team approach and working with the occupational therapist, speech therapist, and others is important for success. Parents also should be members of the team and counseled that changes will take time. Unfortunately, there have been no double-blind, randomized, controlled studies.

Follow-up is an important component of all therapy. From a nutritional standpoint, routine measures of height and weight should be scheduled, and there should be regular evaluation of eating and feeding behavior related to increasing the ability to self-feed and accept new and different foods.

Attention-Deficit/Hyperactivity Disorder

Attention-deficit/hyperactivity disorder (ADHD) is a neurobehavioral problem seen in children with increasing frequency. It has been associated with learning disorders, inappropriate degrees of impulsiveness, hyperactivity, and attention deficit. Diagnostic criteria, developed by the American Psychiatric Association, designate three types: (1) combined type of hyperactivity and attention deficit, (2) predominately inattentive type, and (3) predominately hyperactive-impulse type. ADHD affects the child at home, in school, and in social situations. The causes of ADHD are not well understood, but environmental and genetic factors may be indicated. A long-term study of 64,322 children and their mothers found that use of acetaminophen during pregnancy was a contributing factor to ADHD in the children at the age of 7 (Liew Z et al, 2014).

Nutrition Assessment

Many factors should be considered, along with the usual anthropometric measures, particularly when the individual is on medication.

Anthropometric Measures. Measurements of height and weight should be taken and recorded on a regular basis because the medications used in treatment may cause anorexia if given at inappropriate times, resulting in inadequate

TABLE 44-5 Comparison of Foods Allowed in the Gluten-Free and Casein-Free Diet, Specific Carbohydrate Diet, and Body Ecology Diet

Food	Gluten- and Casein-Free	Specific Carbohydrate Diet	Body Ecology Diet
Gluten-containing grains (wheat, rye, barley, spelt, kamut, possibly oats) and any products from those grains	Not allowed	Not allowed	Not recommended
Rice	Unlimited	Not allowed	Not recommended
Corn	Unlimited	Not allowed	Some OK if tolerated
Millet, quinoa, amaranth, buckwheat	Unlimited	Not allowed	Unlimited (80/20 rule)*, presoaked
Eggs and meat (beef, fish, lamb, chicken, turkey)	Unlimited	Allowed, processed not permitted	Recommended, organic free range or wild caught preferred, use 80/20 rule*
Vegetables	Unlimited	Fresh or frozen allowed, no canned, no potatoes and yams	Unlimited, fermented vegetables highly recommended
Fruits	Unlimited	Allowed, cooked in initial phase, no canned	Not recommended except lemon, lime, cranberry or black currants; no tomatoes
Milk products	Not allowed	Not initially; then 24-hr goat yogurt, dry curd cottage cheese, specific cheeses and butter	Raw butter and cream initially, kefir in 1 month
Sweeteners	Unlimited	Honey and saccharin	Stevia only
Vinegar	Unlimited	White or apple cider	Raw apple cider only
Juice	Unlimited	Those with no added sugar	Only those from fruits listed previously
Oils	Unlimited	Unlimited	Olive, coconut, pumpkin seed
Condiments	Unlimited	No added sugars, spices	Wheat-free tamari, herbs and spices, Celtic sea salt
Nuts and seeds	Unlimited	Most nuts, no seeds for 3 months	Unlimited raw and soaked
Seaweed	Unlimited	Not allowed	Highly recommended
Beans	Unlimited	Allowed after 3 months and then soaked 12 hr	Not recommended
Coffee and tea	Unlimited	Allowed weak	Only herb tea or green tea
Coconut products	Unlimited	Fresh only	All recommended
Gelatin	Unlimited	Allowed	Not recommended. Use agar-agar instead

Developed by Houston-Ludlam GA: Reprinted with permission from The ANDI News, Autism Network for Dietary Intervention, 2005.

*80/20 = meal contains: (1) 80% land and ocean vegetables and 20% either protein or a grain and (2) 80% alkaline-forming foods and 20% acid forming foods.

energy intake and potential slowing of growth. However, a 10-year prospective study of more than 250 children with and without ADHD, treated or not treated with medication, found no evidence of limited growth in height over time (Biederman et al, 2010).

Biochemical Measures. These measurements should include a complete blood count and blood and tissue levels of vitamin and minerals if megavitamin therapy is used.

Dietary Intake. A detailed dietary history would include infant feeding history, food likes and dislikes, behavior at mealtimes, snacking behavior, presence of food allergies or food intolerances, or use of special diets. If the individual is on medications, the time of administration in relation to mealtime is important. Information should be obtained regarding any specific diet for the child or individual and how closely it is being followed.

Feeding evaluations should include observing the individual at mealtime. Generally the problems around feeding will be behavioral and will not include oral-motor or positioning peculiarities. Evaluating the environment around mealtime is important because distractions can be problematic.

Medical Nutrition Therapy

Current treatment may include psychotropic medications and the use of consistent behavioral management techniques. The

timing and type of medication must be adjusted so that there is minimum influence on the child's dietary intake.

Specific diets have been used for many years, but they are not based on scientific research. For example, parents have been advised to use the Feingold diet, which states that foods containing synthetic food colors and naturally occurring salicylates be removed from the diet because of their neurologic effect.

Recently there has been renewed interest in the role of artificial food colorings (previously identified by Feingold) as exacerbating hyperactivity in some children. Eight dyes are included: FD&C Blue 1 and 2, FD&C green 3, Orange B, FD&C Red 3, Red 40, FD&C Yellow 5 and 6 (see Table 44-6). The outcome of current interest involves the Food and Drug Administration and committee discussion related to removing food coloring from the food supply (Pelsser et al 2011). A study by Purdue University reported that many children could be consuming far more dyes than previously thought (Stevens et al, 2014). A major source of the artificial food dyes are beverages such as sports drinks, powdered beverages, and fruit drinks, not juice. The recommended amount of artificial food dyes for children has been set at 12 mg per day; however high usage of beverages, colored cereals, and candies can result in 100 mg per day (Stevens et al, 2014). Some manufacturers are now reducing the amount of artificial food colorings in their food products for children.

TABLE 44-6 Food Dyes and Where They are Found

FD&C Blue No. 1 – Brilliant Blue (dye and lake)	Ice cream, canned processed peas, packet soups, bottled food colorings, icings, ice pops, blue raspberry flavored products, dairy products, sweets and drinks
FD&C Blue No. 2 – Indigotine (dye and lake)	Gelatin desserts, ice cream, biscuits, soda pop, candies, cereals, sports drinks, soft drinks, and pet foods
FD&C Green No. 3 – Fast Green (dye and lake)	Jellies, sauces, fish, desserts, and dry bakery mixes
FD&C Red No. 3 – Erythrosine (dye)	Candies and popsicles, and even more widely used in cake-decorating gels. It is also used to color pistachio shells
FD&C Red No. 40 – Allura Red (dye and lake)	Soft drinks, children's medications, and cotton candy. It is by far the most commonly used red dye in the United States
FD&C Yellow No. 5 – Tartrazine (dye and lake)	Desserts and sweets: ice cream, ice pops and popsicles, confectionery and hard candy (such as gummy bears, Peeps marshmallow treats, etc.), cotton candy, instant puddings and gelatin (such as Jell-O), cake mixes, pastries (such as Pillsbury pastries), custard powder, marzipan, biscuits, and cookies Beverages: soft drinks (such as Mountain Dew), energy and sports drinks, powdered drink mixes (such as Kool-aid), fruit cordials, and flavored/mixed alcoholic beverages Snacks: flavored corn chips (such as Doritos, nachos), chewing gum, popcorn (microwave and cinema-popped), and potato chips Condiments and spreads: jam, jelly (including mint jelly), marmalade, mustard, horseradish, pickles (and other products containing pickles such as tartar sauce and dill pickle dip), and processed sauces Other processed foods: cereal (such as corn flakes, muesli), instant or "cube" soups, rice (e.g., paella, risotto), noodles (such as some varieties of Kraft dinner) and pureed fruit Orange sodas, marzipan, Swiss rolls, apricot jam, citrus marmalade, lemon curd, sweets, beverage mix and packet soups, margarine, custard powders, packaged lemon gelatin desserts, energy drinks such as Lucozade, breadcrumbs, snack chips such as Doritos, packaged instant noodles, cheese sauce mixes and powdered marinades, bottled yellow and green food coloring, ice creams, pharmaceutical pills and prescription medicines, over-the-counter medicines (especially children's medicines) cake decorations and icings, squashes, and other products with artificial yellow, orange, or red colors
FD&C Yellow No. 6 – Sunset Yellow (dye and lake)	

Stevens LJ et al: Amounts of artificial food dyes and added sugars in foods and sweets commonly consumed by children, *Clin Pediatr (Phila)*, 2014 (Epub ahead of print).
MCT, Medium-chain triglyceride.

Other recommendations have included the elimination of sugar, the elimination of caffeine, or the addition of large doses of vitamins (megavitamin therapy). A series of well-designed studies to evaluate the effectiveness of these recommendations have generally had negative results, and successful outcomes are largely anecdotal (*American Academy of Pediatrics [AAP], 2013*).

For the child or adult who is up and down throughout the meal, behavior modification may be indicated, and it should be a part of the overall behavioral management program. Distractions should be eliminated.

The most effective treatment for the individual with ADHD is a diet based on wholesome foods as outlined in the Dietary Guidelines or MyPlate and in Chapter 11. The food should be served at regular times, with small servings followed by refills. This is an important concept because of the tendency of the child or individual to eat very small amounts and leave the table, planning to return or graze throughout the day. Some programs recommend removing the food and returning it only once after explaining why this is being done. The intervention requires that the child or individual sit at the table or in the high chair away from television or other distractions. These suggestions are most applicable to children in preschool settings and in the school cafeteria or classroom.

One suggestion is that a lack of EFAs is a possible cause of hyperactivity in children. It is more likely the result of varying biochemical influences. These children have a deficiency of EFAs because they cannot metabolize linoleic acid normally, they cannot absorb EFAs effectively from the intestine, or their EFA requirements are higher than normal. A recent study in Germany of 810 children ages 5 to 12 provided a food supplement containing omega-3 and omega-6 fatty acids plus zinc

and magnesium, and it resulted in considerable reduction in attention deficit and hyperactivity in the children after 12 weeks of supplementation (*Huss et al, 2010*). This type of supplementation can be considered. Other clinical trials using EPA and DHA from fish oil supplements in children with ADD or ADHD have reported benefit, but this is not true for all the studies. The difference in findings may be due to many variables including study design, dose, age of supplementation, the present nutritional status, genetics, and teacher or family dynamics (*Gillies et al, 2012*).

Cleft Lip and Palate

Cleft lip and cleft palate (CL/CP) are the most commonly occurring craniofacial birth defects (*Shkoukani et al, 2013*). **Cleft lip** is a condition that creates an opening of the upper lip. It can range from a slight notch to complete separation in one or both sides of the lips, and extending upward. If it occurs on one side of the lip, it is called a unilateral cleft lip; if it occurs on both sides, it is called a bilateral cleft lip. The cleft palate occurs when the roof of the mouth has not joined completely; it can be either unilateral or bilateral. **Cleft palate** can range from just an opening at the back of the soft palate or separation of the roof of the mouth with both soft and hard palate involved. **CL/CP** result from incomplete merging and fusion of embryonic processes during formation of the face. There is also a condition called submucous cleft palate in which there is incomplete fusion of the muscular layers of the soft palate with fusion of the overlying mucosa (see *Figures 44-8 and 44-9*).

Lip and palate development occur between 5 and 12 weeks of gestation. Lip development begins first, usually at

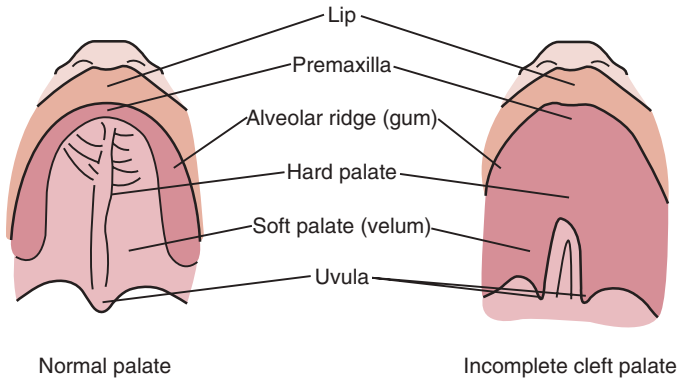

FIGURE 44-8 Cleft palate. (From the Cleft Palate Foundation: www.cleftline.org, 2014. Accessed January 7, 2015.)

FIGURE 44-9 Cleft lip. (From the Cleft Palate Foundation: www.cleftline.org, 2014. Accessed January 7, 2015.)

5 weeks of gestation, followed by the development of the maxilla prominences and the primary palate. Fusion of the hard palate is completed by 10 weeks of gestation and the soft palate by 12 weeks.

The incidence of CL/CP varies, but is generally 1 in 1000 live births. CL/CP have multiple causes and often are associated with underlying syndromes such as Pierre Robin sequence. The Pierre Robin syndrome or complex is a birth condition that involves the lower jaw being either small in size (micrognathia) or set back from the upper jaw (retrognathia) (Cleft Palate Foundation, 2007). As a result, the tongue tends to be displaced back toward the throat, where it can fall back and obstruct the airway. Most infants with Pierre Robin will have a cleft palate, but none will have a cleft lip. The incidence of Pierre Robin ranges from 1 in 2000 to 30,000 births, based on how strictly the diagnosis is made. The basic cause appears to be the failure of the lower jaw to develop normally before birth.

Approximately 50% of children with cleft palate have an underlying syndrome or multiple anomalies. Wide ranges of studies in developmental biology have shown that genetics and environmental factors are involved in causing oral clefts. Some of the risk factors from the environment include maternal folic acid deficiency, smoking, alcohol use, anticonvulsant use, and some maternal illnesses. Genetic counseling can now identify high-risk families.

Nutrition Assessment

Nutrition assessment for CL/CP includes the usual anthropometric measures for all infants and children. Biochemical measures

are also those used with nonaffected children, and dietary intake information depends on the feeding problems that exist. Other problems include dental abnormalities and missing teeth, speech difficulties, and increased incidence of middle ear infections. The feeding evaluation is a major part of the assessment and is best accomplished with a team approach, including the parents. Because the major problem in CL/CP is feeding and providing adequate intake, growth can be jeopardized and must be assessed regularly.

Medical Nutrition Therapy

Surgical repair of the cleft lip generally is performed at 2 to 3 months of age, and cleft palate repair at 9 months. Other operations may involve minor improvements to the lip or nose and usually are completed before the child starts school.

Breastfeeding is difficult for these infants because of problems with sucking, although those infants with just the cleft lip may be successful. It is generally recommended that the mother who wishes to breastfeed express her milk and give it to her baby from a specialized bottle and nipple. Parents and caregivers must be educated in the positioning of the child for feeding, nipple selection, bottle selection, and monitoring of intake (Goyal et al, 2014).

Energy needs are generally the same as for a nonaffected infant or child, but, if the feeding process is too difficult, the energy needs may not be met. Strategies for solving that problem vary, with some professionals advising tube feeding, whereas others recommend continuing with appropriate bottles and nipples but using more concentrated formula or breastmilk (see Chapter 42 and Table 44-7).

Effective feeding requires that the infant be able to form a vacuum inside the mouth and form a seal around the nipple

TABLE 44-7 Increasing Calories Through Concentration of Formulas and Addition of Oils and Carbohydrates

Using 20 cal/oz		
Formula Caloric Density Required Per Ounce	Measures of Powder	Water Added
20 calories	1 scoop	2 fl oz
22 calories	2 scoops	3.5 fl oz
24 calories	3 scoops	5 fl oz
27 calories	3 scoops	4.25 fl oz
Using 22 cal/oz Formula		
22 cal	1 scoop	2 fl oz
24 cal	3 scoops	5.5 fl oz
27 cal	5 scoops	8 fl oz
Adding Oil or Carbohydrates		
Product	kcal	Source
Corn oil or safflower oil	9/g or 8.3/ml	Corn or safflower oil
Microlipid	4.5/ml	Safflower oil
MCT oil	8.3/g or 7.6/ml	Fractionated coconut oil
Karo syrup	1 Tbsp = 58 kcal	Polysaccharides
Polycose liquid	2/ml or 60/fl oz	Glucose polymers
Polycose powder	3.8/g; 8/tsp; 23/Tbsp	Glucose polymers
Moducal powder	30/Tbsp	Glucose polymers

with the lips. This is achieved through the proper bottle, nipple, and position for feeding. Some of the acceptable nipples and bottles include a regular newborn nipple with enlarged holes, a Ross cleft palate assembly, an obturator nipple, and the orthodontic vented nipple. Bottles can vary from a very soft bottle with a cross-cut nipple to a Haberman feeder, squeeze bottle, or an Aseptofeeder.

Individuals with CL/CP are different; thus it is extremely important that the feeding team evaluate various types of equipment and carefully educate the parent in their use. Palate obturators have been used to cover the cleft palate until the child can have surgery to close it; their use results in improved intake, better feeding skills, increased weight gain, and growth of the dental arches. Disadvantages include cost and the inconvenience of refabricating the devices as the infant grows to maintain effectiveness. One review article (Goyal et al, 2014) measured growth and the length of feeding, looking at all the various nipples and bottles and the obturator, and found no significant differences in growth, leading the researchers to conclude that the obturator along with special bottles and nipples were all effective. Positioning in an upright position, choosing the appropriate nipple, and directing the liquid flow to the side or back of the mouth seem to be just as effective in promoting optimal feeding and are recommended. The baby should be given ample opportunities for frequent burping in an upright position.

Introduction of solid foods for the CL/CP infant can follow the usual protocol at 4 to 6 months of age. By this time the cleft lip should have been repaired, and the child has achieved good head control and trunk stability. Care that the food is presented slowly is important, allowing the infant to control each bite while gradually learning how to direct the food around the cleft if it hasn't been repaired yet. After the repair and healing of the cleft palate, feeding along the developmental pathway should progress slowly but normally (see Chapter 16 and Table 44-6).

FETAL ALCOHOL SYNDROME

Fetal alcohol spectrum disorders (FASD) are a group of conditions that can develop in the fetus of a woman who drinks alcohol during pregnancy. The effects of the alcohol consumption include growth retardation and usually characteristic facial stigmata, damaged neurons, and brain structures, which can result in psychologic or behavioral problems and other physical problems. The prevalence rate in the US and Europe is estimated to be between 0.2 and 1.5 in every 1000 live births. Fetal alcohol syndrome (FAS) was named in 1973 by Drs. Kenneth Jones and David Smith at the University of Washington School of Medicine after identifying a pattern of craniofacial, limb, and cardiovascular defects in eight unrelated children of three ethnic groups all born to women who were alcoholics (Jones et al, 1973).

Diagnosis of fetal alcohol syndrome requires that the following criteria are fully met: (1) growth deficiency, (2) FAS facial features, (3) central nervous system damage, and (4) prenatal alcohol exposure. The three facial features include smooth filtrum (the groove between the upper lip and the nose); thin upper lip; and small palpebral (between the upper and lower eyelid) fissures (see Figure 15-4). There are two other terms used to describe FASD: **alcohol-related neurodevelopmental disorders (ARND)** and **alcohol-related birth defects (ARBD)**.

Children with ARND may have intellectual disabilities and problems with behavior and learning, particularly with math, memory, attention, judgment, and poor impulse control. Children with ARBD may have problems with the heart, kidney, bones, or with hearing.

Nutrition Assessment

Anthropometric measures are very important in the assessment of the FASD child because growth deficiency is part of the diagnosis. In severe growth deficiency the height and weight are below the 3rd percentile, whereas in moderate cases of growth deficiency, either the height or weight is below the 3rd percentile, but not both. Growth should be evaluated frequently and plotted on the CDC and WHO growth curves. Studies have shown that the prenatal growth retardation of the infant may persist postnatally, and some infants have failure to thrive (Huber and Ekvall, 2005). Feeding problems have also been associated with FAS, including having a weak suck and oral motor problems, making these babies difficult to feed. This would contribute to failure to thrive.

Medical Nutrition Therapy

Nutritional intervention for the child with FASD is focused on the specific nutrition problem that exists for that child. Working with growth deficiency, failure to thrive, and feeding problems requires the usual evaluation and intervention used in other infants and children with developmental disabilities. Energy and nutrient needs are the same as for nonaffected children, although strategies for increasing calories would be required for those who have failure to thrive. For some children ADHD has been reported, and the treatment should be the same as already described.

CONTROVERSIAL NUTRITION THERAPY

An important factor in providing MNT for children and adults with developmental disabilities is realizing that counseling may have been inadequate in helping the parent accept the limitations of the disorder - limitations such as growth, feeding problems, and cognitive ability. As a result, many parents look for unusual medical or nutrition therapies. Major sources of information are often the Internet and parent support groups. Recent media coverage has promoted the use of antioxidant vitamins (A, C, and E) and minerals (zinc, copper, manganese, and selenium) along with the amino acids glutamine, tyrosine, and tryptophan. The expected outcomes are improved growth; increased cognition, alertness, and attention span; and changed facial features.

Little scientific information validates these therapies. Research studies have addressed the vitamin needs of children with DS, spina bifida, fragile X syndrome, and autism, and findings do not indicate that the vitamin and mineral needs of these children with developmental disabilities are higher than normal. Numerous historical studies have searched for nutritional deficiencies as causative factors in DS (Tenenbaum et al, 2011). Traditionally, the studies have included numerous vitamins, minerals, fatty acids, digestive enzymes, lipotropic nutrients, and numerous drugs, with no definitive results (Solar Marin and Xandri Graupera, 2011).

The key concept in the proposed nutrition interventions for DS is metabolic correction of genetic overexpression. It

is postulated that presence of the third chromosome 21 causes overproduction of superoxide dismutase and cystathionine- β [SPC1]-synthase, which disrupts active methylation pathways. Vitamin supplements of folic acid and antioxidants counteract this and are considered key to the treatment. However, these are just theories, and at this point nutrition supplements are considered an expensive, questionable approach.

Parents of children with ADHD report that omitting sugar from the children's diets decreases hyperactivity, but no scientific evidence supports this. However, it is a good idea to eliminate or at least reduce the sugar intake in any child's diet to promote better nutritional intake. Blue-green algae has been promoted for children with DS and other developmental disabilities, purportedly to increase attention span and concentration. High-dose supplementation of vitamin B₆ and magnesium has been proposed for autism to diminish tantrums and self-stimulation activities and improve attention and speech. Another proposed treatment is dimethyl glycine. Limited research is available.

COMMUNITY RESOURCES

For many types of nutrition problems and MNT, the school system is an excellent resource through the school lunch and school breakfast programs. Children and adolescents may receive modified meals at school. Child and adult care food programs must provide meals at no extra cost for children and adolescents with special needs and developmental disabilities. School food service is required to offer special meals at no additional cost to children whose disabilities restrict their diets

as defined in the U.S. Department of Agriculture's nondiscrimination regulations.

The term "child with a disability" under Part B of the Individuals with Disabilities Education Act (IDEA) refers to a child evaluated in accordance with IDEA as having one of the 13 recognized disability categories: (1) autism; (2) deaf-blindness; (3) deafness; (4) mental retardation; (5) orthopedic impairments; (6) other health impairments caused by chronic or acute health problems such as asthma, nephritis, diabetes, sickle cell anemia, a heart condition, epilepsy, rheumatic fever, hemophilia, leukemia, lead poisoning, or tuberculosis; (7) emotional disturbances; (8) specific learning disabilities; (9) speech or language impairment; (10) traumatic brain injury; (11) visual impairment; (12) multiple disabilities; and (13) developmental delays. Attention deficit disorder may fall under 1 of the 13 categories.

When a referral is made to the school system for a special meal related to a developmental disability, it must be accompanied by a medical statement for a child with special dietary needs. The request requires an identification of the medical or other special dietary condition, the food or foods to be omitted, and the food or choice of foods to be substituted. The statement requires the signature of the physician or recognized medical authority. The school food service may make food substitutions for individual children who do not have a disability but who are medically certified as having a special medical or dietary need. An example is the child with severe allergies or an inborn error of metabolism. The availability of school food service for children with developmental disabilities is an important resource in the long-term implementation of MNT.

CLINICAL CASE STUDY - CHILD WITH DOWN SYNDROME

Nutrition Assessment

Client History

Colin is a 21-month-old boy with Down's syndrome. He was born prematurely (30 weeks of gestation) and was started on gastrostomy tube feeding at 10 days of age because of his poor weight gain and severe gastroesophageal reflux. The poor weight gain was caused by a poor suck, although swallowing was not a problem. He was first seen by a nutritionist in an early intervention program at 4 months of age when he was 22.5 in long and weighed 10 lb 7 oz.

Food/Nutrition-Related History

At 16 months Colin was tube fed Pediasure and started eating table foods. His usual intake is 1 jar of baby food a day along with the tube-feeding formula.

Anthropometric Measurements

At 4 months of age he was 22.5 in long and weighed 10 lb. 7 oz.
At 21 months, height was 28", weight was 18.5 lb and he was in the 5% for length and weight.

Physical Findings

He is crawling but not yet walking, and he has very limited self-feeding skills. Now at age 21 months his mother's highest priority is to stop the tube feeding and have Colin continue to grow well. She is concerned about his rate of weight gain. She also is concerned that constipation has become a problem requiring use of the medication lactulose. He also has respiratory problems and extreme hypotonia.

Feeding problems identified:

Weak suck, and swallow

Hyperactive gag reflex

Refusal to drink formula from a bottle or cup due to g-tube

Poor appetite

Not self-feeding

Nutrition Diagnostic Statements

Tube-fed toddler with caloric intake estimated at 100 kcal per kg. NI-1.4
Self-feeding difficulty related to developmental delays as evidenced by inability to feed himself most foods offered. NB-2.6
Inadequate intake of baby food and table food. NI-2.1
Refusal to drink his formula or other beverages from a cup. NC-1.1

Nutrition Intervention

1. Introduction of drinking from a cup with a straw using formula and water.
2. Introduction of soft table foods before gastrostomy feedings.
3. Reduction of size of servings of food offered.
4. Work with occupational therapy in promoting eating of finger foods.

Nutrition Care Questions

1. What would be your approach in working with this mother and the other team members?
2. What do you think would be his nutritional needs, starting with energy?
3. How many ounces of a 30 cal/oz tube-feeding formula would you recommend for Colin to promote weight gain?
4. What steps should be taken to increase his oral intake and decrease the tube feeding?
5. What would you recommend for management of his constipation?

CLINICAL CASE STUDY - ADOLESCENT WITH DOWN SYNDROME AND OBESITY

Nutrition Assessment**History**

Alicia, a 14-year-old girl with Down's syndrome, is admitted to a mental health services facility for treatment of sleep apnea, prediabetes, and severe behavioral activities. The contributing factor to the medical problems is her severe obesity. Before her admission to the facility she had been in public school in a special education program, but her behavior was so difficult to control that the school transferred her to this mental health facility. She is the only individual in her family with Down's syndrome, and was born when her mother was 40. There is a history of diabetes in the family and food has always been used as a reward for Alicia.

Food/Nutrition-Related History

Alicia's birthweight was 7 lb 8 oz, her birth length was 19," and she was full term. She was breast fed until age 3 months when she was transferred to Similac formula and reportedly had no feeding problems other than consuming more than 36 oz of milk daily, and eating baby food in unusually large amounts. Her weaning to a cup was late, at 18 months, and her motor-skill development was late; she did not walk until 28 months of age. She also had low muscle tone.

By the time she was 12 months of age her weight was 28 lb, placing her above the 95th percentile. Each subsequent year she remained between the 75th and 95th percentile for her weight but at the 10th percentile for her height.

During her preschool and school years Alicia's intake was reported as very limited in variety with a heavy concentration of foods from fast food restaurants, and little intake of fruits and vegetables. She drank milk, but preferred soft drinks and sweetened tea. She also consumed many sweetened desserts, cookies, and bakery products. Although her mother reported trying to control Alicia's overeating behavior, a grandparent was very indulgent. Alicia also developed behavioral problems with a great deal of acting out at home and at school. It was this behavior that led to her referral to the mental health facility.

Anthropometric measurements:

Weight 247 # > 97th%

Height: 56" - 50% to 75%

H/W relationship: > 97th%

BM index: > 97%

Estimated energy needs: 1716 kcal

Estimated energy intake at home: 3000 kcal (based on maternal report)

Estimated protein need: 52 g

Biochemical Data

Hgb: 14 gm/dL —(12-14.9)

Hct: 36% (39.) low

Cholesterol: 210 mg/dL (high) <170 acceptable

Glucose: 120 mg/dL (high) 70-100 acceptable

Medications: Topomax and Clonidine, for seizures and behavioral problems.

Diet order after physical examination: 1500 calories per day and exercise.

Nutrition-Focused Physical Findings

Excessive appetite

Dry skin

Inactivity with behavioral outbursts related to walking

Feeding problems—very rapid eating with possibility of choking

Low muscle tone

Constipation

Nutrition Diagnostic Statements

Obesity: NC 3.3

Excessive intake of carbohydrates: N1-53.2

Excessive oral food/beverage intake: NI-2.2

Intervention Goals

1. Weight loss and acceptance of difference in food provided.
2. Increase consumption of high fiber foods.
3. Limit between meal to fruit and vegetables. ND-1
4. Counsel parents related to meal management and poor behavior related to food. FH 3.1
5. Increase physical activity at school and home. FH 6.3

Nutrition Intervention

1. Modify the menus to provide 1500 calories including snacks. ND-1
2. Provide copies of menu to group home staff and parents. ND 1.2
3. Increase availability of fresh fruit and raw vegetables for snacks. ND 1.2
4. Increase water intake. ND 1.3

Monitoring and Evaluation

1. Weigh monthly and plot on growth grid with report to parents.
2. Counsel parents monthly or as necessary related to food intake and exercise at home.
3. Record amount of walking at school with teachers and other students.

Nutrition Care Questions

1. Teachers report that student eats only part of the meal provided and refuses the snacks offered. What would be your response?
2. The parents report in their monthly conference that Alicia is very rebellious and refuses to participate in the family activities unless provided with a trip to a fast food restaurant for hamburgers and French fries. What could you suggest?
3. Monthly weights show a loss of 2 to 3 pounds each month. Should there be a reward system? Could you use motivational interviewing with the family? How would you modify this approach with Alicia?

Unit Abbreviations

Along with the specialized vocabulary that is used in the medical, dietetic, and nursing fields, there are acceptable forms of abbreviations.

The following is a list of abbreviations commonly used.

aa:	Gr. <i>ana</i> ; of each	mEq:	milliequivalent
ac:	L. <i>ante cibum</i> ; before meals	mg:	milligram
ad, add:	L. <i>adde, addatus, or addantur</i> ; add or added	mil or mL:	milliliter
ad lib:	L. <i>ad libitum</i> ; at pleasure, as desired	mM:	millimole
aq:	L. <i>aqua</i> ; water	μmol:	micromol
aq dest:	L. <i>aqua destillata</i> ; distilled water	mOsm:	milliosmole
bid, bis in d:	L. <i>bis in die</i> ; twice a day	oz:	ounce
̄:	L. <i>cum</i> ; with	prn:	L. <i>pro re nata</i> ; as needed
c:	cup	pt:	pint
Cent; cent; C:	centigrade, Celsius	pulv:	L. <i>pulvis</i> ; powder
cm:	centimeter	qd:	L. <i>quaque die</i> ; every day
dilut:	L. <i>dilutus</i> ; dilute	QID, qid:	L. <i>quater in die</i> ; four times daily
div:	L. <i>divide</i> ; divide	q3h:	every 3 hours
fac:	make	qs:	L. <i>quantum satis</i> ; a sufficient quantity
g:	gram	qt:	quart
gr:	L. <i>granum</i> ; grain	RE:	retinal equivalent
gtt:	L. <i>guttae</i> ; drops	̄:	L. <i>sine</i> ; without
hs:	L. <i>hora somni</i> ; at hour of sleep	sol:	solution
IU:	international unit	ss:	L. <i>semis</i> ; half
kcal:	kilocalorie	stat:	L. <i>statim</i> ; immediately
kg:	kilogram	t, tsp:	teaspoon
kJ:	kilojoule	Ț, Tbsp:	tablespoon
lb:	pound	tid:	L. <i>ter in die</i> ; three times a day
mcg:	microgram

Milliequivalents and Milligrams of Electrolytes

To Convert Milligrams to Milliequivalents: Divide milligrams by atomic weight and then multiply by the valence.

$$\text{Example : } \frac{\text{Milligrams}}{\text{Atomic weight}} \times \text{Valence} = \text{Milliequivalents}$$

Mineral Element	Chemical Symbol	Atomic Weight (mg)	Valence
Calcium	Ca	40	2
Chlorine	Cl	35	1
Magnesium	Mg	24	2
Phosphorus	P	31	2
Potassium	K	39	1
Sodium	Na	23	1
Sulfate	SO ₄	96	2
Sulfur	S	32	

To Convert Specific Weight of Sodium to Sodium Chloride: Multiply by 2.54.

$$\text{Example } 1000 \text{ mg Sodium } \times 2.54 = 2540 \text{ mg Sodium chloride (2.5g)}$$

To Convert Specific Weight of Sodium Chloride to Sodium: Multiply by 0.393.

$$\text{Example } 2.5 \text{ g Sodium chloride } \times 0.393 = 1000 \text{ mg sodium}$$

Milligrams	Sodium in Milliequivalents (mEq)	Grams of Sodium Chloride
500	21.8	1.3
1000	43.5	2.5
1500	75.3	3.8
2000	87.0	5.0

Modified from Merck Manual, Ready Reference Guide. Accessed 22 March 2011 from <http://www.merckmanuals.com/professional/print/appendixes/ap1/ap1a.html>; Nelson JK et al: Mayo Clinic diet manual, ed 7, St Louis, 1994, Mosby.

Equivalents, Conversions,* and Portion (Scoop) Sizes

LIQUID MEASURE—VOLUME EQUIVALENTS

- 1 tsp = $\frac{1}{3}$ Tbsp = 5 mL or cc
- 1 Tbsp = 3 tsp = 15 mL or cc
- 2 Tbsp = 1 fluid oz = $\frac{1}{8}$ cup = 30 mL or cc
- 2 Tbsp + 2 tsp = $\frac{1}{6}$ cup = 40 mL or cc
- 4 Tbsp = $\frac{1}{4}$ cup = 2 fluid oz = 60 mL or cc
- 5 Tbsp + 1 tsp = $\frac{1}{3}$ cup = 80 mL or cc
- 6 Tbsp = 3 fluid oz = $\frac{3}{8}$ cup = 90 mL or cc
- 8 Tbsp = $\frac{1}{2}$ cup = 120 mL or cc
- 10 Tbsp + 2 tsp = $\frac{2}{3}$ cup = 160 mL or cc
- 12 Tbsp = $\frac{3}{4}$ cup = 180 mL or cc
- 48 tsp = 16 Tbsp = 1 cup (8 fluid ounces) = $\frac{1}{2}$ pint = 240 mL or cc
- 2 cups = 1 pint (16 fluid oz) = 0.4732 L
- 4 cups = 2 pints = 1 quart (32 fluid oz) = 0.9462 L
- 1.06 quarts = 34 fluid oz = 1000 mL or cc
- 4 quarts = 1 gallon = 3785 mL or cc

DRY MEASURE

- 1 quart = 2 pints = 1.101 L
- Dry measure and quarts are approximately $\frac{1}{6}$ larger than liquid measure pints and quarts.

WEIGHTS	
English (Avoirdupois)	Metric
1 oz	Approx 30 g
1 lb (16 oz)	454 g
2.2 lb	1 kg

SCOOP SIZES

It is important to use the proper scoop size when portioning out foods to serve to patients.

Number	Approximate Liquid Volume
6	$\frac{2}{3}$ cup (5 fluid oz)
8	$\frac{1}{2}$ cup (4 fluid oz)
10	$\frac{3}{8}$ cup (3 $\frac{1}{4}$ fluid oz)
12	$\frac{1}{3}$ cup (2 $\frac{2}{3}$ fluid oz)
16	$\frac{1}{4}$ cup (2 fluid oz)
20	3 $\frac{1}{6}$ Tbsp (1 $\frac{3}{8}$ fluid oz)
24	2 $\frac{2}{3}$ Tbsp (1 $\frac{1}{3}$ fluid oz)
30	2 $\frac{1}{2}$ Tbsp (1 fluid oz)
40	1 $\frac{1}{2}$ Tbsp (0.8 fluid oz)
60	1 Tbsp (0.5 fluid oz)

Metric Conversion Factors		
Multiply	By	To Get
Fluid ounces	29.57	Grams
Ounces (dry)	28.35	Grams
Grams	0.0353	Ounces
Grams	0.0022	Pounds
Kilograms	2.21	Pounds
Pounds	453.6	Grams
Pounds	0.4536	Kilograms
Quarts	0.946	Liters
Quarts (dry)	67.2	Cubic inches
Quarts (liquid)	57.7	Cubic inches
Liters	1.0567	Quarts
Gallons	3.785	Cubic centimeters
Gallons	3.785	Liters

From North Carolina Dietetic Association: *Nutrition care manual*, 2011, Raleigh, NC, The Association.

*Note: In the U.S. measuring systems the same word may have two meanings. For example, an ounce may mean 1/16 of a pound and 1/16 of a pint; but the former is strictly a weight measure, and the latter is a volume measure. Except in the case of water, milk, or other liquids of the same density, a fluid ounce and an ounce of weight are two completely different quantities. These measures are not to be used interchangeably.

Tanner Stages of Adolescent Development for Girls

Chronologic age is not always the best way to assess adolescent growth because of individual variations in beginning and completing the growth sequence. A more useful way of describing pubertal development, and thus the varying needs for nutrients throughout adolescence, is to divide growth into

stages of breast and pubic hair development in girls. These are termed the *Tanner Stages of Adolescent Development*. Nutritional requirements vary, depending on the stage of development.

From Mahan LK, Rees JM: Nutrition in adolescence, St Louis, 1984, Mosby.

Tanner Stages of Adolescent Development for Boys

Chronologic age is not always the best way to assess adolescent growth because of individual variations in beginning and completing the growth sequence. A more useful way of describing pubertal development, and thus the varying needs for nutrients throughout adolescence, is to divide growth into

stages pubic hair and penis and testicle development in boys. These are termed the *Tanner Stages of Adolescent Development*. Nutritional requirements vary, depending on the stage of development.

From Mahan LK, Rees JM: *Nutrition in adolescence*, St. Louis, 1984, Mosby.

Direct Methods for Measuring Height and Weight

HEIGHT

1. Height should be measured without shoes.
2. The individual's feet should be together, with the heels against the wall or measuring board.
3. The individual should stand erect, neither slumped nor stretching, looking straight ahead, without tipping the head up or down. The top of the ear and outer corner of the eye should be in a line parallel to the floor (the "Frankfort plane").
4. A horizontal bar, a rectangular block of wood, or the top of the stadiometer should be lowered to rest flat on the top of the head.
5. Height should be read to the nearest $\frac{1}{4}$ inch or 0.5 cm.

WEIGHT

1. Scale accuracy must be determined. Frequent calibration is required.
2. Use a beam balance scale, not a spring scale, whenever possible.
3. Weigh the subject in light clothing without shoes.
4. Record weight to the nearest $\frac{1}{2}$ lb or 0.2 kg for adults and $\frac{1}{4}$ lb or 0.1 kg for infants. Measurements above the 90th percentile or below the 10th percentile warrant further evaluation.

*When weighing patients on bed scales, see manufacturer guidelines for directions.

Indirect Methods for Measuring Height

MEASURING ARM SPAN

Steps:

1. The arms are extended straight out to the sides at a 90-degree angle from the body.
2. The distance from the longest fingertip of one hand to the longest finger of the other hand is measured.

ADULT RECUMBENT

Steps:

1. Stand on right side of the body.
2. Align body so that the lower extremities, trunk, shoulders, and head are straight.
3. Place a mark at the top of the sheet in line with the crown of the head and one at the bottom of the sheet in line with the base of the heels.
4. Measure length between marks with measuring tape.

KNEE HEIGHT

Knee height measurement is highly correlated with upright height. It is useful in those who cannot stand and in those who may have curvatures of the spine.

Steps:

1. Use the left leg for measurements.
2. Bend the left knee and the left ankle to 90-degree angles. A triangle may be used if available.
3. Using knee height calipers, open the caliper and place the fixed part under the heel. Place the sliding blade down against the thigh (approximately 2 inches behind the patella).
4. Measure from the heel to the anterior surface of the thigh, using a cloth measuring tape.

5. Obtain the measurement and convert it to centimeters by multiplying by 2.54.
6. Formulas to use to calculate estimated height from knee height:

$$\text{Men (height in centimeters)} = 64.19 (0.04 \text{ Age}) + (2.02 \times \text{Knee height in centimeters})$$

$$\text{Women (height in centimeters)} = 84.8 (0.24 \text{ Age}) + (1.83 \times \text{Knee height in centimeters})$$

Using Population-Specific Formula, Calculate Height from Standard Formula:

Population and Gender Group	Equation: Stature (cm) =
Non-Hispanic white men (U.S.) ¹¹ [SEE = 3.74 cm]	$78.31 + (1.94 \times \text{knee height}) - (0.14 \times \text{age})$
Non-Hispanic black men (U.S.) ¹¹ [SEE = 3.80 cm]	$79.69 + (1.85 \times \text{knee height}) - (0.14 \times \text{age})$
Mexican-American men (U.S.) ¹¹ [SEE = 3.68 cm]	$82.77 + (1.83 \times \text{knee height}) - (0.16 \times \text{age})$
Non-Hispanic white women (U.S.) ¹¹ [SEE = 3.98 cm]	$82.21 + (1.85 \times \text{knee height}) - (0.21 \times \text{age})$
Non-Hispanic black women (U.S.) ¹¹ [SEE = 3.82 cm]	$89.58 + (1.61 \times \text{knee height}) - (0.17 \times \text{age})$
Mexican-American women (U.S.) ¹¹ [SEE = 3.77 cm]	$84.25 + (1.82 \times \text{knee height}) - (0.26 \times \text{age})$
Taiwanese men ¹² [SEE = 3.86 cm]	$85.10 + (1.73 \times \text{knee height}) - (0.11 \times \text{age})$
Taiwanese women ¹² [SEE = 3.79 cm]	$91.45 + (1.53 \times \text{knee height}) - (0.16 \times \text{age})$
Elderly Italian men ¹³ [SEE = 4.3 cm]	$94.87 + (1.58 \times \text{knee height}) - (0.23 \times \text{age}) + 4.8$
Elderly Italian women ¹³ [SEE = 4.3 cm]	$94.87 + (1.58 \times \text{knee height}) - (0.23 \times \text{age})$
French men ¹⁴ [SEE = 3.8 cm]	$74.7 + (2.07 \times \text{knee height}) - (-0.21 \times \text{age})$
French women ¹⁴ [SEE = 3.5 cm]	$67.00 + (2.2 \times \text{knee height}) - (0.25 \times \text{age})$
Mexican Men ¹⁵ [SEE = 3.31 cm]	$52.6 + (2.17 \times \text{knee height})$
Mexican Women ¹⁵ [SEE = 2.99 cm]	$73.70 + (1.99 \times \text{knee height}) - (0.23 \times \text{age})$
Filipino Men ¹⁶	$96.50 + (1.38 \times \text{knee height}) - (0.08 \times \text{age})$
Filipino Women ¹⁶	$89.63 + (1.53 \times \text{knee height}) - (0.17 \times \text{age})$
Malaysian men ¹⁷ [SEE = 3.51 cm]	$(1.924 \times \text{knee height}) + 69.38$
Malaysian women ¹⁷ [SEE = 3.40]	$(2.225 \times \text{knee height}) + 50.25$

SEE = Standard Error of Estimate¹¹

Determination of Frame Size

Method 1: Height is recorded without shoes. Wrist circumference is measured just distal to the styloid process at the wrist crease on the right arm, using a tape measure. The following formula is used (From Grant JP: Handbook of total parenteral nutrition, Philadelphia, 1980, Saunders):

$$r = \frac{\text{Height (cm)}}{\text{Wrist circumference (cm)}}$$

Frame size can be determined as follows:

Males	Females
r >10.4 small	r >11.0 small
r = 9.6-10.4 medium	r = 10.1-11.0 medium
r < 9.6 large	r <10.1 large

Method 2: The patient's right arm is extended forward perpendicular to the body, with the arm bent so the angle at the elbow forms 90 degrees with the fingers pointing up and the

palm turned away from the body. The greatest breadth across the elbow joint is measured with a sliding caliper along the axis of the upper arm on the two prominent bones on either side of the elbow. This is recorded as the elbow breadth. The following tables give the elbow breadth measurements for medium-framed men and women of various heights (from Metropolitan Life Insurance Co., 1983). Measurements lower than those listed indicate a small frame size; higher measurements indicate a large frame size.

MEN		WOMEN	
Height in 1" Heels	Elbow Breadth (inches)	Height in 1" Heels	Elbow Breadth (inches)
5'2"-5'3"	2½-2⅞	4'10"-4'11"	2¼-2½
5'4"-5'7"	2⅝-2⅞	5'0"-5'3"	2¼-2½
5'8"-5'11"	2¾-3	5'4"-5'7"	2⅜-2⅝
6'0"-6'3"	2¾-3⅛	5'8"-5'11"	2⅜-2⅝
6'4"	2⅞-3¼	6'0"

Adjustment of Desirable Body Weight for Amputees

The percentages listed here are estimates because body proportions vary in individuals. Use of these percentages provides an approximation of desirable body weight, which is more accurate than a comparison with the standards for adults without amputations. Ideal body weight (IBW) must be adjusted downward to compensate for missing limbs or paralysis. It is estimated that 5% to 10% should be subtracted from IBW for a paraplegic and from 10% to 15% subtracted for a tetraplegic (quadriplegic.)

Adjustment of Ideal Body Weight for Amputees

Body Segment	Average % of Total Weight
Lower arm and hand	2.3
Trunk without extremities	50.0
Entire arm	5.0
Hand	0.7
Entire lower leg	16.0
Below knee including foot	5.9
Lower leg without foot	4.4
Foot	1.5

Lefton J., Malone A. Anthropometric Assessment. In Charney P, Malone A, eds. ADA Pocket Guide to Nutrition Assessment, 2nd edition. Chicago, IL: American Dietetic Association; 2009:160.

$$\text{Estimated IBW} = \frac{100 - \% \text{ amputation}}{100} \times \text{IBW for original height}$$

To use this information, determine the patient's approximate height before the amputation. Span measurement is a rough

estimate of height at maturity and is calculated as follows: with the upper extremities, including the hands, fully extended and parallel to the ground, measure the distance between the tip of one middle finger and the tip of the other middle finger. Use this height or actual measurement to calculate the desirable body weight for the normal body size; then adjust the figures according to the type of amputation performed.

Example: To determine the desirable body weight for a 5'10" male with a below-the-knee amputation:

1. Calculate desirable body weight for a 5'10" male:	166 lb
2. Subtract weight of amputated limb (6%) = 166 × 0.06:	$\frac{-9.96}{156 \text{ lb}}$ (approx. 10 lb)
3. Desirable weight of a 5'10" male with a below-knee amputation:	

From North Carolina Dietetic Association: Nutrition care manual, 2011, Raleigh, NC, The Association.

Nutrition-Focused Physical Assessment

PART 1: Parameters Useful in the Assessment of General Nutritional Status and the Presence of Malnutrition

Exam Areas	Tips	Severe Malnutrition	Mild-Moderate Malnutrition	Well Nourished
Subcutaneous Fat Loss				
Orbital Region – Surrounding the Eye	View patient when standing directly in front of them, touch above cheekbone	Hollow look, depressions, dark circles, loose skin	Slightly dark circles, somewhat hollow look	Slightly bulged fat pads. Fluid retention may mask loss
Upper Arm Region – Triceps/ biceps	Arm bent, roll skin between fingers, do not include muscle in pinch	Very little space between folds, fingers touch	Some depth pinch, but not ample	Ample fat tissue obvious between folds of skin
Thoracic and Lumbar Region – Ribs, Lower Back, Midaxillary line	Have patient press hands hard against a solid object	Depression between the ribs very apparent. Iliac Crest very prominent	Ribs apparent, depressions between them less pronounced. Iliac Crest somewhat prominent	Chest is full, ribs do not show. Slight to no protrusion of the iliac crest.
Muscle Loss				
Temple Region – Temporalis Muscle	View patient when standing directly in front of them, ask patient to turn head side to side	Hollowing, scooping, depression	Slight depression	Can see/feel well-defined muscle
Clavicle Bone Region – Pectoralis Major, Deltoid, Trapezius Muscles	Look for prominent bone. Make sure patient is not hunched forward	Protruding, prominent bone	Visible in male, some protrusion in female	Not visible in male, visible but not prominent in female
Clavicle and Acromion Bone Region – Deltoid Muscle	Patient arms at side; observe shape	Shoulder to arm joint looks square. Bones prominent. Acromion protrusion very prominent	Acromion process may slightly protrude	Rounded, curves at arm/ shoulder/neck
Scapular Bone Region – Trapezius, Supraspinus, Infraspinus Muscles	Ask patient to extend hands straight out, push against solid object	Prominent, visible bones, depressions between ribs/scapula or shoulder/ spine	Mild depression or bone may show slightly	Bones not prominent, no significant depressions
Dorsal Hand – Interosseous Muscle	Look at thumb side of hand; look at pads of thumb when tip of forefinger touching tip of thumb	Depressed area between thumb- forefinger	Slightly depressed	Muscle bulges, could be flat in some well nourished people
Lower Body Less Sensitive to Change				
Patellar Region – Quadricep Muscle	Ask patient to sit with leg propped up, bent at knee	Bones prominent, little sign of muscle around knee	Kneecap less prominent, more rounded	Muscles protrude, bones not prominent
Anterior Thigh Region – Quadriceps Muscles	Ask patient to sit, prop leg up on low furniture. Grasp quads to differentiate amount of muscle tissue from fat tissue	Depression/line on thigh, obviously thin	Mild depression on inner thigh	Well rounded, well developed
Posterior Calf Region- Gastrocnemius Muscle	Grasp the calf muscle to determine amount of tissue	Thin, minimal to no muscle definition	Not well developed	Well-developed bulb of muscle

Continued

Part 2: Clinical Characteristics That the Clinician Can Obtain and Document to Support a Diagnosis of Malnutrition (Academy/A.S.P.E.N.)—cont’d

Clinical Characteristic	MALNUTRITION IN THE CONTEXT OF SOCIAL OR ENVIRONMENTAL CIRCUMSTANCES		MALNUTRITION IN THE CONTEXT OF CHRONIC ILLNESS		MALNUTRITION IN THE CONTEXT OF ACUTE ILLNESS OR INJURY	
	Nonsevere (Moderate) Malnutrition	Severe Malnutrition	Nonsevere (Moderate) Malnutrition	Severe Malnutrition	Nonsevere (Moderate) Malnutrition	Severe Malnutrition
(3) Body fat Loss of subcutaneous fat (eg, orbital, triceps, fat overlying the ribs)	Mild	Moderate	Mild	Severe	Mild	Severe
(4) Muscle mass Muscle loss (eg, wasting of the temples [temporalis muscle], clavicles [pectoralis and deltoids], shoulders [deltoids], interosseous muscles, scapula [latissimus dorsi, trapezius, deltoids], thigh [quadriceps], and calf [gastrocnemius])	Mild	Moderate	Mild	Severe	Mild	Severe
(5) Fluid accumulation The clinician may evaluate generalized or localized fluid accumulation evident on exam (extremities, vulvar/scrotal edema, or ascites). Weight loss is often masked by generalized fluid retention (edema), and weight gain may be observed.	Mild	Moderate to severe	Mild	Severe	Mild	Severe
(6) Reduced grip strength ⁷ Consult normative standards supplied by the manufacturer of the measurement device	NA	Measurably reduced	NA	Measurably reduced	NA	Measurably reduced

A minimum of 2 of the 6 characteristics above is recommended for diagnosis of either severe or nonsevere malnutrition. NA, not applicable.

Notes:

Height and weight should be measured rather than estimated to determine body mass index (BMI).

Usual weight should be obtained to determine the percentage and to interpret the significance of weight loss.

Basic indicators of nutrition status such as body weight, weight change, and appetite may substantively improve with refeeding in the absence of inflammation. Refeeding and/or nutrition support may stabilize but not significantly improve nutrition parameters in the presence of inflammation.

The National Center for Health Statistics defines *chronic* as a disease/condition lasting 3 months or longer.⁸

Serum proteins such as serum albumin and prealbumin are not included as defining characteristics of malnutrition because recent evidence analysis shows that serum levels of these proteins do not change in response to changes in nutrient intake.⁹⁻¹²

This table was developed by Annalynn Skipper PhD, RD, FADA. The content was developed by an Academy workgroup composed of Jane White, PhD, RD, FADA, LDN, Chair; Maree Ferguson, MBA, PhD, RD; Sherri Jones, MS, MBA, RD, LDN; Ainsley Malone, MS, RD, LD, CNSD; Louise Merriman, MS, RD, CDN; Terese Scollard, MBA, RD; Annalynn Skipper, PhD, RD, FADA; and Academy staff member Pam Michael, MBA, RD. Content was approved by an A.S.P.E.N. committee consisting of Gordon L. Jensen, MD, PhD, Co-Chair; Ainsley Malone, MS, RD, CNSD, Co-Chair; Rose Ann Dimaria, PhD, RN, CNSN; Christine M. Framson, RD, PHD, CSND; Nilesh Mehta, MD, DCH; Steve Plogsted, PharmD, RPh, BCNSP; Annalynn Skipper, PhD, RD, FADA; Jennifer Wooley, MS, RD, CNSD; Jay Mirtallo, RPh, BCNSP, Board Liaison; and A.S.P.E.N. staff member Peggi Guenter, PhD, RN. Subsequently, it was approved by the A.S.P.E.N. Board of Directors. The information in the table is current as of February 1, 2012. Changes are anticipated as new research becomes available. System	Normal Findings	Abnormal Findings	Possible Nutrition and Metabolic Etiologies	Nonnutritional Etiologies
Body Habitus – See Part 1. General survey	Weight for height appropriate, well-nourished, alert, and cooperative with good stamina	Loss of weight, muscle mass and fat stores, skeletal muscle wasting (hands, face, quadriceps, and deltoids), subcutaneous fat loss (face, triceps, thighs, waist) or overall weight loss, sarcopenia (loss of lean body mass in older adults). See Part 1 Growth retardation in children Inappropriate rates of height and weight gain in children and adolescents	Sub-optimal energy and protein intakes Non-severe malnutrition Severe malnutrition	Endocrine disorders, osteogenic disorders, menopausal disorders secondary to estrogen depletion Sarcopenia related to decreased physical activity, increased cytokine (interleukin-6) and decreased levels of growth hormone and insulin-like growth factor
Skin	Healthy color, soft, moist turgor with instant recoil, smooth appearance	Excess fat stores Poor or delayed wound healing, pressure ulcers Dry with fine lines and shedding, scaly (xerosis) Spinelike plaques around hair follicles on buttocks, thighs, or knees (follicular hyperkeratosis) Pellagrous dermatitis (hyperpigmentation of skin exposed to sunlight) Pallor Generalized dermatitis Yellow pigmentation Poor skin turgor Petechiae, ecchymoses	Excess energy intake Protein deficiency Vitamin C deficiency Zinc deficiency Essential fat deficiency Vitamin A deficiency Vitamin A deficiency Essential fat deficiency Niacin deficiency Tryptophan deficiency Iron deficiency Folic acid deficiency Vitamin B ₁₂ deficiency Zinc deficiency Essential fatty acid deficiency Carotene excess Vitamin B ₁₂ deficiency Fluid loss Vitamin K deficiency Vitamin C deficiency Iron deficiency Non-severe malnutrition Severe malnutrition	Diabetes, steroids Poor vascular perfusion Environmental or hygiene factors Thermal, sun, or chemical burns; Addison's disease Skin pigmentation disorders, hemorrhage, low volume, low perfusion state Atopic dermatitis, contact dermatitis, allergic or medication rash, psoriasis, connective tissue disease Jaundice Aging process Aspirin overdose, liver disease, or trauma COPD, heart disease, aortic stenosis, diabetes, lupus, chemotherapy
Nails	Smooth, translucent, slightly curved nail surface and firmly attached to nail bed; nail beds with brisk capillary refill	Spoon-shaped (koilonychia) Dull, lackluster Pale, mottled, poor blanching Ridging, transverse-more than one extremity	Iron deficiency Non-severe malnutrition Severe malnutrition Protein deficiency Iron deficiency Vitamin A deficiency Vitamin C deficiency Protein deficiency	Chemical effects Infection, chemical effects Beau's lines, grooves caused by trauma, coronary occlusion, skin disease, transient illness
Scalp	Pink, no lesions, tenderness; fontanels without softening, bulging	Softening or craniotabes Open anterior fontanel (usually closes by ≈ 18 months of age)	Vitamin D deficiency Vitamin D deficiency	Hydrocephalus
Hair	Natural shine, consistency in color and quantity, fine to coarse texture	Lack of shine and luster, thin, sparse	Protein deficiency Zinc deficiency Biotin deficiency, Linoleic acid deficiency	Hypothyroidism, chemotherapy, psoriasis, color treatment

PART 3: Nutrition-Focused Physical Examination—cont'd

System	Normal Findings	Abnormal Findings	Possible Nutrition and Metabolic Etiologies	Nonnutritional Etiologies
Face	Skin warm, smooth, dry, soft, moist with instant recoil	Easily pluckable	Protein deficiency Biotin deficiency	Hypothyroidism, chemotherapy, psoriasis, color treatment
		Alternating bands of light and dark hair in young children (flag sign)	Protein deficiency	Chemically processed or bleached hair
		“Corkscrew” hair	Copper deficiency Vitamin C deficiency	Menkes disease Chemical alteration
		Premature whitening	Selenium deficiency Vitamin B ₁₂ deficiency	Graves disease, medications
		Diffuse depigmentation, swollen	Protein deficiency	Steroids and other medications
		Pallor	Iron deficiency Folic acid deficiency Vitamin B ₁₂ deficiency	Low-perfusion, low-volume states
Eyes	Evenly distributed brows, lids, lashes; conjunctiva pink without discharge; sclerae without spots; cornea clear; skin without cracks or lesions	Moon face	Protein deficiency	Cushing’s disease, steroids
		Bilateral temporal wasting. See Part 1	Protein deficiency Energy deficit	Neuromuscular disorders
		Undifferentiated mucocutaneous border	Riboflavin deficiency	
		Pale conjunctiva	Iron deficiency Folate deficiency Vitamin B ₁₂ deficiency	Low output states
		Night blindness	Vitamin A deficiency	
		Dry, grayish, yellow or white foamy spots on whites of eyes (Bitot’s spots)	Vitamin A deficiency	Pterygium, Gaucher’s disease
Nose	Uniform shape, septum slightly to left of midline, nares patent bilaterally, mucosa pink and moist, able to identify aromas	Dull, milky, or opaque cornea (corneal xerosis)	Vitamin A deficiency	
		Dull, dry, rough appearance to whites of eyes and inner lids (conjunctival xerosis)	Vitamin A deficiency	Chemical, environmental
		Softening of cornea (keratomalacia)	Vitamin A deficiency	
		Cracked and reddened corners of eyes (angular palpebritis)	Riboflavin deficiency Niacin deficiency	Infection, foreign objects
		Scaly, greasy, with gray or yellowish material around nares (nasolabial seborrhea)	Riboflavin deficiency Niacin deficiency Pyridoxine deficiency	
		Inflammation, redness of sinus tract, discharge, obstruction or polyps	Irritation of skin membranes	Need to reconsider if placing nasoenteric feeding tube; evaluate for nonfood allergies
Oral Cavity				
Lips, mouth	Pink, symmetric, smooth intact	Angular Stomatitis (Bilateral cracks, redness of lips)	Riboflavin deficiency Niacin deficiency Pyridoxine deficiency Dehydration	Poor-fitting dentures, herpes, syphilis, HIV, environmental exposure,
		Cheilosis (Vertical cracks of lips or fissuring)	Riboflavin deficiency Niacin deficiency Dehydration	HIV (Kaposi’s sarcoma), environmental exposure,
		Chapped or peeling General inflammation	Dehydration Protein, energy, folic acid	Environmental exposure Xerostomia

Continued

PART 3: Nutrition-Focused Physical Examination—cont'd

System	Normal Findings	Abnormal Findings	Possible Nutrition and Metabolic Etiologies	Nonnutritional Etiologies
Tongue	Pink, moist, midline, symmetric with rough texture	Magenta (purplish-red color), inflammation of the tongue (glossitis)	Riboflavin deficiency, B ₆ deficiency Niacin deficiency Folate deficiency Vitamin B ₁₂ deficiency Riboflavin deficiency, Iron deficiency	Crohn's Disease, uremia, Infectious disease state, antibiotics, malignancy, Irritants (excess tobacco, alcohol, spices), generalized skin disorder
		Smooth, slick, loss of papillae (atrophic filiform papillae)	Folate deficiency Niacin deficiency Riboflavin deficiency Iron deficiency Vitamin B ₁₂ deficiency Non-Severe Malnutrition Severe Malnutrition	
		Distorted taste (dysgeusia)	Zinc deficiency	Cancer therapy, medications, advanced age, trauma, syphilis, xerostomia, poor-fitting dentures, poor hygiene
		Decreased taste (hypogeusia)	Zinc deficiency, Vitamin A deficiency	Cancer therapy, advanced age, medications, xerostomia
Gums	Pink, moist without sponginess	Spongy, bleeding, receding	Vitamin C deficiency Riboflavin deficiency	Dilantin and other medication, poor hygiene, lymphoma, polycythemia, thrombocytopenia
		Red, swollen interdental gingival hypertrophy	Vitamin C deficiency, folic acid deficiency, vitamin B ₁₂ deficiency	Dilantin, poor oral hygiene, lymphoma, vitamin A toxicity
Teeth	Repaired, no loose teeth; color may be various shades of white	Missing, poor repair, caries, loose teeth	Excess sugar intake	Trauma, syphilis, aging, poor dental hygiene
		White or brownish patches (mottled)	Excess fluoride	Enamel hypoplasia, erosion
Cranial nerves	Intact	Abnormal	Feeding route	
Gag reflex	Intact	Absent	Route of feeding	
Jaw	Proper alignment, movement from side to side	Improper alignment and movement	Ability to chew properly	
Parotid gland	Located anterior to earlobe, no enlargement	Bilateral enlargement	Non-Severe Malnutrition Severe Malnutrition	Bulimia, cysts, tumors, hyperparathyroidism
Neck nodules	Trachea midline, freely movable without enlargement or nodules	Enlarged thyroid	Iodine deficiency	Cancer, allergy, cold infection
Cardiopulmonary				
Chest, lungs	Anterior and posterior thorax; adequate muscle and fat stores, respirations even and unlabored, symmetric rise and fall of chest during inspiration and expiration, lung sounds clear	Somatic muscle- and fat-wasting; labored respirations; breath sounds such as crackles, rhonchi, and wheezing: evaluate for fluid status vs. tenacious secretions that may labor breathing and increase energy expenditure; also consider increased rate and depth, decreased rate and depth	Non-Severe Malnutrition Severe Malnutrition Metabolic acidosis Metabolic alkalosis	Respiratory disease (e.g., COPD)
Heart	Rhythm regular and rate within normal range; S ₁ and S ₂ heart sounds	Irregular rhythm	Potassium deficiency or excess Calcium deficiency Magnesium deficiency or excess Phosphorus deficiency	Cardiopulmonary disease states, stress
		Enlarged heart	Thiamin deficiency associated with anemia and beriberi	

PART 3: Nutrition-Focused Physical Examination—cont'd

System	Normal Findings	Abnormal Findings	Possible Nutrition and Metabolic Etiologies	Nonnutritional Etiologies
Vascular access devices intact	No swelling, redness, drainage	Pitting edema	Retention of sodium chloride, which causes the body to retain water Edema-associated disease of heart, liver, kidneys Fluid leaking into the interstitial tissue spaces Nutrition effects if device has to be removed	
Abdomen	Soft, nondistended, symmetric, bilateral without masses, umbilicus in midline, no ascites, bowel sounds present and normoactive; tympanic on percussion; feeding device intact without redness, swelling	Purulent drainage, swelling, excessive redness Generalized symmetric distention	Obesity	Enlarged organs, fluid, or gas, ileus from other disease
		Protruding, everted umbilicus; tight glistening appearance (ascites) Scaphoid appearance	Effects on protein, fluid, sodium concerns of feeding Non-Severe Malnutrition Severe Malnutrition	
		Increased bowel sounds	Nutrition effects in gastroenteritis (normal if hunger pains)	
		High-pitched tinkling	Nutrition effects if intestinal fluid and air present, indicating early obstruction	
		Decreased bowel sounds	Nutrition effects if peritonitis or paralytic ileus present	
Kidney, ureter, bladder	Urine golden yellow (ranges from pale yellow to deep gold), clear without cloudiness, adequate output	Decreased output, extremely dark, concentrated	Dehydration	
Musculoskeletal	Full range of motion without joint swelling or pain, adequate muscle strength	Inability to flex, extend, and rotate neck adequately	Interference with ability to feed or make hand-to-mouth contact	
		Decreased range of motion, swelling, impaired joint mobility of upper extremities; muscle wasting on arms, legs; skin folding on buttocks	Non-Severe Malnutrition Severe Malnutrition	
		Swollen, painful joints	Vitamin C deficiency Vitamin D deficiency Vitamin A deficiency	Connective tissue disease
		Bone tenderness Enlargement of epiphyses at wrist, ankle, or knees Bowed legs	Vitamins D deficiency Vitamin C deficiency Vitamin D deficiency Calcium deficiency	Trauma, deformity, or congenital cause
		Beading of ribs	Vitamin D deficiency Calcium deficiency	Renal rickets, malabsorption
		Pain in calves, thighs	Thiamin deficiency	Deep vein thrombosis, other neuropathy or other
Neurologic	Alert, oriented, hand-to-mouth coordination; no weakness or tremors	Decreased or absent mental alertness; inadequate or absent hand-to-mouth coordination	Interference with the ability to feed or make hand-to-mouth contact	

Continued

PART 3: Nutrition-Focused Physical Examination—cont'd

System	Normal Findings	Abnormal Findings	Possible Nutrition and Metabolic Etiologies	Nonnutritional Etiologies
		Psychomotor changes, cognitive and sensory deficits, memory loss, confusion, peripheral neuropathy	Non-Severe Malnutrition Severe Malnutrition; Thiamin deficiency, Pyridoxine deficiency, Vitamin B ₁₂ deficiency	Trauma, neurologic disease, brain injury, brain tumor, chemotherapy
		Dementia	Thiamin deficiency Niacin deficiency Vitamin B ₁₂ deficiency	Trauma, neurologic disease, vascular disease, brain injury, brain tumor, chemotherapy
		Tetany	Calcium deficiency Magnesium deficiency	
		Paresthesias or numbness in stocking-glove distribution	Vitamin B ₁₂ deficiency Thiamin deficiency	Diabetic neuropathy
	Cranial nerves intact: primary nutritionally focused ones include trigeminal, facial, glossopharyngeal, vagus, and hypoglossal			
	Reflexes (biceps, brachioradialis patella, and Achilles common in examination), functioning within normal range of 2 ⁺⁺	Hyperactive reflexes	Hypocalcemia	Tetany, upper motor neuron disease
	Hypoactive reflexes	Hypokalemia		Associated with metabolic diseases such as diabetes mellitus and hypothyroidism
		Hypoactive Achilles, patellar reflex	Thiamin deficiency, Vitamin B ₁₂ deficiency	Neurologic disorder

Laboratory Values for Nutritional Assessment and Monitoring

*Diana Noland, MPH, RD, CCN,
Mary Litchford, PhD, RDN, LDN*

I. PRINCIPLES OF NUTRITIONAL LABORATORY TESTING

A. Purpose

Laboratory-based testing is used to estimate nutrient availability in biologic fluids and tissues. It is critical for assessment of both nutrient insufficiencies and frank deficiencies. Laboratory data are the only objective data used in nutrition assessment that are “controlled”—that is, the validity of the method of the measurement is checked each time a specimen is assayed by also assaying a sample with a known value. The known sample is called a *control*, and if the value obtained for the sample is outside the range of normal analytic variability, both the specimen and control are measured again.

The nutrition professional can use laboratory test results to support subjective data and clinical findings to determine a personalized nutritional assessment leading to more targeted interventions and successful outcomes. The lab values provide objective data useful in regular monitoring and can be used to assess progress and manage side effects such as inflammation, aberrant lipid and glucose metabolism, and poor immune health. Furthermore, because numeric values do not themselves connote personal judgment, this kind of data can often be passed on to a patient or client without implicit or perceived blame.

B. Specimen Types

Ideally the specimen to be tested reflects a high percentage of total body content of the nutrient to be assessed. However, often the best specimen is not readily available. The most common specimens for analysis are the following:

Whole blood—Must be collected with an anticoagulant if entire content of the blood is to be evaluated. The two common anticoagulants for whole blood analyses are ethylenediaminetetraacetic acid, a calcium chelator used in hematologic analyses, and heparin (maintains the blood in its most natural state).

*Samples obtained for blood coagulation tests are diluted with solutions containing sodium citrate (a calcium chelator). Because of the dilutional effect of the anticoagulant solutions, citrated samples are not suitable for measurement of the concentrations of analytes.

[†]Clark GH, Fraser CG: Biological variation of acute phase proteins, *Ann Clin Biochem* 30:373, 1993.

Blood cells—Separated from uncoagulated whole blood for measurement of cellular analyte content: Red blood cells (indicate a 120-day window into intracellular and membrane composition), various blood components like white blood cells, protein-bound molecules, and others.

Plasma—The uncoagulated fluid that bathes the formed elements (blood cells).

Serum—The fluid that remains after whole blood or plasma has coagulated. Coagulation proteins and related substances are missing or significantly reduced.

Urine—Contains a concentrate of excreted metabolites and potential toxins.

Feces—Important in identifying various gastrointestinal functional parameters including inflammatory markers, microbiology, mycology, parasitology, digestive markers and nutritional analyses when nutrients are not absorbed and therefore are present in fecal material.

Saliva—laboratory analysis to identify endocrine, inflammatory, infectious, immunologic, some nutrients and other parameters with buccal cell or whole saliva samples.

Genomic—expanding beyond the historical metabolic macro- and micronutrient testing, genomic polymerase chain reaction (PCR) assays are emerging genomic clinical indicators for nutrigenetic and nutrigenomic influences on the metabolism of an individual (see Chapter 5).

Expired Air—Concentration of expired gases is a noninvasive and useful estimate of bacterial metabolism. Emerging measurements of expired nitric oxide and ketosis may be useful in estimating inflammatory or ketotic status in selected medical conditions.

Hair—An easy-to-collect tissue; most commonly measuring minerals; usually a poor indicator of actual body levels.

Other tissues—Fat biopsies have been used to estimate vitamin D stores in research studies.

C. Interpretation of Laboratory Data

As with all data, nutrition data may be quantitative (e.g., how much, how often, how fast), semiquantitative (e.g., many, most, few, a lot, usually, majority, several), or qualitative (e.g., color, shape, species). The advantage of quantitative data is that they are less ambiguous or more objective than other types of observations. Although objective laboratory data are extremely important resources in nutrition assessment, one should be extremely cautious about using a single isolated laboratory test value to make an assessment. An isolated value

is often misleading, especially when used without the context of an individual's lifestyle habits, clinical status, dietary, medical and genomic histories. Besides the importance of identifying frank deficiencies or excesses of nutrients, the best data are obtained from analysis of changes in laboratory values. It is especially important to monitor laboratory values when contemplating nutritional interventions that involve potentially unsafe levels beyond upper limits (UL), such as fat-soluble vitamins or a mineral like selenium.

When monitoring patients for changes in nutrition test values, one must consider how much change is necessary to give confidence that a difference is significant. The change required for statistical significance has been called the *critical difference*. It is calculated from measurement of the variances calculated from repeated measurements of an analyte: (1) specimens that have been obtained, at several different times, from each of several healthy persons (intrasubject variation); and (2) separate samples from a large specimen pool (analytic variation).

In practice, assessments are not based on the measurement of a single analyte at one point in time except in the case of severe deficiencies or dangerous excesses. Changes in laboratory tests may have biologic significance (e.g., patient's condition is improving) long before statistical significance is achieved. The changes in laboratory data may precede changes in other nutritional indices, but generally, although not always, the data available should point to the same conclusion.

D. Reference Ranges

To determine whether a particular laboratory value is abnormal, particularly when serial data are not available, the value is generally compared to a diagnostic reference range. The reference range is constructed from a large number of test values (20 to >1000). The average value and the standard deviation for these data are determined, and the reference range is calculated from the mean ± 2 standard deviations. If the sample group is representative of the reference population, the reference range will include values that reflect those found in approximately 95% of the reference population. Approximately 2.5% of this normal population will have values greater than the upper end of the reference range, and 2.5% will have values less than the lower end. This means that one normal individual in 20 would have a value below or above the reference range.

Reference ranges can be made for different populations. For example, reference ranges based on gender, age, race, and so forth, can be developed. In practice, the differences between populations are often ignored because the importance of small differences in a nutrient analyte is not usually significant. However, in the event of borderline values, the possible influence of differences between the patient's population and the reference population may need to be considered. Reference ranges are often determined by obtaining blood from personnel working in or near the clinical laboratory. This population is often skewed toward younger persons, has few minorities, and is overrepresented by women.

As the science of nutrition continues to rapidly evolve due to technological and scientific advances, changes in laboratory values can be interpreted as indicating metabolic trends, even within the reference range of a test. The nutritionist's skill in perceiving nutrient insufficiencies or imbalances related to nutritional influences can provide a more targeted assessment resulting in improved outcomes from therapy.

E. Units

Many types of units are used in reporting nutrient-dependent laboratory values. Two basic systems of units are in common use: the conventional system and the *Système Internationale d'Unités* (SI) system. The conventional system sometimes lacks convention; thus different laboratories adopt different units to report the same analyte. For example, the conventional report of an ionized calcium value could be 2.3 mEq/L, 46 mg/L or 4.6 mg/dL. However, in the SI system only 1.15 mmol/L is allowed.

F. Nature of Nutritional Testing and Types of Tests

Typically laboratory tests are static assays (i.e., the concentration of an analyte is measured in a biologic fluid [e.g., a fasting blood specimen] at a point in time). Assessment of nutrient status made by this approach is often inaccurate or distorted. Some nutrients can be assessed by tests that are based on measurements that reflect the endogenous availability of a nutrient to a measurable biologic function (e.g., biochemical, tissue, or organ). Most often, functional assessment of nutrient status may be done by measurement of a biochemical marker (i.e., a normal or abnormal metabolite) of function. The results of this type of testing can be reliably considered to reflect the adequacy of a nutrient pool or possible individual genomic nutrient requirements.

NEW DIRECTIONS

Bioelectrical Impedance Analysis (BIA) and Bioimpedance Spectroscopy (BIS)— A New Functional Test

Nutrition assessment is taking on a new level of specificity with the explosion of technology and discoveries of the pathophysiology of disease and functions of the human body. These breakthroughs assist in molecular level identification of nutrition status. Bioelectrical Impedance Analysis (BIA) and Bioimpedance Spectroscopy (BIS) have a credible history of use in research, but recently have found an increasing use as a clinical tool in nutrition assessment.

BIA estimates body composition and cellular activity by measuring the bulk electrical impedance of the body. The testing procedure involves application of conductors (electrodes) to a person's hand and foot, and sending a small alternating electric current through the body (see figure on next page). The different electrical conductive properties of various body tissues (adipose, muscular and skeletal) and hydration affect the impedance measurement. An

algorithm derived from statistical analysis of BIA measurements is used to calculate the various parameters that can be measured by this technique.

Normal hydration is critical for results to be valid, with these guidelines prior to testing:

- 1) Drink water (16-24 oz during 4 hours prior to test)
- 2) No alcohol for 12 hours prior to test
- 3) No food or caffeine drinks for 4 hours before test
- 4) No moderate to intense exercise for 12 hours prior to test.

Contraindications to BIA testing are pregnancy, or the presence of implants like pacemakers or defibrillators. Follow-up monitoring of BIA testing should attempt to be near the same time of day.

There are commercially available BIA devices that measure only body fat % and weight. But professional BIA or BIS instruments are available

NEW DIRECTIONS—cont'd

Bioelectrical Impedance Analysis (BIA) and Bioimpedance Spectroscopy (BIS)— A New Functional Test

that provide reliable, more comprehensive full body data, and automatically calculate total body water, intracellular and extracellular water, fat-free mass, percent body fat, phase angle, capacitance and body cell mass. They are very useful in tracking changes in an individual's progress over time. Research in the past decade has shown promise for the BIA Phase Angle as a prognostic indicator of some cancers (Norman 2010,) and other chronic conditions (Maddocks et al, 2014).

The multiple parameters measured in a BIA or BIS test provide three categories of data:

1. **Anthropometry:** BMI (body mass index), BMR (basal metabolic rate), body fat percentage, and lean body mass percentage. These measurements are used with weight management, monitoring of wasting syndromes, and acute care formulation of dietary prescriptions. Weight/height/age/gender data must be entered to obtain these results.
2. **Cellular metabolism:** Phase angle, which measures cell membrane fluidity and is a prognostic marker of mortality, capacitance (electrical resistance of the cell membrane) and body cell mass (the number or amount of metabolically active cells). Using these three measurements provides an easy-to-use, non-invasive, and reproducible technique to evaluate changes in body composition and nutritional status. Phase angle (BIA) detects changes in tissue electrical properties, and is hypothesized as a marker of malnutrition for investigating various diseases in the clinical setting. Lower phase angles suggest cell death or decreased cell integrity, while higher phase angles suggest large quantities of intact cell membranes (Selberg and Selberg, 2002).

3. **Hydration:** Total body water (in pounds and as a percentage), intracellular water (in pounds and as a percentage), and extracellular water (in pounds and as a percentage).

Every professional practicing nutrition therapy can now consider adding a reasonably priced BIA or BIS instrument to their nutritional assessment tool box to assist in the management of a client or patient. The four companies from which professional BIA or BIS instruments can currently be obtained are:

www.impedimed.com
www.inbody.com
www.biodynamics.com
www.rjlsystems.com

These companies also provide informative education on the technology and operation of their bioimpedance or bioimpedance spectroscopy instruments.

II. Clinical Chemistry

A. Protein Markers

Test	Principles	Interpretation	Reference Range	Limitations and Implications
Normalized Protein Catabolic Rate (nPCR)	nPCR is determined by measuring the intradialytic appearance of urea in body fluids plus any urea lost in the urine in patients with residual renal function. $nPCR = 0.22 + (0.036 \times \text{intradialytic rise in BUN} \times 24) / (\text{intradialytic interval})$ (also called: Protein Nitrogen Appearance rate (PNA) (g/day) = $13 + 7.31 \text{ UNA (mmol/day)}$ $[\text{UNA (mmol/day)} = \text{Vd(ml)} \times \text{Cd (mmol/L)} + \text{Vu (ml)} + \text{Cu (mmol/L)}]$	Useful in assessing Dietary Protein Intake (DPI) in patients who are in a steady state on hemodialysis, as a means toward determining adequate nutrition status.	0.81-1.02 g UN/kg per day	nPCR considered superior to sAlb for monitoring nutrition protein status due to sAlb influence by processes other than nutrition status. ² During hemodialysis the PCR can also reflect inadequate dialysis. For CAPD patients the nPCR value has not been consistently predictive of outcome. ³
Urine creatinine (U : Cr)	U : Cr concentration in fasting, first-void urine used to compare amino acid catabolism (BUN) with muscle mass (creatinine).	Urine concentration (mg/dL) $U : Cr = \text{Urine area (mg/dL)} \div \text{Urine creatinine (mg/dL)}$. The U : Cr is used in comparing other markers like microalbumin, albumin, GFR ratios.	Risk Low Medium High	Ratio >12.0 $6.0-12.0$ <6.0
Urea Urinary Nitrogen (UUN)	The protein pool (visceral and somatic) N is catabolized to urea; urine urea represents ~80% of N catabolized; requires accurate estimate of protein intake; thus usually used only for PN or tube-feeding patients.	UUN is compared with the actual N intake. $\text{Nitrogen Balance} = \text{Nitrogen intake (Protein g/day} \div 6.25) - \text{Nitrogen Losses (UUN (g) + 4)}^a$	- = Catabolism 0 = Catabolism + = Anabolism (3-6 g/24 hr = optimal use range)	24 hour urine collection must be quantitative (complete); UUN not appropriate in renal insufficiency; does not account for wound leakage, cell losses, or diarrhea; inaccurate in metabolically stressed patients.
Total Urinary Nitrogen (TUN)	Some N is excreted as non-urea N (e.g., ammonia and creatinine); 24-hour TUN reflects total protein catabolism, accounting for all sources of urinary N; as for UUN, requires accurate protein intake. Used primarily to accurately follow the protein catabolic response during disease and response to nutritional support.	TUN is compared with the actual N intake; $\text{Nitrogen Balance} = \text{Nitrogen intake (Protein g/day} \div 6.25) - \text{Nitrogen Losses (TUN (g) + 2)}^b$	- = Catabolism 0 = Catabolism + = Anabolism (3-6 g/24 hr = optimal use range)	Urine 24 hour collection must be quantitative (complete); TUN not appropriate in renal insufficiency; does not account for wound leakage, cell losses, or diarrhea.
Urea Kinetic Modeling (UKM)	Formulas used to estimate nPCR (normalized protein catabolic rate) from changes in BUN concentration in patients with impaired renal function.	Urinary urea (KrU) and BUN levels (urea generation rate—UG) are used to determine nPCR; 1- to 3-day diet intake compared with nPCR. Urea kinetic Modeling (Kt/V_{urea} and nPCR)	In protein balance, nPCR = protein intake (g/kg/day)	Urea lost in dialysis must be accounted for in calculating urea nitrogen appearance. Dietary protein intake hard to estimate.

B. Inflammatory Markers

Albumin (ALB)	Easily and quickly measured colorimetrically; large body pool (3-5 g/kg body weight), ~60% is outside the plasma in the extravascular pool; long half-life of 3 weeks.	Decreased levels can occur following acute and chronic inflammatory states; often associated with other deficiencies (i.e., zinc, iron, and vitamin A) reflecting that ALB transports (many small molecules).	3.5-5 g/dL (35-50 g/L)	Stable half life ~3 weeks. A negative phase reactant, impacted by inflammatory stress, (protein losing conditions and hemodilution. Hepatic proteins are indicators of morbidity and mortality:
Globulin (GLOB)	Large body pool (3-5 g/kg body weight), ~35% is outside the plasma in the extravascular pool; long half-life averages 23 days, but varies with particular globulins.	Globulin proteins include enzymes and carriers that transport proteins including antibodies that primarily assist in immune function and fight infection.	2.3-3.4 g/dL (23-34 g/L)	Significance confounded by acute stress reaction, infection, inflammatory conditions.
A/G Ratio	Calculated from ALB and GLOB values by direct measurement of TP and ALB.	It represents the relative amounts of ALB and GLOB	A/G Ratio 1 : 1 - normal $<1 : 1$ - disease state	Albumin levels fall and globulin levels rise with inflammatory stress.

Transferrin (Tf or TFN)	The iron bound globulin protein that responds to the need for iron. Can be calculated from TIBC and serum iron; half-life ~9 days. See Chapter 7.	Tf increased with low iron stores, and prevents build up of highly toxic excess unbound iron in circulation. In iron overload states Tf levels decrease. Because B ₆ is required for iron to bind to Hgb, B ₆ deficiency promotes ↑ Tf from the ↑ circulating iron that binds to Tf; smaller extravascular pool than albumin.	Adult male: 215-365 mg/dL (2.15-3.65 g/L) Adult female: 250-380 mg/dL (2.50-3.80 g/L) Newborn: 130-275 mg/dL (1.3-2.75 g/L) Child: 203-360 mg/dL (2.03-3.6 g/L) Pregnancy and estrogen HRT associated with ↑ Tf.	Lead can biologically mimic and displace iron thus releasing Fe into circulation and ↑ Tf. Tf is a negative acute phase reactant diminished in chronic illness and hypoproteinemia.
Transferrin Saturation (Tf-sat or TSAT)	$Tf\text{-sat} (\%) = \frac{\text{Serum iron}}{\text{TIBC}} \times 100\%$	Tf-sat decreases to <15% in Fe deficiency; useful in diagnosis of iron toxicity or Fe overload (hemochromatosis). See Chapter 32.	M: 20%-50% F: 15%-50% Chronic illness: normal Tf-sat%. Late pregnancy: low Tf-sat%.	Increased Tf-sat when low vitamin B ₆ as in aplastic anemia.
PreAlbumin (PAB)/ Transthyretin (TTR)	Transports T ₄ and acts as a carrier for retinol-binding protein; PAB also called thyroxin-binding protein; half-life 2 days.	Measure of inflammatory status. Zinc deficiency reduces PAB levels.	15-36 mg/dL or 150-360 mg/dL (15-36 mg/dL female 21-43 mg/dL male) Malnutrition: <8 mg/dL (<0.8 g/L or <80 mg/L)	Sensitive to acute zinc deficiency and acute stress reaction. PAB values do not reflect protein status, but is a prognostic index for mortality and morbidity. ⁴
Retinol-binding protein (RBP)	Transport retinol; because of low molecular weight, RBP is filtered by glomerulus and catabolized by the kidney tubule; half-life = 12 hours	Measure of inflammatory status.	2.6-7.6 mg/dL (1.43-2.86 mmol/L)	Sensitive to stress response; vitamin A and zinc deficiencies, and hemodilution; increased in chronic renal disease.
C-Reactive Protein high sensitivity (hs-CRP)	A nonspecific acute phase reactant; short half life 5-7 hr; CRP responds to inflammation in 6-10 hours. (also called CRP-ultra sensitivity and CRP-cardio)	A sensitive marker of bacterial disease and systemic inflammation; associated with periodontitis, trauma, cardiovascular disease, neoplastic proliferation and bacterial infections.	Low Risk for CVD = Less than 1.0 mg/L Intermediate Risk for CVD = 2.9 mg/L High Risk for CVD = Greater than 3.0 mg/L Seek inflammatory cause if >10 mg/L	Useful metabolic indicator for adults. ⁹ Acute-phase reactant; relates mostly to bacterial infection, central adiposity, trauma and neoplastic activity.
Fibrinogen	Acute-phase reactant protein essential to blood-clotting mechanism/coagulation system.	Decreased fibrinogen related to prolonged Pro Time (PT) and Partial Thromboplastin Time (PTT); produced in liver; rises sharply during tissue inflammation or necrosis; association with CHD, stroke, myocardial infarction and peripheral arterial disease.	200-400 mg/dL If <100 mg/dL, increased risk of bleeding. Should be monitored in conjunction with blood platelet levels involved with coagulation status.	Good test and retest reliability, and covariance is stable over time; diets rich in Omega 3/6 fatty acids reduce fibrinogen blood levels.
C. Metabolic Indicators				
Insulin-like growth factor-1 (IGF-1) or Somatomedin C	The peptide mediator of growth hormone activity produced by the liver; half-life of a few hours; much less sensitive to stress response than other proteins.	Low in chronic undernutrition; increases rapidly during nutrition repletion; TSAT, PAB, and RBP are not affected. Elevated levels associated with elevated GH in acromegaly and neoplastic activity.	Adult: 42-110 ng/mL Children age 0-19: can vary with age, gender and Tanner Stages (Appendices 17 & 18) used for references per age	Reduced levels seen in hypopituitarism, hypothyroidism, liver disease, and with estrogen use. Growing evidence of elevated IGF-1 as a prognostic biomarker of neoplastic activity. ^{5,6}
Hemoglobin A1C (HgbA1C)	Glycosylated hemoglobin; dependent on blood glucose level over life span of RBC (120 days); the more glucose the Hgb is exposed to, the greater the % HgbA1C.	Assessment of the mean glycemic blood level and of chronic diabetic control detecting for the previous 2-3 months. ⁷	Non-diabetic adult/child: 4%-5.9% Controlled diabetes (DM): 4-7% Fair DM control: 7-8% Poor DM control: >8%	HgbA1 measurement is a simple, rapid, and objective procedure. Home testing available.

Insulin, fasting	Pancreatic hormone signaling cell membrane insulin receptors to initiate glucose transport into cell; test fasting 7 hours, or 1 or 2 hours post prandial; usually ordered with blood glucose test.	Elevated levels associated with hyperinsulinemia related to metabolic syndrome; diagnosis of insulin-producing neoplasms; excess insulin associated with inflammatory conditions.	Adult values: Fasting 6-27 μ IU/mL 1 or 2 hour PP: see lab reference	Good to test and retest reliability, and covariance is stable over time. ⁸ Insulin antibodies may invalidate the test.
D. Immune Dysregulation Tests				
Allergies/Sensitivity				
Immunoglobulins (IgA, IgG, IgE, IgM,)	Serologic antibody screening tests; testing of Immunoglobulins; Total IgE ELISA; RAST (radioallergosorbent-blood IgE); Bloodspot; IgG Provocative specific antigen skin prick; (IgE related skin response) used to diagnose allergy and identify the allergen.	Used to determine immunodeficiency states; measurement of +IgE = allergic disorders; (see Table 27-3) +IgG = delayed immunologic sensitivity or intolerance response (see Table 27-3). IgA = largest % Ig primarily made in GI lymphoid tissue and marker of immune strength and response.	Total IgA: Adults = 85-463 mg/dL Children = 1-350 mg/dL Total IgG: < 2.0 mcg/mL Total IgE = <10 IU/mL RAST IgE = <1 IU/mL low allergic risk Total IgM: Adults 48-271 mg/dL Children 17-200 mg/dL Total IgD = < 15.3 mg/dL	NSAIDS, glucocorticosteroids, vitamin C, bioflavonoids can suppress the immunologic response and promote a false negative. IgA used as a biomarker reference of adequate immune response to enable measurement of IgG, IgE, IgM, IgD
Innate Immune Factors				
Total Leukocyte Count (TLC)	Calculated from the percentage of lymphocytes reported in the hemogram and the WBC count. Units = cells/ μ l or cells/mm ³	Decreased in protein-energy malnutrition and immunocompromised state.	Normal: >2700 Moderate depletion: 900-1800 Severe depletion: <900	
Delayed cutaneous hypersensitivity	Anergy for antigens, such as mumps and <i>Candida</i> ; occurs in malnutrition; antigens intradermal injection; redness (erythema) and hardness (induration) read 1, 2, or 3 days later.	Response affected by protein-energy status and vitamin A, iron, zinc, and vitamin B ₆ deficiencies.	Induration 1+: <5 mm 2+: 6-10 mm 3+: 11-20 mm 4+: >20 mm Erythema present or absent	Usefulness in acute care limited by drugs, effect of aging and disease (metabolic, malignant, and infectious diseases); difficult to administer and interpret results; semiquantitative.
Cytokines	Serum or joint fluid proteins tested from venous blood. They include lymphocytes, (T & B cells), monocytes, leukocytes (interleukins), eosinophils, interferon and growth factors. (See Chapter 3)	A group of immune reactant proteins that have many functions even from one cell to another. They respond to the environmental influences to communicate and orchestrate the immune response to protect from cancer, infection and inflammation.	Cytokine examples: Interleukins: IL-1, IL-6, IL-8, IL-10, TNF- α , TH-1, TH-2 (per lab references)	
Adaptive Immune Factors				
Eosinophils (Eosinophil leukocyte)	Blood: Bronchoalveolar lavage (BAL) fluid CSF specimen to rule out eosinophilic meningitis.	Blood: Wide range of clinical conditions reflect nonspecific eosinophilia; elevated related to possible allergies, asthma, sensitivities, or cancers; particularly elevated eosinophils are found with intestinal parasites; noninfectious conditions.	Blood: 1% to 3% 50-500/mm ³ BAL negative for infection CSF < 10 mm ³	Because of the nonspecific nature of blood eosinophilia, it can require further clinical investigation to determine the causal agent.
Food Intolerance/Sensitivity Panels				
Antigen Leucocyte Cellular Antibody Test (ALCAT)	Measurement of leukocyte cellular reactivity in whole blood, measures levels of mediators by blood cells presented with food or chemical antigens; measures relative changes in cell size (see Table 26-4)	Food and chemical non-IgE sensitivity (intolerance) testing for up to 350 foods plus gliadin/gluten, casein/whey, and candida albicans; food additives, molds, environmental chemicals, pharmacologic agents, and other suspected items upon request.	350 Foods: Acceptable Foods Normal = no response Mild Intolerance Moderate Intolerance Severe Intolerance Candida/gluten-gliadin/casein-whey, chemicals/molds: No Reaction Mild, Moderate or Severe Reaction	NSAIDS, glucocorticosteroids, vitamin C, bioflavonoids can suppress the immunologic response and promote a false negative. IgA used as a biomarker reference of adequate immune response.

<p>Mediator Release Test (MRT) (immunologic food reaction test)</p>	<p>Untreated whole blood assay; sample is divided into 150 aliquots plus control samples and incubated with a precise dilution of pure extract of a specific food or food additive^c (see Chapter 26)</p>	<p>Non IgE-mediated reactions; measurement of blood components; blood specimen checked against the specific signs of cell-mediated reactivity to the antigen challenged (imminent or actual mediator release). See Table 26-4.</p>	<p>Normal = no response Mild, moderate or severe reactions are delineated.</p>	<p>NSAIDS, glucocorticosteroids, vitamin C, bioflavonoids can suppress the immunologic response and promote a false negative. IgA used as a biomarker of adequate immune response.</p>
<p>Celiac Panel/ Gluten Sensitivity Panel</p>	<p>1. Immunologic and genomic for celiac or gluten sensitivity-related genes.</p>	<p>Measurements to identify a possible genetic or immunologic disease of the small bowel in response to exposure to gluten or gliadin molecules in diet. Continued long-term exposure to gluten or gliadin molecules leads to nutrient deficiencies and insufficiencies.</p>	<p>See celiac tests 2.- 10.</p>	<p>Any of the celiac tests 2-10 tests should be compared with baseline IgA serum levels and presence of immune suppressive medications to rule out IgA deficiency, which can skew test results to false negative because of compromised or suppressed immune response. Undiagnosed celiac is associated with increased incidence of all chronic diseases and shortened lifespan^{10,11,12}</p>
	<p>2. Endomysial antibodies (EMA)</p>	<p>High specificity for celiac disease; may obviate need for small bowel biopsy for diagnosis; become negative on gluten-free diet;</p>	<p>EMA negative</p>	<p>Sensitivity/Specificity 90+%/95%</p>
	<p>3. TissueTransglutaminase (tTG-IgA, tTG-IgG)</p>	<p>Autoantigen of celiac disease, tTG is indicative of villous atrophy secondary to gluten exposure causing damage to GI small intestine villi. tTG negative test results indicate gluten-free diet compliance; marker of restoration of GI villi tight junctions and small bowel villi integrity.</p>	<p>tTG IgA negative tTG IgG negative</p>	<p>Sensitivity/specificity 98%/95% in adults; 96%/99% in children. Best age to begin measuring tTG is age 2-3 years.¹³</p>
	<p>4. Antigliadin antibodies (AGA IgA, AGA IgG)</p>	<p>Positive results are evidence of immune response to the gliadin proteins in gluten-containing foods.</p>	<p>AGA IgA negative AGA IgG negative</p>	<p>Lowest sensitivity among celiac panel (70%-85%) and specificity (70%-90%) for celiac. Also useful for non-celiac gluten sensitivity.</p>
	<p>5. Deamidated gliadin peptide (DGP)</p>	<p>DGP antibodies improves¹⁴ diagnostic accuracy for diagnosis of CD when tested with tTG; proteins present in the submucosa of affected person's bond to deamidated peptides to form molecular complexes that stimulate the immune system.</p>	<p>DGP negative</p>	<p>Specificity varied between 97.3% and 99.3%. Sensitivity of IgG anti-DGP significantly better than that of IgG anti-tTG ($p < 0.05$). Specificity was significantly better than IgA and IgG AGA¹⁵</p>
	<p>6. Celiac genetic HLA haplotype HLA-DQ2 HLA-DQ8 Cellular assay/MLC to test HLA class II types</p>	<p>HLA-DQ2 and HLA-DQ8 positive indicates a low positive predictive value but a very high negative predictive value for celiac disease. Higher prevalence of CD in patients with Type 1 DM or autoimmune thyroid disease (2%-4%) than in general population</p>	<p>Genotype: HLA DQ2 negative HLA DQ8 negative</p>	<p>More than 97% of individuals with celiac disease share the two HLA markers DQ2 and DQ8, which have high sensitivity and poor specificity. One of the markers can increase possible non-celiac gluten sensitivity (e.g., Type 1 DM DQA1*0501:DQB1*0201 haplotype).^{14,15,16}</p>

Continued

7. Wheat/Gluten Proteome Reactivity & Autoimmunity

Functional medicine serum lab tests to broaden the view of celiac and gluten sensitivity by assessing antibody production against an array of protein, enzyme and peptide antigens; includes *glutens*, *lectins*, *opioids* and the enzyme *glutamic decarboxylase* (GAD65) IgG, IgA. Available from www.cyrexlabs.com.

ELISA Index
Wheat
IgG 0.30-1.30 mcg/mL
IgA 0.40-2.40 mg/dL
Agglutinin
IgG 0.30-1.50 mcg/mL
IgA 0.90-1.90 mg/dL
Alpha Gliadin 17 MER
IgG 0.30-1.50 mcg/mL
IgA 0.60-2.00 mg/dL
Alpha Gliadin 33 MER
IgG 0.30-1.40 mcg/mL
IgA 0.60-1.80 mg/dL
Gamma Gliadin 15 MER
Omega Gliadin
IgG 0.50-1.60 mcg/mL
IgA 0.60-1.80 mg/dL
Glutenin
IgG 0.20-1.50 mcg/mL
IgA 0.50-1.70 mg/dL
Gluteomorphin
IgG 0.30-1.50 mcg/mL
IgA 0.60-1.80 mg/dL
Prodynorphin
IgG 0.40-1.70 mcg/mL
IgA 0.60-1.80 mg/dL
GAD65
IgG 0.40-1.30 mcg/mL
IgA 0.80-1.50 mg/dL

Enhances clinical sensitivity and specificity in detection of celiac and gluten sensitivity reactions

8. Gluten-Associated Cross-Reactive Foods and Foods Sensitivity
IgG + IgA Combined
Cow's Milk
Alpha-Casein & Beta-Casein
Casomorphin
Milk Butyrophilin
American Cheese
Chocolate
(Others available)

Functional medicine serum lab tests to assess IgG and IgA immune antibody reactions to known cross-reactive food antigens, with the most common being casein. Other foods included are: sesame, hemp, rye, barley, wheat, buckwheat, sorghum, millet, spelt, amaranth, quinoa, yeast, tapioca, oats, coffee, corn, rice, potato.

ELISA Index:
IgG & IgA combined
0.20 mcg/mL /0.40 mg/dL -1.80 mcg/mL /2.00 mg/dL

Assists further dietary evaluation for celiac or gluten sensitive individuals that are non-responsive to a gluten-free diet; can relate to gut dysbiosis and continued GI inflammation. Available from cyrexlabs.com.

III. Tests of Carbohydrate Absorption

Lactose Intolerance

Hydrogen Breath Test for Lactose (HBT-lactose)

Lactose loading (2 g/kg) in lactase deficiency allows bacterial metabolism of lactose with production of H₂ gas. Breath analyzed for H₂ by gas chromatography.

Breath H₂ measured fasting and 0.5 and 2 hours after dosing with lactose; a significant increase is associated with malabsorption.

Normal increase:
<50 parts/million (i.e., <50 ppm)
Lactose intolerance:
50 ppm or greater

Bacterial overgrowth can cause false-positive results; consumption of soluble fiber or legumes, and smoking are associated with H₂ production; false-negative results caused by antibiotics.

Lactose tolerance test

Lactose loading (50 g) followed by blood sampling at 5, 10, 30, 60, 90, and 120 min after dose; glucose produced from lactose is assayed.

Lactase deficiency associated with <20 mg/dL increase in serum glucose.

Normal serum glucose
Lactose increase
>20 mg/dL

Test is not specific (many false positives) or sensitive (many false negatives).

Fructose Intolerance

Hydrogen Breath Test-Fructose (HBT-fructose)	An assessment for the change in the level of hydrogen and/or methane gas is diagnostic for fructose malabsorption.	HBT-fructose can be used to diagnose a mutation in the aldolase B gene. If hereditary fructose intolerance, may result in gastrointestinal symptoms and hypoglycemia.	Normal increase <20 parts/million (<20 ppm) Positive BHT-fructose >20 parts per million (>20 ppm)	Positive test results indicate probable benefit of a fructose-restricted diet; research supports use in abdominal pain, IBS, gout.
Fructose Sensitivity	Blood lymphocyte specimen grown with a mitogen to measure growth by incorporating tritiated radioactive thymidine into the DNA of the cells A functional test of fructose metabolism.	Functional intracellular metabolic test of possible genetic errors compromising fructose metabolism like fructose-6-phosphate	>34% patient's growth response test media measured by DNA synthesis compared to optimal growth observed in 100% media. (valid for male and female of 12 years or older)	Rule out fructose sensitivity in hypoglycemia of unknown etiology, overweight, obesity.

IV. Tests of Lipid Status

Lipids

Cholesterol, Total serum or plasma (CHOL)	CHOL is enzymatically released from cholesterol esters; fasting test	Total CHOL correlated with risk for cardiovascular diseases.	AHA/ACC/NHLBI 2014 Guidelines do not have target levels for cholesterol. Generally < than 200 mg/dL is desirable (see Chapter 33).	Cholesterol measurements have considerable within-subject variability. May partly result from variability in specimen collection or handling.
High Density Lipoproteins (HDL-c)	LDL-c (and VLDL-c) are precipitated from the serum before measurement of residual HDL-c particle size; direct measurement of HDL-c is now done in some laboratories.	HDL-c is called "good cholesterol" to indicate that it is protective against atherosclerotic vascular development	Generally, levels should be above 40 mg/dL. The higher the better.	Some precipitation methods cause underestimation of HDL; HDL can be divided into classes: HDL ₁ , HDL ₂ , and HDL ₃ ; Elevated HDL ₃ correlates with risk of CVD.
Low Density Lipoproteins (LDL-c)	LDL-c is estimated by the Friedewald formula, LDL-c = total cholesterol – HDL-c – TG/5, or by new direct assays. Available lipid particle size testing examples: www.privateMDLab.com (VAP Lipid Profile) www.BerkeleyHeartLab.com	LDL-c is called "bad cholesterol" to indicate that it is a positive risk factor for CVD. See NCEP guidelines in Chapter 33. Lipoprotein particle (LPP) size: Pattern B (small, dense LDL-C) is associated with increased risk of CHD and is responsive to diet. Pattern A (larger, buoyant LDL) is not associated with risk. LPP are not recommended in new ATP4.	Generally, below 130 mg/dL is considered desirable.	Calculation only valid when TG concentration is <400 mg/dL, cannot be determined in non-fasting serum or plasma. Direct assay methods preferred.
Triglycerides (TGs)	Lipases release glycerol and fatty acids from TGs;	The association of TGs and CHD has been shown. Elevated TG increases blood viscosity.	<150 mg/dL normal >500 mg/dL high	Fasting specimen is essential; sugar concentrated foods and alcohol ingestion can increase TG level; some anticoagulants may affect TG level; carnitine-dependent fatty acids synthesis.

Fat Malabsorption

Fecal fat screening	Microscopic inspection of fat-stained (Sudan stain) specimens for the presence of lipid droplets.	Trained observers are able to identify excessive fat in ~80% of persons with fat malabsorption.	Qualitative results	Patient must be consuming sufficient fat for analysis to reveal malabsorption. Semiquantitative.
Prothrombin time (PT)	Fat malabsorption decreases absorption of fat-soluble vitamins A,E,D,K,Beta-Carotene; low vitamin K levels impair coagulation, causing a prolonged PT. (also can be called INR (international normalized ratio))	A prolonged PT is a relatively sensitive but nonspecific indicator of the fat-soluble vitamin K from fat malabsorption.	10-15 sec INR: 0.8-1.1 Possible critical value: > 20 sec. INR: > 5.5	Tests affected by oral anticoagulants and other drugs, reduced platelet count, acquired and hereditary bleeding diseases, and liver disease PT.

Continued

Quantitative fecal fat determination	Patient must consume 100 g fat/day (4-8 oz whole milk/day, and 2 Tbsp vegetable oil/meal/day) for 2 days before collection	Quantitative 72-hour stool collection required for accurate assessment; average daily discharge used for interpretation.	Normal: <5 g fat/24 hr Malabsorption: >10 g/24 hr	Failure to adhere to the diet invalidates the results.
Vitamin A, D, E, K	See V. Tests of Micronutrient Status.			
Fatty acid analysis	Whole blood or RBC levels of ALA (C18 : 3n3) and LA (C18 : 2n6) reflect essential fatty acid status; Also, complex relationships regarding fatty acid analysis are related to neurological and inflammatory diseases, cell membrane dysfunction and genetic disorders ^{17,18}	RBC fatty acid shown to be associated with fatty acid tissue composition. Plasma fatty acid levels are associated with dietary fat or supplement intake or fat digestion and absorption.	Arachidonic Acid (AA)/Eicosapentaenoic acid (EPA) = 1.5-3.0 = Normal AA/EPA = High Risk >15 Omega-3 (EP+DHA) Index Risk: Index <2.2 High Index 2.2-3.2 Moderate Index >3.2 Low Omega 6/Omega-3 Ratio 5.7-21 EPA/AA Ratio </= 0.2 Arachidonic Acid 520-1490 nmol/mL 5.2-12.9% EPA 14-100 nmol/mL 0.2-1.5% DHA 30-250 nmol/mL 0.2-3.9% GLA 16-150 nmol/mL Omega-6 : omega-3 optimal between 1 : 1 and 4 : 1.	Is not specific for risk of atherosclerotic disease; inflammation influences this fatty acid test. Likely causes are minor injuries, trauma, and bacterial infections, periodontal/cavitations, orodental disease, ¹⁹ <i>chlamydia pneumoniae</i> , ²⁰ dietary fats and central adiposity ²¹

V. Tests of Micronutrient Status

A. Vitamins

Thiamin (B ₁) ^c	Thiamin status is usually assessed by measuring the amount of TPP needed to fully activate the RBC enzyme transketolase.	The TPP needed to fully activate transketolase is inversely related to B ₁ status; percent stimulation by TTP.	Normal: 70-200 nmol/L (for individuals not taking thiamine (B1)) Stimulation >20% (index >1.2) indicates deficiency	Amount (and activity) of enzyme affected by drugs, iron, folate, or vitamin B ₁₂ status, malignant or GI diseases, and diabetes.
Riboflavin (B ₂)	Riboflavin status is assessed by measuring the amount of FAD needed to fully activate RBC enzyme GR	The FAD needed to fully activate GR is inversely related to B ₂ status; percent stimulation.	% Stimulation >40% (index >1.4) indicates deficiency	Amount or activity of enzyme may change with age, iron status, liver disease, and glucose-6-phosphate dehydrogenase deficiency.
Niacin (B ₃)	Urinary excretion of N ¹ -methylnicotinamide (NMN) is decreased; <0.8 mg/day (<5.8 μmol/day) suggests a niacin deficiency.	Blood: Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) Niacin (nicotinic acid) is a water-soluble vitamin that is also referred to as vitamin B ₃ .	Nicotinic acid: 0.0–5.0 ng/mL Nicotinamide: 5.2–72.1 ng/mL	Niacin (nicotinic acid) is a water-soluble vitamin that is also referred to as vitamin B ₃ . Nicotinamide (nicotinic acid amide) is the derivative of niacin
Pyridoxine (B ₆) ^e PLP (pyridoxal-5-phosphate) compounds	1. RBC enzymes, ALT (SGPT) or AST (SGOT), ^e are assayed for the presence of PLP as the enzymes' cofactor. 2. Plasma PLP can be directly measured by High-pressure liquid chromatography (HPLC) with fluorescence detection	1. Difference between enzyme activities before and after addition of PLP is inversely related to B ₆ status. 2. PLP is major transport form of B ₆ ; therefore serum levels reflect body stores.	1. % ALT stimulation of >25% or AST activity of >50% in deficiency 2. Normal: 0.50-3.0 mcg/dL (20-120 nmol/L) Male: 5.3–46.7 μg/L Female: 2.0–32.8 μg/L	1. Disease and drugs that affect the liver and heart, and pregnancy confound interpretation. 2. Deficiency may be seen clinically before plasma PLP levels decrease.

<p>Folate⁹</p>	<p>3. Trp load test, measures excretion of the PLP-dependent metabolite xanthurenate acid (XA). 24 hour urine collection required.</p> <p>1. Because of ↓ DNA synthesis, large RBCs are produced. See Chapter 32.</p> <p>2. Shape of neutrophil nucleus affected by folate deficiency.</p> <p>3. Blood folate levels can be directly measured by radioimmunoassay.</p> <p>4. Functional folate status assayed by FIGLU in 24-hour urine or after oral histidine loading.</p> <p>5. Single Nucleotide Polymorphisms (SNPs) MTHFR 677C MTHFR1298C</p>	<p>3. Functional test indicating marginal vitamin B₆ status when the levels of urinary XA decrease significantly following the ingestion of 3-5 g of L-Trp</p> <p>1. Deficiency leads to increase in MCV (mean corpuscular volume) and macrocytic RBCs</p> <p>2. Increased neutrophil lobe count seen in folate deficiency.</p> <p>3. Both RBC and serum folate are indicators of body stores.</p> <p>4. After 2-15 g loading dose, 10-50 mg of FIGLU should be excreted in 8 hours.</p> <p>5. SNPs of compromised methylation (transfer of methyl groups in metabolism) potential in use and conversion of folate or folic acid intracellularly. See Chapter 5.</p>	<p>3. Marginal status: Level of urinary XA decreases <50 mg/24 hr</p> <p>1. Normal: MCV 80-100 fL</p> <p>2. Normal: < or equal 4 lobes per neutrophil</p> <p>3. 2-10 mcg/L serum; 140-960 ng/L RBC (3.2-22 nmol/L)</p> <p>4. Normal: <7.4 mg/24 hours (<42.6 mmol/24 hr) without loading</p> <p>MTHF 677C/1298C Normal = Wild type -/-</p>	<p>3. Steroid drugs and estrogen enzyme activity and some drugs cause analytic errors. Trp load test most sensitive and responsive to functional adequacy of B₆.</p> <p>1. Not sensitive or specific for folate. Possible involvement with B₆, B₁₂, SAME and other cofactors in the methionine pathway.</p> <p>2. Lobe count sensitive but not specific.</p> <p>3. Plasma from non-fasting subjects may reflect recent intake; RBC folate is not measured accurately.</p> <p>4. FIGLU affected by vitamin B₁₂, drugs, liver disease, cancer, tuberculosis, and pregnancy.</p> <p>Other SNPs are known that affect methylation metabolism: COMT, CYP1B1, and other cytochrome enzymes. See Chapter 5.</p>
<p>Cobalamin (B₁₂)</p>	<p>1. Because of low B₁₂ resulting in decreased DNA synthesis, large RBCs are produced.</p> <p>2. Shape of neutrophil nucleus is affected by B₁₂ deficiency.</p> <p>3. B₁₂ can be directly measured by radioimmunoassay.</p> <p>4. Methylmalonic acid excretion (MMA) reflects a functional test of B₁₂ availability for BCAA (branched chain amino acid) metabolism.</p> <p>5. Schilling test for intrinsic factor and B₁₂ absorption assesses radiolabeled B₁₂ absorption as reflected by urinary excretion.</p> <p>6. Homocysteine (Hcy)</p>	<p>1. Deficiency leads to increase in MCV</p> <p>2. Increased neutrophil lobe count in B₁₂ deficiency.</p> <p>3. Levels <150 ng/L indicate deficiency (age affects level).</p> <p>4. MMA excretion >300 mg/24 hr in B₁₂ deficiency. Sensitive test without being overly specific.</p> <p>5. Abnormal B₁₂ absorption indicated by excretion <3% of B₁₂ radioactivity per 24 hours.</p> <p>Hcy level is an independent risk factor for CVD, venous thrombotic disease, and other diseases; folic acid and vitamins B₁₂ and B₆ reduce plasma Hcy levels. Total Hcy (oxidized + reduced forms) is an intermediate amino acid in methionine metabolism.</p>	<p>1. Normal: MCV 80-100 fL</p> <p>2. Normal: < or equal 4 lobes per neutrophil</p> <p>3. 160-950 pg/mL (118-701 pmol/L)</p> <p>4. Normal excretion: 5 mg/24 hr (42 mmol/24 hr) Serum MMA - 0.08-0.56 mmol/L (Normal < 105 ng/mL)</p> <p>5. Normal excretion: ~8% of radioactivity per 24 hours</p> <p>Normal: 4-14 mmol/L Suggested optimal levels: 4-7 mmol/L</p>	<p>1. Not sensitive or specific for B₁₂.</p> <p>2. Lobe count sensitive but not specific.</p> <p>3. Marginal deficiency not correlated with level.</p> <p>4. Specific for B₁₂ but requires normal BCAA levels; available at most laboratories.</p> <p>5. Test must be repeated with oral administration of intrinsic factor (IF) to differentiate IF deficiency and malabsorption. Rarely used because of necessity of radioactive B₁₂.</p> <p>Cardiovascular event risk is increased even at slightly elevated levels.</p> <p>Hcy has a strong association with degenerative neurologic conditions like Parkinson's disease and dementias.</p> <p>Hcy suggests poor methylating capacity of client with need for increased intake of folic acid, B₆, B₁₂, and SAME.</p>

Continued

Ascorbic acid (vitamin C)	Plasma or leukocyte vitamin C measured by (1) chromatography; (2) by ascorbate oxidase; (3) spectrophotometrically by reaction with 2,4-dinitrophenylhydrazine.	Leukocyte C is less affected by recent intake, but plasma levels in fasting person parallel leukocyte levels; plasma preferred for acutely ill patients because leukocyte level is affected by infection, ²² some drugs, and hyperglycemia;	Normal: 0 to 11 months: Not established 1 to 12 years: 0.2–2.3 mg/dL 13+ years: 0.2–2.0 mg/dL (30–80 mmol/L) Adult: 0.2–1.5 mg/dL (12–90 mmol/L) Leukocyte vitamin C: 20–50 mcg/10 ⁸	Blood samples must be carefully prepared for assay to prevent vitamin C breakdown. Oxalate, glucose, and proteins interfere with some assays; recent intake can mask deficiency.
Retinols (vitamin A)	Serum retinol and retinol esters; functional tests (e.g., dark adaptation) only detect severe deficiency; Age and sex important determining factors for normal retinol levels.	Retinol levels <20 mcg/dL (<0.7 mmol/L) indicate severe deficiency; specific levels are being determined for placental/newborn deficiency serum levels.	Normal: 20 to 100 mcg/dL (0.7–3.5 mmol/L) Suboptimum (NHANES II/ Gibson): Age 3–11 y: <0.35 mmol/L Age 12–17 y <0.70 mmol/L Age 18–74 y 0.70–1.05 mmol/L Pregnancy 0.79–1.91 mmol/L Upper Limit: 3.5 mmol/L	Exposure of serum to bright light or oxygen destroys vitamin A; low RBP (retinol binding protein) level is associated with low vitamin A, zinc and iron (see protein-energy section). Vitamin A's gene transcription is on the nuclear RXR; ²² the vitamin D receptor forms a heterodimer, requiring balance between vitamins A and D for optimum function.
Carotene, Serum Total (CARO)	Carotenoids, fat-soluble pigments in plant foods, poorly absorbed in fat malabsorption; light sensitive; transport specimen in amber transport tube; Quantitative Spectrophotometry testing. See Raman Spectroscopy, Chapter 7.	A CARO level of less than 50 mg/dL is seen in ~85% of patients with fat malabsorption.	50–200 mcg/dL (0.74–3.72 mmol/L)	Decreased CARO levels or low spectrophotometry score are also seen in those with low vegetable and fruit diets (e.g., in PN or tube feeding), liver failure, celiac disease, cystic fibrosis, human immunodeficiency virus, and some lipoprotein disorders.
Tocopherols (vitamin E)	Serum alpha- and beta-gammatocopherols serve different antioxidant functions. Growing evidence that beta and gamma tocopherols may be more important than alpha-tocopherol for human vitamin E nutrition.	Lower values found in infants. Interpretation requires monitoring lipid levels; if hyperlipidemia calculate plasma alpha-tocopherol: cholesterol mmol/L ratio <2.2 or alpha-tocopherol <5 mg/L indicates risk of vitamin E deficiency ²³	Normal: alpha-tocopherol 5.7–20 mg/L beta-gammatocopherol 4.3 or less mg/L	Plasma level depends on recent intake and level of lipids, especially TGs, in blood. Smoking and BMI also negatively affect tocopherol levels.
Cholecalciferol (D ₃) and (D ₂) ergocalciferol	1. Alkaline phosphatase activity reflects level of bone activity and indirectly vitamin D status. (see further discussion of ALP in Liver Enzymes section). 2. Cholecalcidiol (D ₃ 25-OH-D) and ergocalciferol (D ₂ 25-OH-D). 3. Calcitriol (1,25-[OH] ₂ -D ₃)	2. <20 ng/mL (<50 nmol/L) indicates deficiency; >200 ng/mL (500 nmol/L) indicates hypervitaminosis D. 3. Used to show that vitamin D metabolism is occurring normally; Active vitamin D to signal nuclear RXR receptor.	Adult: 25–100 U/L Child 1–12 yr: <350 U/L 2. 30 – 100 ng/mL (75 – 250 nmol/L) 3. 2.5–4.5 ng/dL (60–108 pmol/L) (little seasonal change)	1. Not specific, but a sensitive indicator; serum Ca and PO ₄ should also be evaluated. Zinc and B ₁₂ are rate-limiting cofactors for production of alkaline phosphatase; therefore low levels of < 40 U/L suggest possible zinc or B ₁₂ or intrinsic factor insufficiencies. 2. Best indicator of status (liver stores), but marginal levels hard to interpret. ²⁴ Increased BMI and body fat % may reduce serum D ₃ 25-OH vit D. 3. Poor indicator of status because of tight control of synthesis independent of body stores.

<p>25-hydroxyvitamin D (25-OH-D) / Calcifediol/ Calcidiol</p>	<p>Prohormone Vitamin D malabsorption can lead to secondary malabsorption of calcium. Vitamin D supplementation can lead to increased absorption of calcium and phosphorus; supplementation contraindicated for individuals with kidney or gall stones, sarcoidosis, tuberculosis, lymphoma, or when become hypercalcemic with vitamin D supplementation.</p>	<p>Vitamin D insufficiency is defined as the lowest threshold value for plasma 25-OH-D that prevents secondary hyperparathyroidism, bone turnover, bone mineral loss, or seasonal variations in plasma PTH.</p>	<p>25-OH-D: 30-100 ng/mL (85-160 nmol/L) Deficiency: <20 ng/mL (<50 nmol/L) (lab references vary per individual laboratory)</p>	<p>Available at all laboratories. If elevated serum calcium, further evaluation recommended by testing vitamin 1,25 DOH, PTH, ionized or free calcium, vitamin A retinol and osteocalcin (as a vitamin K2 marker) before supplementation.</p>
<p>Phylloquinone (K₁) and Menaquinone (K₂) Menadi- one (K₃)</p>	<p>Normal coagulation factor synthesis requires K1; PT assesses coagulation status. K2 primarily involved with calcium metabolism, including bone health.</p>	<p>In K1 deficiency, PT increases with increasing production of abnormal coagulation factors.^h K1 vegetable plant source; drug-nutrient interaction with blood thinners. K2 animal and bacterial fermented sources. K3 synthetic form of Vitamin K; vitamin precursor to Vitamin K2 known as a provitamin.</p>	<p>K1: 0.13-1.19 ng/mL (0.29-2.64 nmol/L) K2: (not commercially available—see K2 marker, Osteocalcin, below)</p>	<p>The level of vitamin K available for vitamin K-dependent bone proteins may not be reflected by the PT; test references vary significantly with method.</p>
<p>Osteocalcin (OC) / undercarboxylated osteocalcin (ucOC) (K2 marker)</p>	<p>Serum noncollagenous protein specific for bone and dentin formation and turnover. Functional marker of vitamin K2, a rate-limiting cofactor of formation of osteocalcin. One of the osteocalcin fragments, undercarboxylated osteocalcin, is most sensitive K2 marker and associated with risk of fracture.</p>	<p>Can be used as a marker of metabolic trend, suggesting low or high vitamin K2; useful in assessing need for a vitamin K2 rich diet or K2 supplementation to optimize formation of intracellular bone osteocalcin. K2 inhibits soft tissue calcification. OC and ucOC are considered more sensitive markers of bone activity than alkaline phosphatase during corticosteroid therapy.</p>	<p>OC: 11-50 ng/mL ucOC: Normal < 1.65 ng/mL High > 1.65 ng/mL NOTE: Elevated levels associated with low 25-OH-vit D levels</p>	<p>Vitamin K2 is not as involved with coagulation as K1. Vitamin K2 is important in calcium metabolism and therefore calcium and vitamin D status. There is a synthetic vitamin K3, usually administered IV that has similar actions as K2, and is being used as adjunctive to integrative cancer therapy.</p>
<p>B. Minerals</p>				
<p>Electrolytes</p>				
<p>Sodium (Na⁺) Potassium (K⁺) Chloride (Cl⁻) Bicarbonate or total CO₂</p>	<p>Serum electrolytes, including bicarbonate, are usually measured together by ion-specific electrodes in autoanalyzers; sometimes Na and K are measured by flame emission spectrophotometry.^l</p>	<p>Elevated serum Na seen in water loss; decreased serum Na and K occurs in diarrhea and with poor dietary intake or cellular uptake. Decreased chloride levels are seen with cation and osmotic changes in the body. Bicarbonate levels reflect acid-base balance.</p>	<p>Na: 135-145 mEq/L (135-145 mmol/L) K: 3.5-5 mEq/L (3.5-5 mmol/L) Cl: 100-110 mEq/L (100-110 mmol/L) Bicarb or total CO₂: 21-30 mEq/L (21-30 mmol/L)</p>	<p>Electrolytes change rapidly in response to changes in physiology (e.g., hormonal stimulus, renal and other organ dysfunction, acid-base balance changes, and drug action). Serum electrolytes are minimally affected by diet.</p>
<p>Major Minerals</p>				
<p>Calcium (Ca²⁺)</p>	<p>1. Total serum Ca²⁺ (bound and unbound)</p>	<p>Usually slightly more than half of the serum Ca²⁺ is bound to albumin or complexed with other molecules; the remaining Ca²⁺ is called <i>ionized Ca (ICA)</i>; ICA is available physiologically. Elevated IgE and mast cell release increases intracellular calcium ion levels and negatively distributes ICA.</p>	<p>1. 8.6 - 10 mg/dL (2.15-2.5 mmol/L)</p>	<p>Calcium status is related to many factors, including vitamin D, vitamin K2, phosphate, parathyroid function, renal function; medications (thiazide diuretics, lithium), vitamin A toxicity, presence of malignancy</p>
	<p>2. Ionized (free) Ca²⁺</p>	<p>Interpretation of ionized calcium levels requires consideration of other related markers: osteocalcin, vitamin D25-OH vit D and D1,25-OH vit D, and serum retinol (vit A.)</p>	<p>2. 4.64-5.28 mg/dL (1.16-1.32 mmol/L)</p>	<p>Ionized calcium depends on vitamin K2 to enter the bone matrix and to prevent calcification of soft tissue. If phosphate <3.0 mg/dL, check intake of phosphate-binding medications.</p>

Continued

Phosphate (H_2PO_4 , Phosphorus)	Phosphorus in body as phosphate form; test measures inorganic phosphate. Most phosphate is part of organic compounds; small part is inorganic.	Abnormal P level is most closely associated with disturbed intake, distribution, or renal function.	2. 7-4.5 mg/dL (0.87-1.45 mmol/L) (higher in children)	Reported as phosphorus (P), not phosphate; hemolyzed blood cannot be used because of high RBC phosphate levels.
Magnesium (Mg^{2+})	1. Total serum Mg^{2+} measured after reaction to form chromogenic or fluorescent complexes. 2. Ionized (free) Mg^{2+}	Neuromuscular function. Hyperirritability, tetany, convulsion, and electrocardiographic changes occur when levels of total serum Mg^{2+} fall to <1 mEq/L.	1. 1.3-2.5 mEq/L (0.65-1.25 mmol/L) 2. 0.7-1.2 mEq/L (0.35-0.60 mmol/L)	Usually 45% of the serum Mg^{2+} is complexed with other molecules; the remaining Mg^{2+} is called ionized magnesium. Serum levels remain constant until body stores are nearly depleted.
Trace Minerals				
Iron CBC* and RBC indices	1. HCT = % RBC in whole blood 2. Hgb = blood hemoglobin concentration 3. MCV = mean RBC volume = mean corpuscular volume	A CBC with RBC indices is one of the first set of tests that a patient receives; although CBC data are not specific for nutrition status, their universal and repeated presence in the patient's record makes them very important.	1. Females: 35%-47% (0.35-0.47) ¹ Males: 42%-52% (0.42-0.52) 2. Females: 12-15 g/dL (7.45-9.31 mmol/L) Males: 14-17 g/dL (8.44-10.6 mmol/L) 3. 82-99 mm^3 (82-99 fL)	These tests are affected only when iron stores are essentially depleted. HCT and Hgb are sensitive to hydration status; low MCV also occurs in thalassemias and lead poisoning as well as with iron and copper deficiencies; high MCV suggests macrocytic RBCs and possible inadequate folate, vitamins B ₆ , or B ₁₂ .
Serum iron (Fe)	Serum Fe^{3+} reduced to Fe^{2+} and then complexed with chromogen.	Slightly higher in males than in premenopausal females; reflects recent Fe intake.	F: 40-150 mcg/dL (7.2-26.9 mmol/L) M: 50-160 mg/dL (8.9-28.7 mmol/L)	Very insensitive index of total Fe stores; extremely variable (day-to-day and diurnal).
Total Iron Binding Capacity (TIBC)	TIBC determined by saturating serum transferrin with Fe and then remeasuring serum Fe.	Reflects transferrin concentration.	250-400 mcg/dL (45-71 mmol/L)	TIBC does not increase until Fe stores are essentially completely depleted. TIBC decreases with increased Fe stores; used to rule out excess iron intake or hemochromatosis. See Chapter 32
Transferrin (Tf or TFN)	The iron bound globulin protein that responds to the need for iron; half-life ~9 days. (see Chapter 7)	(see Section I:A. Protein Status: Tf)	Females: 250-380 mg/dL (2.15-3.80 g/L) Males: 215-365 mg/dL (2.15-3.65 g/L) Newborn: 130-275 mg/dL Child: 203-360 mg/dL	Transferrin is low when Fe stores essentially depleted. Transferrin is low with low vitamin B ₆ and low Tf-sat in aplastic anemia.
Transferrin Saturation (Tf-sat or TSAT)	Tf-sat (%) = Serum iron level ÷ TIBC × 100%	(see Section I:A. Protein Status : Tf-sat)	Females: 15%-50% Males: 20%-50% Chronic illness - normal Tf-sat%. Late pregnancy low Tf-sat%.	
RBC Distribution Width (RDW)	Measurement of variation in RBC diameter (anisocytosis); reported to be helpful in distinguishing Fe deficiency from anemia associated with chronic inflammation.	Very sensitive indicator of Fe status; normal RDW reportedly rules out anemia caused by chronic inflammatory diseases. ^m Thalassemia (low MCV, normal RDW) differentiated from iron-deficiency (low MCV, high RDW)	Normal value: 11.0-14.5% Microscopic electronic interpretation required.	Specificity of RDW for Fe deficiency is relatively low; interpretation confounded by RBC transfusion; measurement usually not reported.

Ferritin	The primary intracellular Fe-storage protein; stored mostly in liver; serum levels parallel iron stores;	Best biochemical index of uncomplicated iron deficiency or overload (iron toxicity) and excess storage. Rule out hemochromatosis or pancreatitis if Ferritin >1000 ng/dL (>1000 mcg/L).	Iron overload: >400 ng/mL (mcg/L) With anemia of chronic disease: <100 ng/mL (<100 mcg/L) F: 10-150 ng/mL (10-150 mcg/L) M: 12-300 ng/mL (12-300 mcg/L) Females with anemia of chronic disease: <20 ng/mL (<20 mcg/L) 6 mos.-15 yr: 7-142 ng/mL (7-142 mcg/L) <1 mo. - 5 mos.: 50-200 ng/mL (50-200 mcg/L) Newborn: 25-200 ng/mL (25-200 mcg/L)	A positive acute phase reactant that increases during metabolic response to injury, even when Fe stores are adequate; not useful in anemia of chronic and inflammation diseases.
Zinc (Zn) ⁿ	Serum levels measured by atomic absorption spectrophotometry.	Serum levels affected by diet and the inflammatory response. Zinc deficiency associated with many diseases and trauma.	0.7-1.2 mg/L (11-18 mmol/L)	Serum levels detect frank—but not marginal—deficiency; blood must be collected in zinc-free tubes.
Copper (Cu)	1. Serum levels measured by flame emission atomic absorption spectrophotometry (AS) or Inductively-Coupled Plasma/Mass Spectrometry (ICP/MS). 2. Ceruloplasmin is the major Cu-containing plasma protein; measured by immunoassay (e.g., nephelometry).	1. Cu deficiency is associated with neutropenia, anemia, and scurvy-like bone disease and megadoses of zinc. 2. Ceruloplasmin is required for conversion of Fe ³⁺ to Fe ²⁺ during cellular Fe uptake. Anemia can result from low ceruloplasmin. Ceruloplasmin is useful biomarker to follow Tetrathiomolybdate™ (T.M.) copper chelation for Wilson's Disease and cancer anti-angiogenesis copper chelation therapy. ²⁵	Adult: 70-175 mcg/dL (11-28 mmol/L) 20 to 35 mg/dL (1-4 mmol/L)	1. Serum levels detect frank but not marginal deficiency; use of oral contraceptives lowers serum Cu. 2. Ceruloplasmin not a useful marker of Cu status, but can be used to assess changes in status after supplementation; useful to calculate free copper index with serum zinc and serum copper as a cancer biomarker. ^{26,28,29}
Selenium (Se)	1. Serum selenium test 2. Whole blood levels better reflect long-term status.	Margin between deficiency and toxicity is narrower for Se than any other trace component of the antioxidant enzyme element; important in glutathione peroxidase.	(1) 80-320 mcg/L (1-4 mmol/L) (2) 60-340 mcg/L (0.75-4.3 mmol/L)	Cutoff points for deficiency or toxicity are not well established.
Iodine (I)	Urinary excretion is best indicator of I status, either mcg/24 hr or mcg/g creatinine; thyroid hormone level related to I status. Urine test can use 50 mg I/KI challenge.	Excretion should be 24-hour urine >70 mcg/g creatinine. it can be beneficial to test thyroid hormone and antibodies (TSH, T ₃ -free, T ₄ -free, thyroid peroxidase and thyroglobulin antibodies) for improved interpretation. Iodine important for other metabolic functions.	No urinary I reference range; T ₄ reference range: F: 5-12 mcg/dL (64-154 mmol/L) M: 4-12 mcg/dL (51-154 mmol/L)	Thyroid hormone levels are affected by many factors besides iodine status. Other halogen elements (Br+, I+, Cl+) are known antagonists to iodine metabolism; when completing the iodine urine testing, some laboratories will also test for bromine, fluorine, and chlorine.
Creatinine (Cr)	Urinary excretion usually tested by atomic absorption spectrophotometry.	Excretion should be 0.63-2.50 g/24 hr; deficiency reported in patients on long-term PN; decreased levels in diabetes mellitus.	10-200 ng/dL (1.9-38 nmol/L)	Test not available in most clinical laboratories; special handling required to prevent specimen contamination during collection.

Continued

VI. Blood Gases and Hydration Status

pH	pH = $-\log [H^+]$; H^+ depends mainly on the CO_2 from respiration: $CO_2 + H_2O \leftrightarrow H_2CO_3 \leftrightarrow HCO_3^- + H^+$ Measured by ion-selective electrodes (like those found in common pH meters)	Acidosis: pH <7.35 Alkalosis: pH >7.45 pH compatible with life: 6.80-7.80.	Whole blood: Arterial pH: 7.35-7.45 Venous pH: 7.32-7.42	Blood must not be exposed to air before or during measurement.
PO_2 and O_2 saturation (SaO ₂)	Whole blood O_2 measured by oxygen electrode. PO_2 = "pressure" contributed by O_2 to the total "pressure" of all the gases dissolved in blood. O_2 Content (CaO ₂) = $O_2/gm\ SaO_2 \times Hgb\ (gm/dl) \times 1.34\ ml + PaO_2 \times (.003\ ml\ O_2/mm\ Hg/dl)$ $PaO_2 = FIO_2(PB-47) - 1.2(PaCO_2)$	Affected by alveolar gas exchange, ventilation-perfusion inequalities, and generalized alveolar hypoventilation.	Arterial blood: PaO ₂ : 83-108 mm Hg <40 mm Hg = critical value (gravely dangerous) O_2 saturation: 0.95-0.98 (95%-98%) Elderly = 95% Newborn = 40-90%	Blood must not be exposed to air before or during measurement.
PCO ₂	Measured by ion-selective electrode; "pressure" contributed by CO_2 to the total "pressure" of all the gases dissolved in blood.	Increased in respiratory acidosis (increased CO_2 in inspired air or decreased in alveolar ventilation) and decreased in respiratory alkalosis (e.g., in hyperventilation from anxiety, mechanical ventilator, or closed head injury [damaged respiratory center]).	Whole blood: Arterial F: 32-45 mm Hg M: 35-48 mm Hg Venous 6-7 mm Hg higher	Blood must not be exposed to air before or during measurement.
Bicarbonate (HCO_3^-) and total CO_2 (tCO ₂)	For whole blood (HCO_3^-) is calculated from the equation given in pH section.	Increased in compensated respiratory acidosis and in metabolic acidosis; decreased in metabolic acidosis and in compensated respiratory alkalosis.	Whole blood, arterial: 21-28 mEq/L (21-28 mmol/L)	Blood must not be exposed to air before or during measurement.
Osmolality (Osmol), serum	Osmol depends on amount of particles (solutes) dissolved in a solution; measurement based on relationship between solute concentration and freezing point; serum osmol assesses hydration status and solute load.	Serum Osmol increases in dehydration, diabetic coma, diabetic ketoacidosis; also estimated from the formula: $mOsmol/L = 2\ (Na^+) + (Glucose\ mg/dL)/18 + (BUN\ mg/dL)/2.8$	282-300 mOsm/kg H ₂ O (1 Osmol = 1 mol of solute particles; 1 kg serum/L)	Freezing point depression gives a more accurate estimate of osmol than the calculated value (e.g., in ketoacidosis).
Urinalysis: Specific Gravity (Sp.Gr.)	Specimen midstream clean-catch if infection suspected, or regular collection. Dip Stick or laboratory testing for Specific Gravity.	One of a multiple of tests on a urine specimen. Sp.Gr. is a measure of concentration of particles and electrolytes in the urine.	Adult: 1.005-1.030 Sp.Gr. Newborn: 1.001-1.020 Sp.Gr.	Appearance can also give subjective indication of fluid concentration; darker color = higher concentration.

VII. Tests of Antioxidant Status and Oxidative Stress

Water-soluble compounds	See Vitamin C above.			
Lipid-soluble compounds: see Vitamin E, Carotenoids, and Coenzyme Q ₁₀	The carotenoids: lutein, xanthine zeaxanthin, alpha- and beta-carotene, and lycopene; carotenoids and coenzyme Q ₁₀ (ubiquinone-10) are measured chromatographically	Reference ranges for these compounds vary greatly, depending on the method used for their assay.	See reference for carotenoid range under fat malabsorption	Tests for carotenoids and coenzyme Q are not yet available for routine clinical use.
Total antioxidant capacity (e.g., ORAC, TEAC, FRAP)	ORAC: Oxygen radical absorbance capacity TEAC: Trolox-equivalent antioxidant capacity FRAP: Ferric-reducing ability of plasma. See Raman Spectroscopy in Chapter 7 for carotenoid assessment.	These assays reflect the presence of all of plasma or serum antioxidants, including vitamins C and E, carotenoids, coenzyme Q ₁₀ , glutathione, uric acid, bilirubin, superoxide dismutase, catalase, glutathione peroxidase, and albumin.		These assays are now commercially available but are currently performed only in specialized laboratories. Testing botanicals also available.

Oxidative stress markers:	Free radical oxidation products of lipids	8-Isoprostane (also called 8-epi-prostaglandin F _{2a}) increases in plasma or urine of patients with lung disease, hypercholesterolemia, or diabetes mellitus. 8HDG represents whole-body cytosolic and nuclear free radical activity, including status of DNA. Lipid peroxides is a marker of membrane oxidative damage by reactive oxygen species (ROS) to PUFAs of cell membranes.	Examples: o-tyrosine nitro-tyrosine 8-isoprostane 4-hydroxynonenal malondialdehyde Lipid Peroxides 8-hydroxy-2-deoxyguanosine (8-OHDG) (refer to Laboratory references)	8-Isoprostane assays are now commercially available. Markers of oxidative stress are currently assayed only in specialized laboratories.
VIII. Tests for Monitoring Nutrition Support				
CRP (see section V. hs-CRP)	CRP is an acute-phase protein used to assess inflammatory status.	Large increases in CRP are associated with development of a catabolic state during the stress response; CRP levels begin to fall when the anabolic phase is entered.	CRP <10 mg/L	Serial values rather than a single value must be used to specify the stage of the stress response.
Chemistry panel with phosphate and Mg ²⁺	Panel includes electrolytes, glucose, creatinine, BUN, and total CO ₂ (bicarbonate); see earlier discussion for additional test information.	Used to monitor carbohydrate tolerance, hydration status, and major organ system function.	See earlier discussion on phosphate and magnesium.	Very frequently ordered test panel.
Osmolality	(see discussion in VII. Blood Gases and Hydration Status)			
Protein-Energy Balance	(see earlier discussion on PAB, RBP, Tf, ALB, nPCR, Nitrogen Balance, UUN and TUN)			
Minerals: Zn, Cu, Se, Cr	(see earlier discussion of serum zinc, serum copper, ceruloplasmin, and lymphocyte micronutrient testing)			
Vitamins C, D and A	(see earlier discussion of vitamins C, D and A) Because vitamins C, 25-OH-D, and A are important in immune function and wound healing, they should be assessed regularly.	Note regarding TPN nutritional monitoring: Vitamin C levels can ↓ sharply in response to stress. Vitamin D and A nuclear receptors share the same connection with the RXR receptor which have synergistic function and should be monitored congruently. ^{27,28}		Note regarding TPN nutritional monitoring. Systematic, regular monitoring protocol should be followed. 25-OH-vit D is produced in the liver and can be suppressed with hepatic stress conditions. ²⁹
Vitamin K1 & K2 status	(TPN only) (see earlier discussion) Contribution of the gut flora to vitamin K status is absent during TPN, and basic TPN formulas are devoid of it.			Important to differentiate between vitamin K1 and K2.
IX. Liver Function Tests				
Bilirubin (BILI T/D) (Direct and Indirect)	Total serum bilirubin represents both conjugated or direct bilirubin, and unconjugated or indirect bilirubin. Elevated levels suggest medical problem.	Conjugated bilirubin levels are elevated with cancer of pancreas or liver and bile duct obstruction; unconjugated bilirubin level elevated with hepatitis and jaundice anemias	Total bilirubin: 0.3-1 mg/dL (5.1-17 mmol/L) Direct bilirubin: 0.1-0.3 mg/dL; (1.7-5.1 mmol/L) Indirect bilirubin: 0.2-0.8 mg/dL (3.4-12 mmol/L)	Many medications are associated with elevated bilirubin levels.
Alanine Amino Transferase (ALT)	Enzyme found primarily in the liver (also called serum glutamic pyruvic transaminase (SGPT).	Injury to the liver results in elevated levels of ALT. Depressed in malnutrition.	4-36 U/L Infant: 2 x adult levels	Many medications and alcohol intake are associated with elevated ALT levels. ALT levels are often compared with AST for differential diagnosis.
Gamma-glutamyl transferase (GGT)	Biliary excretory enzyme involved in transfer of amino acids across cell membranes.	Used to evaluate progression of liver disease and screening for alcoholism	F: 4-25 U/L M: 12-38 U/L	Many medications are associated with elevated GGT levels.

Continued

Alkaline phosphatase (ALP)	Enzyme found primarily in the bone, liver, and biliary tract; increased in an alkaline environment.	Elevated levels noted in liver and bone disorders.	30-120 U/L	Nonspecific test; other tests need to confirm diagnosis. Many medications are associated with elevated ALP levels.
Aspartate Amino Transferase (AST)	Enzyme primarily found in the heart, liver, and skeletal muscle cells. (Also called serum glutamic oxaloacetic transaminase (SGOT))	Diagnostic tool when coronary occlusive heart disease or hepatocellular disease is suspected.	0-35 U/L	Many medications are associated with elevated AST levels. AST levels are often compared with ALT for differential diagnosis.
Alpha 1 Antitrypsin (A1AT)	A1AT is a serine protease inhibitor secreted primarily by hepatocytes. Most common genetic A1AT variants are ZZ, SS, MZ, SZ. Measured by serum electrophoresis.	Decreased or absent Alpha-1-band in serum electrophoresis; A1AT is an acute-phase reactant associated with emphysema, COPD and cirrhosis of the liver; A1AT elevated with states of inflammation, infection or malignancy.	85-213 mg/dL (0.85-2.13 g/L) Homozygous + + variants: severe disease early in life. 80 known variants of A1AT gene: heterozygous ZZ and SS gene variants: majority have hepatic or pulmonary symptoms MZ and SZ milder gene variants: rarely have symptoms. ^{9,P}	There are 100 known variants of the A1AT gene. ^{9,P} If a person is not diagnosed with a severe form as a child, an individual may not be identified until an adult with end-stage lung and liver disease.
X. Thyroid Function Tests				
Thyroxine Total T ₄ and free T ₄	Measures the total amount of T ₄ in the blood; free T ₄ is the active form. See Chapter 31.	T ₄ increased in hyperthyroidism; T ₄ decreased in hypothyroidism and malnutrition	T ₄ , Total F: 5-12 mcg/dL; (64-154 nmol/L) M: 4-12 mcg/dL (51-154 nmol/L) Free T ₄ = 0.7-1.9 ng/dl (10-23 pmol/L)	Tests are ordered to distinguish between euthyroidism, or hyperthyroidism and hypothyroidism. Can be related to iodine deficiencies.
Triiodothyronine T ₃ , Total and free T ₃	Measures the total amount of T ₃ in the blood; free T ₃ active form. See Chapter 31.	Hyperthyroidism-usually elevated; hypothyroidism-usually decreased and can show low function of thyroid peroxidase enzyme when T ₄ normal or high, and T ₃ low (poor conversion).	Total T ₃ 20-50 yr: 70-205 ng/dL (1.2-3.4 nmol/L) >50 yr: 40-180 ng/dL (0.6-2.8 nmol/L) Free T ₃ : 230-619 pg/mL	Tests are ordered to distinguish between euthyroidism, or hyperthyroidism and hypothyroidism. If low T ₃ levels, consider insufficient nutrient cofactors (selenium, vitamin E) for thyroid peroxidase enzyme conversion of T ₄ to T ₃ .
Thyroid-stimulating hormone (TSH)	Used to monitor exogenous thyroid replacement or thyroid suppression; also used as a screening test for thyroid function. See Chapter 31.	Decreased TSH in hyperthyroidism; elevated TSH in hypothyroidism	0.5-5 mIU/L AACE Standards: Target TSH: 0.3-3.0 µIU/mL ⁹	Tests are ordered to distinguish between euthyroidism, hyperthyroidism and hypothyroidism. If depressed, use caution with iodine intake. If elevated, consider assessing nutrient cofactors: iodine, selenium, vitamin E, A.
Antithyroglobulin antibody (anti-TG)	Anti-TG blood test used as a marker for autoimmune thyroiditis and related diseases. ³⁰ High prevalence of thyroid autoantibodies in celiac and rheumatoid arthritis patients	Anti-TG autoantibodies bind to thyroglobulin and affect thyroid hormone synthesis, storage and release. Recommend investigation of gluten intolerance if elevated Anti-TG.	Titer <4 IU/mL Anti-TG often tested in conjunction with Anti-TPO test.	Resulting disordered thyroid function seen most with common related conditions: Hashimoto's thyroiditis and autoimmune hypothyroid.
Antithyroid peroxidase antibody (Anti-TPO or TPO-AB)	Anti-TPO blood test used in the diagnosis of thyroid diseases, such as Hashimoto's thyroiditis or chronic lymphocytic thyroiditis (in children). High prevalence of thyroid autoantibodies in celiac and rheumatoid arthritis patients	Thyroid microsomal antibodies act on section of the microsome in the thyroid cell and initiate inflammatory and cytotoxic effects on the thyroid follicle. Recommend investigation of gluten intolerance if elevated Anti-TPO.	TPO AB <9 IU/mL Anti-TPO often tested in conjunction with Anti-TG test.	Most sensitive assay for antimicrosomal antibody. Nutritional considerations are vitamin E and selenium cofactors for production of TPO enzyme.

XI. Tests for Metabolic Disease

<p>Amino acidurias</p>	<p>Dietary treatment is the major therapy for many of these genetic diseases: phenylketonuria, cystinuria, maple syrup urine disease, tyrosinemia, homocystinuria, Hartnup disease. See Chapter 42. Urine or plasma amino acid testing.</p>	<p>Monitoring amino acid level in urine or serum is necessary to assess adequacy of treatment.</p>	<p>Examples: Phe: 2-6 g/L (120-360 mmol/L) Phe (during pregnancy): 2-6 mg/dL (120-360 mmol/L) Cys: 2-22 g/L (10-90 mmol/L) Val: 17-37 g/L (145-315 mmol/L) Tyr: 4-16 g/L (20-90 mmol/L) (see particular lab references)</p>	<p>There are several methods used to measure (e.g., phenylalanine); these usually do not have exactly equivalent reference ranges.</p>
<p>Organic Acids Panel</p>	<p>Urine organic acids panel; home collection of 10 ml sample of nocturnal and first morning urine, frozen and then shipped to lab.⁹</p>	<p>Sensitive, broad range test that evaluates comprehensive functional markers for metabolic nutrient pathway functions that can suggest early markers for risk of disease or metabolic imbalances.</p>		<p>Excellent for overview of metabolic function and non-invasive pediatric testing.</p>
<p>Diabetes Mellitus (See Chapter 31)</p>				
<p>Prediabetes diagnosis</p>	<p>Fasting Blood Glucose (FBG)</p>	<p>Prediabetes, blood glucose levels are higher than normal but not high enough for a diagnosis of diabetes.</p>	<p>Non-diabetic FBG = < 99 mg/dL Impaired fasting glucose: 100-125 mg/dL</p>	<p>American Diabetes Association recommends testing for prediabetes in adults without symptoms who are overweight or obese, and who have one or more additional risk factors for diabetes.</p>
<p>Diabetes diagnosis</p>	<p>1. Serum or whole blood glucose: after fasting 8-16 hours or on a random blood sample. 2. Glucose tolerance test (GGT); 75 g glucose (100 g during pregnancy) given after fasting; serum glucose measured by before and five times during the next 3 hours after oral dosing. Glucose measured by automated chemistry procedure.</p>	<p>1. Two or more FBG levels >126 mg/dL are diagnostic; random level >200 mg/dL followed by fasting level >126 mg/dL are diagnostic. Fasting levels of 110 to 126 mg/dL indicate impaired glucose tolerance (IGT.) 2. Serum levels FBG >200 mg/dL at 2-hour point is diagnostic; 2-hour level <140 and all 0- to 2-hour levels <200 are normal; 140-199 at 2 hours indicates IGT. Gestational diabetes: fasting >105; 1-hour GGT >190; 2 hour GGT >165; and 3-hour GGT >145 mg/dL.</p>	<p>2. Serum: Fasting: <110 mg/dL (<6.1 mmol/L) 30 min: <200 mg/dL (<11.1 mmol/L) 1 hour: <200 mg/dL (<11.1 mmol/L) 2 hours: <140 mg/dL (<7.8 mmol/L) 3 hours: 70-115 mg/dL (<6.4 mmol/L) 4 hours: 70-115 mg/dL (<6.4 mmol/L) Urine: glucose negative</p>	<p>1. Elevated glucose levels normally appear with physiologic stress; whole blood gives slightly lower values. 2. Often used for confirmation; ambulatory patient only; bed rest or stress impairs GGT; inadequate carbohydrate consumption before test invalidates results.</p>

Continued

Diabetes monitoring	<ol style="list-style-type: none"> 1. Blood glucose—monitoring requires that <i>the patient</i> monitor blood glucose level. 2. Serum fructosamine—assesses medium-term glucose control by measured glycated serum proteins; currently testing available in the laboratory and home tests. 3. Serum glycated hemoglobin or HgbA1C—assesses longer-term glucose control. 4. Porphyrin urine or whole blood testing for dioxin,³¹ a toxin with significant association with promoting diabetes 	<ol style="list-style-type: none"> 1. Tight diabetes control requires frequent monitoring of glucose levels. 2. Allows assessment of average glucose levels for previous 2-3 weeks. 3. Allows assessment of average glucose levels for previous 2-3 months and verification of patient's serum glucose log. 	<ol style="list-style-type: none"> 1. 70-99 mg/dL (3.9-5.5 mmol/L) 2. Normal levels: 1%-2% of total protein Ranges vary according to method used. 3. Normal levels: Nondiabetic: 4-5.9% Good diabetic control: 4-7% Fair diabetic control: 6%-8% Poor diabetic control: >8%; Mean blood sugar 205 mg/dL or greater is associated with increased risk of side effects 	<p>A combination of glucose monitoring (by patient) and laboratory measurement of glycated proteins are needed to effectively monitor glucose control; fructosamine must be interpreted in light of plasma protein half-lives, and HgbA1C must be interpreted in light of RBC half-life.</p> <p>Department of Defense study (July 2005) 47% percent increase in diabetes among veterans with the highest levels of dioxin.³¹</p>

A1AT, alpha 1 antitrypsin; AACE, American Association of Clinical Endocrinologists; A/C ratio, albumin/globulin ratio; AGA, antigliadin antibodies; ALA, alpha linolenic acid; ALB, albumin; ALP, alkaline phosphatase; ALT, alanine amino transferase; Anti-TG, antithyroglobulin antibody; Anti-TPO, antithyroid peroxidase antibody; AST, aspartate aminotransferase; BAL, bronchoalveolar lavage; BCAA, branched-chain amino acid; BILI T/D, Bilirubin Total/Direct; BUN, blood urea nitrogen; CAPD, continuous ambulatory peritoneal dialysis; CBC, complete blood count; CD, cardiac disease; CHD, coronary heart disease; Cr, chromium; CRP, C-reactive protein; CSF, cerebrospinal fluid; CVD, cardiovascular disease; DGLA, dihomogammalinolenic acid; DGP, deamidated gliadin peptide antibody; DHA, docosahexaenoic acid; DNA, deoxyribonucleic acid; DRI, dietary reference intake; DRT, diet readiness test; EDTA, ethylenediaminetetraacetic acid; EFA, essential fatty acid; EMA, endomysium antibody; EPA, eicosapentaenoic acid; FAD, flavin adenine dinucleotide; FIGLU, formiminoglutamic acid; FBG, fasting blood glucose; FBS, fasting blood sugar; FPG, fasting plasma glucose; FRAP, ferric-reducing ability of plasma; GGT, gamma glutamyl transferase; GH, growth hormone; GI, gastrointestinal; GLOB, globulin; GOT, glutamic-oxalacetic transaminase; GPT, glutamic-pyruvate transaminase; GR, glutathione reductase; GU, urea generation rate; HBT-lactose, hydrogen breath test-lactose; HBT-fructose, hydrogen breath test-fructose; HCT, hematocrit; Hcy, homocysteine; Hgb, hemoglobin; HLA, human leukocyte antigen; HPLC, high performance liquid chromatography; hs-CRP, high-sensitivity C-reactive protein; I, iodine; ICA, ionized calcium; Ig, immunoglobulin; IGF, insulin-like growth factor; IGT, impaired glucose tolerance; IV, intravenously; KrU, residual renal urea clearance; KtV_{urea}, urea kinetics(kinetic dialyzer) x time(min)/volume urea(ml); LA, linoleic acid; LDL, low-density lipoprotein; MCV, mean cell volume; MLC, mixed lymphocyte culture; N, nitrogen; NCEP, National Cholesterol Education Program; NSAID, nonsteroidal antiinflammatory disease; nPCR, normalized protein catabolic rate; ORAC, oxygen radical absorbance capacity; PAB, prealbumin; PCR, protein catabolic rate; PEM, protein-energy malnutrition; PLP, pyridoxal phosphate; PNA, protein equivalent of nitrogen appearance; PT, prothrombin time; PTH, parathyroid hormone; PTT, partial thromboplastin time; PUFA, polyunsaturated fatty acid; RBC, red blood cell; RBP, retinol-binding protein; RDW, RBC distribution width; ROS, reaction oxygen species; RXR, retinoid X receptor; SAME, s-adenosylmethionine; SNP, single nucleotide polymorphism; T₃, triiodothyronine; T₄, thyroxine; T1DM, type 1 diabetes mellitus; TEAC, trolox-equivalent antioxidant capacity; Tf-sat, transferrin saturation; TG, triglyceride; TIBC, total iron-binding capacity; TLC, total lymphocyte count; TP, total protein; TPN, total parenteral nutrition; TPP, thiamin pyrophosphate; Trp, tryptophan; TSAT, transferrin saturation; tTG, tissue transglutaminase; TUN, total urinary nitrogen; U: Cr, urea/creatinine ratio; UUN, urea urinary nitrogen; VLDL, very-low-density lipoprotein; WBC, white blood cell; XA, xanthuric acid.

*Factor = 5.95 for TPN; reflects severity of metabolic stress.

*Factor = 5.95 for TPN; reflects severity of metabolic stress; TUN gives the most accurate estimation of total protein catabolism.

*Red blood cells are separated from plasma by centrifugation and washed with saline; after hemolyzing the cells, the intracellular material is analyzed for vitamin availability.

*No biochemical tests have been developed to assess B₃ status; the fraction of whole blood niacin as NAD is a potentially useful test (see Powers HJ: Current knowledge concerning optimum nutritional status of riboflavin, niacin, and pyridoxine, *Proc Nutr Soc* 58:435, 1999).

*ALT and GPT are the same enzyme; AST and GOT are the same enzyme.

*PLP is a rate-limiting co-enzyme in the transamination of amino acids (ALT and AST). PLP found primarily in liver and muscles.

*Microbiologic growth assays, the deoxyuridine suppression test, and recently developed research tests for folate and vitamin B₁₂ are not generally offered in the contemporary clinical laboratory.

*More sensitive procedures for measurement of vitamin K include serum chromatography and determination of the serum level of vitamin K-dependent bone protein called osteocalcin. Deficiency significantly increases the amount of abnormal forms of this protein. These tests are not yet widely available.

*These substances are measured by similar techniques when the concentration in urine or other body fluids is determined.

*These tests are combined with serum glucose, creatinine, and BUN on a test battery or panel. This set of tests is among the first and most frequently administered laboratory tests.

*The CBC includes the red cell count, the red cell indices, Hb concentration, HCT, MCV, mean cell hemoglobin (MCH), mean cell hemoglobin concentration (MCHC), and white cell and platelet counts. Only HCT, Hb, and MCV are discussed here (see Savage RA: The red cell indices: yesterday, today, and tomorrow, *Clin Lab Med* 13:773-785, 1993).

*Ranges are for adult men and premenopausal women. Pregnant women, infants, and children have different reference ranges.

**See van Zeven D et al: Evaluation of microcytosis using serum ferritin and red cell distribution width, *Eur J Haematol* 44:106-109, 1990.

*Taste acuity tests can be used to supplement laboratory methods (see, e.g., Gibson RS et al: A growth limiting mild zinc deficiency syndrome in some Southern Ontario boys with low growth percentiles, *Am J Clin Nutr* 49:1266, 1989)

*AACE supports target TSH level between 0.3- and 3.0 mIU/mL to reduce the incidence of risks associated with subclinical hypothyroidism. AACE Task Force Thyroid Guidelines, *Endocr Pract*. 8:466, 2002.

*More recent awareness of the highly undiagnosed common disease of A1AT is improving education of healthcare providers regarding this condition. Kohnlein, T, Welte T: alpha-1 antitrypsin deficiency: pathogenesis, clinical presentation, diagnosis, and treatment, *The Am J of Med* 121:3, 2008.

*organic acid functional markers for metabolic effects of micronutrient inadequacies, toxic exposure, neuroendocrine activity and intestinal bacterial overgrowth. Lord R, Bralley J: Organics in urine: assessment of gut dysbiosis, nutrient deficiencies and toxemia. *Nutr Pers* 1997:20:25.

Nutritional Implications of Selected Drugs

Doris Dudley Wales BA, BS, RPh,
DeeAnna Wales VanReken, MS, RDN, CD

Drug	Drug Effect	Nutritional Implications and Cautions
Selected Antiinfective Drugs		
Antibacterial Agents		
Penicillins		
<ul style="list-style-type: none"> amoxicillin (Amoxil) amoxicillin/clavulanic acid (Augmentin) 	<p>Long-term use may lead to oral candidiasis, diarrhea, epigastric distress. Some products contain high amounts of potassium or sodium. May cause <i>Clostridium difficile</i>.</p>	<p>Use caution with low-sodium diet or potassium supplements. Augmentin: take with food to ↓ GI distress. Replace fluids & electrolytes for diarrhea. Probiotic is advised.</p>
Macrolides		
<ul style="list-style-type: none"> azithromycin (Zithromax) clarithromycin (Biaxin) erythromycin (Ery-Tab) 	<p>May cause GI distress, anorexia, stomatitis, dysgeusia, or diarrhea. May increase sedative effect of alcohol. May cause <i>Clostridium difficile</i>.</p>	<p>Take with food to ↓ GI distress. Eat frequent, small, appealing meals to counteract anorexia. Use mouth rinses, fresh mint, or lemon water for dysgeusia. Replace fluids & electrolytes for diarrhea. Avoid alcohol. Probiotic is advised.</p>
Sulfonamide Combination		
<ul style="list-style-type: none"> sulfamethoxazole/trimethoprim (Bactrim) 	<p>May interfere with folate metabolism, especially with long-term use. May cause stomatitis, anorexia, nausea and vomiting, severe allergic reactions. May cause <i>Clostridium difficile</i>.</p>	<p>Take with food and 8 oz fluid to ↓ nausea, vomiting, and anorexia. Replace fluids & electrolytes for diarrhea. Supplement folic acid as needed. Discontinue and consult physician at first sign of allergic reaction. Probiotic is advised.</p>
Cephalosporins		
<ul style="list-style-type: none"> cephalexin (Keflex) cefprozil (Cefzil) ceftriaxone (Rocephin) cefuroxime (Ceftin) cefdinir (Omnicef) 	<p>May cause stomatitis, sore mouth and tongue and interfere with eating. May cause diarrhea and <i>Clostridium difficile</i>.</p>	<p>Replace fluids & electrolytes for diarrhea. Eat moist, soft, low-salt foods and cold foods such as ice chips, sherbet, and yogurt for stomatitis and sore mouth. Probiotic is advised.</p>
Fluoroquinolones		
<ul style="list-style-type: none"> ciprofloxacin (Cipro) levofloxacin (Levaquin) moxifloxacin (Avelox) 	<p>Food ↑ bioavailability of tablets and suspension. Antacids, Ca, and Mg supplements may ↓ bioavailability. Drug may rarely precipitate in renal tubules. Drug will bind to magnesium, calcium, zinc, and iron, forming an insoluble, unabsorbable complex. May cause <i>Clostridium difficile</i>.</p>	<p>Take with a meal for optimal bioavailability. Take separately from antacids, Ca, or Mg supplements. Probiotic may be advised.</p>
Cipro: Inhibits metabolism of caffeine, and can therefore ↑ CNS stimulation.		
Antimicrobial Agents		
Oxazolidinone		
<ul style="list-style-type: none"> linezolid (Zyvox) 	<p>Drug exhibits mild monoamine oxidase inhibition. May cause taste change, oral candidiasis, and <i>Clostridium difficile</i>.</p>	<p>Avoid significant amounts (>100 mg) of high tyramine/pressor foods. See chart in 18th ed. of <i>Food Medication Interactions</i>. Eat small, frequent, appealing meals if tastes change. Replace fluids & electrolytes for diarrhea. Probiotic is advised.</p>
Tetracyclines		
<ul style="list-style-type: none"> tetracycline (Sumycin) doxycycline (Vibramycin) 	<p>Often used to treat Lyme disease; may cause anorexia. Binds to Mg, Ca, Zn, and Fe, forming an insoluble unabsorbable complex. May ↓ bacterial production of vitamin K in GI tract. Long-term use may cause B vitamin deficiencies. Combining with vitamin A may ↑ risk of benign intracranial hypertension. May cause <i>Clostridium difficile</i>.</p>	<p>Take supplements separately by 3 hours. Eat frequent, small, appealing meals to ↓ anorexia. Avoid excessive vitamin A while taking drug. Long-term use may warrant Vitamins K and B supplementation. Probiotic is advised. Replace fluids & electrolytes for diarrhea. Sumycin: Take drug 1 hour before or 2 hours after food or milk.</p>
Antiprotozoal/Antibacterial		
<ul style="list-style-type: none"> metronidazole (Flagyl) clindamycin (Cleocin) 	<p>May cause anorexia, GI distress, stomatitis, and metallic taste in mouth. May cause disulfiram-like reaction when ingested with alcohol. Often used to treat <i>Clostridium difficile</i>. May cause weight loss, increased thirst, esophagitis, nausea, vomiting, cramps, flatulence, bloating, or diarrhea. May cause severe <i>Clostridium difficile</i>.</p>	<p>Take with food to ↓ GI distress. Eat small, frequent, appealing meals to decrease anorexia. Avoid all alcohol during use and for 3 days after discontinuation. Probiotic is advised.</p> <p>Take oral forms with food or 8oz water to decrease esophageal irritation. Replace fluids & electrolytes for diarrhea. Probiotic is advised.</p>

Continued

Drug	Drug Effect	Nutritional Implications and Cautions
Nitrofurantoin <ul style="list-style-type: none"> nitrofurantoin (Macrobid) 	Peripheral neuropathy, muscle weakness and wasting may occur with preexisting anemia, vitamin B deficiency or electrolyte abnormalities. May cause <i>Clostridium difficile</i> .	Drug should be taken with adequate calories, protein, and vitamin B complex. Avoid in G-6-PD deficiency because of increased risk of hemolytic anemia. Replace fluids & electrolytes for diarrhea. Probiotic is advised.
Antituberculars <ul style="list-style-type: none"> isoniazid (Nydrazid) rifampin (Rifadin) ethambutol (Myambutol) pyrazinamide (Rifater) 	<p>Drug may cause pyridoxine (vitamin B₆) and niacin (vitamin B₃) deficiency resulting in peripheral neuropathy and pellagra. Drug may affect vitamin D metabolism and ↓ calcium and phosphate absorption. Drug has MAO inhibitor–like activity.</p> <p>Drug may increase metabolism of vitamin D. Rare cases of osteomalacia have been reported.</p> <p>Drug may ↓ the excretion of uric acid, leading to hyperuricemia and gout.</p> <p>Myambutol: may ↓ copper and zinc.</p>	<p>Avoid in malnourished individuals and others at ↑ risk for peripheral neuropathy. Supplement with 25-50 mg of pyridoxine and possibly B-complex if skin changes occur. Avoid foods high in tyramine (e.g., aged cheeses). Maintain adequate calcium and vitamin D intake.</p> <p>May need vitamin D supplement with long-term use.</p> <p>Maintain adequate hydration and purine-restricted diet.</p> <p>Myambutol: ↑ foods high in Cu and Zn; daily multivitamin with long term use.</p>
Antifungal Agents <ul style="list-style-type: none"> amphotericin B (Fungizone) ketoconazole (Nizoral) terbinafine (Lamisil) 	<p>Drug may cause anorexia and weight loss. Drug causes loss of potassium, magnesium, and calcium.</p> <p>Drug does not dissolve at pH >5.</p> <p>Drug may cause taste changes or loss, dyspepsia, abdominal pain, and diarrhea, weight loss, and headaches.</p>	<p>Eat frequent, small, appealing meals high in magnesium, potassium, and calcium. Ensure adequate hydration.</p> <p>Take with food to ↑ absorption. Take with acidic liquid (e.g., cola), especially individuals with achlorhydria.</p> <p>Avoid taking with acidic foods such as applesauce or fruit based foods. Limit alcohol and caffeine.</p>
Selected Antithrombotic/Hematologic Drugs		
Anticoagulant Agents		
Vitamin K Antagonist <ul style="list-style-type: none"> warfarin (Coumadin) 	Prevents the conversion of oxidized vitamin K to the active form. Produces systemic anticoagulation. May inhibit mineralization of newly formed bone.	Consistent intake of vitamin K containing foods and supplements is needed to achieve desired state of anticoagulation. Monitor bone mineral density in individuals on long-term therapy.
Direct Thrombin Inhibitor <ul style="list-style-type: none"> dabigatran (Pradaxa) 	Drug may cause dyspepsia, abdominal pain, GERD, esophagitis, erosive gastritis, diarrhea, gastric hemorrhage, or GI ulcer. Alcohol may cause bleeding.	Avoid alcohol and supplements. SJW can ↓ drug effectiveness. Chewing can ↓ bioavailability by 75%. Take with food if GI distress occurs.
Factor Xa Inhibitors <ul style="list-style-type: none"> rivaroxaban (Xarelto) apixavan (Eliquis) 	Drug may cause abdominal pain, oropharyngeal pain, toothaches, dyspepsia, and anemia. Excess alcohol can ↑ bleeding risk.	Avoid Vitamin E and herbal products with antiplatelet or anticoagulant effects. Avoid SJW and grapefruit/related citrus (limes, pomelo, Seville oranges). Minimize alcohol intake.
Antiplatelet Agents		
Platelet Aggregation Inhibitors		
<ul style="list-style-type: none"> aspirin/salicylate (Bayer) clopidogrel (Plavix) 	<p>Drug may cause GI irritation and bleeding; ↓ systemic levels of iron, folic acid, sodium, and potassium with high dose long-term use. Drug may ↓ uptake of vitamin C and ↑ urinary loss.</p> <p>Drug may cause dyspepsia, nausea and vomiting, abdominal pain, GI bleeding/hemorrhage, diarrhea, and constipation.</p>	<p>Incorporate foods high in vitamin C and folate Monitor electrolytes and hemoglobin to determine need for potassium or iron supplements.</p> <p>Avoid alcohol consumption.</p> <p>Food ↑ bioavailability. Take with food if GI distress occurs. Avoid grapefruit/related citrus (limes, pomelo, Seville oranges). Replace fluids & electrolytes for diarrhea.</p>
Selected Antihyperglycemic Drugs		
Insulin Sensitizing Agents		
Biguanide <ul style="list-style-type: none"> metformin (Glucophage) 	Drug may ↓ absorption of vitamin B ₁₂ and folic acid. May cause lactic acidosis. Drug does not cause hypoglycemia.	Follow American Diabetes Association dietary guidelines. ↑ foods high in vitamin B ₁₂ and folate; supplement if necessary. Avoid alcohol to ↓ risk of lactic acidosis.
Thiazolidinedione (TZD) <ul style="list-style-type: none"> rosiglitazone (Avandia) pioglitazone (Actos) 	<p>Drugs may lead to ↑ weight and insulin sensitivity, and ↓ gluconeogenesis.</p> <p>Avandia may ↑ total cholesterol, LDL, triglycerides and ↓ HDL.</p> <p>Actos may ↓ total cholesterol, LDL, triglycerides, and ↑ HDL.</p> <p>Rarely, drugs may cause hypoglycemia.</p>	Follow American Diabetes Association dietary guidelines. Reduce calorie intake if weight loss is the goal. Avoid SJW. Monitor blood lipid levels closely and encourage anti-inflammatory diet to manage undesirable fluctuations.
Insulin Stimulating Agents		
Sulfonylureas		
<ul style="list-style-type: none"> glipizide (Glucotrol) glyburide (Diabeta) glimepiride (Amaryl) 	Drug may cause ↑ or ↓ in appetite, weight gain, dyspepsia, nausea, diarrhea, or constipation. Drugs may lead to hypoglycemia.	Follow American Diabetes Association dietary guidelines and encourage regular exercise. Time food intake according to pharmaceutical recommendations.

Drug	Drug Effect	Nutritional Implications and Cautions
Meglitinides <ul style="list-style-type: none"> repaglinide (Prandin) 	Drug stimulates the release of insulin and may lead to weight gain. May also cause nausea, vomiting, diarrhea, or constipation. Drug may cause hypoglycemia.	Follow American Diabetes Association dietary guidelines and encourage exercise. Reduce calories if weight loss is the goal. Time food intake according to drug recommendations. Limit alcohol intake.
Enzyme Inhibitor Agents		
Alpha-glucosidase Inhibitors <ul style="list-style-type: none"> miglitol (Glycet) acarbose (Precose) 	Drugs may delay the absorption of dietary disaccharides and complex carbohydrates. May also cause abdominal pain, diarrhea, and gas. Glycet: may reduce Iron absorption. Drugs do not cause hypoglycemia.	Follow American Diabetes Association dietary guidelines. Avoid digestive enzymes and limit alcohol. Precose: Monitor liver enzymes (AST, ALT) quarterly during the first year. Glycet: Monitor Iron levels and supplement as needed.
Dipeptidyl Peptidase-4 (DPP-4) Inhibitors (Gliptins) <ul style="list-style-type: none"> sitagliptin (Januvia) saxagliptin (Onglyza) linagliptin (Tradjenta) 	Drugs may lead to weight gain, abdominal pain, constipation, diarrhea, gastroenteritis, nausea, vomiting, and rarely, pancreatitis. Drug may cause hypoglycemia.	Follow American Diabetes Association dietary guidelines. ↓ calories if weight loss is the goal. Onglyza: Avoid grapefruit/related citrus (limes, pomelo, Seville oranges). Onglyza/Tradjenta: Avoid SJW.
Glucose Reabsorption Inhibitor Agents		
SGLT-2 Inhibitors (Gliflozins) <ul style="list-style-type: none"> canagliflozin (Invokana) dapagliflozin (Farxiga) 	Drugs ↓ reabsorption of glucose and ↑ urinary glucose excretion. Drugs may lead to weight loss, polydipsia, ↑ LDL, hypovolemia, and dehydration. Drugs may cause hypoglycemia.	Follow American Diabetes Association dietary guidelines. Reduce calorie intake if weight loss is the goal. Monitor LDL and encourage appropriate fat intake. Invokana: Avoid SJW.
Selected Steroidal/Hormonal Drugs		
Corticosteroids <ul style="list-style-type: none"> prednisone (Deltasone) methylprednisolone (Medrol) 	Drug induces protein catabolism, resulting in muscle wasting, and atrophy of bone protein matrix, delayed wound healing. Drug ↓ intestinal absorption of calcium; ↑ urinary loss of calcium, potassium, zinc, vitamin C, and nitrogen; causes sodium retention.	Maintain diet high in Ca, vitamin D, protein, K ⁺ , Zn, and vitamin C, and low in sodium. Ca and vitamin D supplements recommended to prevent osteoporosis with long-term use of drug.
Bisphosphonates <ul style="list-style-type: none"> alendronate (Fosamax) ibandronate (Boniva) 	Drug may induce mild ↓ in serum calcium. Long-term use may cause zinc deficiency.	Pair with diet high in Ca or use Ca/Vitamin D supplement. Monitor for signs of zinc deficiency. Drug must be taken 30 minutes to 1 hour before first intake of day with plain water only. Take zinc supplements 2 hours away from drug.
Sex Hormones <ul style="list-style-type: none"> estrogen (Premarin) Oral Contraceptives 	Drug may ↓ absorption and tissue uptake of vitamin C but may ↑ absorption of vitamin A. May inhibit folate conjugate and decrease serum folic acid. Drug may ↓ serum vitamin B ₆ , B ₁₂ , riboflavin, magnesium, zinc.	Maintain diet with adequate Mg, folate, vitamin B ₆ and B ₁₂ , riboflavin, and zinc. Calcium and vitamin D supplements may be advised with estrogen as hormone replacement for postmenopausal women.
Thyroid Hormones <ul style="list-style-type: none"> levothyroxine (Synthroid) 	Drug may cause appetite changes, weight loss, and nausea/diarrhea. Iron, Calcium or Magnesium may ↓ absorption of drug. Soy, walnuts, cottonseed oil, or high fiber foods may also ↓ absorption.	Take Fe, Ca, or Mg supplements away from drug by ≥ 4 hours; take drug 2-3 hours before soy. Eat walnuts, cottonseed oil, or high fiber foods away from medication. Use caution with grapefruit/related citrus (limes, pomelo, Seville oranges). Take drug 30 minutes before a meal.
Selected Cardiovascular Drugs		
Cardiac Glycoside Agent <ul style="list-style-type: none"> digoxin (Lanoxin) 	Drug may ↑ urinary loss of magnesium and ↓ serum levels of potassium.	Hypokalemia, hypomagnesemia, and hypercalcemia ↑ drug toxicity. Maintain diet high in potassium and magnesium. Monitor magnesium levels and use caution with calcium supplements and antacids.

Continued

Drug	Drug Effect	Nutritional Implications and Cautions
Beta Blocking Agents		
<ul style="list-style-type: none"> metoprolol (Lopressor, Toprol XL) atenolol (Tenormin) carvedilol (Coreg) 	<p>Drugs may mask signs of or prolong hypoglycemia. Drug may ↓ insulin release in response to hyperglycemia.</p> <p>Drug may cause wt gain, nausea, vomiting, and diarrhea. May mask symptoms of diabetic hyperglycemia.</p>	<p>Monitoring of blood glucose levels for hypoglycemia or hyperglycemia may be recommended upon initiation of drugs.</p> <p>Avoid natural licorice and encourage low sodium diet. ↓ calories if weight loss is the goal. Patients with diabetes should monitor glucose regularly.</p>
ACE Inhibitor Agents		
<ul style="list-style-type: none"> enalapril (Vasotec) lisinopril (Zestril) benazepril (Lotensin) ramipril (Altace) 	<p>Drugs may ↑ serum potassium.</p> <p>Drugs may cause abdominal pain, constipation, or diarrhea.</p>	<p>Caution with high potassium diet or supplements. Avoid salt substitutes. Ensure adequate fluid intake. Avoid natural licorice. Limit Alcohol.</p>
Angiotensin II Receptor Antagonists		
<ul style="list-style-type: none"> losartan (Cozaar) valsartan (Diovan) irbesartan (Avapro) telmisartan (Micardis) 	<p>Drugs may ↑ serum potassium.</p>	<p>Caution with high-potassium diet or supplements. Ensure adequate hydration. Avoid natural licorice and salt substitutes.</p> <p>Cozaar: avoid grapefruit/related citrus (limes, pomelo, Seville oranges).</p>
Calcium Channel Blocking Agents		
<ul style="list-style-type: none"> amlodipine (Norvasc) diltiazem (Cardizem) 	<p>Drug may cause dysphagia, nausea, cramps, and edema.</p> <p>Drug may cause anorexia, dry mouth, dyspepsia, nausea, vomiting, constipation, and diarrhea.</p>	<p>If GI distress occurs, take with food. Avoid natural licorice. Reduce sodium intake.</p> <p>Avoid natural licorice. Strict adherence to a low sodium diet may ↓ antihypertensive effect.</p>
Alpha Adrenergic Agonist		
<ul style="list-style-type: none"> clonidine (Catapres) 	<p>Drug commonly causes dizziness, drowsiness, and sedation.</p>	<p>Avoid alcohol and alcohol products. Drug ↑ sensitivity to alcohol, which may ↑ sedation caused by drug alone.</p>
Peripheral Vasodilator		
<ul style="list-style-type: none"> hydralazine (Apresoline) 	<p>Drug interferes with pyridoxine (vitamin B₆) metabolism and may result in pyridoxine deficiency.</p>	<p>Maintain a diet high in pyridoxine. Supplementation may be necessary.</p>
Antiarrhythmic Agent		
<ul style="list-style-type: none"> amiodarone (Pacerone) 	<p>Drug may cause anorexia, nausea, vomiting, taste changes, or increases in liver enzymes or thyroid hormones.</p>	<p>Avoid grapefruit/related citrus (limes, pomelo, Seville oranges) and SJW. Monitor hepatic and thyroid function. Encourage appealing foods.</p>
Selected Antihyperlipidemic Drugs		
HMG Co-A Reductase Inhibitors		
<ul style="list-style-type: none"> atorvastatin (Lipitor) simvastatin (Zocor) pravastatin (Pravachol) rosuvastatin (Crestor) 	<p>Drug may cause significant reduction in Co Q₁₀.</p> <p>Drug lowers LDL cholesterol; raises HDL cholesterol.</p>	<p>Supplementation with Co Q₁₀ has not been shown to ↓ statin myopathy but may still be advisable for repletion of the nutrient. Encourage anti-inflammatory diet for optimal drug effect.</p> <p>Lipitor/Zocor: Avoid grapefruit/related citrus (limes, pomelo, Seville oranges)</p>
Fibric Acid Derivative		
<ul style="list-style-type: none"> gemfibrozil (Lopid) fenofibrate (Tricor) 	<p>Drug decreases serum triglycerides.</p> <p>Lopid: Taste changes may occur.</p>	<p>Encourage anti-inflammatory diet for optimal drug effect. Avoid alcohol.</p> <p>Lopid: encourage small appealing meals.</p>
Bile Acid Sequestrant		
<ul style="list-style-type: none"> cholestyramine (Questran) 	<p>Drug binds fat-soluble vitamins (A, E, D, K), β-carotene, calcium, magnesium, iron, zinc, and folic acid.</p>	<p>Take fat-soluble vitamins in water-miscible form or take vitamin supplement at least 1 hour before first dose of drug daily. Maintain diet high in folate, Mg, Ca, Fe, Zn or supplement as needed. Monitor serum nutrient levels for long-term use.</p>
Nicotinic Acid		
<ul style="list-style-type: none"> niacin (Niaspan) 	<p>High dose may elevate blood glucose and uric acid.</p>	<p>Low-purine diet as recommended. Monitor blood glucose with diabetes.</p>

Drug	Drug Effect	Nutritional Implications and Cautions
Selected Diuretic Drugs		
Loop Diuretics		
<ul style="list-style-type: none"> furosemide (Lasix) bumetanide (Bumex) 	Drug ↑ urinary excretion of sodium, potassium, magnesium, and calcium. Long-term use can lead to ↑ urinary zinc excretion.	Maintain diet high in zinc, potassium, magnesium, and calcium. Avoid natural licorice, which may counteract diuretic effect of drug. Monitor electrolytes; supplement as needed.
Thiazide Diuretic		
<ul style="list-style-type: none"> hydrochlorothiazide (Hydrodiuril) 	Drug ↑ urinary excretion of sodium, potassium, magnesium and ↑ renal resorption of calcium. Long-term use can lead to ↑ urinary zinc excretion.	Maintain diet high in zinc, potassium, and magnesium. Avoid natural licorice, which may counteract diuretic effect of drug. Monitor electrolytes and supplement as needed. Use caution with Ca supplements.
Potassium-Sparing Diuretics		
<ul style="list-style-type: none"> triamterene (Dyrenium) spironolactone (Aldactone) 	Drug ↑ renal resorption of potassium. Long-term use can lead to ↑ urinary zinc excretion.	Avoid salt substitutes. Use caution with potassium supplements. Avoid excessive potassium intake in diet. Monitor for signs of zinc deficiency.
Selected Analgesic Drugs		
Non-Narcotic Analgesics		
<ul style="list-style-type: none"> acetaminophen (Tylenol) 	Drug may cause hepatotoxicity at high dose. Chronic alcohol ingestion ↑ risk of hepatotoxicity.	Maximum safe adult dose is ≤ 3 g/day Avoid alcohol or limit to ≤ 2 drinks/day.
Non-Steroidal Anti-Inflammatory Drugs (NSAIDs)		
<ul style="list-style-type: none"> ibuprofen (Motrin) naproxen (Naprosyn) meloxicam (Mobic) ketorolac (Toradol) 	<p>Standard warning with NSAIDs: GI: ↑ risk of serious GI events (bleeding, ulceration, perforation of stomach & intestines) can occur at anytime during use without warning. The elderly are at greater risk.</p> <p>Cardiovascular: ↑ risk of serious cardiovascular thrombotic events, myocardial infarction & stroke.</p>	Take drug with food or milk to decrease risk of GI toxicity. Avoid use in the elderly or in individuals with severe cardiovascular disease.
Cox-2 Inhibitor		
<ul style="list-style-type: none"> celecoxib (Celebrex) 	Drug may cause GI distress, weight gain, taste changes, dyspepsia, nausea, abdominal pain, diarrhea, and flatulence. Rare sudden, serious GI bleeding and colitis can occur.	If GI distress occurs, take with food and limit caffeine. High fat meals can delay concentration, but ↑ absorption.
Narcotic Analgesic Agents (Opioids)		
<ul style="list-style-type: none"> morphine (MS Contin) codeine/apap (Tylenol #3) hydrocodone/apap (Norco) oxycodone (OxyContin) hydromorphone (Dilaudid) fentanyl (Duragesic) methadone (Dolophine) 	<p>Narcotics can be highly addictive and may cause severe dose-related sedation, respiratory depression, dry mouth, and constipation.</p> <p>Drugs cause slowing of digestion.</p>	<p>Monitor respiratory function and bowel function (not with paralytic ileus).</p> <p>Do not crush or chew sustained-release.</p> <p>OxyContin/Fentanyl/Methadone: Caution with grapefruit/related citrus (limes, pomelo, Seville oranges).</p>
Synthetic Opioid Analgesic		
<ul style="list-style-type: none"> tramadol (Ultram) 	Drug may cause anorexia, dry mouth, dyspepsia, nausea/vomiting, abdominal pain, constipation, diarrhea, or gas.	Avoid alcohol. Use caution with SJW.
Selected Antidepressant Drugs		
Selective Serotonin Reuptake Inhibitors (SSRIs)		
<ul style="list-style-type: none"> sertraline (Zoloft) citalopram (Celexa) escitalopram (Lexapro) fluoxetine (Prozac) paroxetine (Paxil) 	<p>Drugs may ↑ weight, appetite. Some herbs and supplements may ↑ toxicity.</p> <p>Prozac: may cause weight loss; may ↓ absorption of leucine.</p>	Avoid tryptophan, SJW. Additive effects may produce adverse effects or serotonin syndrome. Monitor weight trends as appropriate. Avoid alcohol.
Serotonin Antagonist/Reuptake Inhibitor (SARI) & Serotonin-Norepinephrine Reuptake Inhibitors (SNRIs)		
<ul style="list-style-type: none"> trazodone (Desyrel) - SARI venlafaxine (Effexor XR) - SNRI desvenlafaxine (Pristiq) - SNRI 	Some herbal and natural products may ↑ toxicity.	Avoid tryptophan and SJW. Additive effects may produce adverse effects or serotonin syndrome.

Continued

Drug	Drug Effect	Nutritional Implications and Cautions
TriCyclic Antidepressants (TCAs)		
<ul style="list-style-type: none"> amitriptyline (Elavil) 	Drug may cause ↑ appetite (especially for carbohydrates/sweets) and weight gain. High fiber may ↓ drug absorption.	Monitor caloric intake. Maintain consistent amount of fiber in diet.
Noradrenergic/Specific Serotonic Antidepressants (NaSSA)		
<ul style="list-style-type: none"> mirtazapine (Remeron) 	Some herbal and natural products may ↑ toxicity. Drug can also be used as an appetite stimulant and may cause significant ↑ in appetite/weight gain.	Avoid tryptophan and SJW. Additive effects may produce adverse effects or serotonin syndrome.
Norepinephrine/Dopamine Reuptake Inhibitor (NDRI)		
<ul style="list-style-type: none"> bupropion (Wellbutrin) 	Drug may cause anorexia, weight loss or gain, ↑ appetite, dry mouth, stomatitis, taste changes, dysphagia, pharyngitis, nausea/vomiting, dyspepsia, or GI distress.	Minimize or avoid alcohol. Take with food to decrease GI irritation. Avoid mixing with SJW.
Monoamine Oxidase Inhibitors (MAOIs)		
<ul style="list-style-type: none"> phenelzine (Nardil) 	Drug may cause ↑ appetite (especially for carbohydrates and sweets) and weight gain. Risk for severe reaction with dietary tyramine.	Avoid foods high in tyramine during drug use and for 2 weeks after discontinuation to prevent hypertensive crisis. Monitor caloric intake to avoid weight gain.
Mood Stabilizers		
<ul style="list-style-type: none"> lithium (Lithobid) 	Sodium intake affects drug levels. May cause dry mouth, dehydration, and thirst, reflective of ↑ drug toxicity. Drug may cause GI irritation.	Drink 2 to 3 L of fluid daily to avoid dehydration. Maintain consistent dietary sodium intake. Take with food to ↓ GI irritation. Limit caffeine.
Selected Antipsychotic & Antianxiety/Hypnotic Drugs		
Typical Antipsychotic Agent		
<ul style="list-style-type: none"> haloperidol (Haldol) 	May cause ↑ appetite, weight gain or loss, constipation, or dry mouth. Risk for tardive dyskinesia.	Monitor weight and calorie count. Tardive dyskinesia may interfere with biting, chewing, swallowing.
Atypical Antipsychotic Agents		
<ul style="list-style-type: none"> risperidone (Risperdal) quetiapine (Seroquel) olanzapine (Zyprexa) 	Drugs may cause ↑ appetite and weight gain. May also cause ↑ blood sugar, HbA1c, or lipids/triglycerides.	Monitor weight, fasting blood sugar, HbA1c, and lipids/triglycerides. Do not use in elderly dementia patients; may ↑ risk of stroke.
Antianxiety/Hypnotic Agents		
<ul style="list-style-type: none"> lorazepam (Ativan) alprazolam (Xanax) clonazepam (Klonopin) diazepam (Valium) temazepam (Restoril) zolpidem (Ambien) 	Drugs may cause significant sedation. Benzodiazepine drugs are highly addictive.	Avoid concurrent ingestion of alcohol, which will produce CNS depression. Limit or avoid caffeine, which may decrease the therapeutic effect of the drug. Use caution with herbal and natural products that cause CNS stimulation or sedation.
Selected Anticonvulsant Drugs		
Caboxamides		
<ul style="list-style-type: none"> carbamazepine (Tegretol) 	Drug may ↓ biotin, folic acid, and vitamin D levels. Long-term therapy (>6 months) may cause loss of bone mineral density.	Maintain diet high in folate and vitamin D. Calcium and vitamin D supplements may be necessary for long-term therapy. Use caution with grapefruit/related citrus (limes, pomelo, Seville oranges). Star fruit or pomegranate may ↑ drug levels and lead to toxicity. Avoid alcohol.
Hydantoin		
<ul style="list-style-type: none"> phenytoin (Dilantin) 	Drug may ↓ serum folic acid, calcium, vitamin D, biotin, and thiamine. Drug can cause altered taste, dysphagia, nausea, vomiting, and constipation. Alcohol intake disrupts drug function. Ca and Mg may ↓ absorption.	May be paired with daily folic acid supplement; monitor levels. Consider Ca, vitamin D and B vitamin supplements with long-term use. Ca, Mg, or antacids should be taken 2 hours away from drug. Holding tube feeds 1 hour before & 1 hour after drug is recommend. Avoid alcohol and SJW.

Drug	Drug Effect	Nutritional Implications and Cautions
Barbiturate <ul style="list-style-type: none"> phenobarbital (Luminal) 	Drug may induce rapid metabolism of vitamin D, leading to Vitamin D and Calcium deficiencies. May also ↑ the metabolism of vitamin K and ↓ serum folic acid and vitamin B ₁₂ .	Encourage ↑ dietary intake of Ca, vitamin D, and folate. Consider Ca, vitamin D, folic acid, and vitamin B ₁₂ supplementation with long-term use.
GABA Analogues <ul style="list-style-type: none"> gabapentin (Neurontin) pregabalin (Lyrica) 	Drugs used for neuropathy, hot flashes, migraines, and as mood stabilizers. Mg can interfere with drug efficacy by ↓ absorption. Can cause ↑ weight and appetite, nausea, gingivitis, constipation, vomiting and diarrhea.	Take Mg supplements separately by 2 hours.
Fructose Derivative <ul style="list-style-type: none"> topiramate (Topamax) 	May cause weight loss, anorexia, dry mouth, gingivitis, taste changes, GERD, nausea, dyspepsia, constipation, or diarrhea.	Encourage adequate fluid intake to ↓ risk of kidney stones. Replace fluids & electrolytes for diarrhea. Avoid alcohol.
Selected Anti-Dementia Drugs Cholinesterase Inhibitors <ul style="list-style-type: none"> donepezil (Aricept) rivastigmine (Exelon) 	Drug is highly cholinergic; may cause weight loss, diarrhea, nausea/vomiting, ↑ gastric acid, and GI bleeding.	Take with food to prevent GI irritation. Monitor food intake and weight trends.
NMDA Receptor Antagonist <ul style="list-style-type: none"> memantine (Namenda) 	Drug is cleared from the body almost exclusively by renal excretion. Urine pH >8 decreases renal excretion by 80%.	Avoid diet that alkalizes the urine (predominantly milk products, citrus fruit) to avoid drug toxicity.
Selected Gastrointestinal Drugs H₂ Receptor Antagonist <ul style="list-style-type: none"> ranitidine (Zantac) famotidine (Pepcid) 	Drug may reduce the absorption of vitamin B ₁₂ and iron.	Monitor iron studies, vitamin B ₁₂ level on long-term therapy. Supplement as needed.
Proton Pump Inhibitors <ul style="list-style-type: none"> omeprazole (Prilosec) lansoprazole (Prevacid) esomeprazole (Nexium) pantoprazole (Protonix) dexlansoprazole (Dexilant) 	Long-term ↓ acid secretion may inhibit the absorption of iron and vitamin B ₁₂ ; ↓ calcium absorption may lead to osteoporosis. Low Mg may occur. Inhibition of acid secretion may also ↑ the risk of <i>Clostridium difficile</i> . Some studies have also shown correlation between PPI therapy, Small Intestine Bacterial Overgrowth (SIBO), and IBS	Monitor iron studies, vitamin B ₁₂ , magnesium levels, and bone density with long-term use; supplement as needed. Consider alternatives in those with a diagnosis of SIBO and/or IBS. Prilosec: Avoid SJW & Gingko. Hold tube feeds 1 hour before and 1 hour after drug.
Prokinetic Agent <ul style="list-style-type: none"> metoclopramide (Reglan) 	Drug ↑ gastric emptying; may change insulin requirements in persons with diabetes; may ↑ CNS depressant effects of alcohol. Drug may cause tardive dyskinesia with extended use.	Monitor blood glucose in persons with diabetes carefully when drug is initiated. Avoid alcohol. Tardive dyskinesia may interfere with biting, chewing, swallowing.
Selected Antineoplastic Drugs Folate Antagonist <ul style="list-style-type: none"> methotrexate (Rheumatrex) 	Drug inhibits dihydrofolate reductase; decreased formation of active folate. Drug may cause GI irritation or injury. All antineoplastic drugs are cytotoxic; potential to damage intestinal mucosa. Drug also used as an antirheumatic.	Maintain diet high in folate and vitamin B ₁₂ . Daily folic acid supplement may be recommended with antirheumatic doses but is not advised with antineoplastic. Leucovorin rescue may be necessary with antineoplastic doses.
Alkylating Agent <ul style="list-style-type: none"> cyclophosphamide (Cytoxan) 	Drug metabolite causes bladder irritation, acute hemorrhagic cystitis. All antineoplastic drugs are cytotoxic; potential to damage intestinal mucosa.	Maintain high fluid intake (2-3 L daily) to induce frequent voiding.

Continued

Drug	Drug Effect	Nutritional Implications and Cautions
Epidermal Growth Factor Inhibitor		
<ul style="list-style-type: none"> erlotinib (Tarceva) 	Drug may cause anorexia, weight loss, stomatitis, nausea, vomiting, diarrhea. Rarely, GI bleeding can occur.	Avoid SJW and grapefruit/related citrus (limes, pomelo, Seville oranges). Hold tube feeds 2 hour before and 1 hour after drug.
Selected Anti-Parkinson's Drugs		
Dopamine Precursor		
<ul style="list-style-type: none"> carbidopa/levodopa (Sinemet) 	Carbidopa protects levodopa against pyridoxine-enhanced peripheral decarboxylation to dopamine.	Pyridoxine supplements > 10-25 mg daily may ↑ carbidopa requirements and ↑ adverse effects of levodopa.
Dopamine Agonist		
<ul style="list-style-type: none"> bromocriptine (Parlodel) 	Drug may cause GI irritation, nausea, vomiting, and GI bleeding.	Take with food to prevent GI irritation. Take at bedtime to ↓ nausea.
MAO-B Inhibitor		
<ul style="list-style-type: none"> selegiline (Eldepryl) 	Drug selectively inhibits MAO-B at 10 mg or less per day. Drug loses selectivity at higher doses.	Avoid high-tyramine foods at doses > 10 mg/day. May precipitate hypertension.
COMT Inhibitor		
<ul style="list-style-type: none"> entacapone (Comtan) 	Drug chelates iron, which for some patients, may ↓ serum iron and make the drug less effective.	Monitor iron levels. Take iron supplement as needed 2-3 hours away from drug. Avoid alcohol.
Selected ADHD Treatment Drugs		
CNS Stimulants		
<ul style="list-style-type: none"> methylphenidate (Ritalin, Concerta) dextroamphetamine & amphetamine (Adderall) 	Drugs may cause anorexia, weight loss, and ↓ growth in children. Dry mouth, metallic taste and GI upset can occur. May be habit forming.	Monitor children's weight/growth; ensure adequate calories. Limit caffeine & alcohol. Ritalin/Concerta: Avoid SJW. Adderall: High-dose vitamin C and acidifying foods may ↓ absorption and ↑ excretion.

ACE, Angiotensin-converting enzyme; CNS, central nervous system; Co-A, coenzyme A; COMT, catechol-o-methyl transferase; G-6-PD, glucose-6-phosphate dehydrogenase; GI, gastrointestinal; HbA1c, hemoglobin A1c; HMG, 3-hydroxy-3-methyl-glutaryl; MAO, monoamine oxidase; NSAID, nonsteroidal antiinflammatory drug; PKU, phenylketonuria; ↓↑, increase/decrease; SJW, St. John's Wort.

Enteral (Tube Feeding) Formulas for Adults Marketed in the USA

This table does not reference products marketed only for oral use or not intended to provide complete nutrition support. Product composition and availability are subject to change.

Consult Abbott Nutrition, <http://abbottnutrition.com/>, and Nestlé Nutrition, www.nestle-nutrition.com for current, detailed information.

See http://www.medicine.virginia.edu/clinical/departments/medicine/divisions/digestive-health/nutrition-support-team/clinician-resources/BLENDERIZED_TUBE_FEEDING.pdf for safety tips, use suggestions, and recipes that may be used to create hoe blenderized feedings.

Enteral Formulas	kcal/ mL	Protein (g/L)	CHO (g/L)	Fat (g/L)	mOsm/kg water	Water (mL/L)	Notes
Whole food based (commercial)	1.06	48	132	40	340	854	Contains chicken, peas, carrots, tomatoes, cranberry juice with added vitamins/minerals
Polymeric, standard	1-1.5	44-68	144-216	35-65	300-650	760-1260	Suitable for most patients; higher caloric density products provide less volume; some contain fiber
Polymeric, high-protein	1-1.2	53-63	130-160	26-39	340-490	818-839	Higher protein content relative to energy; some contain fiber
Polymeric, low electrolyte	1.8-2	35-81	161-290	83-100	600-960	700-736	Volume restricted; lower concentrations of some vitamins/minerals
Polymeric, modified carbohydrate	1-1.5	40-83	96-100	48-75	280-875	859-854	Proprietary carbohydrate blends; some with pureed fruits and vegetables and without sugar alcohols; some with fiber
Polymeric; reduced carbohydrate	1.5	63-68	100-106	93-95	330-785	535-785	Lower carbohydrate with MCT oil; marketed as possible option to reduce diet-induced carbon dioxide production
Peptide-based	1-1.5	40-94	78-188	39-64	345-610	759-848	Di- and tri-peptides from whey or casein; MCT oil; some with MCT combined with fish oil; some with fructooligosaccharides; varying protein to energy ratios
Critical Care (polymeric or free amino acid options)	1-1.5	50-78	134-176	28-94	460-630	759-868	Various formulations marketed as support for the immune system and healing; some with omega-3 fatty acids, fiber, and/or free amino acids
Modular Additives							
Modular Additives	kcal	Protein (g)	CHO (g)	Fat (g)			
Liquid Protein & Carbohydrate/30 mL	100	10	14 (glycerin)	0	Hydrolyzed collagen fortified with tryptophan		
Powdered Protein/7 g	25	6	0	0	Whey protein		
Fat & Carbohydrate blend/10g	49	0	7.3	2.2	Cornstarch, vegetable oil, MCT oil

Sample Stepwise Method to Calculate a PN Formula

1. Determine total calories needed (see energy equations in Ch 3)
2. Determine total protein need: Recommendations - Range of 1-2 gm protein/kg or provide 20% of total calories as protein
3. Determine total fat needs: Recommendations -1 gm/kg/day or 20-30% of total calories
4. Balance kcals with carbohydrate (dextrose)

PN FORMULA

EX: Female, Ht: 65 in (165 cm), Wt: 145 pounds (65.9 kg), Age: 43

Recommended Energy Intake: 1800 calories (kcals)/day with 1.4 gm protein/kg (moderate stress)

Macronutrients:

1. Protein (amino acids) = 90 gm
(Using a 10% amino acid solution - 100gm amino acids/liter)
EX: 20% of 1800 kcal = 360 kcal from protein * 4 kcal/gm = 90 gm protein = 900 ml
2. Fat (lipid emulsion) = ~50-55 gm
(Using 20% lipid emulsion which provides 2 kcal/ml)
EX: 25% of 1800 kcal = 450 kcal = 225 ml

3. Balance of kcals as carbohydrate = 990 kcal = 291 gm
(Using 70% dextrose = 700 g/1000mL * 3.4 kcal/g = 2380 kcal/1000 mL)
EX: 990 kcal needed * 2380 kcal/1000ml = 415 mL

Macronutrients:

10% amino acids	= 900 ml
20% lipid	= 225 ml
70% dextrose	= <u>415 ml</u>
Total	= 1540 ml

4. Micronutrients:
add multivitamin infusion (MVI) + trace elements = 12-15 ml = 1555 ml
5. Electrolytes/additives: (~100 ml) = 100 ml = 1665 ml (to balance - based on current labs*)
6. Total nutritional fluids: 1665 ml
7. Fluids needs 2000 ml/day = add 335 ml sterile water to equal = 2000 ml/day

*labs that are significantly below normal due to disease fluctuations may need to be treated outside the PN solution.

DASH Diet

The DASH diet is an eating pattern that reduces high blood pressure. It is not the traditional low-salt diet. DASH uses foods high in the minerals calcium, potassium, and magnesium, which, when combined, help lower blood pressure. It is also low in fat and high in fiber, an eating style recommended for everyone.

The Healthy Eating Pattern is the template for the DASH eating pattern, with inclusion of ½ to 1 serving of nuts, seeds, and legumes daily, limited fats and oils, and use of nonfat or low-fat milk. The eating pattern is reduced in saturated fat, total fat, cholesterol, and sweet and sugar-containing beverages; and provides abundant servings of fruits and vegetables.

Although the DASH eating plan is naturally lower in salt because of the emphasis on fruits and vegetables, all adults should still make an effort to reduce packaged and processed foods and high-sodium snacks (such as salted chips, pretzels, and crackers) and use less or no salt at the table.

DASH can be an excellent way to lose weight. Because weight loss can help lower blood pressure, it is often suggested. In addition to following DASH, try adding in daily physical activity such as walking or other exercise. You may want to check with your doctor first.

Current recommendations include:

THE DASH DIET

Food Group	1600 kcal Servings/Day	2000 kcal Servings/Day	2600 kcal Servings/Day	3100 kcal Servings/Day
Grains (whole grains)	6	7-8	10-11	12-13
Vegetables	3-4	4-5	5-6	6
Fruits and juices	4	4-5	5-6	6
Milk, nonfat or low-fat	2-3	2-3	3	3-4
Meats, poultry, and fish	1-2	2 or less	6	2-3
Nuts, seeds, and legumes	3/week	½-1	1	1
Fats and oils	2	2-3	3	4
Sweets	0	5/week	Less than 2	2

DIETARY GUIDELINES				
Food Group	Servings/Day	Serving Sizes	Examples	Significance of Each Food Group
Grains	6-13	1 slice bread ½ cup (1 oz) dry cereal* ½ cup cooked rice, pasta, or cereal and fiber	Whole-wheat bread, English muffin, pita bread, bagel, cereals, grits, oatmeal, crackers, unsalted pretzels, and popcorn	Major sources of energy
Vegetables	3-6	1 cup raw, leafy veg ½ cup cooked veg 6 oz veg juice	Tomatoes, potatoes, carrots, peas, kale, squash, broccoli, turnip greens, collards, spinach, artichokes, beans, sweet potatoes	Rich sources of potassium, magnesium, antioxidants, and fiber
Fruits	4-6	6 oz fruit juice 1 medium fruit ¼ cup dried fruit ½ cup fresh, frozen, or canned fruit	Apricots, bananas, dates, grapes, oranges and juice, tangerines, strawberries, mangoes, melons, peaches, pineapples, prunes, raisins, grapefruit and juice	Important sources of energy, potassium, magnesium, and fiber
Low-fat dairy	2-4	8 oz milk, 1 cup yogurt, or 1.5 oz cheese	Fat-free or 1% milk, fat-free or low-fat buttermilk, yogurt, or cheese	Major sources of calcium, vitamin D, and protein

Continued

DIETARY GUIDELINES

Food Group	Servings/Day	Serving Sizes	Examples	Significance of Each Food Group
Meat, poultry, fish	1-3	3 oz cooked meats, poultry, or fish 1 egg white [†]	Select only lean meats; trim away visible fats, broil, roast, boil, instead of frying; remove skin from poultry	Rich sources of protein, zinc, and magnesium
Nuts, seeds, legumes	3/wk-1/day	1.5 oz (½ cup) nuts, ½ oz or 2 tbsp seeds, ½ cup cooked legumes	Almonds, filberts, mixed nuts, walnuts, sunflower seeds, kidney beans, lentils	Rich sources of energy, magnesium, protein, monounsaturated fats, and fiber
Fat	2-4	1 tsp soft margarine, veg oil, 1 Tbsp low-fat mayo or salad dressing, or 2 Tbsp light salad dressing [‡]	Soft margarine, low fat mayo, veg oil, light salad dressing	The DASH study had 27% of calories as fat, including fat in or added to foods Sweets should be low in fat

National Institutes of Health, National Heart, Lung, and Blood Institute: YOUR GUIDE TO Lowering Your Blood Pressure With DASH, U.S. Department of Health and Human Services, NIH Publication No. 06-4082, 2006.

*Serving sizes vary between ½ cup and 1¼ cup, depending on cereal type. Check the product's Nutrition Facts label.

[†]Because eggs are high in cholesterol, limit egg yolk intake to no more than four per week; two egg whites have the same protein content as 1 oz of meat.

[‡]Fat content changes serving amount for fats and oils. For example, 1 Tbsp of regular salad dressing equals one serving; 1 Tbsp of a low-fat dressing equals one-half serving; 1 Tbsp of a fat-free dressing equals zero servings.

SAMPLE MENU

Breakfast	Lunch	Dinner
1 cup calcium-fortified orange juice ¾ cup Raisin Bran 1 cup skim milk Mini –whole-wheat bagel 1½ tsp soft margarine 1 cup coffee 2 tsp sugar	3-oz boneless skinless chicken breast 2 slices reduced-fat cheese 2 large leaves lettuce 2 slices tomato 1 Tbsp light mayonnaise 2 slices whole wheat bread 1 medium apple ½ cup raw carrot sticks 1 cup iced tea	1 cup spaghetti with vegetarian/low-sodium tomato sauce 3 Tbsp Parmesan cheese ½ cup green beans 1 cup spinach, raw ½ cup mushrooms, raw 2 Tbsp croutons 2 Tbsp low-fat Italian dressing 1 slice Italian bread ½ cup frozen yogurt
Midmorning Snack	Midafternoon Snack	
1 cup apple juice 2 oz walnuts	1 large banana

HOW THIS EXCHANGE LIST WORKS WITH MEAL PLANNING

There are three main groups of foods in this exchange list. They are based on the three major nutrients: carbohydrates, protein (meat and meat substitutes), and fat. Each food list contains foods grouped together because they have similar nutrient content and serving sizes. Each serving of a food has about the same amount of carbohydrate, protein, fat, and calories as the other foods on the same list.

- Foods on the **Starch** list, **Fruits** list, **Milk** list, and **Sweets, Desserts, and Other Carbohydrates** list are similar because they contain 12 to 15 grams of carbohydrate per serving.
- Foods on the **Fat** list and **Meat and Meat Substitutes** list usually do not have carbohydrate (except for the plant-based meat substitutes such as beans and lentils).

- Foods on the Starchy Vegetables list (part of the **Starch** list and including foods (such as potatoes, corn, and peas) contain 15 grams of carbohydrate per serving.
- Foods on the **Nonstarchy Vegetables** list (such as green beans, tomatoes, and carrots) contain 5 grams of carbohydrate per serving.
- Some foods have so little carbohydrate and calories that they are considered “free,” if eaten in small amounts. You can find these foods on the **Free Foods** list.
- Foods that have different amounts of carbohydrates and calories are listed as **Combination Foods** (such as lasagna) or **Fast Foods**.

Foods are listed with their serving sizes, which are usually measured after cooking. When you begin, measuring the size of each serving will help you learn to “eyeball” correct serving sizes. The following chart shows the amount of nutrients in one serving from each list:

Food List	Carbohydrate (grams)	Protein (grams)	Fat (grams)	Calories
Carbohydrates				
Starch: breads, cereals and grains, starchy vegetables, crackers and snacks, and beans, peas, and lentils	15	0-3	0-1	80
Fruits	15	—	—	60
Milk				
Fat-free, low-fat, 1%	12	8	0-3	100
Reduced fat, 2%	12	8	5	120
Whole	12	8	8	160
Sweets, desserts, and other carbohydrates	15	Varies	Varies	Varies
Nonstarchy Vegetables	5	2	—	25
Meat and Meat Substitutes				
Lean	—	7	0-3	45
Medium-fat	—	7	4-7	75
High-fat	—	7	8+	100
Plant-based proteins	Varies	7	Varies	Varies
Fats	—	—	5	45
Alcohol	Varies	—	—	100

STARCH

Cereals, grains, pasta, breads, crackers, snacks, starchy vegetables, and cooked beans, peas, and lentils are starches. In general, 1 starch is:

- ½ cup of cooked cereal, grain, or starchy vegetable
- ½ cup of cooked rice or pasta
- 1 oz of a bread product, such as 1 slice of bread
- ¾ oz to 1 oz of most snack foods (some snack foods may also have extra fat)

Nutrition Tips

1. A choice on the **Starch** list has 15 grams of carbohydrate, 0-3 grams of protein, 0-1 grams of fat, and 80 calories.
2. For maximum health benefits, eat three or more servings of whole grains each day. A serving of whole grain is about

½ cup of cooked cereal or grain, 1 slice of whole-grain bread, or 1 cup of whole-grain cold breakfast cereal.

Selection Tips

1. Choose low-fat starches as often as you can.
2. Starchy vegetables, baked goods, and grains prepared with fat count as 1 starch and 1 fat.
3. For many starchy foods (bagels, muffins, dinner rolls, buns), a general rule of thumb is 1 oz equals 1 serving. Always check the size you eat. Because of their large size, some foods have a lot more carbohydrate (and calories) than you might think. For example, a large bagel may weigh 4 oz and equal 4 carbohydrate servings.
4. For specific information, read the Nutrition Facts panel on the food label.

Food	Serving Size	Food	Serving Size
Bread		Cereals and Grains	
Bagel, large (about 4 oz)	¼ (1 oz)	Barley, cooked	⅓ cup
Biscuit, 2½ inches across†	1	Bran, dry	
Bread		Oat*	¼ cup

Crackers and Snacks		Animal crackers	8
Crackers		Crackers	
Round-butter type [†]	6	Round-butter type [†]	6
Saltine-type	6	Saltine-type	6

*More than 3 grams of dietary fiber per serving.

[†]Extra fat, or prepared with added fat. (Count as 1 starch + 1 fat.)

[†]480 milligrams or more of sodium per serving.

Fresh, frozen, canned, and dried fruits and fruit juices are on this list. In general, 1 fruit choice is:

- 1/2 cup of canned or fresh fruit or unsweetened fruit juice
- 1 small fresh fruit (4 oz)
- 2 tablespoons of dried fruit

Nutrition Tips

1. A choice on the **Fruits** list has 15 grams of carbohydrate, 0 grams of protein, 0 grams of fat, and 60 calories.
2. Fresh, frozen, and dried fruits are good sources of fiber. Fruit juices contain very little fiber. Choose fruits instead of juices whenever possible.
3. Citrus fruits, berries, and melons are good sources of vitamin C.

Selection Tips

1. Use a food scale to weigh fresh fruits. Practice builds portion skills.
2. The weight listed includes skin, core, seeds, and rind.
3. Read the Nutrition Facts on the food label. If 1 serving has more than 15 g of carbohydrate, you may need to adjust the size of the serving.
4. Portion sizes for canned fruits are for the fruit and a small amount of juice (1 to 2 tablespoons).
5. Food labels for fruits may contain the words *no sugar added* or *unsweetened*. This means that no sucrose (table sugar) has been added; it *does not* mean the food contains no sugar.
6. Fruit canned in *extra light syrup* has the same amount of carbohydrate per serving as the *no sugar added* or the *juice pack*. All canned fruits on the **Fruits** list are based on one of these three types of pack. Avoid fruit canned in heavy syrup.

The weight listed includes skin, core, seeds, and rind.

Food	Serving Size
Fruit	
Apple, unpeeled, small	1 (4 oz)
Apples, dried	4 rings
Applesauce, unsweetened	½ cup
Apricots	
Canned	½ cup
Dried	8 halves
Fresh*	4 whole (5½ oz)
Banana, extra small	1 (4 oz)
Blackberries*	¾ cup
Blueberries	¾ cup
Cantaloupe, small	⅓ melon or 1 cup cubed (11 oz)
Cherries	
Sweet, canned	½ cup
Sweet fresh	12 (3 oz)
Dates	3
Dried fruits (blueberries, cherries, cranberries, mixed fruit, raisins)	2 Tbsp
Figs	
Dried	1½
Fresh*	1½ large or 2 medium (3½ oz)
Fruit cocktail	½ cup
Grapefruit	
Large	½ (11 oz)
Sections, canned	¾ cup
Grapes, small	17 (3 oz)
Honeydew melon	1 slice or 1 cup cubed (10 oz)
Kiwi*	1 (3½ oz)
Mandarin oranges, canned	¾ cup
Mango, small	½ fruit (5½ oz) or ½ cup
Nectarine, small	1 (5 oz)
Orange, small*	1 (6½ oz)
Papaya	½ fruit or 1 cup cubed (8 oz)
Peaches	
Canned	½ cup
Fresh, medium	1 (6 oz)
Pears	
Canned	½ cup
Fresh, large	½ (4 oz)
Pineapple	
Canned	½ cup
Fresh	¾ cup
Plums	
Canned	½ cup
Dried (prunes)	3
Small	2 (5 oz)
Raspberries*	1 cup
Strawberries*	1¼ cup whole berries
Tangerines, small*	2 (8 oz)
Watermelon	1 slice or 1¼ cups cubes (13½ oz)
Fruit Juice	
Apple juice/cider	½ cup
Fruit juice blends, 100% juice	⅓ cup
Grape juice	⅓ cup
Grapefruit juice	½ cup
Orange juice	½ cup
Pineapple juice	½ cup
Prune juice	⅓ cup

*More than 3 grams of dietary fiber per serving.

MILK

Different types of milk and milk products are on this list. However, 2 types of milk products are found in other lists:

- Cheeses are on the **Meat and Meat Substitutes** list (because they are rich in protein).
- Cream and other dairy fats are on the **Fats** list.

Milks and yogurts are grouped in 3 categories (fat-free/low-fat, reduced-fat, or whole) based on the amount of fat they have. The following chart shows you what 1 milk choice contains:

	Carbohydrate (grams)	Protein (grams)	Fat (grams)	Calories
Fat-free (skim), low-fat (1%)	12	8	0-3	100
Reduced-fat (2%)	12	8	5	120
Whole	12	8	8	160

Nutrition Tips

1. Milk and yogurt are good sources of calcium and protein.
2. The higher the fat content of milk and yogurt, the more saturated fat and cholesterol it has.
3. Children over the age of 2 and adults should choose lower-fat varieties such as skim, 1%, or 2% milks or yogurts.

Selection Tips

1. 1 cup equals 8 fluid oz or ½ pint.
2. If you choose 2%, or whole-milk foods, be aware of the extra fat.

Food	Serving Size	Count As
Milk and Yogurts		
Fat-free or low-fat (1%)		
Milk, buttermilk, acidophilus milk, Lactaid	1 cup	1 fat-free milk
Evaporated milk	½ cup	1 fat-free milk
Yogurt, plain or flavored with an artificial sweetener	⅔ cup (6 oz)	1 fat-free milk
Reduced-fat (2%)		
Milk, acidophilus milk, kefir, Lactaid	1 cup	1 reduced-fat milk
Yogurt, plain	⅔ cup (6 oz)	1 reduced-fat milk
Whole		
Milk, buttermilk, goat's milk	1 cup	1 whole milk
Evaporated milk	½ cup	1 whole milk
Yogurt, plain	8 oz	1 whole milk
Dairy-Like Foods		
Chocolate milk		
Fat-free	1 cup	1 fat-free milk + 1 carbohydrate
Whole	1 cup	1 whole milk + 1 carbohydrate

Food	Serving Size	Count As
Eggnog, whole milk	½ cup	1 carbohydrate + 2 fats
Rice drink		
Flavored, low-fat	1 cup	2 carbohydrates
Plain, fat-free	1 cup	1 carbohydrate
Smoothies, flavored, regular	10 oz	1 fat-free milk + 2½ carbohydrates
Soy milk		
Light	1 cup	1 carbohydrate + ½ fat
Regular, plain	1 cup	1 carbohydrate + 1 fat
Yogurt		
And juice blends	1 cup	1 fat-free milk + 1 carbohydrate
Low carbohydrate (less than 6 grams carbohydrate per choice)	⅔ cup (6 oz)	½ fat-free milk
With fruit, low-fat	⅔ cup (6 oz)	1 fat-free milk + 1 carbohydrate

SWEETS, DESSERTS, AND OTHER CARBOHYDRATES

You can substitute food choices from this list for other carbohydrate-containing foods (such as those found on the **Starch, Fruit, or Milk** lists) in your meal plan, even though these foods have added sugars or fat.

Common Measurements

Dry:

- 3 tsp = 1 Tbsp
- 4 oz = ½ cup
- 8 oz = 1 cup

Liquid:

- 4 Tbsp = ¼ cup
- 8 oz = ½ pint

Nutrition Tips

1. A carbohydrate choice has 15 grams of carbohydrate, variable grams of protein, variable grams of fat, and variable calories.
2. The foods on this list do not have as many vitamins, minerals, and fiber as the choices on the **Starch, Fruits, or Milk** lists. When choosing sweets, desserts, and other carbohydrate foods, you should also eat foods from other food lists to balance out your meals.
3. Many of these foods don't equal a single choice. Some will also count as one or more fat choices.
4. If you are trying to lose weight, choose foods from this list less often.
5. The serving sizes for these foods are small because of their fat content.

Selection Tips

1. Read the Nutrition facts on the food label to find the serving size and nutrient information.
2. Many sugar-free, fat-free, or reduced-fat products are made with ingredients that contain carbohydrate. These types of food usually have the same amount of carbohydrate as the regular foods they are replacing. Talk with your RD and find out how to fit these foods into your meal plan.

Food	Serving Size	Count As	Food	Serving Size	Count As
Beverages, Soda, and Energy/Sports Drinks			Cookies		
Cranberry juice cocktail	½ cup	1 carbohydrate	Chocolate chip	2 cookies (2¼ inches across)	1 carbohydrate + 2 fats
Energy drink	1 can (8.3 oz)	2 carbohydrates	Gingersnap	3 cookies	1 carbohydrate
Fruit drink or lemonade	1 cup (8 oz)	2 carbohydrates	Sandwich, with creme filling	2 small (about ⅔ oz)	1 carbohydrate + 1 fat
Hot Chocolate			Sugar-free	3 small or 1 large (¾-1 oz)	1 carbohydrate + 1-2 fats
Regular	1 envelope added to 8 oz water	1 carbohydrate + 1 fat	Vanilla wafer	5 cookies	1 carbohydrate + 1 fat
Sugar-free or light	1 envelope added to 8 oz water	1 carbohydrate	Cupcake, frosted	1 small (about 1¾ oz)	2 carbohydrates + 1-1½ fats
Soft drink (soda), regular	1 can (12 oz)	2½ carbohydrates	Fruit cobbler	½ cup (3½ oz)	3 carbohydrates + 1 fat
Sports drink	1 cup (8 oz)	1 carbohydrate	Gelatin, regular	½ cup	1 carbohydrate
Brownies, Cake, Cookies, Gelatin, Pie, and Pudding			Pie		
Brownie, small, unfrosted	1¼-inch square, ⅞ inch high (about 1 oz)	1 carbohydrate + 1 fat	Commercially prepared fruit, 2 crusts	⅓ of 8-inch pie	3 carbohydrates + 2 fats
Cake			Pumpkin or custard	⅓ of 8-inch pie	1½ carbohydrates + 1½ fats
Angel food, unfrosted	½ of cake (about 2 oz)	2 carbohydrates	Pudding		
Frosted	2-inch square (about 2 oz)	2 carbohydrates + 1 fat	Regular (made with reduced-fat milk)	½ cup	2 carbohydrates
Unfrosted	2-inch square (about 2 oz)	1 carbohydrate + 1 fat	Sugar-free or sugar- and fat-free (made with fat-free milk)	½ cup	1 carbohydrate

Glazed	¾ inches across (2 oz)	2 carbohydrates + 2 fats			

[†]480 mg or more of sodium per serving.

NONSTARCHY VEGETABLES

Vegetable choices include vegetables in this **Nonstarchy Vegetables** list and the Starchy Vegetables list found within the **Starch** list. Vegetables with small amounts of carbohydrate and calories are on the **Nonstarchy Vegetables** list. Vegetables contain important nutrients. Try to eat at least 2 to 3 nonstarchy vegetable choices each day (as well as choices from the Starchy Vegetables list). In general, 1 nonstarchy vegetable choice is:

- ½ cup of cooked vegetables or vegetable juice
- 1 cup of raw vegetables

If you eat 3 cups or more of raw vegetables or 1½ cups of cooked vegetables in a meal, count them as 1 carbohydrate choice.

Nutrition Tips

1. A choice on this list (½ cup cooked or 1 cup raw) equals 5 grams of carbohydrate, 2 grams of protein, 0 grams of fat, and 25 calories.
2. Fresh and frozen vegetables have less added salt than canned vegetables. Drain and rinse canned vegetables to remove some salt.

3. Choose dark green and dark yellow vegetables each day. Spinach, broccoli, romaine, carrots, chilies, squash, and peppers are great choices.
4. Brussels sprouts, broccoli, cauliflower, greens, peppers, spinach, and tomatoes are good sources of vitamin C.
5. Eat vegetables from the cruciferous family several times each week. Cruciferous vegetables include bok choy, broccoli, brussels sprouts, cabbage, cauliflower, collards, kale, kohlrabi, radishes, rutabaga, turnip, and watercress.

Selection Tips

1. Canned vegetables and juices are also available without added salt.
2. A 1-cup portion of broccoli is a portion about the size of a regular light bulb.
3. Starchy vegetables such as corn, peas, winter squash, and potatoes that have more calories and carbohydrates are on the Starchy Vegetables section in the **Starch** list.
4. The tomato sauce referred to in this list is different from spaghetti/pasta sauce, which is on the Starchy Vegetables list.

Nonstarchy Vegetables

Amaranth or Chinese spinach	Cucumber	Peppers (all varieties)*
Artichoke	Eggplant	Radishes
Artichoke hearts	Gourds (bitter, bottle, luffa, bitter melon)	Rutabaga
Asparagus	Green onions or scallions	Sauerkraut†
Baby corn	Greens (collard, kale, mustard, turnip)	Soybean sprouts
Bamboo shoots	Hearts of palm	Spinach
Beans (green, wax, Italian)	Jicama	Squash (summer, crookneck, zucchini)
Bean sprouts	Kohlrabi	Sugar pea snaps
Beets	Leeks	Swiss chard*
Borscht†	Mixed vegetables (without corn, peas, or pasta)	Tomato
Broccoli	Mung bean sprouts	Tomatoes, canned
Brussels sprouts*	Mushrooms, all kinds, fresh	Tomato sauce†
Cabbage (green, bok choy, Chinese)	Okra	Tomato/vegetable juice‡
Carrots*	Onions	Turnips
Cauliflower	Oriental radish or daikon	Water chestnuts
Celery	Pea pods	Yard-long beans
Chayote*		
Coleslaw, packaged, no dressing		

*More than 3 grams of dietary fiber per serving.
 †480 milligrams or more of sodium per serving.

MEAT AND MEAT SUBSTITUTES

Meat and meat substitutes are rich in protein. Foods from this list are divided into 4 groups based on the amount of fat they contain. These groups are lean meat, medium-fat meat, high-fat meat, and plant-based proteins. The following chart shows you what one choice includes:

	Carbohydrate (grams)	Protein (grams)	Fat (grams)	Calories
Lean meat	—	7	0-3	45
Medium-fat meat	—	7	4-7	75
High-fat meat	—	7	8+	100
Plant-based protein	Varies	7	Varies	Varies

Nutrition Tips

1. Read labels to find foods low in fat and cholesterol. Try for 3 grams of fat or less per serving.
2. Read labels to find “hidden” carbohydrate. For example, hot dogs actually contain a lot of carbohydrate. Most hot dogs are also high in fat, but are often sold in lower-fat versions.

3. Whenever possible, choose lean meats.
 - a. Select grades of meat that are the leanest.
 - b. Choice grades have a moderate amount of fat.
 - c. Prime cuts of meat have the highest amount of fat.
4. Fish such as herring, mackerel, salmon, sardines, halibut, trout, and tuna are rich in omega-3 fats, which may help reduce risk for heart disease. Choose fish (not commercially fried fish fillets) two or more times each week.
5. Bake, roast, broil, grill, poach, steam, or boil instead of frying.

Selection Tips

1. Trim off visible fat or skin.
2. Roast, broil, or grill meat on a rack so that the fat will drain off during cooking.
3. Use a nonstick spray and a nonstick pan to brown or fry foods.
4. Some processed meats, seafood, and soy products contain carbohydrate. Read the food label to see if the amount of carbohydrate in the serving size you plan to eat is close to 13 grams. If so, count it as 1 carbohydrate choice and 1 or more meat choice.
5. Meat or fish that is breaded with cornmeal, flour, or dried bread crumbs contain carbohydrate. Count 3 Tbsp of one of these dry grains as 15 grams of carbohydrate.

Food	Amount
Lean Meats and Meat Substitutes	
Beef: Select or Choice grades trimmed of fat: ground round, roast (chuck, rib, rump), round, sirloin, steak (cubed, flank, porterhouse, T-bone), tenderloin	1 oz
Beef jerky†	1 oz
Cheeses with 3 grams of fat or less per oz	1 oz
Cottage cheese	¼ cup
Egg substitutes, plain	¼ cup
Egg whites	2
Fish, fresh or frozen, plain: catfish, cod, flounder, haddock, halibut, orange roughy, salmon, tilapia, trout, tuna	1 oz
Fish, smoked: herring or salmon (lox)‡	1 oz
Game: buffalo, ostrich, rabbit, venison	1 oz
Hot dog with 3 grams of fat or less per oz† (8 dogs per 14 oz package) (Note: Maybe high in carbohydrate)	1
Lamb: chop, leg, or roast	1 oz
Organ meats: heart, kidney, liver (Note: Maybe high in cholesterol)	1 oz
Oysters, fresh or frozen	6 medium
Pork, Lean	
Canadian bacon†	1 oz
Rib or loin chop/roast, ham, tenderloin	1 oz
Poultry, without skin: Cornish hen, chicken, domestic duck or goose (well-drained of fat), turkey	1 oz
Processed sandwich meats with 3 grams of fat or less per oz: chipped beef, deli thin-sliced meats, turkey ham, turkey kielbasa, turkey pastrami	1 oz
Salmon, canned	1 oz
Sardines, canned	2 medium
Sausage with 3 grams of fat or less per oz†	1 oz
Shellfish: clams, crab, imitation shellfish, lobster, scallops, shrimp	1 oz
Tuna, canned in water or oil, drained	1 oz
Veal, loin chop, roast	1 oz

Food	Amount
Medium-Fat Meat and Meat Substitutes	
Beef: corned beef, ground beef, meatloaf, Prime grades trimmed of fat (prime rib), short ribs, tongue	1 oz
Cheeses with 4-7 grams of fat per oz: feta, mozzarella, pasteurized processed cheese spread, reduced-fat cheeses, string	1 oz
Egg (Note: High in cholesterol, so limit to 3 per week)	1
Fish, any fried product	1 oz
Lamb: ground, rib roast	1 oz
Pork: cutlet, shoulder roast	1 oz
Poultry: chicken with skin; dove, pheasant, wild duck, or goose; fried chicken; ground turkey	1 oz
Ricotta cheese	2 oz or ¼ cup
Sausage with 4-7 grams of fat per oz [†]	1 oz
Veal, cutlet (no breading)	1 oz

[†]480 milligrams or more of sodium per serving.

The following foods are high in saturated fat, cholesterol, and calories and may raise blood cholesterol levels if eaten on a regular basis. Try to eat 3 or fewer servings from this group per week.

High-Fat Meat and Meat Substitutes	
Food	Amount
Bacon	
Pork [†]	2 slices (16 slices per lb or 1 oz each, before cooking)
Turkey [†]	3 slices (½ oz each before cooking)
Cheese, regular: American, bleu, brie, cheddar, hard goat, Monterey jack, queso, and Swiss	1 oz
Hot dog: beef, pork, or combination (10 per lb-sized package) ^{††}	1
Hot dog: turkey or chicken (10 per lb-sized package) [†]	1
Pork: ground, sausage, spareribs	1 oz
Processed sandwich meats with 8 grams of fat or more per oz: bologna, pastrami, hard salami	1 oz
Sausage with 8 grams fat or more per oz: bratwurst, chorizo, Italian, knockwurst, Polish, smoked, summer ^{††}	1 oz

[†]Extra fat, or prepared with added fat. (Add an additional fat choice to this food.)

^{††}480 milligrams or more of sodium per serving.

Because carbohydrate content varies among plant-based proteins, you should read the food label.

Food	Amount	Countas
Plant-Based Proteins		
"Bacon" strips, soy-based	3 strips	1 medium-fat meat
Baked beans*	½ cup	1 starch + 1 lean meat
Beans, cooked: black, garbanzo, kidney, lima, navy, pinto, white*	½ cup	1 starch + 1 lean meat

Food	Amount	Countas
"Beef" or "sausage" crumbles, soy-based*	2 oz	½ carbohydrate + 1 lean meat
"Chicken" nuggets, soy-based	2 nuggets (1½ oz)	½ carbohydrate + 1 medium-fat meat
Edamame*	½ cup	½ carbohydrate + 1 lean meat
Falafel (spiced chickpea and wheat patties)	3 patties (about 2 inches across)	1 carbohydrate + 1 high-fat meat
Hot dog, soy-based	1 (1½ oz)	½ carbohydrate + 1 lean meat
Hummus*	⅓ cup	1 carbohydrate + 1 high-fat meat
Lentils, brown, green, or yellow*	½ cup	1 carbohydrate + 1 lean meat
Meatless burger, soy-based*	3 oz	½ carbohydrate + 2 lean meats
Meatless burger, vegetable- and starch-based*	1 patty (about 2½ oz)	1 carbohydrate + 2 lean meats
Nut spreads: almond butter, cashew butter, peanut butter, soy nut butter	1 Tbsp	1 high-fat meat
Peas, cooked: black-eyed and split peas*	½ cup	1 starch + 1 lean meat
Refried beans, canned ^{†*}	½ cup	1 starch + 1 lean meat
"Sausage" patties, soy-based	1 (1½ oz)	1 medium-fat meat
Soy nuts, unsalted	¾ oz	½ carbohydrate + 1 medium-fat meat
Tempeh	¼ cup	1 medium-fat meat
Tofu	4 oz (½ oz)	1 medium-fat meat
Tofu, light	4 oz (½ oz)	1 lean meat

*More than 3 grams of dietary fiber per serving.

[†]480 milligrams or more of sodium per serving.

FATS

Fats are divided into 3 groups, based on the main type of fat they contain:

- **Unsaturated fats** (omega-3, monounsaturated, and polyunsaturated) are primarily vegetable and are liquid at room temperature. These fats have good health benefits.
- **Omega-3 fats** are a type of polyunsaturated fat and can help lower triglyceride levels and the risk of heart disease.
- **Monounsaturated fats** also help lower cholesterol levels and may help raise HDL (good) cholesterol levels.
- **Polyunsaturated fats** can help lower cholesterol levels.
- **Saturated fats** have been linked with heart disease. They can raise LDL (bad) cholesterol levels and should be eaten in small amounts. Saturated fats are solid at room temperature.
- **Trans fats** are made in a process that changes vegetable oils into semi-solid fats. These fats can raise blood cholesterol levels and should be eaten in small amounts. Partially hydrogenated and hydrogenated fats are types of man-made *trans* fats and should be avoided. *Trans* fats are also found naturally occurring in some animal products such as meat, cheese, butter, and dairy products.

Nutrition Tips

1. A choice on the **Fats** list contains 5 grams of fat and 45 calories.
2. All fats are high in calories. Limit serving sizes for good nutrition and health.
3. Limit the amount of fried foods you eat.
4. Nuts and seeds are good sources of unsaturated fats if eaten in moderation. They have small amounts of fiber, protein, and magnesium.
5. Good sources of omega-3 fatty acids include:
 - a. Fish such as albacore tuna, halibut, herring, mackerel, salmon, sardines, and trout
 - b. Flaxseeds and English walnuts
 - c. Oils such as canola, soybean, flaxseed, and walnut.

Selection Tips

1. Read the Nutrition Facts on food labels for serving sizes. One fat choice is based on a serving size that has 5 grams of fat.

2. The food label also lists total fat grams, saturated fat, and *trans* fat grams per serving. When most of the calories come from saturated fat, the food is part of the Saturated Fats list.
3. When selecting fats, consider replacing saturated fats with monounsaturated fats and omega-3 fats. Talk with your RD about the best choices for you.
4. When selecting regular margarine, choose those that list liquid vegetable oil as the first ingredient. Soft or tub margarines have less saturated fat than stick margarines and are a healthier choice. Look for *trans* fat-free soft margarines.
5. When selecting reduced-fat or lower-fat margarines, look for liquid vegetable oil (*trans* fat-free). Water is usually the first ingredient.

Fats and oils have mixtures of unsaturated (polyunsaturated and monounsaturated) and saturated fats. Foods on the Fats list are grouped together based on the major type of fat they contain. In general, 1 fat choice equals:

- 1 teaspoon of regular margarine, vegetable oil, or butter
- 1 tablespoon of regular salad dressing

Food	Serving Size	Food	Serving Size
Unsaturated Fats—Monounsaturated Fats		Seeds	
Avocado, medium	2 Tbsp (1 oz)	Flaxseed, whole	1 Tbsp
Nut butters (<i>trans</i> fat-free): almond butter, cashew butter, peanut butter (smooth or crunchy)	1½ tsp	Pumpkin, sunflower	1 Tbsp
		Sesame seeds	1 Tbsp
		Tahini or sesame paste	2 tsp
Nuts		Saturated Fats	
Almonds	6 nuts	Bacon, cooked, regular or turkey	1 slice
Brazil	2 nuts		
Cashews	6 nuts		
Filberts (hazelnuts)	5 nuts		
Macadamia	3 nuts		
Mixed (50% peanuts)	6 nuts		
Peanuts	10 nuts		
Pecans	4 halves		
Pistachios	16 nuts		
Oil: canola, olive, peanut	1 tsp		
Olives		Butter	
Black (ripe)	8 large	Reduced-fat	1 Tbsp
Green, stuffed	10 large	Stick	1 tsp
		Whipped	2 tsp
Polyunsaturated Fats		Butter Blends Made with Oil	
Margarine: lower-fat spread (30%-50% vegetable oil, <i>trans</i> fat-free)	1 Tbsp	Reduced-fat or light	1 Tbsp
Margarine: stick, tub (<i>trans</i> fat-free), or squeeze (<i>trans</i> fat-free)	1 tsp	Regular	1½ tsp
		Chitterlings, boiled	2 Tbsp (½ oz)
		Coconut, sweetened, shredded	2 Tbsp
Mayonnaise		Coconut Milk	
Reduced-fat	1 Tbsp	Light	½ cup
Regular	1 tsp	Regular	1½ Tbsp
Mayonnaise-Style Salad Dressing		Cream	
Reduced-fat	1 Tbsp	Half and half	2 Tbsp
Regular	2 tsp	Heavy	1 Tbsp
		Light	1½ Tbsp
		Whipped	2 Tbsp
		Whipped, pressurized	¼ cup
Nuts		Cream Cheese	
Walnuts, English	4 halves	Reduced-fat	1½ Tbsp (¾ oz)
Pignolia (pine nuts)	1 Tbsp	Regular	1 Tbsp (½ oz)
Oil: corn, cottonseed, flaxseed, grape seed, safflower, soybean, sunflower	1 tsp	Lard	1 tsp
Oil: made from soybean and canola oil—Enova	1 tsp	Oil: coconut, palm, palm kernel	1 tsp
		Salt pork	¼ oz
		Shortening, solid	1 tsp
Plant Stanol Esters		Sour Cream	
Light	1 Tbsp	Reduced-fat or light	3 Tbsp
Regular	2 tsp	Regular	2 Tbsp
Salad Dressing			
Reduced-fat (Note: May be high in carbohydrate) [†]	2 Tbsp		
Regular [†]	1 Tbsp		

[†]480 milligrams or more of sodium per serving.

FREE FOODS

A “free” food is any food or drink choice that has less than 20 calories and 5 grams or less of carbohydrate per serving.

Selection Tips

1. Most foods on this list should be limited to 3 servings (as listed here) per day. Spread out the servings throughout the

day. If you eat all 3 servings at once, it could raise your blood glucose level.

2. Food and drink choices listed here without a serving size can be eaten whenever you like.

Food	Serving Size	Food	Serving Size
Low Carbohydrate Foods		Mayonnaise-style Salad Dressing	
Cabbage, raw	½ cup	Fat-free	1 Tbsp
Candy, hard (regular or sugar-free)	1 piece	Reduced-fat	1 tsp
Carrots, cauliflower, or green beans, cooked	¼ cup	Salad Dressing	
Cranberries, sweetened with sugar substitute	½ cup	Fat-free or low-fat	1 Tbsp
Cucumber, sliced	½ cup	Fat-free, Italian	2 Tbsp
Gelatin		Sour cream, fat-free or reduced-fat	1 Tbsp
Dessert, sugar-free		Whipped Topping	
Unflavored		Light or fat-free	2 Tbsp
Gum		Regular	1 Tbsp
Jam or jelly, light or no sugar added	2 tsp	Condiments	
Rhubarb, sweetened with sugar substitute	½ cup	Barbecue sauce	2 tsp
Salad greens		Catsup (ketchup)	1 Tbsp
Sugar substitutes (artificial sweeteners)		Honey mustard	1 Tbsp
Syrup, sugar-free	2 Tbsp	Horseradish	
Modified Fat Foods with Carbohydrate		Lemon juice	
Cream cheese, fat-free	1 Tbsp (½ oz)	Miso	1½ tsp
Creamers		Mustard	
Nondairy, liquid	1 Tbsp	Parmesan cheese, freshly grated	1 Tbsp
Nondairy, powdered	2 tsp	Pickle relish	1 Tbsp
Margarine Spread		Pickles	
Fat-free	1 Tbsp	Dill [†]	1½ medium
Reduced-fat	1 tsp	Sweet, bread and butter	2 slices
Mayonnaise		Sweet, gherkin	¾ oz
Fat-free	1 Tbsp	Salsa	¼ cup
Reduced-fat	1 tsp	Soy sauce, light or regular [†]	1 Tbsp
		Sweet and sour sauce	2 tsp
		Sweet chili sauce	2 tsp
		Taco sauce	1 Tbsp
		Vinegar	
		Yogurt, any type	2 Tbsp

[†]480 milligrams or more of sodium per serving.

Free Snacks

These foods in these serving sizes are perfect free-food snacks:

- 5 baby carrots and celery sticks
- ¼ cup blueberries
- ½ oz sliced cheese, fat-free
- 10 goldfish-style crackers
- 2 saltine-type crackers
- 1 frozen cream pop, sugar-free
- ½ oz lean meat
- 1 cup light popcorn
- 1 vanilla wafer

Drinks/Mixes

Any food on this list—without a serving size listed—can be consumed in any moderate amount:

- Bouillon, broth, consommé[‡]
- Bouillon or broth, low-sodium
- Carbonated or mineral water
- Club soda
- Cocoa powder, unsweetened (1 Tbsp)

- Coffee, unsweetened or with sugar substitute
- Diet soft drinks, sugar-free
- Drink mixes, sugar-free
- Tea, unsweetened or with sugar substitute
- Tonic water, diet
- Water
- Water, flavored, carbohydrate free

Seasonings

Any food on this list can be consumed in any moderate amount:

- Flavoring extracts (for example, vanilla, almond, peppermint)
- Garlic
- Herbs, fresh or dried
- Nonstick cooking spray
- Pimento
- Spices
- Hot pepper sauce
- Wine, used in cooking
- Worcestershire sauce

COMBINATION FOODS

Many of the foods you eat are mixed together in various combinations, such as casseroles. These “combination” foods do not fit into any one choice list. This is a list of choices for some typical combination foods. This list will help you fit these foods into your meal plan. Ask your RD for nutrient information about other combination foods you would like to eat, including your own recipes.

Food	Serving Size	Count As
Entrees		
Casserole type (tuna noodle, lasagna, spaghetti with meatballs, chili with beans, macaroni and cheese) [†]	1 cup (8 oz)	2 carbohydrates + 2 medium-fat meats
Stews (beef/other meats and vegetables) [†]	1 cup (8 oz)	1 carbohydrate + 1 medium-fat meat + 0-3 fats
Tuna salad or chicken salad	½ cup (3½ oz)	½ carbohydrate + 2 lean meats + 1 fat
Frozen Meals/Entrees		
Burrito (beef and bean) ^{†*}	1 (5 oz)	3 carbohydrates + 1 lean meat + 2 fats
Dinner-type meal [†]	Generally 14-17 oz	3 carbohydrates + 3 medium-fat meats + 3 fats
Entree or meal with less than 340 calories [†]	About 8-11 oz	2-3 carbohydrates + 1-2 lean meats
Pizza		
Cheese/vegetarian, thin crust [†]	¼ of a 12 inch (4½-5 oz)	2 carbohydrates + 2 medium-fat meats
Meat topping, thin crust [†]	¼ of a 12 inch (5 oz)	2 carbohydrates + 2 medium-fat meats + 1½ fats
Pocket sandwich [†]	1 (4½ oz)	3 carbohydrates + 1 lean meat + 1-2 fats
Pot pie [†]	1 (7 oz)	2½ carbohydrates + 1 medium-fat meat + 3 fats
Salads (Deli-Style)		
Coleslaw	½ cup	1 carbohydrate + 1½ fats
Macaroni/pasta salad	½ cup	2 carbohydrates + 3 fats
Potato salad [†]	½ cup	1½-2 carbohydrates + 1-2 fats
Soups		
Bean, lentil, or split pea [†]	1 cup	1 carbohydrate + 1 lean meat
Chowder (made with milk) [†]	1 cup (8 oz)	1 carbohydrate + 1 lean meat + 1½ fats
Cream (made with water) [†]	1 cup (8 oz)	1 carbohydrate + 1 fat
Instant [†]	6 oz prepared	1 carbohydrate
With beans or lentils [†]	8 oz prepared	2½ carbohydrates + 1 lean meat
Miso soup [†]	1 cup	½ carbohydrate + 1 fat
Oriental noodle [†]	1 cup	2 carbohydrates + 2 fats
Rice (congee)	1 cup	1 carbohydrate
Tomato (made with water) [†]	1 cup (8 oz)	1 carbohydrate
Vegetable beef, chicken noodle, or other broth-type [†]	1 cup (8 oz)	1 carbohydrate

*More than 3 grams of dietary fiber per serving.

†600 milligrams or more of sodium per serving (for combination food main dishes/meals).

FAST FOODS

The choices in the **Fast Foods** list are not specific fast food meals or items, but are estimates based on popular foods. You can get specific nutrition information for almost every fast food or restaurant chain. Ask the restaurant or check its website for nutrition information about your favorite fast foods.

Food	Serving Size	Count As
Breakfast Sandwiches		
Egg, cheese, meat, English muffin [†]	1 sandwich	2 carbohydrates + 2 medium-fat meats
Sausage biscuit sandwich [†]	1 sandwich	2 carbohydrates + 2 high-fat meats + 3½ fats
Main Dishes/Entrees		
Burrito (beef and beans) ^{†*}	1 (about 8 oz)	3 carbohydrates + 3 medium-fat meats + 3 fats
Chicken breast, breaded and fried [†]	1 (about 5 oz)	1 carbohydrate + 4 medium-fat meats
Chicken drumstick, breaded and fried	1 (about 2 oz)	2 medium-fat meats
Chicken nuggets [†]	6 (about 3½ oz)	1 carbohydrate + 2 medium-fat meats + 1 fat
Chicken thigh, breaded and fried [†]	1 (about 4 oz)	½ carbohydrate + 3 medium-fat meats + 1½ fats
Chicken wings, hot [†]	6 (5 oz)	5 medium-fat meats + 1½ fats
Oriental		
Beef/chicken/shrimp with vegetables in sauce [†]	1 cup (about 5 oz)	1 carbohydrate + 1 lean meat + 1 fat
Egg roll, meat [†]	1 (about 3 oz)	1 carbohydrate + 1 lean meat + 1 fat
Fried rice, meatless	½ cup	1½ carbohydrates + 1½ fats
Meat and sweet sauce (orange chicken) [†]	1 cup	3 carbohydrates + 3 medium-fat meats + 2 fats
Noodles and vegetables in sauce (chow mein, lo mein) ^{†*}	1 cup	2 carbohydrates + 1 fat
Pizza		
Cheese, pepperoni, regular crust [†]	⅛ of a 14 inch (about 4 oz)	2½ carbohydrates + 1 medium-fat meat + 1½ fats
Cheese/vegetarian, thin crust [†]	¼ of a 12 inch (about 6 oz)	2½ carbohydrates + 2 medium-fat meats + 1½ fats
Sandwiches		
Chicken sandwich, grilled [†]	1	3 carbohydrates + 4 lean meats
Chicken sandwich, crispy [†]	1	3½ carbohydrates + 3 medium-fat meats + 1 fat
Fish sandwich with tartar sauce	1	2½ carbohydrates + 2 medium-fat meats + 2 fats

Continued

Food	Serving Size	Count As
Hamburger		
Large with cheese [†]	1	2½ carbohydrates + 4 medium-fat meats + 1 fat
Regular	1	2 carbohydrates + 1 medium-fat meat + 1 fat
Hot dog with bun [†]	1	1 carbohydrate + 1 high-fat meat + 1 fat
Submarine sandwich		
Less than 6 grams fat [‡]	6-inch sub	3 carbohydrates + 2 lean meats
Regular [†]	6-inch sub	3½ carbohydrates + 2 medium-fat meats + 1 fat
Taco, hard or soft shell (meat and cheese)	1 small	1 carbohydrate + 1 medium-fat meat + 1½ fats
Salads		
Salad, main dish (grilled chicken type, no dressing or croutons) ^{†*}	Salad	1 carbohydrate + 4 lean meats
Salad, side, no dressing or cheese	Small (about 5 oz)	1 vegetable
Sides/Appetizers		
French fries, restaurant style [†]	Small	3 carbohydrates + 3 fats
	Medium	4 carbohydrates + 4 fats
	Large	5 carbohydrates + 6 fats
Nachos with cheese [†]	Small (about 4½ oz)	2½ carbohydrates + 4 fats
Onion rings [†]	1 serving (about 3 oz)	2½ carbohydrates + 3 fats
Desserts		
Milkshake, any flavor	12 oz	6 carbohydrates + 2 fats
Soft-serve ice cream cone	1 small	2½ carbohydrates + 1 fat

*More than 3 grams of dietary fiber per serving.

[†]Extra fat, or prepared with extra fat.

[‡]600 milligrams or more of sodium per serving (for fast food main dishes/meals).

ALCOHOL

Nutrition Tips

1. In general, 1 alcohol choice (½ oz absolute alcohol) has about 100 calories.

Selection Tips

1. If you choose to drink alcohol, you should limit it to 1 drink or less per day for women, and 2 drinks or less per day for men.
2. To reduce your risk of low blood glucose (hypoglycemia), especially if you take insulin or a diabetes pill that increases insulin, always drink alcohol with food.
3. While alcohol, by itself, does not directly affect blood glucose, be aware of the carbohydrate (for example, in mixed drinks, beer, and wine) that may raise your blood glucose.
4. Check with your RD if you would like to fit alcohol into your meal plan.

Alcoholic Beverage	Serving Size	Count As
Beer		
Light (4.2%)	12 fl oz	1 alcohol equivalent + ½ carbohydrate
Regular (4.9%)	12 fl oz	1 alcohol equivalent + 1 carbohydrate
Distilled spirits: vodka, rum, gin, whiskey 80 or 86 proof	1½ fl oz	1 alcohol equivalent
Liqueur, coffee (53 proof)	1 fl oz	1 alcohol equivalent + 1 carbohydrate
Sake	1 fl oz	½ alcohol equivalent
Wine		
Dessert (sherry)	3½ fl oz	1 alcohol equivalent + 1 carbohydrate
Dry, red or white (10%)	5 fl oz	1 alcohol equivalent

Development of Standardized Dysphagia Diets

TEXTURE MODIFICATIONS

Level 3: Dysphagia Advanced (Previously: Mechanical Soft):

- Soft-solid foods. Includes easy-to-cut whole meats, soft fruits and vegetables (i.e. bananas, peaches, melon without seeds, tender meat cut into small pieces and well moistened with extra gravy or sauce).
- Crusts should be cut off of bread.
- Most is chopped or cut into small pieces.
EXCLUDES hard, crunchy fruits and vegetables, sticky foods, and very dry foods. NO nuts, seeds, popcorn, potato chips, coconut, hard rolls, raw vegetables, potato skins, corn, etc. Most food is chopped/cut into small pieces.

Level 2: *Dysphagia Mechanically-Altered (Previously: Ground):

- Cohesive, moist, semisolid foods that require some chewing ability.
- Includes fork-mashable fruits and vegetables (i.e. soft canned, or cooked fruits with vegetables in pieces smaller than ½ inch).
- Meat should be ground and moist. Extra sauce and gravy should be served.
EXCLUDES most bread products, crackers, and other dry foods. No whole grain cereal with nuts, seeds and coconut.

No food with large chunks. Most food should be ground texture.

Level 1: *Dysphagia Puree:

- Smooth, pureed, homogenous, very cohesive, pudding-like foods that require little or no chewing ability.
- No whole foods.
- Includes mashed potatoes with gravy, yogurt with no fruit added, pudding, soups pureed smooth, pureed fruits and vegetables, pureed meat/poultry/fish, sauces/gravies, and pureed desserts without nuts, seeds, or coconut.
AVOID scrambled, fried, or hard boiled eggs.

FLUID MODIFICATIONS

Thin Liquids: includes water, soda, juice broth, coffee, tea. This also includes foods like jello, ice cream and sherbet that melt and become thin when swallowed.

Nectar-thick Liquids: are pourable and the consistency of apricot nectar

Honey-thick Liquids: slightly thicker than nectar and can be drizzled; consistency of honey.

Pudding-thick Liquids: also called pudding-thick; should hold their shape, and a spoon should stand up in them; they are not pourable and are eaten with a spoon.

Renal Diet for Dialysis

Your diet depends on your kidney function. Most of the information here relates to people on dialysis. What is right for others is not always right for you. As your kidney function changes, your diet may change as well. This guide will help you do two things: plan nutritious meals you enjoy and keep your body working at its best. Your renal dietitian will work with you to make any changes needed to your usual meal plan, but this appendix contains helpful guidelines.

1. Increase Protein

You will need to eat a high-protein diet. Beef, pork, lamb, fish, shellfish, chicken, eggs, and other animal foods provide most of the protein in your diet. Your protein needs are based on your weight. Most people need at least 6 to 8 oz of protein per day. A deck of cards is about the size of a 3-oz serving of protein.

2. Limit Potassium

Most foods contain some potassium, but fruits and vegetables are the easiest to control. Limit fruits, vegetables, and juices to 6 servings per day. A serving is usually ½ cup.

Do not use salt substitute or “lite” salt because they are made with potassium.

3. Limit Salt

Limit the salt you eat. Don’t add salt during cooking or at the table. Avoid high-salt foods such as frozen meals; canned or dried foods; “fast foods”; and salted meats such as ham, sausage, and luncheon meats. Use salt-free spices or spice mixes such as Mrs. Dash instead of salt to add flavor to your food.

4. Limit Phosphorus

Use only 1 serving of milk or dairy food per day. A serving is usually ½ to 1 cup. Take phosphate binders such as Tums, PhosLo, Renagel, or Fosrenol with your meals as prescribed by your doctor.

5. Fluid

A safe amount of fluid to drink is different for everyone. It depends on how much urine you are making. Try not to drink more than 3 cups (24 oz) of fluid each day plus the amount equal to your urine output. If you are limiting your salt intake, you should not feel thirsty.

Fluids include all beverages and foods that are liquid at room temperature such as Jell-O, ice cream, ice, and soup.

6. Poor Appetite and Weight Loss

It is common to have a poor appetite if you are new to dialysis. If your appetite has been poor, try eating small frequent meals and extra snacks.

Try adding high-calorie fats such as butter, margarine, and oils; sauces and gravies; and sour cream, cream cheese,

or whipped cream for extra calories. Adding rice, pasta, bread, and rolls to meals also adds calories.

Sugar and sweets such as cakes, candies, and pastries are also a good source of calories if you are not following a diabetic diet.

Talk to your nutritionist about trying a nutritional supplement.

PROTEIN

When on dialysis, you need to eat a high-protein diet. This is because you lose protein during each dialysis treatment. To stay healthy, you need to eat enough protein for your daily needs and also make up for the amount lost during dialysis. Meat, fish, poultry, eggs, and other animal foods provide most of the protein in your diet. Your body uses protein to build and repair muscles, skin, blood, and other tissues.

ALBUMIN

Albumin is a protein found in blood. Each month a laboratory test measures your albumin. It is a good way to know how healthy you are. Your albumin level should be more than 3.4 mg/dL.

KEEPING A HEALTHY ALBUMIN LEVEL

Make sure that you eat enough protein every day. How much protein you need daily depends on how much you weigh.

Find your weight on the chart below to see how many protein servings you need each day.

PROTEIN SERVINGS FOR YOU

If you weigh:	You need:
40 kg	4-5 servings
50 kg	5-6 servings
60 kg	6-7 servings
70 kg	7-8 servings
80 kg	8-9 servings
90 kg	9-10 servings
Your weight: _____ kg	
You need: _____ protein servings each day	

ONE SERVING OF PROTEIN IS:

- 1 egg
- 1 oz cooked meat, fish, poultry
- ¼ cup cooked or canned fish, seafood

½ cup tofu
 1 cup milk
 1 oz cheese
 ¼ cup cottage cheese
 ¾ cup pudding or custard
 2 Tbsp peanut butter
 1 scoop protein powder
 ½ protein bar

COMMON SERVING SIZES

Most people eat protein foods in portions larger than 1 serving. Here are some examples:

Average hamburger patty (3 oz) = 3 protein servings
 Small beefsteak (3 in × 4 in) = 4 protein servings
 Half chicken breast (3 oz) = 3 protein servings
 Chicken drumstick or thigh (2 oz) = 2 protein servings
 Average pork chop (3 oz) = 3 protein servings
 Fish fillet (3 in × 3 in) = 3 protein servings

ESTIMATING SERVING SIZES

Here are some other easy ways to estimate protein serving sizes:

- Your whole thumb is about the size of 1 oz.
- Three stacked dice are about the size of 1 oz.
- A deck of cards is about the size of 3 oz.
- The palm of your hand is about the size of 3 to 4 oz.
- Your clenched fist is about the size of 1 cup.

TIPS FOR EATING MORE PROTEIN

Some people on dialysis dislike the taste of protein. Some people find cooking smells unpleasant. Still others are not able to eat enough protein each day.

The following tips will be helpful:

- Use gravy, sauces, seasonings, or spices to improve or hide flavors.
- Prepare meals ahead of time, or stay away from kitchen smells if they spoil your appetite.
- Eat cooked protein foods cold. Try cold fried chicken, a roast beef sandwich, or shrimp salad.
- Add cut-up meats or beans to soups or salads.
- Use more eggs. Try hardboiled eggs, egg salad sandwiches, custards, or quiches. Stir beaten eggs into casseroles and soups.
- Try other protein foods such as angel food cake, peanut butter, or bean salads.
- Eat a protein bar. Your nutritionist can help you choose one.
- Use a protein powder. Your nutritionist can help you choose one and give you ideas for using it.

NUTRITIONAL SUPPLEMENTS

Nutritional supplements provide extra calories and protein. In general, use one can of supplement as a snack each day. Add one extra can for each meal you miss.

Not all nutritional supplements are safe for dialysis patients. Check with your nutritionist before using any supplement. Here are some of the supplements that are used by people on dialysis:

MALNUTRITION

If you are not eating enough meat, fish, poultry, eggs, and other high-protein foods, your albumin level will drop below the recommended level.

If your albumin level is low, the cells in your body cannot hold fluid well. This leads to swelling (edema) and low blood pressure during dialysis. Low albumin increases your risk of death. Patients with albumin levels above 4 have the lowest death rate.

It is also important to eat enough calories. Your nutritionist can help you make sure you are getting plenty of protein and calories.

EXERCISE

Try to be active in some way each day (e.g., walk, swim, garden, stretch). Using your muscles helps keep them strong. Protein that is stored in your muscles helps support your albumin level.

POTASSIUM FOR PEOPLE ON HEMODIALYSIS

- Most foods have some potassium, but fruits and vegetables are the easiest form to control in your diet. The following list groups vegetables and fruits by the amount of potassium in one serving.
- Remember, there are no foods that you cannot eat on your diet. What is important is the amount of foods you eat and how often you eat them. Keep this list handy for shopping or eating out.
- If there are fruits and vegetables you enjoy that are not on the list, ask your nutritionist about them.

MOST PEOPLE ON HEMODIALYSIS MAY HAVE

- 1 serving per day from the high-potassium group
- 2 servings per day from the medium-potassium group
- 2 to 3 servings per day from the low-potassium group

This is approximately 2000 to 3000 mg of potassium per day with the other foods you eat. Check the serving size for each food, listed in parentheses next to the item.

SOAKING VEGETABLES AND BEANS

Soaking works well for high-potassium foods such as potatoes, parsnips, sweet potatoes, winter squash, and beans. The procedure for soaking follows.

1. Peel vegetables and slice thinly ($\frac{1}{8}$ inch). Rinse well. Place them in a bowl of warm water, using four times more water than vegetable. For example, soak 1 cup of sliced vegetables in 4 cups of water. Soak at least 1 hour. Drain and rinse again.
2. Vegetables that have been soaked this way can then be fried, mashed, scalloped, put in soups or stews, or served fresh. If you are boiling the food, use four times more water than food and cook as usual.
3. Dried beans should be cooked and then chopped and soaked, using the preceding directions. Canned beans can simply be chopped, rinsed, and soaked.

Low-Potassium Foods 5-150 mg		Medium-Potassium Foods 150-250 mg	High-Potassium Foods 250-500 mg	
Food Category				
Fruits	Applesauce (½ cup)	Apple (1 medium), cherries (8-10)	Apricots (3)	
	Blackberries (½ cup)	Fruit cocktail (½ cup)	Avocados (¼)	
	Blueberries (1 cup)	Grapes (10-15)	Banana (1 medium)	
	Grapefruit (½ cup)	Mango (½ medium)	Dates (5)	
	Pears, canned (½ cup)	Melons: cantaloupe, honeydew (½ cup), papaya (½ cup)	Figs (3)	
	Pineapple (½ cup)	Peaches, canned (½ cup)	Kiwi (1)	
	Plums, canned (½ cup)	Pear, fresh (1 medium)	Nectarine (1 medium)	
	Raspberries (½ cup)	Plums (2)	Orange (1 medium)	
	Rhubarb, cooked (½ cup)	Watermelon (1 cup)	Peach, fresh (1 medium)	
	Strawberries (½ cup)		Prunes (5)	
	Tangerine (1)		Raisins and dried fruit (¼ cup)	
	Vegetables	Asparagus (4 spears)	Broccoli (½ cup)	Artichoke (1 medium)
		Bean sprouts (½ cup)	Brussels sprouts (4-6)	Beans: lima, kidney, navy, pinto (½ cup)
Cabbage (½ cup)		Beets (½ cup)	Greens: beet, collard, mustard, spinach, turnip (½ cup)	
Cauliflower (½ cup)		Carrots (½ cup)	Lentils, split peas, chickpeas, black-eyed peas (½ cup)	
Corn (½ cup)		Celery (½ cup)	Nuts: all kinds (½ cup)	
Cucumber (½)		Eggplant (½ cup)	Parsnips (½ cup)	
Green and wax beans (½ cup)		Mixed vegetables (½ cup)	Potatoes (½ cup or 1 small)	
Lettuce (1 cup)		Mushrooms (½ cup)	Pumpkin (½ cup)	
Okra (3 pods)		Peanut butter (2 Tbsp)	Spinach (½ cup)	
Onions (½ cup)		Pepper, green (1)	Tomato (1 medium)	
Peas (½ cup)		Potato chips (10)	Tomato sauce, tomato salsa (¼ cup)	
Radishes (5)		Soaked potatoes (½ cup)	Winter squash (½ cup)	
Rutabagas (½ cup)			Yams, sweet potatoes (½ cup)	
Summer squash (½ cup)				
Turnips (½ cup)				
Water chestnuts (4)				
Juices		Apple juice (½ cup)	Apricot nectar (½ cup)	Pomegranate juice (½ cup)
	Cranberry juices (1 cup)	Grape juice, canned (½ cup)	Prune juice (½ cup)	
	Grape juice, frozen (1 cup)	Grapefruit juice (½ cup)	Tomato juice (½ cup)	
	Tang, Hi-C and other fruit drinks (1 cup), Kool-Aid (1 cup)	Pineapple juice (½ cup)	V-8 juice (½ cup)	
	Lemonade and limeade (1 cup)			
	Peach or pear nectar (½ cup)			

OTHER HIGH-POTASSIUM FOODS

- Milk is high in potassium. Limit milk to 1 cup per day unless you are told to do otherwise.
- Supplements such as Ensure Plus and Enhancer Plus also contain a lot of potassium. Always speak to your nutritionist before using supplements.
- Most salt substitutes and “lite” salt products are made with potassium. Do not use these products. If you are unsure, ask your nutritionist.

SHAKING THE SALT HABIT

Salt, or “sodium chloride,” is found in convenience and preserved foods. Foods that do not spoil easily are usually high in sodium. The more sodium you eat, the thirstier you will be. The following list of foods is grouped by sodium levels.

Following a low-sodium diet can be challenging. This list of sodium levels of foods is meant to help you learn what foods and how much of them you can enjoy.

Remember, there are no foods that you cannot eat on your diet. What is important is the amount of foods you eat and

how often you eat them. Keep this list handy for shopping or dining.

MOST PEOPLE ON DIALYSIS MAY HAVE

- 1 serving per day from the high group
 - 1 serving per day from the medium group
 - As many servings as desired from the low group
 - 3 servings per day from the medium group
 - As many servings as you want from the low group
- This is 2000 to 3000 mg of sodium per day. Check the serving size for each food, listed in parentheses next to the item.

RINSING CANNED FOODS TO LOWER SODIUM (CANNED VEGETABLES, CHUNK OR FLAKED FISH OR SHELLFISH, POULTRY OR MEATS)

1. Empty can into colander or sieve.
2. Drain brine and discard.
3. Break up chunks into flakes or smaller pieces.
4. Rinse under running water for 1 min.
5. Drain food until most moisture is gone.

Low-Sodium Foods 1-150 mg		Medium-Sodium Foods 150-250 mg	High-Sodium Foods 250-700 mg
Food Category			
Breads and cereals	Breads, white, whole grain Cakes, cookies, crepes, doughnuts Cereals: cooked, granola, puffed rice, puffed wheat, Shredded Wheat, Sugar Pops, Sugar Smacks, Sugar Crisps Crackers: graham, low salt, melba toast Macaroni, noodles, spaghetti, rice	Biscuits, rolls, muffins: homemade (1) Pancakes (1) "Ready-to-eat" cereals (¾ cup) Saltine crackers (6) Sweet roll (1)	All Bran (¼ cup) Instant mixes: noodles, potatoes, rice (½ cup) Instant mixes: biscuits, breads, muffins, rolls (1 serving) Waffles (1)
Condiments	Butter, margarine, oil Horseradish, mustard, spices, herbs, sugar, syrup, Tabasco, vinegar, Worcestershire	Bacon (2 slices) Catsup, steak sauce (1 Tbsp) Commercial salad dressing (1 Tbsp) Gravy (2 Tbsp) Low-sodium soy sauce (2 tsp) Mayonnaise (2 Tbsp) Pickle relish (2 Tbsp) Sweet pickles (2 small)	Salt (¼ tsp)
Dairy products	Cheeses: cream, Monterey, Mozzarella, Ricotta, low-salt types Cream: half-and-half, sour, whipping Custard, ice cream, sherbet Milk: all kinds, yogurt Nondairy creamer	Cheeses (1-oz slice) Cottage cheese (½ cup) Pudding (¾ cup)	Buttermilk (1 cup) Processed cheeses and cheese spreads (1 slice or 2 Tbsp)
Main dishes	All unprocessed meats, fish, poultry Eggs Peanut butter Tuna: low-sodium or rinsed		Broth (½ cup) Canned fish, meat (¼ cup) Canned soups (½ cup) Hot dog (1) Luncheon meat (1 slice) Canned entrees (e.g., pork and beans, spaghetti, stew) (1 cup) Sausage (1 oz) Canned tomato sauce or puree (¼ cup) Frozen vegetables with special sauce (½ cup) Sauerkraut (¼ cup)
Fruits and vegetables	All fresh or frozen vegetables All fruits and juices Canned tomatoes, tomato paste Canned vegetables: low-sodium or rinsed	Vegetables (½ cup) Juices: tomato, vegetable (½ cup)	
Beverages and snacks	Beer, wine, coffee, tea Candy: all kinds Fruit drinks, Popsicles, soda pop, Kool-Aid, Tang Low-salt products: without potassium substitutes Unsalted nuts, unsalted popcorn	Potato and corn chips (1 cup) Snack crackers (5-10)	Commercial dips (¼ cup) Dill pickle chips (3 slices) Olives (5) Salted nuts (½ cup)

PHOSPHORUS

Low-Phosphorus Diet

When phosphorus is high for too long, bones become brittle and weak. You may have joint and bone pain. Extra phosphorus may go into your soft tissue, causing hard or soft lumps. Also, you may have severe itching.

The good news is that with diet, binders, and good dialysis, you can keep your phosphorus level under control.

Phosphorus is a mineral found in most foods. Dialysis does not remove it easily. Your phosphorus level depends on the foods you eat and your medications. Keeping your phosphorus at a safe level will help keep your bones healthy.

Each month your phosphorus level will be measured. High phosphorus is a common problem for people on dialysis. A good phosphorus level in your blood is between 3 and 6 g/dL.

High-Phosphorus Foods

Phosphorus is found in most foods you eat, especially protein foods. The foods that are highest in phosphorus are milk and things made from milk (dairy foods).

By limiting these foods you can cut down on the phosphorus you are eating. Most people on dialysis can have one serving daily from this list of dairy foods. The serving size is also noted.

You can also eat part of a serving of different foods to add up to 1 serving.

Milk (1 cup)
Cheese (2 oz)
Cottage cheese (¾ cup)
Yogurt (1 cup)
Ice cream (1½ cup)
Frozen yogurt (1½ cup)
Milkshake (1 cup)
Hot chocolate (1 cup)
Pudding or custard (1 cup)

Other High-Phosphorus Foods

When your phosphorus level is high, you may need to limit these foods to once a week.

Bran cereals (1 oz)
Dried beans or peas (½ cup cooked)
Chili (½ cup)

Nuts (½ cup)
Frozen waffles (1)

Phosphorus and Potassium

High-phosphorus foods are often high in potassium as well. This is another reason to limit dairy foods and other high-phosphorus foods.

Phosphate Binders

Phosphate binders are pills you take when you eat. Binders help keep phosphorus in your food from going into your blood.

Your doctor will decide which binder is best for you and how many you should take each time you eat.

It is important to take all your binders planned for each day.

You can take your binders just before you start a meal, during the meal, or right after eating.

If you forget to take them or skip a meal, it may be difficult to get your full binder dose. Ask your doctor what to do if this happens.

It may take some hard work to remember to take binders each time you eat. Try these ideas:

- Each morning take out the number of binders you need that day. Put them in a small container to carry with you. It should be empty at the end of the day.
- Carry a spare container of binders for when you travel or eat out.
- Take your binders with high-protein snacks such as sandwiches or dairy foods.
- Binders may cause constipation. Talk with your nutritionist about ideas to help with bowel movements.
- There are many types of binders. If you don't like the kind you are taking, talk with your doctor, pharmacist, or nutritionist about other kinds.

Lower-Phosphorus Ideas

Following are some lower-phosphorus choices you can make in the place of milk and other creamy dairy products. Check those you will try.

- Use nondairy creamer such as Mocha Mix or Coffee Rich on cereal, for creamy sauces or soups, and in shakes.
- Try rice milk or soymilk. They are lower in potassium too.
- Try soy cheese or soy yogurt. They are available in a variety of flavors.
- Use cream cheese in the place of regular cheese or cottage cheese.
- Use sour cream or imitation sour cream on fruits or to replace yogurt in dips.
- Try a nondairy frozen ice cream made from soy, rice, or nondairy creamer such as Mocha Mix.
- Enjoy sorbet or sherbet instead of ice cream.

High Phosphorus Levels

Following are some reasons for a high phosphorus level. Check the ones that you think may apply to you:

- Eating too many high-phosphorus foods
- Forgetting to take your binders
- Not taking all the phosphate binders ordered for you
- Not taking your phosphate binders at the right times

Even if you follow your diet and take your binders, your phosphorus level may be high. When calcium and phosphorus are out of balance, your parathyroid gland becomes overactive. High levels of parathyroid hormone damage your bones. Your doctor can test for this problem and recommend treatment.

Appendix created by Katy G. Wilkens, MS, RD.

NOTE: Some foods are very high in sodium and should be used only once a week. These include Chinese, Oriental foods; corned beef; ham, pastrami; fast foods (e.g., commercial hamburgers, pizza, tacos); pickles; soy sauce; and TV dinners and frozen entrees.

This page intentionally left blank

Sodium in Food

The 2015 US Dietary Guidelines specify an upper limit of 2300 mg/day of sodium for adults. This is approximately a teaspoon of table salt. In the past this level of sodium was considered to be a restriction. Currently, the average American eats almost double the recommended daily amount of sodium, so sodium restrictions continue to be commonly prescribed for patients with heart disease, kidney disease and liver disease.

The sodium in food is added in processing. Virtually no food is naturally high in sodium (see selected food list below). Food manufacturers have been responding to the call from health professionals and consumers to lower the amount of sodium in processed foods, but processed foods remain the main source of sodium in the US diet.

SPECIAL CONSIDERATIONS

A therapeutic sodium-restricted meal plan should be prescribed in terms of milligrams of sodium desired on a daily basis. The following are the commonly used levels of sodium restrictions:

No Added Salt (NAS): This is the least restrictive of the sodium-restricted diets. Table salt should not be used, and salt should not be added in cooking. High-sodium foods such as smoked, cured, or dried meats and cheeses; condiments and seasonings, salted snacks, and canned and dried soups and bouillon are restricted. The NAS diet provides no more than 3000 mg of sodium daily. It is desirable to be closer to the 2300 mg of sodium when possible.

2000 mg sodium: This diet may be appropriate for people with some types of liver disease and renal disease. It is no longer recommended for patients with heart failure (see chapter 33). This diet *eliminates* processed and prepared foods and beverages that are high in sodium. In addition to limiting all the foods in the NAS diet, baked products must also be limited. Milk and milk products are limited to 16 oz daily. Only salt-free commercially prepared foods should be used.

GUIDELINES FOR SODIUM RESTRICTION

Salt substitutes containing potassium chloride should be recommended only if approved by a physician. Potassium is generally contraindicated for patients with renal disease. Salt-free, herb-based seasoning products are readily available in most grocery stores and should be suggested instead.

- Instruct patients/clients on reading the Nutrition Facts food label for sodium content of foods.
- Encourage patients to prepare food at home without adding salt and to limit eating in restaurants.

- Recommend baked products, using sodium-free baking powder, potassium bicarbonate (instead of sodium bicarbonate or baking soda), and salt-free shortening in place of those containing sodium.
- Avoid obviously salted foods such as bouillon, soup and gravy bases, canned soups and stews; bread and rolls with salt toppings, salted crackers; salted nuts or popcorn, potato chips, pretzels, and other salted snack foods. Avoid buying vegetables prepared in sauce.
- Avoid smoked or cured meats, such as bacon, bologna, cold cuts, other processed meats, chipped or corned beef, frankfurters, ham, koshered or kosher style meats, and canned meat poultry.
- Avoid salted and smoked fish such as cod, herring, and sardines.
- Avoid sauerkraut, olives, pickles, relishes, kimchi, and other vegetables prepared in brine, tomato, and vegetable cocktail juices.
- Avoid seasonings such as celery salt, garlic salt, Worcestershire sauce, fish sauce and soy sauce. Reduced sodium versions of items like soy sauce can still be very high in sodium.
- Serve cheeses in limited amounts. Swiss cheese and cream cheese are relatively low in sodium.
- Monitor the sodium content of various medications, including over-the-counter brands.

The front of the food package can be used to quickly identify foods that may contain less sodium, but it is important to understand the terminology. For example, look for foods with claims such as:

- **Salt/Sodium-Free** → Less than 5 mg of sodium per serving
- **Very Low Sodium** → 35 mg of sodium or less per serving
- **Low Sodium** → 140 mg of sodium or less per serving
- **Reduced Sodium** → At least 25% less sodium than in the original product
- **Light in Sodium or Lightly Salted** → At least 50% less sodium added than in the regular product
- **No-Salt-Added or Unsalted** → No salt is added during processing, but not necessarily sodium-free. Check the Nutrition Facts Label.

Seasoning without salt: Flavorings or seasonings will make food more appetizing. For example:

- Lemon or vinegar is excellent with fish or meat and with many vegetables such as broccoli, asparagus, green beans, or salads.
- Meat may be seasoned with onion, garlic, green pepper, nutmeg, ginger, dry mustard, sage, cumin and marjoram. It may be cooked with fresh mushrooms or unsalted tomato juice. Curries made without salt are a good way to season meats and lentils.

- Cranberry sauce, applesauce, or jellies make appetizing accompaniments to meats and poultry.
- Vegetables can be flavored by the addition of onion, mint, ginger, mace, dill seed, parsley, green pepper, or fresh mushrooms.
- Unsalted cottage cheese can be flavored with minced onion, chopped chives, raw green pepper, grated carrots, chopped parsley, or crushed pineapple.
- A number of salt-free seasonings for use in cooking are available in the spice section of most supermarkets.

Sodium Content of Selected Common Foods			
1 cup of whole or reduced fat milk	107 mg	1 avocado	11 mg
1 slice whole wheat bread	110-170 mg	1 small potato with skin, baked	12 mg
1 hamburger bun	300-375 mg	1 cup chopped broccoli, raw	30 mg
1 slice American cheese	270-280 mg	½ cup broccoli in cheese sauce (Green Giant)	420 mg
1 slice Swiss cheese (non-processed)	50-65 mg	1 cup brown rice, cooked	8 mg
2 oz. mozzarella cheese, part skim	350 mg	1 cup white rice, cooked	0 mg
2 oz. cream cheese	178 mg	1 cup prepared rice pilaf (Rice-a-Roni)	970 mg
3 oz corned beef (brisket)	900-1100 mg	1 cup pasta, enriched	3-8 mg
3 oz. lean ground beef	55-60 mg	1 large egg, raw	71 mg
3 oz. chicken, raw broiler without the skin	65 mg	1 large olive, ripe	65 mg
1 slice bacon, pork	185 mgR	1 tbsp olive oil	0 mg
1 cup kidney beans, cooked without salt	2 mg	2 tbsp ranch dressing	270 mg
1 cup canned kidney beans, drained	230-250 mg	2 tbsp balsamic vinegar	8 mg
1 tbsp soy sauce (tamari)	1000 mg	2 tbsp sour cream, cultured	8 mg
1 tbsp reduced sodium soy sauce	450 mg	12 oz cola, regular	11 mg
1 cup chopped celery, raw	80 mg	1 slice cheese pizza (Domino's)	565 mg
1 cup chopped onion, raw	6 mg	1 slice pepperoni pizza (Pizza Hut)	769 mg
1 tbsp garlic	0 mg	1 Big Mac (McDonald's)	460 mg
1 med banana	1 mg	1 6-in Subway Club on white bread	720 mg

The Anti-Inflammatory Diet

Kelly Morrow, MS, RDN,
Mary Purdy, MS, RDN

DIETARY APPROACHES TO REDUCE INFLAMMATION

Inflammation is thought to underlie most chronic health conditions including metabolic syndrome, type 2 diabetes, cancer, cardiovascular disease, arthritis, autoimmune diseases, atopic conditions, inflammatory bowel disease, and there is now evidence linking it to cognitive decline. Various nutrients, foods and dietary patterns have been shown to reduce inflammatory markers as well as subjective and objective measures of inflammation.

Multiple iterations of an anti-inflammatory diet exist: DASH (Dietary Approaches to Stop Hypertension), Mediterranean, MIND (Mediterranean-DASH Intervention for Neurodegenerative Delay), vegetarian, food allergy elimination, calorie

restriction, and low histamine. In most cases, overall dietary and lifestyle habits are more important to consider rather than any single change. Which diet is right for any individual often depends on trial and error (Saneei, et al. 2014) (Rajaie et al, 2013).

The Dietary Inflammatory Index (DII) has been developed and validated as a tool to evaluate the overall inflammatory potential of the diet based on evaluation of over 6500 peer reviewed research articles. The DII consists of 45 foods, spices, nutrients and bioactive compounds in relation to six inflammatory biomarkers IL-1 β , IL-4, IL-6, IL-10, TNF- α and C-reactive protein (Shivappa et al., 2014)(Garcia-Arellano et al. 2014).

Dietary components with the most anti-inflammatory effect are included as negative numbers in the Overall Inflammatory Effect Score as shown in the table below.

Food Parameters in the Dietary Inflammatory Index and Overall Inflammatory Effect Score

Food Parameter	Overall Inflammatory Effect Score	Food Parameter	Overall Inflammatory Effect Score
Alcohol (g)	-0-278	Riboflavin (mg)	-0-068
Vitamin B ₁₂ (μ g)	0-106	Saffron (g)	-0-140
Vitamin B ₆ (mg)	-0-365	Saturated fat (g)	0-373
β -Carotene (μ g)	-0-584	Se (μ g)	-0-191
Caffeine (g)	-0-110	Thiamin (mg)	-0-098
Carbohydrate (g)	0-097	<i>Trans</i> fat (g)	0-229
Cholesterol (mg)	0-110	Turmeric (mg)	-0-785
Energy (kcal)	0-180	Vitamin A (RE)	-0-401
Eugenol (mg)	-0-140	Vitamin C (mg)	-0-424
Total fat (g)	0-298	Vitamin D (μ g)	-0-446
Fibre (g)	-0-663	Vitamin E (mg)	-0-419
Folic acid (μ g)	-0-190	Zn (mg)	-0-313
Garlic (g)	-0-412	Green/black tea (g)	-0-536
Ginger (g)	-0-453	Flavan-3-ol (mg)	-0-415
Fe (mg)	0-032	Flavones (mg)	-0-616
Mg (mg)	-0-484	Flavonols (mg)	-0-467
MUFA (g)	-0-009	Flavonones (mg)	-0-250
Niacin (mg)	-0-246	Anthocyanidins (mg)	-0-131
<i>n</i> -3 Fatty acids (g)	-0-436	Isoflavones (mg)	-0-593
<i>n</i> -6 Fatty acids (g)	-0-159	Pepper (g)	-0-131
Onion (g)	-0-301	Thyme/oregano (mg)	-0-102
Protein (g)	0-021	Rosemary (mg)	-0-013
PUFA (g)	-0-337		

RE, retinol equivalents.

Adapted from Shivappa N et al. Designing and developing a literature derived population based dietary inflammatory index. *Public Health Nutrition*, 17:1689, 2013.

The following recommendations reflect an effort to consolidate similarities among the various anti-inflammatory diets.

CONSUME AN ABUNDANCE OF FRUITS, VEGETABLES, HERBS AND SPICES

Colorful fruits and vegetables contain a myriad of anti-inflammatory phytochemicals and fiber and are thought to be the cornerstone of an anti-inflammatory diet due to their ability to down-regulate markers such as C-reactive protein (CRP), Nuclear Factor-kappa Beta (NFkB), histamine and other inflammatory cytokines in vivo and in vitro. (Jungberger and Medjakovic, 2012), (Habauzit, 2012), (Hagenlocher, 2014) (Jiang et al., 2014).

Although most plant based foods contain anti-inflammatory properties, the following fruits and vegetables appear to be the most anti-inflammatory based on their mention in research: cruciferous vegetables, onions, berries, purple grapes, cherries, citrus fruits, tomatoes, and pomegranates. Anti-inflammatory herbs and spices include: green and black tea, turmeric, garlic, ginger, rosemary, oregano, fenugreek, caraway, anise, cocoa, mint, clove, coriander, cinnamon, nutmeg, red chili powder, lemongrass, fennel, saffron, black pepper, parsley, sage, dill, Bay leaf, and basil. (Jiang et al., 2014), (Aggarwal, 2004), (Habauzit, 2012), (Galland, 2010), (Jungbauer and Medjakovic, 2011)

EAT A LOW GLYCEMIC DIET

Excessive amounts of refined carbohydrates and sugars may be pro-inflammatory. Regular consumption of these high glycemic foods can increase blood glucose and insulin levels which, when chronically elevated, can trigger an inflammatory response. Choosing low glycemic foods has been shown to reduce post prandial glucose and insulin levels and “modestly lower” concentrations of the insulin-like growth factor and improve the inflammatory and adipokine (inflammatory proteins secreted by adipose tissue) profiles (Runchey, 2012) (Neuhausser, 2012). It’s important to look at the glycemic load of a food versus the glycemic index because the load is a better indicator of the actual portion of food. See Appendix 37. For example, beets have a high glycemic index: 64, but a low glycemic load: 5.

High Glycemic Foods	Low Glycemic Foods
Cookies, cakes, pastries*, chips, white flour breads, crackers, tortillas, pasta, white rice	Whole and unprocessed grains, (like oats, brown rice, quinoa, whole wheat) high fiber or whole grain pastas
Large amounts of fruit juice and dried fruits	Fresh fruit
White (russet potatoes) mashed or baked without the skin	Sweet potatoes, pumpkin, squashes, beans and lentils, nuts and seeds
Sugar-sweetened sodas and other beverages	Most vegetables**

*cookies, cakes etc, can be made using low glycemic ingredients like oats and nuts which can reduce their glycemic load

**Consuming large amounts of certain juiced vegetables like carrots or beets will produce a higher glycemic load.

HAVE NUTS AND SEEDS OR NUT AND SEED BUTTERS EVERY DAY

Nuts and seeds not only provide anti-inflammatory and valuable phenolic compounds, but they provide a beneficial ratio of polyunsaturated fats (omega-6 and omega-3) that helps to support a healthy inflammatory response in the body. (Sears et al., 2011) Consume a variety of nuts in order to gain the spectrum of nutrients that each has to offer. Especially beneficial are pumpkin seeds, sunflower seeds, almonds, cashews, Brazil nuts, flaxseed, sesame seeds, and walnuts.

ADJUST THE QUALITY AND QUANTITY OF DIETARY FAT AND OILS

Increase:

Unsaturated fats high in omega-3 fatty acids (alpha-linolenic acid) which are anti-inflammatory. Best sources include cold water fish, flax, chia and hemp seeds, and walnuts. Flaxseed and walnut oil are excellent plant sources of omega-3 fatty acids, and are great for salad dressings, but should not be heated. Canola is also a price-friendly option for obtaining more omega 3’s in the diet, but is considered by some to be more processed.

Monounsaturated fats:

Use extra virgin olive oil as the main ingredient for sauces, salad dressings, and marinades. Unrefined coconut oil can be used for sautéing.

Avocados can replace cheese or mayonnaise on sandwiches, and can be added to dips, smoothies and salads.

Decrease:

Excessive amounts of animal protein contain arachidonic acid, which can increase inflammation in excess.

Processed foods and oils are high in omega-6 fatty acids (linoleic acid) such as soybean, corn, safflower, and sunflower oils. Omega-6 fatty acids can increase pro-inflammatory markers in the body if eaten in excess. Many of these oils are widely used in processed foods.

Avoid hydrogenated fats and trans fats that are found in many baked and prepackaged foods and are in hydrogenated vegetable shortening and many margarines. Trans fat consumption has been shown to increase markers of systemic inflammation and is particularly associated with coronary artery disease. (Bendsen et al, 2011). Trans fats were banned in processed foods in the US in July of 2015, but manufacturers have 3 years to completely remove it.

GET ADEQUATE SOURCES OF PROBIOTICS

Supporting the gut ecology helps to keep the digestive tract healthy and balance the immune system, which may reduce inflammation. Fermented and cultured foods are an excellent source of probiotic bacteria. Sources include miso, sauerkraut, yogurt, kefir, and kimchi, tempeh and kombucha (a fermented beverage). Getting sufficient pre-biotics to feed the good bacteria is also important. Inulin and fructooligosaccharides are examples of prebiotics and can be found in bananas, asparagus, maple syrup, onions, garlic, chicory, artichoke and many other plant foods.

CONSIDER FOOD ALLERGY OR SENSITIVITY ELIMINATION

A food allergy is a systemic immune mediated response that involves both the innate (macrophages, mast cells) and adaptive immune system (antibodies). A food intolerance or sensitivity happens within the gut and can be the result of an enzyme deficiency or a reaction to a food additive or to naturally occurring chemicals in foods. These adverse reactions to food can induce the production of a variety of inflammatory mediators including immunoglobulins, cytokines and histamine. Reactions can be either immediate or delayed, and their intensity may depend on dose and individual tolerance. Risk may depend on timing and composition of food exposure in early life, diet quality and gastrointestinal microflora balance. See Chapter 26.

The 8 common food allergens that must be listed on food labels are: milk, eggs, fish, wheat, tree nuts, peanuts, soybeans and shellfish.

Common food intolerances are non-celiac gluten, lactose, soy, histamine and salicylate intolerances

Common food additive intolerances are to sulfites, tartrazine (Yellow 5), benzoic acid, and monosodium glutamate (MSG) (Wilson, 2005)

Eliminating these foods and additives, or even *some* of these foods and additives for a period of two weeks and assessing any improvement in symptoms, may help determine whether there is an adverse food reaction. Additionally some individuals find themselves to be sensitive to a compound called “solanine” found in nightshade family of fruits and vegetables. One can try removing nightshade foods (eggplant, peppers, tomatoes, tomatillos, goji berries and potatoes) from the diet temporarily to assess the impact on inflammation, especially in the joints. See Chapter 39.

AVOID CHEMICALS

Many industrial chemicals and pesticides can irritate or disrupt the immune system and cause inflammation. Choose organic or low pesticide foods and “green” personal care and cleaning products to reduce exposure. Many canned foods contain bisphenol A in their linings. Bisphenol A (aka “BPA”), which is also found in many plastic bottles and food containers, is an endocrine disruptor, impairs the action of insulin in the body, and up-regulates inflammatory pathways. (Valentino, R, et al., 2013) Seek out “BPA-Free” cans, and use glass containers and bottles as often as possible. Refer to the Environmental Working Group www.ewg.org for more information.

DRINK ALCOHOL IN MODERATION

Alcohol can have the effect of both increasing and decreasing markers of inflammation, depending on the individual person and the amount consumed. High intake, especially for prolonged periods, can increase inflammatory cytokines (Miller et al. 2011). In the PREDIMED trial, moderate alcohol consumption was associated with improved lipid profiles, blood pressure, endothelial function and reduced reactive oxygen species (ROS) and was associated with about a 1 drink equivalent (10g) per day. Red wine is the most commonly featured alcoholic beverage with its high anti-inflammatory polyphenol content and can be found in discussions about the Mediterranean diet and MIND diet. (Widmer et al., 2015) (Garcia-Arellano et al., 2015)

STRESS AND SLEEP

High stress levels and lack of adequate sleep are both associated with inflammation. Elevated circulating cortisol levels found under conditions of psychological stress are associated with elevated inflammatory cytokines. Sustained sleep restriction has also been associated with an inflammatory state and an elevation of TNF- α , IL-1 β , IL-2, IL-4 and monocyte chemo-attractant protein-1 (MCP-1). (Axelsson et al, 2013) Intentionally practicing stress reduction techniques such as meditation has been shown to reduce the inflammatory response in human experimental models (Kox et al, 2014).

EXAMPLE OF AN ANTI-INFLAMMATORY 1 DAY DIET BASED ON THE DASH*, MIND AND MEDITERRANEAN MEAL PATTERNS*

Breakfast: Vegetable frittata with onions, garlic, basil, spinach, artichoke hearts and tomato. Baked sweet potato wedges. Herbal tea.

Lunch: Lentil vegetable soup and a green salad with arugula, purple cabbage, red onion, cucumber, carrot, walnuts and a mustard vinaigrette. Whole grain bread or crackers. Iced black tea with lemon

Snack: Greek yogurt with berries and green tea

Dinner: Lemon dill baked fish over brown rice with garlic sautéed kale and a glass of red wine

Dessert: Dark chocolate and cherries

Nutritional Facts on Alcoholic Beverages

Alcohol may have beneficial effects when consumed in moderation. The lowest all-cause mortality occurs at an intake of one to two drinks per day. The lowest coronary heart disease mortality also occurs at an intake of one to two drinks per day. Morbidity and mortality are highest among those drinking large amounts of alcohol. Guidelines:

- Alcoholic beverages should not be consumed by some individuals, including those who cannot restrict their alcohol intake, women of childbearing age who may become pregnant, pregnant and lactating women, children and adolescents, individuals taking medications that can interact with alcohol, and those with specific medical conditions.
- Those who choose to drink alcoholic beverages should do so sensibly and in moderation—defined as the consumption of

up to one drink per day for women and up to two drinks per day for men.

- Alcoholic beverages should be avoided by individuals engaging in activities that require attention, skill, or coordination, such as driving or operating machinery.

CALORIES IN SELECTED ALCOHOLIC BEVERAGES*

This table is a guide to estimate the caloric intake from various alcoholic beverages. A sample serving volume and the calories in that drink are shown for beer, wine, and distilled spirits. Higher alcohol content (higher percent alcohol or higher proof) and mixing alcohol with other beverages such as sweetened soft drinks, tonic water, fruit juice, or cream increase the amount of calories in the beverage. Alcoholic beverages supply calories but provide few essential nutrients.

Beverage	Serving (oz)	Alcohol (g)	Carbohydrate (g)	Calories	Exchanges for Calorie or Diabetes Control
Beer					
Regular	12	13	13	150	1 starch, 2 fat
Light	12	11	5	100	2 fat
Near beer	12	1.5	12	60	1 starch
Distilled Spirits					
80-Proof (gin, rum, vodka, whiskey, scotch)	1.5	14	Trace	100	2 fat
Dry brandy, cognac	1	11	Trace	75	1.5 fat
Table Wines					
Dry white	4	11	Trace	80	2 fat

From Franz MJ: Alcohol and diabetes: its metabolism and guidelines for its occasional use. Part I, Diabetes Spectrum 3(4):210-216, 1990.

The caloric contribution from alcohol of an alcoholic beverage can be estimated by multiplying the number of ounces by the proof and then again by the factor 0.8. For beers and wines, kilocalories from alcohol can be estimated by multiplying ounces by percentage of alcohol (by volume) and then by the factor 1.6.

Nutritional Facts on Caffeine-Containing Products

Caffeine is similar in structure to adenosine, a chemical found in the brain that slows down its activity. Because the two compete, the more caffeine that is consumed, the less adenosine that is available up to a point. Caffeine temporarily heightens concentration and wards off fatigue. Within 30 to 60 minutes of drinking a cup of coffee, caffeine reaches peak concentrations in the bloodstream and takes 4 to 6 hours for its effects to wear off. The average

American adult consumes about 200 mg of caffeine a day, and many may consume twice that level. It is generally safe to consume no more than the equivalent amount of caffeine in 1 to 2 cups of coffee daily during pregnancy or lactation. Individuals with heart disease and hypertension may benefit from a reduction in caffeine consumption. To reduce caffeine and its stimulant effects, monitor intake from foods and beverages listed below.

Selected Food and Beverage Sources of Caffeine

Caffeine-Containing Products	Serving (mg)	Caffeine-Containing Products	Serving (mg)
Coffee		Regular or diet cola, cherry colas, Dr. Pepper, Mr. Pibb, 12 oz	35-50
Starbucks coffee (in store), 16 oz.	330	Decaffeinated drinks, 12 oz	Trace
Starbucks coffee (at home), 16 oz.	260	Cocoa and Chocolate	
Brewed, drip method, 6 oz	103	Chocolate, baking, unsweetened, 1 oz	58
Brewed, percolator method, 6 oz	75	Chocolate, sweet, semisweet, dark, milk, 1 oz	8-20
Instant, 1 rounded tsp	57	Milk chocolate bar, 1.5 oz	10
Flavored, regular and sugar-free, 6 oz	26-75	Chocolate milk, 8 oz	8
Espresso, 1 oz	40	Cocoa beverage, 6-oz cup	4
Café Latte, short (8 oz) or tall (12 oz) (Starbucks)	35	Chocolate-flavored syrup, 1 oz	5
Decaffeinated, 6 oz	2	Chocolate pudding, ½ cup	4-8
Tea		Miscellaneous	
Black or green tea, 16 oz	60-100	Powershot (8 oz)	800
3-minute brew, 12-oz	72	Rock Star, 16 oz	240
Lipton, Arizona, or Snapple tea, 16 oz	30-60	NoDoz, Maximum Strength (1), or Vivarin (1)	200
Instant, 1 rounded tsp in 8 oz of water	25-35	Pit Bull Energy Bar, 2 oz	165
Tea, green brewed, 8 oz	30	Excedrin (2)	130
Tea, bottles (12 oz) or from instant mix, 8 oz	14	NoDoz, Regular Strength (1)	100
Decaffeinated, 5- minute brew, 6-oz cup	1	Red Bull (8.3 oz)	80
Carbonated Beverages		Water, caffeinated (Edge 2 O), (8 oz)	70
7-Eleven Big Gulp cola, 64 oz	190	Anacin (2)	65
Mountain Dew MDX or Vault, 12 oz	120	Bud Extra Beer, 10 oz	55
Diet Pepsi Max, 20 oz	70	Propel Invigorating water	50
Mountain Dew, 12 oz, regular or diet	54	Jolt (8 oz)	48
Mellow Yellow, 12 oz, regular or diet	52

Nutritional Facts on Essential (Omega) Fatty Acids

Essential fatty acids (EFAs) are fatty acids that are required in the human diet. They must be obtained from food because human cells have no biochemical pathways capable of producing them internally. There are two closely related families of EFAs: **omega-3 (Ω -3 or ω -3)** and **omega-6 (Ω -6 or ω -6)**. Only one substance in each of these families is truly essential, because, for example, the body can convert one ω -3 to another ω -3 but cannot create an ω -3 from scratch.

In the body essential fatty acids serve multiple functions. In each of these the balance between dietary ω -3 and ω -6 strongly affects function. They are modified to make the eicosanoids (affecting inflammation and many other cellular functions); the endogenous cannabinoids (affecting mood, behavior, and inflammation); the lipoxins from ω -6 EFAs and resolvins from ω -3 (in the presence of aspirin, down-regulating inflammation); the isofurans, isoprostanes, hepxolins, epoxyeicosatrienoic acids, and neuroprotectin D; and the lipid rafts (affecting cellular signaling). They also act on deoxyribonucleic acid (activating or inhibiting transcription factors for nuclear factor- κ -B [NF κ B], a proinflammatory cytokine).

Between 1930 and 1950 arachidonic and linolenic acids were termed *essential* because each was more or less able to meet the growth requirements of rats given fat-free diets. Further research has shown that **human metabolism requires both fatty acids**. To some extent any ω -3 and any ω -6 can relieve the worst symptoms of fatty acid deficiency. However, in many people the ability to convert the ω -3 α -linolenic acid (ALA) to the ω -3

eicosapentaenoic (EPA) and docosahexaenoic acid (DHA) is only 5% efficient. Therefore it is important to incorporate the EPA and DHA directly into the diet usually as fish or a fish oil supplement. Particular fatty acids such as DHA are needed at critical life stages (e.g., infancy and lactation) and in some disease states.

The essential fatty acids are:

- ALA (18:3)- ω -3
- Linoleic acid (18:2)- ω -6

These two fatty acids cannot be synthesized by humans because humans lack the desaturase enzymes required for their production. They form the starting point for the creation of longer and more desaturated fatty acids, which are also referred to as long-chain polyunsaturates:

Ω -3 FATTY ACIDS:

- EPA (20:5) eicosapentanoic acid
- DHA (22:6) docosahexanoic acid
- ALA (18:) alpha-linolenic acid

Ω -6 FATTY ACIDS:

- γ -Linolenic acid (GLA) (18:3)
- Dihomo- γ -linolenic acid (DGLA) (20:3)
- Arachidonic acid (AA) (20:4)

Ω -9 Fatty acids are not essential in humans, because humans possess all the enzymes required for their synthesis.

ADEQUATE INTAKES FOR Ω -3 FATTY ACIDS FOR CHILDREN AND ADULTS				ADEQUATE INTAKES FOR Ω -6 FATTY ACIDS FOR CHILDREN AND ADULTS			
Age (years)	Males and Females (g/day)	Pregnancy (g/day)	Lactation (g/day)	Age (years)	Males and Females (g/day)	Pregnancy (g/day)	Lactation (g/day)
1-3	0.7	N/A	N/A	1-3	7	N/A	N/A
4-8	0.9	N/A	N/A	4-8	10	N/A	N/A
9-13	1.2 for boys; 1 for girls	N/A	N/A	9-13	12 for boys; 10 for girls	N/A	N/A
14-18	1.6 for boys; 1.1 for girls	1.4	1.3	14-18	16 for boys; 11 for girls	13	13
19+	1.6 for men; 1.1 for women	1.4	1.3	19+	17 for men; 12 for women	13	13

N/A, Not applicable.

DIETARY SOURCES

Some of the food sources of ω -3 and ω -6 fatty acids are fish and shellfish, flaxseed (linseed), soya oil, canola (rapeseed) oil, hemp oil, chia seeds, pumpkin seeds, sunflower seeds, leafy vegetables, and walnuts.

EFAs play a part in many metabolic processes, and there is evidence to suggest that low levels of EFAs or the wrong balance of types among the EFAs may be a factor in a number of illnesses.

Plant sources of ω -3s do not contain EPA and DHA. This is thought to be the reason that absorption of EFAs is much greater from animal rather than plant sources.

EFA content of vegetable sources varies with cultivation conditions. Animal sources vary widely, both with the animal's feed and that the EFA makeup varies markedly with fats from different body parts.

OMEGA-3 FATTY ACIDS

There is some evidence that suggests that ω -3s may:

- Help lower elevated triglyceride levels. High triglyceride levels can contribute to coronary heart disease.
- Reduce the blood's tendency to clot, which may relate to the clogging that occurs with atherosclerosis.
- Reduce the inflammation involved in conditions such as rheumatoid arthritis.
- Improve symptoms of depression and other mental health disorders in some individuals.

Dietary sources of ω -3 fatty acids include fish oil and certain plant and nut oils. Fish oil contains both DHA and EPA, whereas some nuts (English walnuts) and vegetable oils

(canola, soybean, flaxseed and linseed, olive) contain only the ω -3 ALA.

There is evidence from multiple large-scale population (epidemiologic) studies and randomized controlled trials that intake of recommended amounts of DHA and EPA in the form of fish or fish oil supplements lowers triglycerides; reduces the risk of death, heart attack, dangerous abnormal heart rhythms, and strokes in people with known cardiovascular disease; slows the buildup of atherosclerotic plaques ("hardening of the arteries"); and lowers blood pressure slightly. However, high doses may have harmful effects such as an increased risk of bleeding. Some species of fish carry a higher risk of environmental contamination such as with methyl mercury.

COMMON FOOD SOURCES OF OMEGA-3 FATS

Omega-3 Fat	Food Source
ALA	Ground flaxseed and walnuts and soybeans
DHA and EPA	Flaxseed, walnut, soybean and canola oils, and nonhydrogenated canola and soy margarines Mackerel, salmon, herring, trout and sardines, and other fish and shellfish Marine algae supplements

Fish or Other Food Source	Omega-3 Content in a 4-oz Serving
English walnuts	6.8 g
Chinook salmon	3.6 g
Sockeye salmon	2.3 g
Mackerel	1.8-2.6 g
Herring	1.2-2.7 g
Rainbow trout	1.0 g
Wheat germ and oat germ	0.7-1.4 g
Halibut	0.5-1.3 g
White tuna	0.97 g
Light tuna	0.35 g
Whiting	0.9 g
Spinach	0.9 g
Flounder	0.6 g
King crab	0.6 g
Shrimp	0.5 g
Tofu	0.4 g (probably much less in "lite" tofu)
Clam	0.32 g
Cod	0.3 g
Scallop	0.23 g

Supplements*

Cod liver oil	800-100 mg/tsp
Fish body oil	1200-1800 mg/tsp
Omega-3 fatty acid concentrate	250 mg/capsule

Enhancing Intake of Omega-3 Fats

- Eat fish at least two times each week.
- Include canned fish in your diet (examples: salmon, sardines, light tuna). Try sardines on toast.
- Add ground flaxseed to foods such as hot or cold cereal or yogurt. NOTE: Pregnant women should limit their intake of ground flaxseed to occasional use (not daily). Ground flaxseeds contain lignans. There is not enough information about their safety in pregnancy.
- Eat walnuts. Add walnuts to salads, cereals, baking (examples, muffins, cookies, breads) and pancakes.
- Have fresh or frozen soybeans (edamame) as a vegetable at meals.
- Use soybean oil or canola oil in salad dressings and recipes.
- Use nonhydrogenated margarine made from canola or soybean as a spread or in baking.
- Cook with ω -3 liquid eggs or eggs in the shell. Enjoy scrambled eggs or try a homemade egg sandwich.
- Use other ω -3 fortified products such as milk, yogurt, bread, and pasta.
- Substitute $\frac{1}{4}$ cup ground flaxseed for $\frac{1}{4}$ cup flour in bread, pizza dough, muffin, cookie, or meatloaf recipes.
- Replace 1 egg with 1 Tbsp ground flaxseed and 3 Tbsp water in recipes.

*Exact omega-3 content varies per manufacturer. Check label.

Nutritional Facts on a High-Fiber Diet

This diet is a modification of the regular diet. The purpose of this diet is to decrease transit time through the intestine, promote more frequent bowel movements, and softer stools. This diet may be prescribed as a treatment for diverticulosis, irritable bowel syndrome, hemorrhoids, or constipation. A high fiber diet is prescribed for weight loss and prevention of heart disease. It includes all the foods on a regular diet, with emphasis on the proper planning and selection of foods to increase the daily intake of fiber. Fluid intake should be increased. The Academy of Nutrition and Dietetics recommends that the average adult have a daily fiber intake of 20 to 35 g from a variety of sources. For children the child's age plus 5 g of fiber is recommended daily. In cases of severe constipation more fiber is recommended.

Dietary Reference Intakes for Fiber for Children and Adults

Age (years)	Males and Females (g/day)	Pregnancy (g/day)	Lactation (g/day)
1-3	19	N/A	N/A
4-8	25	N/A	N/A
9-13	31 for boys; 26 for girls	N/A	N/A
14-18	38 for boys; 26 for girls	28	29
19+	38 for men; 25 for women	28	29

N/A, Not applicable.

Although numerous over-the-counter fiber supplements are available, food sources provide many nutrients and are the preferred method of increasing dietary fiber. Adequate liquid consumption (at least eight 8-oz glasses per day) is recommended. Fiber should be added to the diet slowly because of possible cramps, bloating, and diarrhea with a sudden fiber increase. Maximum therapeutic benefits of fiber are obtained after several months of compliance. There are two components of dietary fiber, each providing health benefits: insoluble and soluble.

TYPES OF DIETARY FIBER

Type of Fiber	Components of Cells	Food Sources	Health Benefits
Soluble fibers	Gums, mucilages, pectin, certain hemicelluloses	Vegetables, fruits, barley; legumes, oats, and oat-bran	Decrease total blood cholesterol. Guard against diabetes. Prevent constipation. May help manage irritable bowel syndrome. May protect against colon cancer and gallstones.

TYPES OF DIETARY FIBER

Type of Fiber	Components of Cells	Food Sources	Health Benefits
Insoluble fibers	Cellulose, lignin, some hemicelluloses	Whole-wheat products, wheat and corn bran, and many vegetables (including cauliflower, green beans, potatoes, and skins of root vegetables)	May prevent diverticular disease. Prevents constipation. May delay glucose absorption (probably insignificant). May increase satiety and therefore assist with weight loss. Lower cholesterol. May protect against colon cancer.

GUIDELINES FOR HIGH-FIBER DIET

1. Increase consumption of whole-grain breads, cereals, flours, and other whole-grain productions to 6 to 11 servings daily.
2. Increase consumption of vegetables, legumes and fruits, nuts, and edible seeds to 5 to 8 servings daily.
3. Consume high-fiber cereals, granolas, and legumes as needed to bring fiber intake to 25 g or more daily.
4. Increase consumption of fluids to at least 2 L (or approximately 2 qt) daily.
5. For a high-fiber diet of approximately 24 g of dietary fiber: use 12 or more servings of the foods from the groups below (each food contains approximately 2 g of dietary fiber). For example, ½ cup of baked beans (8 Tbsp) would count as 4 servings.

EACH OF THESE FOODS IN THIS AMOUNT CONTAINS 2 G OF DIETARY FIBER

Apple, 1 small	Strawberries, ½ cup
Orange, 1 small	Pear, ½ small
Banana, 1 small	Cherries, 10 large
Peach, 1 medium	Plums, 2 small
Whole-wheat bread, 1 slice	Oatmeal, dry, 3 Tbsp
All Bran, 1 Tbsp	Shredded wheat, ½ biscuit
Rye bread, 1 slice	Wheat bran, 1 tsp
Corn flakes, ⅓ cup	Grape-nuts, 3 Tbsp
Cracked wheat bread, 1 slice	Puffed wheat, 1 ½ cup
Broccoli, ½ stalk	Potato, 2-in diameter
Lettuce, raw, 2 cups	Celery, 1 cup
Brussels sprouts, 4	Tomato, raw, 1 medium
Green beans, ½ cup	Corn on the cob, 2 in
Carrots, ⅓ cup	Baked beans, canned, 2 Tbsp

SELECTED FOOD SOURCES OF FIBER

Food	Grams per Serving	% Daily Value*
Navy beans, cooked, ½ cup	9.5	38
Bran ready-to-eat cereal (100%), ½ cup	8.8	35
Kidney beans, canned, ½ cup	8.2	33
Split peas, cooked, ½ cup	8.1	32
Lentils, cooked, ½ cup	7.8	31
Black beans, cooked, ½ cup	7.5	30
Pinto beans, cooked, ½ cup	7.7	31
Lima beans, cooked, ½ cup	6.6	26
Artichoke, globe, cooked, 1 each	6.5	26
White beans, canned, ½ cup	6.3	25
Chickpeas, cooked, ½ cup	6.2	24
Great northern beans, cooked, ½ cup	6.2	24
Cowpeas, cooked, ½ cup	5.6	22
Soybeans, mature, cooked, ½ cup	5.2	21
Bran ready-to-eat cereals, various, 1 oz	2.6-5.0	10-20
Crackers, rye wafers, plain, 2 wafers	5.0	20
Sweet potato, baked, with peel, 1 medium (146 g)	4.8	19
Asian pear, raw, 1 small	4.4	18
Green peas, cooked, ½ cup	4.4	18
Whole-wheat English muffin, 1 each	4.4	18
Pear, raw, 1 small	4.3	17
Bulgur, cooked, ½ cup	4.1	16
Mixed vegetables, cooked, ½ cup	4.0	16
Raspberries, raw, ½ cup	4.0	16
Sweet potato, boiled, no peel, 1 medium (156 g)	3.9	15.5
Blackberries, raw, ½ cup	3.8	15
Potato, baked, with skin, 1 medium	3.8	15
Soybeans, green, cooked, ½ cup	3.8	15
Stewed prunes, ½ cup	3.8	15
Figs, dried, ¼ cup	3.7	14.5
Dates, ¼ cup	3.6	14
Oat bran, raw, ¼ cup	3.6	14
Pumpkin, canned, ½ cup	3.6	14
Spinach, frozen, cooked, ½ cup	3.5	14
Shredded wheat ready-to-eat cereals, various, ≈ 1 oz	2.8-3.4	11-13
Almonds, 1 oz	3.3	13
Apple with skin, raw, 1 medium	3.3	13
Brussels sprouts, frozen, cooked, ½ cup	3.2	13
Whole-wheat spaghetti, cooked, ½ cup	3.1	12
Banana, 1 medium	3.1	12
Orange, raw, 1 medium	3.1	12
Oat bran muffin, 1 small	3.0	12
Guava, 1 medium	3.0	12

SELECTED FOOD SOURCES OF FIBER

Food	Grams per Serving	% Daily Value*
Pearled barley, cooked, ½ cup	3.0	12
Sauerkraut, canned, solids, and liquids, ½ cup	3.0	12
Tomato paste, ¼ cup	2.9	11.5
Winter squash, cooked, ½ cup	2.9	11.5
Broccoli, cooked, ½ cup	2.8	11
Parsnips, cooked, chopped, ½ cup	2.8	11
Turnip greens, cooked, ½ cup	2.5	10
Collards, cooked, ½ cup	2.7	11
Okra, frozen, cooked, ½ cup	2.6	10
Peas, edible-podded, cooked, ½ cup	2.5	10

*Daily values (DVs) are reference numbers based on the recommended dietary allowance. They were developed to help consumers determine if a food contains a lot or a little of a specific nutrient. The DV for fiber is 25 g. The percent DV (%DV) listed on the Nutrition Facts panel of food labels states the percentage of the DV provided in 1 serving. %DVs are based on a 2000-calorie diet.

Food Sources of Dietary Fiber ranked by grams of dietary fiber per standard amount. (All are $\geq 10\%$ of adequate intake for adult women, which is 25 g/day.)

HIGH-FIBER MEAL PLAN

Breakfast	Lunch	Dinner
1 orange ¾ cup raisin bran	3-oz boneless, skinless chicken breast	1 cup spaghetti with meat sauce
2 slices whole wheat toast	½ cup broccoli	1 cup tossed salad with assorted vegetables and ¼ cup chickpeas*
2 tsp margarine	½ cup long grain and wild rice	1 slice Italian bread
1 cup skim milk	1 whole wheat roll	½ cup apple crisp
1 cup coffee	½ cup chocolate pudding	2 tsp margarine
2 tsp sugar	½ Tbsp whipped topping	1 cup skim milk
	2 tsp margarine	1 cup coffee
	1 cup iced tea	¼ tsp salt
	¼ tsp salt	¼ tsp pepper
	¼ tsp pepper	2 tsp sugar
	2 tsp sugar	

Nutritional Analysis

Kilocalories: 2074
 Protein: 84 g
 Fat: 52 g
 Carbohydrate: 313 g
 Sodium: 4647 mg
 Potassium: 3706 mg
 Fiber: 28 g

*Fiber content may be higher, depending on vegetables selected for salad.

Nutritional Facts on Fluid and Hydration

Adequate **hydration** is essential for life. Body water is necessary to regulate body temperature, transport nutrients, moisten body tissues, compose body fluids, and make waste products soluble for excretion. **Principles:** As the most plentiful substance in the human body, water is also the most plentiful nutrient in the diet. The amount of water recommended for an individual varies with age, activity, medical condition, and physical condition. The water in juice, tea, milk, decaffeinated coffee, and carbonated beverages contributes the majority of water in the diet. Solid foods also contribute water to the diet but usually are not counted in the amount of water provided per day.

Water deficiency, or **dehydration**, is characterized by dark urine; decreased skin turgor; dry mouth, lips, and mucous membranes; headache; a coated, wrinkled tongue; dry or sunken eyes; weight loss; a lowered body temperature; and increased serum sodium, albumin, blood urea nitrogen (BUN), and creatinine values. Dehydration may be caused by inadequate intake in relation to fluid requirements or excessive fluid losses caused by fever, increased urine output, diarrhea, draining wounds, ostomy output, fistulas, environmental temperature, or vomiting. Concentrated or high-protein tube feeding formulas may increase the water requirement.

Thirst is often the first noticed sign of the need for more water. However, athletes or workers exercising or working hard in hot climates may be significantly dehydrated before they realize they are thirsty. In these situations they should be drinking at regular intervals; they may not be able to rely on thirst to determine their need to drink.

Water excess or **overhydration** is rare and may be the result of inadequate output or excessive intake. Overhydration is characterized by increased blood pressure; decreased pulse rate; edema; and decreased serum sodium, potassium, albumin, BUN, and creatinine values. Fluid restrictions may be necessary for certain medical conditions such as kidney or cardiac disease. For those on fluid restrictions, the fluid needs should be calculated on an individual basis. The usual diet provides approximately 1080 mL (36 oz), a little more than a quart of fluid per day.

Estimating Daily Fluid Requirements for Healthy Individuals

Children	Body Weight	Daily Fluid Requirement
Infants		140 to 150 mL/kg
Children		
Method 1		50 to 60 mL/kg
Method 2	3 to 10 kg of body weight	100 mL/kg
	11 to 20 kg of body weight	1000 mL + 50 mL/kg >10
	More than 20 kg	1500 mL + 20 mL/kg >20
Adults*		
Method 1	30 to 35 mL per weight in kilograms	
Method 2	1 mL fluid per calorie consumed	
Method 3	First 10 kg of body weight	100 mL/kg
	Second 10 kg of body weight	+50 mL/kg
	Remaining kg of body weight (age <50)	+20 mL/kg
	Remaining kg of body weight (age >50)	+15 mL/kg
Method 4	Age in years	
	16-30 (active)	40 mL/kg
	20-55	35 mL/kg
	55-75	30 mL/kg
	>75	25 mL/kg

*The 1 mL of fluid per calorie method should be used with caution because it will underestimate the fluid needs of those with low-calorie needs. Persons who are significantly obese may best be evaluated by Method 3 because it adjusts for high body weight.

From the California Diet Manual, ©2003, State of California Department of Developmental Services, revised 2004.

Note: 3 oz is approximately 1/3 cup; 6 oz is approximately 2/3 cup.

Approximate Fluid Content of Common Foods

Food	Fluid Ounces	Household Measure	Metric Measure
Juice	2	1/4 cup	60 mL
	3	1/3 cup	90 mL
	4	1/2 cup	120 mL
	8	1 cup	240 mL
Coffee, tea, decaffeinated coffee	6	2/3 cup	180 mL
Gelatin	4	1/2 cup	120 mL
Ice cream, sherbet	3	1/3 cup	90 mL
Soup	6	2/3 cup	180 mL
Liquid coffee creamer	1	2 Tbsp	30 mL

Nutritional Facts on a High-Protein Diet

A diet high in protein is recommended most often for increased needs for healing. A diet of 1.2gm/kg to 1.5 gm/kg is recommended for healing by the National Pressure Ulcer Advisory Panel. It is now recommended for people on dialysis and for those with some types of liver disease. High protein diets are recommended for athletes who are building muscle. Historically, a high protein diet has been defined as one with at least 100 g of protein per day. This has been replaced by recommendations based on weight. How to accurately determine protein needs in an obese person remains debatable. Some researchers and practitioners recommend a high protein diet provide 1.75 gm/kg of ideal body weight (IBW) for those with obesity.

BEST FOOD SOURCES OF PROTEIN

Meat: most types of meat provide 7 gm per ounce
Fish and shellfish: 7 gm per ounce
Eggs: 6-7 gm per egg, depends on the egg size
Cow's Milk: 8 gm per cup
Goat's Milk: 9 gm per cup
Soy Milk: 7-8 gm per cup
Non-fat milk powder:
Plain yogurt: 6-7 gm per ½ cup
Greek yogurt: 11-15 gm per ½ cup
Cheese: 7 gm per ¼ C. of cottage cheese OR 1 ounce hard cheese.

Peanut butter or nut butter: 8 gm per 2 Tbsp.
Tofu: 4.6 gm per ounce
Lentils: 10 gm per ½ cup, cooked
Chickpeas: 8 gm per ½ cup, cooked
Quinoa: 4 gm per ½ cup, cooked
Teff: 5 gm per ½ cup, cooked
Chia seeds: 5 gm per ounce

PROTEIN SUPPLEMENTS

Nonfat dry milk (NFDM) may be added to cooked foods to increase protein intake. However, when it is added, carbohydrate is also added as the sugar lactose. NFDM can be added to regular milk to create more concentrated milk. Protein powders are a popular way to increase the protein content of the diet, either by adding it to foods or by using it in smoothies or shakes. Whey-based supplements are the most common because they are water-soluble and provide complete protein. Soy-based supplements are also popular, especially for those avoiding animal products. For other vegetable protein sources, see Appendix 39. There are now hundreds of products available, most with other added nutrients.

It is important to note that almond milk, hemp milk and coconut milk in their fluid forms are relatively low in protein. If used for high nutrition impact drinks, an added source of powdered protein may be necessary to meet nutrition goals.

Nutritional Facts on Vegetarian Eating

A well-planned vegetarian diet can meet nutritional needs and can be a healthy way to meet the dietary guidelines. Vegetarian diets are chosen for nutritional, religious, ecologic, or personal reasons. It is the position of the Academy of Nutrition and Dietetics (AND) that “Appropriately planned vegetarian diets are healthful, nutritionally adequate and provide health benefits in the prevention and treatment of certain diseases.”

AND’s practice guideline contains recommendations, based on scientific evidence, designed to assist practitioners on the appropriate nutrition care for vegetarians. The guideline includes recommendations for children, adolescents, adults and women who are pregnant or lactating, providing more than 30 nutrition recommendations related to vegetarian nutrition, including:

- Macronutrients, including protein
- Micronutrients, including vitamin B₁₂
- Knowledge, beliefs and motivations
- Diet diversity
- Nutrition counseling
- Treatment of hyperlipidemia, obesity, Type 2 diabetes
- Adherence to a vegetarian diet

Vegetarian adaptations of the USDA food patterns are included in the 2010 *Dietary Guidelines for Americans*, with sample vegetarian food patterns that allow for additional flexibility in food group choices.

Vegetarian diets are usually classified into one of the following three types:

1. Lacto-ovo-vegetarian is a modification of the diet, which eliminates all dietary sources of animal protein except dairy products and eggs. This is the most common type of vegetarian diet and is the easiest of the vegetarian diets to prepare.
2. Lacto-vegetarian is a modification of the diet, which eliminates all dietary sources of animal protein except dairy products. This requires that baked products be made without eggs and the elimination of egg noodles.
3. Strict vegetarian (vegan diet) is a modification of the diet, which eliminates all dietary sources of animal protein.

Adequacy: The more restrictive the diet, the more challenging it is to ensure adequacy. Lacto-ovo and lacto-vegetarian diets require the same planning as any other diet. The vegan diet is a little more difficult, but can be adequate with some planning. The *Power Plate* is a tool developed by Physicians Committee for Responsible Medicine to assist in planning a nutritionally complete vegan diet and can be accessed at PCRM.org.

The Sustainable Power Plate

SustainablePowerPlate.org

NUTRIENTS TO CONSIDER WHEN PLANNING A VEGETARIAN MENU

Protein

Foods that provide approximately 7 grams of protein per serving:

1/4 cup cottage cheese	1/2 cup legumes, cooked
1 cup cow's milk, goat's milk or soy milk	1/4 cup soy beans
1 oz cheese	3/4 cup of almonds
1/3 cup mixed nuts	1/4 cup tofu (soy cheese)
1 egg	3/4 cup yogurt
2 Tbsp peanut butter	1/4 cup plain, Greek style yogurt
	1 cup of quinoa

Foods that contain the essential amino acids are considered complete proteins. However, foods that are incomplete proteins can be combined to make a complete protein. These are known as complementary proteins. They do not have to be eaten together at the same meal. The most common combination of complementary proteins is beans (legumes) combined with rice or corn.

Calcium: All vegetarians, especially young women, should ensure adequate calcium intake for development and maintenance of strong bones. In place of dairy products, choose abundant amounts of dark, leafy greens (e.g., kale, mustard and turnip greens, collards); bok choy; broccoli; legumes; tofu processed with calcium; dried figs; sunflower seeds; and calcium-fortified cereals and juices can be incorporated into the diet. The following foods provide approximately the same amount of calcium as 1 cup of cow's milk (approximately 300 mg).

1 cup calcium-fortified soy milk, nut milk, grain, or hemp milk	3 cups cooked dried beans
1 $\frac{2}{3}$ cups sunflower seeds	1 cup almonds
1 cup collards or kale, cooked	1.5 oz chia seeds

Iron: Iron deficiency rates are similar between vegetarians and non-vegetarians. When consumed along with foods rich in vitamin C, plant sources of iron are better absorbed. High-iron foods include legumes, dark green vegetables (i.e., spinach and beet greens), dried fruits; prune juice, blackstrap molasses, pumpkin seeds, soy nuts, and iron-fortified breads and cereals.

Vitamin B₁₂. Found only in animal foods, vitamin B₁₂ is not a nutrient of great concern for vegetarians who regularly consume eggs or dairy products (lacto-ovo-vegetarians). However, vegans should include vitamin B₁₂-fortified foods such as fortified soy milk and commercial breakfast cereals, or a B₁₂ supplement in their diets. Vitamin B₁₂ is also found in Brewer's yeast.

Vitamin D: In the United States the primary source of vitamin D is dairy products, most of which are fortified with vitamin D. However, cheese and yogurt do not have to be made from vitamin D-fortified milk and thus are not reliable sources of vitamin D. The other main source results from sunlight exposure, causing vitamin D to be synthesized in the skin. See Appendix 45. If dairy products are not consumed and direct sunlight exposure is limited, supplementation is warranted. Foods containing vitamin D include fortified cow's milk, soy milk, rice milk, or nut milk. Supplementation (at least 1000 IU/day) is needed for individuals who do not consume milk products or who spend little time in the sun.

Zinc: Because zinc is found in animal foods, the vegetarian diet may be limited. The following foods can be included in the diet to increase zinc intake:

- Wheat germ
- Tofu
- Nuts including cashews and almonds
- Seeds including sunflower, flax, poppy and chia seeds
- Dried beans,
- Breakfast cereals, fortified

SPECIAL NOTES

Pregnancy and Lactation: Well-planned vegan and lacto-ovo-vegetarian eating patterns adequately provide for the nutritional needs of pregnant and lactating women (American Dietetic Association, 2009). Folate supplements are recommended for all pregnant women, including vegetarians. Vegans must ensure daily

intake of 2 mcg of vitamin B₁₂ daily during pregnancy and 2.6 mcg during lactation, whether through supplements or fortified foods. Women with limited sun exposure should include vitamin D-fortified foods and possibly a vitamin D supplement. Caution should be used with vitamin D supplementation because excess vitamin D can cause fetal abnormalities.

Infants, Children, and Adolescents: According to the AND, well-planned vegan and lacto-ovo-vegetarian eating patterns adequately provide for the nutritional needs of infants, children, and adolescents. Because of the high bulk of low-fat vegetarian eating patterns, it may be difficult for children and adolescents to consume enough food to provide for their energy needs. Frequent meals and snacks with nutrient-dense foods can help meet energy and nutrient needs. If sun exposure is limited, vitamin D fortified-foods or supplements should be used. For vegan children a reliable source of vitamin B₁₂ should be included in their diets. To provide for growth, calcium, iron, and zinc intakes deserve special attention. It is recommended that parents of vegetarian infants and youth consult a registered dietitian nutritionist (RDN) with expertise in the vegetarian eating pattern.

Meal Pattern: Lacto-Vegetarian

Breakfast	Lunch	Dinner	Snack
½ cup orange juice	Vegetarian chili	Quinoa patties	½ peanut butter sandwich and 8 oz milk
Whole grain cereal and milk	Corn bread	Brown rice	
Berry Yogurt Parfait	Green Salad	Fresh spinach served with lemon and butter if desired	
	Fresh fruit	Banana pudding made with coconut milk	

Meal Pattern: Lacto-Ovo Vegetarian

Breakfast	Lunch	Dinner	Snack
Fresh fruit	Egg Salad sandwich on whole wheat bread with lettuce	Black bean burritos with cheese, avocado and salsa	Apple and cheese
½ cup oatmeal served with Greek yogurt	Cup of tomato soup	Lettuce salad	
1 cup (8 oz) milk	Carrot sticks	Peanut Butter cookie and 8oz milk	
	Fresh fruit		

Meal Pattern: Vegan

Breakfast	Lunch	Dinner	Snack
½ cup orange juice (calcium fortified)	Bean Burritos served with guacamole and salsa	Tofu-Vegetable Stir-fry (include bok choy and spinach for calcium) Top with cashews	½ peanut butter sandwich or ½ cup of edamame
3 whole grain pancakes topped with walnuts, applesauce and cinnamon	Green salad with oil and vinegar	Brown rice	
1 cup fortified soy milk or soy yogurt	1 fresh apple	Cardamom-flavored chia pudding made with soy milk	
	1 cup fortified soy milk	Beverage of choice	

Nutritional Facts on Folic Acid, Vitamin B₆, and Vitamin B₁₂

FOLATE

Folate is a water-soluble B vitamin that occurs naturally in food. Folic acid is the synthetic form of folate that is found in supplements and is added to fortified foods. Folate, formerly known as folacin, is the generic term to refer to both folate and folic acid. Folate functions as an enzyme in single carbon transfers, and is involved in the production and maintenance of new cells, which is especially important during periods of rapid cell division and growth such as infancy, adolescence, and pregnancy. See Chapter 15. Folate is needed to make deoxyribonucleic acid (DNA) and ribonucleic acid, the building blocks of cells. Both adults and children need folate to make normal red blood cells and prevent anemia. See Chapter 32. Folate is also essential for the conversion of homocysteine to methionine in the synthesis of *s*-adenosyl-methionine, and important methyl donor.

A genetic mutation of a folate-metabolizing enzyme (5,10-methylenetetrahydrofolate) results in the inability to convert dietary folate or folic acid into the active form, 5-methyltetrahydrofolate (5-MTHFA). The result is folate deficiency unless folate is consumed in the methylated form as methyltetrahydrofolic acid (MTHFA). See Chapter 5.

Recommended Intakes

Intake recommendations for folate and other nutrients are provided in the Dietary Reference Intakes (DRIs) developed by the Food and Nutrition Board (FNB), Institute of Medicine (IOM) of the National Academies (formerly National Academy of

Sciences). DRI is the general term for a set of reference values used for planning and assessing nutrient intakes of healthy people. These values, which vary by age and gender, include:

- Recommended Dietary Allowance (RDA): average daily level of intake sufficient to meet the nutrient requirements of nearly all (97%–98%) healthy individuals.
- Adequate Intake (AI): established when evidence is insufficient to develop an RDA and is set at a level assumed to ensure nutritional adequacy.
- Tolerable Upper Intake Level (UL): maximum daily intake unlikely to cause adverse health effects. ULs for folic acid are listed on the inside back cover of this text.

The table lists the current RDAs for folate as micrograms (mcg) of dietary folate equivalents (DFEs). The FNB developed DFEs to reflect the higher bioavailability of folic acid than that of food folate. At least 85% of supplemental folic acid is estimated to be bioavailable when taken with food, whereas only about 50% of folate naturally present in food is bioavailable. Based on these values, the FNB defined DFE as follows:

- 1 mcg DFE = 1 mcg food folate
- 1 mcg DFE = 0.6 mcg folic acid from fortified foods or dietary supplements consumed with foods
- 1 mcg DFE = 0.5 mcg folic acid from dietary supplements taken on an empty stomach

For infants from birth to 12 months of age, AIs were established that are equivalent to the mean intake of folate in healthy, breastfed infants in the United States.

Recommended Dietary Allowances (RDAs) for Folate

Age	Male	Female	Pregnant	Lactating
Birth to 6 months*	65 mcg DFE*	65 mcg DFE*	N/A	N/A
7–12 months*	80 mcg DFE*	80 mcg DFE*	N/A	N/A
1–3 years	150 mcg DFE	150 mcg DFE	N/A	N/A
4–8 years	200 mcg DFE	200 mcg DFE	N/A	N/A
9–13 years	300 mcg DFE	300 mcg DFE	N/A	N/A
14–18 years	400 mcg DFE	400 mcg DFE	600 mcg DFE	500 mcg DFE
19+ years	400 mcg DFE	400 mcg DFE	600 mcg DFE	500 mcg DFE

*Adequate Intake (AI)
N/A, Not applicable.

Selected Food Sources of Folate and Folic Acid

Food	mcg DFE per Serving	Percent DV*	Food	mcg DFE per Serving	Percent DV*
Beef liver, braised, 3 ounces	215	54	Rice, white, medium-grain, cooked, ½ cup†	90	23
Spinach, boiled, ½ cup	131	33	Asparagus, boiled, 4 spears	89	22
Black-eyed peas (cowpeas), boiled, ½ cup	105	26	Spaghetti, cooked, enriched, ½ cup†	83	21
Breakfast cereals, fortified with 25% of the DV†	100	25	Brussels sprouts, frozen, boiled, ½ cup	78	20
			Lettuce, romaine, shredded, 1 cup	64	16

Continued

Selected Food Sources of Folate and Folic Acid—cont'd

Food	mcg DFE per Serving	Percent DV*	Food	mcg DFE per Serving	Percent DV*
Avocado, raw, sliced, ½ cup	59	15	Turnip greens, frozen, boiled, ½ cup	32	8
Spinach, raw, 1 cup	58	15	Orange, fresh, 1 small	29	7
Broccoli, chopped, frozen, cooked, ½ cup	52	13	Papaya, raw, cubed, ½ cup	27	7
Mustard greens, chopped, frozen, boiled, ½ cup	52	13	Banana, 1 medium	24	6
Green peas, frozen, boiled, ½ cup	47	12	Yeast, baker's, ¼ teaspoon	23	6
Kidney beans, canned, ½ cup	46	12	Egg, whole, hard-boiled, 1 large	22	6
Bread, white, 1 slice†	43	11	Vegetarian baked beans, canned, ½ cup	15	4
Peanuts, dry roasted, 1 ounce	41	10	Cantaloupe, raw, 1 wedge	14	4
Wheat germ, 2 tablespoons	40	10	Fish, halibut, cooked, 3 ounces	12	3
Tomato juice, canned, ¾ cup	36	9	Milk, 1% fat, 1 cup	12	3
Crab, Dungeness, 3 ounces	36	9	Ground beef, 85% lean, cooked, 3 ounces	7	2
Orange juice, ¾ cup	35	9	Chicken breast, roasted, ½ breast	3	1

*DV = Daily Value. The FDA developed DVs to help consumers compare the nutrient contents of products within the context of a total diet. The DV for folate is 400 mcg for adults and children aged 4 and older. However, the FDA does not require food labels to list folate content unless a food has been fortified with this nutrient. Foods providing 20% or more of the DV are considered to be high sources of a nutrient.

†Fortified with folic acid as part of the folate fortification program.

VITAMIN B₆

Vitamin B₆ is a water-soluble vitamin that exists in three major chemical forms: pyridoxine, pyridoxal, and pyridoxamine and their respective esters. Pyridoxal 5' phosphate (PLP) and pyridoxamine 5' phosphate (PMP) are the active coenzyme forms of vitamin B₆. Vitamin B₆ is naturally present in many foods, is added to others, and also exists as a dietary supplement.

Vitamin B₆ performs a wide variety of functions in the body. It is needed for more than 100 enzymes involved in protein metabolism and is essential for red blood cell metabolism. The nervous and immune systems need vitamin B₆ to function efficiently, and it is also needed for the conversion of tryptophan (an amino acid) to niacin. A vitamin B₆ deficiency can result in a form of anemia that is similar to iron deficiency anemia. See Chapter 32.

Through its involvement in protein metabolism and cellular growth, vitamin B₆ is important to the immune system. It helps maintain the health of lymphoid organs (thymus, spleen, and lymph nodes) that make white blood cells. It is also important for maintaining normal blood glucose levels.

Recommended Intakes

Intake recommendations for vitamin B₆ and other nutrients are provided in the Dietary Reference Intakes (DRIs) developed by the Food and Nutrition Board (FNB) of the Institute of Medicine (IOM) of the National Academies. DRI is the general term for a set of reference values used for planning and assessing nutrient intakes of healthy people. These values, which vary by age and gender, include:

- Recommended Dietary Allowance (RDA): average daily level of intake sufficient to meet the nutrient requirements of nearly all (97%–98%) healthy individuals.
- Adequate Intake (AI): established when evidence is insufficient to develop an RDA and is set at a level assumed to ensure nutritional adequacy.
- Tolerable Upper Intake Level (UL): maximum daily intake unlikely to cause adverse health effects. The ULs for vitamin B₆ are listed on the inside back cover of this text.

Recommended Dietary Allowances for Vitamin B₆ for Children and Adults

Age (years)	Males (mg/day)	Females (mg/day)	Pregnancy (mg/day)	Lactation (mg/day)
0 – 6 mos	.1*	.1*	N/A	N/A
7 – 12 mos	.3*	.3*	N/A	N/A
1-3	0.5	.5	N/A	N/A
4-8	0.6	.6	N/A	N/A
9-13	1.0	1.0	N/A	N/A
14-18	1.3	1.2	1.9	2.0
19 - 50	1.3	1.3	1.9	2.0
51+	1.7	1.5	N/A	N/A

N/A, Not applicable.

*Adequate Intake (AI). AI for vitamin B₆ is equivalent to the mean intake of vitamin B₆ in healthy, breastfed infants.

Substantial proportions of the naturally occurring pyridoxine in fruits, vegetables, and grains exist in glycosylated forms that exhibit reduced bioavailability.

Selected Food Sources of Vitamin B₆

Food	Milligrams (mg) per Serving	Percent DV*
Chickpeas, canned, 1 cup	1.1	55
Beef liver, pan fried, 3 ounces	0.9	45
Tuna, yellowfin, fresh, cooked, 3 ounces	0.9	45
Salmon, sockeye, cooked, 3 ounces	0.6	30
Chicken breast, roasted, 3 ounces	0.5	25
Breakfast cereals, fortified with 25% of the DV for vitamin B ₆	0.5	25
Potatoes, boiled, 1 cup	0.4	20
Turkey, meat only, roasted, 3 ounces	0.4	20
Banana, 1 medium	0.4	20
Marinara (spaghetti) sauce, ready to serve, 1 cup	0.4	20
Ground beef, patty, 85% lean, broiled, 3 ounces	0.3	15

Selected Food Sources of Vitamin B₆—cont'd

Food	Milligrams (mg) per Serving	Percent DV*
Waffles, plain, ready to heat, toasted, 1 waffle	0.3	15
Bulgur, cooked, 1 cup	0.2	10
Cottage cheese, 1% low-fat, 1 cup	0.2	10
Squash, winter, baked, ½ cup	0.2	10
Rice, white, long-grain, enriched, cooked, 1 cup	0.1	5
Nuts, mixed, dry-roasted, 1 ounce	0.1	5
Raisins, seedless, ½ cup	0.1	5
Onions, chopped, ½ cup	0.1	5
Spinach, frozen, chopped, boiled, ½ cup	0.1	5
Tofu, raw, firm, prepared with calcium sulfate, ½ cup	0.1	5
Watermelon, raw, 1 cup	0.1	5

*DV = Daily Value. DVs were developed by the U.S. Food and Drug Administration (FDA) to help consumers compare the nutrient contents of products within the context of a total diet. The DV for vitamin B₆ is 2 mg for adults and children age 4 and older. However, the FDA does not require food labels to list vitamin B₆ content unless a food has been fortified with this nutrient. Foods providing 20% or more of the DV are considered to be high sources of a nutrient.

VITAMIN B₁₂

Vitamin B₁₂ is a member of the vitamin B complex. It contains cobalt; thus it is also known as *cobalamin*. Methylcobalamin and 5-deoxyadenosylcobalamin are the active forms of vitamin B₁₂. Like folate, vitamin B₁₂ is involved in the conversion of homocysteine to methionine.

Vitamin B₁₂ is necessary for the synthesis of red blood cells, the maintenance of the nervous system, DNA synthesis and growth. Deficiency can cause anemia. See Chapter 32. Vitamin B₁₂ neuropathy, involving the degeneration of nerve fibers and irreversible neurologic damage, can also occur.

Proper vitamin B₁₂ absorption requires the presence of hydrochloric acid (HCL) and gastric protease, which cause its release from the protein it is bound to in food, allowing it to be absorbed. B₁₂ then combines with intrinsic factor (IF), secreted by the stomach's parietal cells, and travels down the GI tract where it is absorbed as the B₁₂-IF complex in the distal ileum. See Chapter 1. Because HCL production tends to diminish with age, B₁₂ supplementation where the B₁₂ is already separated from the protein molecule and is in its free form can be useful in treating or preventing a deficiency. Total body store of B₁₂ is 2 to 5 mg in adults. Approximately 80% of this is stored in the liver.

Along with folate and vitamin B₆, vitamin B₁₂ is helpful in lowering the level of the amino acid homocysteine in the blood. It has been hypothesized that at high levels homocysteine might damage coronary arteries or make it easier for blood-clotting cells to clump together and form a clot. This could increase risks for a heart attack or stroke.

Recommended Intakes

- Recommended Dietary Allowance (RDA): average daily level of intake sufficient to meet the nutrient requirements of nearly all (97%–98%) healthy individuals.
- Adequate Intake (AI): established when evidence is insufficient to develop an RDA and is set at a level assumed to ensure nutritional adequacy.

- Tolerable Upper Intake Level (UL): maximum daily intake unlikely to cause adverse health effects. The ULs for vitamin B₁₂ are listed on the inside back cover of this text.

The table below lists the current RDAs for vitamin B₁₂ in micrograms (mcg). For infants aged 0 to 12 months, there are AIs that are equivalent to the mean intake of vitamin B₁₂ in healthy, breastfed infants.

Recommended Dietary Allowances for Vitamin B₁₂ for Children and Adults

Age (years)	Males and Females (mcg/day)	Pregnancy (mcg/day)	Lactation (mcg/day)
0 – 6 mos	0.4*	N/A	N/A
7 – 12 mos	0.5*	N/A	N/A
1-3	0.9	N/A	N/A
4-8	1.2	N/A	N/A
9-13	1.8	N/A	N/A
14 +	2.4	2.6	2.8

N/A, Not applicable.
*Adequate Intake (AI)

Vitamin B₁₂ is found primarily in animal foods such as fish, meat, poultry, eggs, and dairy products. However, it is also synthesized by bacteria and there has been considerable research into proposed plant sources of vitamin B₁₂. Fermented soy products, seaweeds, and algae (spirulina) have all been suggested as containing significant B₁₂. However, the present consensus is that any B₁₂ present in plant foods is likely to be unavailable to humans; thus these foods should not be relied on as safe sources. Vegans need B₁₂ from fortified foods or as a supplement. Fortified breakfast cereals are a readily available source of vitamin B₁₂ with high bioavailability for vegans. Some nutritional yeast products also contain vitamin B₁₂. Fortified foods vary in formulation, so it is important to read product labels.

Many vegan foods are supplemented with B₁₂.

Selected Food Sources of Vitamin B₁₂

Food	Micrograms (mcg) per Serving	Percent DV*
Clams, cooked, 3 ounces	84.1	1,402
Liver, beef, cooked, 3 ounces	70.7	1,178
Breakfast cereals, fortified with 100% of the DV for vitamin B ₁₂ , 1 serving	6.0	100
Trout, rainbow, wild, cooked, 3 ounces	5.4	90
Salmon, sockeye, cooked, 3 ounces	4.8	80
Trout, rainbow, farmed, cooked, 3 ounces	3.5	58
Tuna fish, light, canned in water, 3 ounces	2.5	42
Cheeseburger, double patty and bun, 1 sandwich	2.1	35
Haddock, cooked, 3 ounces	1.8	30
Breakfast cereals, fortified with 25% of the DV for vitamin B ₁₂ , 1 serving	1.5	25

Continued

Selected Food Sources of Vitamin B₁₂—cont'd

Food	Micrograms (mcg) per Serving	Percent DV*
Beef, top sirloin, broiled, 3 ounces	1.4	23
Milk, low-fat, 1 cup	1.2	18
Yogurt, fruit, low-fat, 8 ounces	1.1	18
Cheese, Swiss, 1 ounce	0.9	15
Beef taco, 1 soft taco	0.9	15
Ham, cured, roasted, 3 ounces	0.6	10
Egg, whole, hard boiled, 1 large	0.6	10
Chicken, breast meat, roasted, 3 ounces	0.3	5

*DV = Daily Value. DVs were developed by the U.S. Food and Drug Administration (FDA) to help consumers determine the level of various nutrients in a standard serving of food in relation to their approximate requirement for it. The DV for adults and children aged 4 and older is 6.0 mcg. The %DV listed on the Nutrition Facts label states the percentage of the DV provided per serving. However, the FDA does not require food labels to list vitamin B₁₂ content unless a food has been fortified with this nutrient. Foods providing 20% or more of the DV are considered to be high sources of a nutrient, but foods providing lower percentages of the DV also contribute to a healthful diet.

Nutritional Facts on Vitamin A and Carotenoids

Vitamin A includes a group of compounds that affect vision, bone growth, reproduction, cell division, immunity, and healthy surface linings of the respiratory tract and mucous membranes. There are two categories of vitamin A, depending on whether the food source is an animal or a plant. Vitamin A found in animal foods is called *preformed vitamin A* and is absorbed as retinol. Sources include liver, whole milk, and some fortified food products. In the body retinol can be made into retinal and retinoic acid (other active forms of vitamin A).

Plant sources of vitamin A provide the provitamin A, called *carotenoids*. They can be made into retinol in the body and then into the other active forms of vitamin A. In the United States approximately 26% to 34% of vitamin A consumed is in the form of provitamin A carotenoids. Common provitamin A carotenoids which give plants their color, and are β -carotene, α -carotene, and β -cryptoxanthin. Among these, β -carotene is most efficiently made into retinol. The darker the color of a fruit or vegetable, the greater is its carotenoid content.

Vitamin A deficiency rarely occurs in the United States. Vitamin A deficiency is more common in developing countries, where access to sufficient animal and beta-carotene containing plant sources is limited. Vitamin A deficiency is a leading cause of preventable blindness in children. Children with measles or diarrhea can significantly benefit from increased vitamin A. Fat malabsorption can result in diarrhea and prevent normal absorption of vitamin A; this may result in vitamin A deficiency in celiac disease, Crohn's disease, and pancreatic disorders. The best absorbed form of vitamin A is in the oil form such as in cod liver oil.

RECOMMENDED DIETARY ALLOWANCES (RDA)

The RDA is the average daily dietary intake level that is sufficient to meet the nutrient requirement of the vast majority (97 - 98%) of healthy individuals in a particular gender and age group, with special considerations for pregnancy or lactation, where applicable.

All dietary sources of vitamin A are converted to retinol. Intake recommendations for Vitamin A in foods are expressed

as micrograms of retinol activity equivalents (RAEs) as a way to standardize the variation in bioactivities of retinol and provitamin A carotenoids, and account for the differences based on source. International Units (IU) are a helpful guideline, but conversion rates also vary based on source:

- 1 IU retinol = 0.3 mcg RAE
- 1 IU beta-carotene from dietary supplements = 0.15 mcg RAE
- 1 IU beta-carotene from food = 0.05 mcg RAE
- 1 IU alpha-carotene or beta-cryptoxanthin = 0.025 mcg RAE

Recommended Daily Allowances

Age (years)	Males and Females (mcg RAEs/day)	Pregnancy (mcg RAEs/day)	Lactation (mcg RAEs/day)
0-6 mos	400*	N/A	N/A
0-7 mos	500*	N/A	N/A
1-3	300	N/A	N/A
4-8	400	N/A	N/A
9-13	600	N/A	N/A
14-18	900 for boys; 700 for girls	750	1200
19+	900 for men; 700 for women	770	1300

N/A, Not applicable; RAE, Retinol activity equivalent.

*Adequate Intakes

FOOD SOURCES OF VITAMIN A

Selected Animal Sources of Vitamin A

Food	Vitamin A (IU)	% Daily Value
Liver, beef, cooked, 3 oz	27,185	545
*Liver, chicken, cooked, 3 oz	12,325	245
Milk, fortified skim, 1 cup	500	10
Cheese, cheddar, 1 oz	284	6
Milk, whole (3.25% fat), 1 cup	249	5
Egg substitute, 1/4 cup	226	5

Selected Plant Sources of Vitamin A (from β -Carotene)

Food	Vitamin A (IU)	% Daily Value*	Food	Vitamin A (IU)	% Daily Value*
Carrot juice, canned, ½ cup	22,567	450	Papaya, 1 cup cubes	1532	30
Carrots, boiled, ½ cup slices	13,418	270	Mango, 1 cup sliced	1262	25
Spinach, frozen, boiled, ½ cup	11,458	230	Oatmeal, instant, fortified, plain, prepared with water, 1 cup	1252	25
Kale, frozen, boiled, ½ cup	9558	190	Peas, frozen, boiled, ½ cup	1050	20
Carrots, 1 raw (7½ in)	8666	175	Tomato juice, canned, 6 oz	819	15
Vegetable soup, canned, chunky, ready-to-serve, 1 cup	5820	115	Peaches, canned, juice pack, ½ cup halves or slices	473	10
Cantaloupe, 1 cup cubes	5411	110	Peach, 1 medium	319	6
Spinach, raw, 1 cup	2813	55	Pepper, sweet, red, raw, 1 ring (3 inches diameter by ¼ inch thick)	313	6
Apricots with skin, juice pack, ½ cup	2063	40			
Apricot nectar, canned, ½ cup	1651	35			

*Daily values (DVs) are reference numbers based on the RDA. They were developed to help consumers determine if a food contains a lot or a little of a nutrient. **The DV for vitamin A is 5000 IU.** Most food labels do not list vitamin A content. The %DV column in this table indicates the percentage of the DV provided in one serving. A food providing 5% or less of the DV is a low source, whereas a food that provides 10% to 19% of the DV is a good source. A food that provides 20% or more of the DV is high in that nutrient. It is important to remember that foods that provide lower percentages of the DV also contribute to a healthful diet.

Carotenoids in Fruits and Vegetables (mole %)

	Neoxanthins and Violaxanthins	Lutein and Zeaxanthin	Lutein	Zeaxanthin	Cryptoxanthins	Lycopenes	α -carotene	β -carotene

Table from Sommerburg O et al: Fruits and vegetables that are sources for lutein and zeaxanthin: the macular pigment in human eyes, Br J Ophthalmol 82:907, 1998. The content of the major carotenoids are given in mole%. The amounts of the carotenoids were shown in seven major groups, as 1) neoxanthins and violaxanthins (neoxanthin, violaxanthin, and their related isomers, lutein 5, 6 epoxide), 2) lutein, 3) zeaxanthin, 4) cryptoxanthins (α -cryptoxanthin, β -cryptoxanthins, and related isomers), 5) lycopenes (lycopene and related isomers), 6) α -carotenes, and 7) β -carotene (all *trans* β -carotene and *cis* isomers). Lutein and zeaxanthin are given combined and as single amounts. The data are sorted by the combined amount of lutein and zeaxanthin.

Nutritional Facts on Vitamin C

Vitamin C is a nutrient naturally present in foods (mainly fruits and vegetables) and is also known by the chemical name of its principal form, L-ascorbic acid or simply ascorbic acid. Unlike most animals humans are unable to synthesize vitamin C. Vitamin C is principally known as a water-soluble antioxidant, preventing the damaging effects of free radicals, and it regenerates other antioxidants in the body including vitamin E or alpha-tocopherol. See Chapter 3.

Vitamin C is required for the biosynthesis of collagen, L-carnitine, and certain neurotransmitters; it is also involved in protein metabolism. Collagen is an essential component of connective tissue, which plays a vital role in wound healing, and it plays an important role in immune function. It also improves the absorption of nonheme iron, the form of iron present in plant-based foods. See Chapter 32. Vitamin C prevents scurvy, characterized by fatigue or lassitude, widespread connective tissue weakness, and capillary fragility.

RECOMMENDED INTAKES

Dietary Recommended Intakes for vitamin C were developed by the Food and Nutrition Board (FNB), Institute of Medicine (IOM) of the National Academies (formerly National Academy of Sciences). DRI is the general term for a set of reference values used for planning and assessing nutrient intakes of healthy people. These values include:

- Recommended Dietary Allowance (RDA): average daily level of intake sufficient to meet the nutrient requirements of nearly all (97%–98%) healthy individuals.
- Adequate Intake (AI): established when evidence is insufficient to develop an RDA and is set at a level assumed to ensure nutritional adequacy.
- Tolerable Upper Intake Level (UL): maximum daily intake unlikely to cause adverse health effects. ULs for vitamin C are listed on the inside back cover of this text.

The RDAs for vitamin C are based on its known physiological and antioxidant functions in white blood cells and are much higher than the amount required for protection from deficiency. For infants from birth to 12 months, the FNB established an AI for vitamin C that is equivalent to the mean intake of vitamin C in healthy, breastfed infants

Fruits and vegetables are the best sources of vitamin C especially citrus fruits, red and green peppers, kiwi fruit and tomatoes and tomato juice. Other good food sources include broccoli, strawberries, Brussels sprouts, and cantaloupe. Some fortified breakfast cereals are also good sources of vitamin C.

Recommended Dietary Allowances (RDAs) for Vitamin C for Children and Adults

Age (years)	Males and Females (mg/day)	Pregnancy (mg/day)	Lactation (mg/day)
0 – 6 mos	40*	N/A	N/A
7 – 12 mos	50*	N/A	N/A
1-3	15	N/A	N/A
4-8	25	N/A	N/A
9-13	45	N/A	N/A
14-18	75 for boys; 65 for girls	80	115
19+	90 for men; 75 for women	85	120
Smokers	Individuals who smoke require 35 mg/day more vitamin C than nonsmokers.		

N/A, Not applicable.

The vitamin C content of food can be lessened by prolonged storage and by cooking because ascorbic acid is water soluble and is destroyed by heat. Steaming or microwaving vegetables rather than boiling them may reduce cooking losses. Fortunately, many of the best food sources of vitamin C, such as fruits and vegetables, are usually consumed raw.

Selected Food Sources of Vitamin C

Food	Milligrams (mg) per Serving	Percent (%) DV*
Red pepper, sweet, raw, ½ cup	95	158
Orange juice, ¾ cup	93	155
Orange, 1 medium	70	117
Grapefruit juice, ¾ cup	70	117
Kiwifruit, 1 medium	64	107
Green pepper, sweet, raw, ½ cup	60	100
Broccoli, cooked, ½ cup	51	85
Strawberries, fresh, sliced, ½ cup	49	82
Brussels sprouts, cooked, ½ cup	48	80
Grapefruit, ½ medium	39	65
Broccoli, raw, ½ cup	39	65
Tomato juice, ¾ cup	33	55
Cantaloupe, ½ cup	29	48
Cabbage, cooked, ½ cup	28	47
Cauliflower, raw, ½ cup	26	43
Potato, baked, 1 medium	17	28
Tomato, raw, 1 medium	17	28
Spinach, cooked, ½ cup	9	15
Green peas, frozen, cooked, ½ cup	8	13

*DV = Daily Value. DVs were developed by the U.S. Food and Drug Administration (FDA) to help consumers compare the nutrient contents of products within the context of a total diet. **The DV for vitamin C is 60 mg for adults and children aged 4 and older.** The FDA requires all food labels to list the percent DV for vitamin C. Foods providing 20% or more of the DV are considered to be high sources of a nutrient.

Dietary Supplements

Supplements typically contain vitamin C in the form of ascorbic acid, which has equivalent bioavailability to that of naturally occurring ascorbic acid in foods, such as orange juice and broccoli. Other forms of vitamin C supplements include sodium ascorbate; calcium ascorbate; other mineral ascorbates; ascorbic acid with bioflavonoids; and combination products, such as Ester-C[®], which contains calcium ascorbate, dehydroascorbate, calcium threonate, xylonate and lyxonate. It is still controversial whether Ester-C[®] is more bioavailable or effective than ascorbic acid in improving vitamin C status.

Nutritional Facts on Vitamin E

Vitamin E is a naturally occurring fat-soluble vitamin that exists in eight different forms: alpha-, beta-, gamma-, and delta-tocopherol, and alpha-, beta-, gamma-, and delta-tocotrienol that have varying levels of biological activity. Alpha- (or α -) tocopherol appears to be the most active form, and is the only form that is recognized to meet human requirements. Serum concentrations of alpha-tocopherol depend on the liver, which takes up the nutrient after absorption of all the forms from the small intestine. The liver then preferentially secretes only alpha-tocopherol, and metabolizes and excretes the other vitamin E forms. As a result, blood and cellular concentrations of other forms of vitamin E are lower than those of alpha-tocopherol and thus have been less studied.

Vitamin E has powerful antioxidant activities which protect cells from the damaging effects of free radicals. Free radicals combine with oxygen and form reactive oxygen species (ROS) that damage cells. Free radicals are produced endogenously when the body metabolizes food to energy. Exogenous sources come from exposure to cigarette smoke, air pollution, and ultraviolet radiation from the sun. ROS are part of signaling mechanisms among cells and antioxidant vitamin E protects the cells against free radical damage. See Chapter 3. Scientists are investigating whether, by limiting free-radical production and possibly through other mechanisms, vitamin E might help prevent or delay the chronic diseases associated with free radicals. Besides functioning as an antioxidant, vitamin E is also involved in immune function and, as shown primarily by *in vitro* studies of cells, cell signaling, regulation of gene expression, and other metabolic processes.

Vitamin E in supplements is usually sold as α -tocopheryl acetate, a form of α -tocopherol that protects its ability to function as an antioxidant. The synthetic form is labeled *dl*, whereas the natural form is labeled *d*. The synthetic form is only half as active as the natural form. It is important to include foods high in vitamin E on a daily basis to get enough vitamin E from foods alone. Vegetable oils, nuts, green leafy vegetables, and fortified cereals are common food sources of vitamin E.

RECOMMENDED INTAKES

Recommendations for vitamin E are provided in the Dietary Reference Intakes (DRIs) developed by the Food and Nutrition Board (FNB), Institute of Medicine (IOM), The National Academies (formerly National Academy of Sciences). DRI is the general term for a set of reference values used to plan and assess nutrient intakes of healthy people. These values, which vary by age and gender, include:

- Recommended Dietary Allowance (RDA): average daily level of intake sufficient to meet the nutrient requirements of nearly all (97%–98%) healthy people.

- Adequate Intake (AI): established when evidence is insufficient to develop an RDA and is set at a level assumed to ensure nutritional adequacy.
- Tolerable Upper Intake Level (UL): maximum daily intake unlikely to cause adverse health effects. ULs for vitamin E are listed inside the cover of this text.

The FNB's vitamin E recommendations are for alpha-tocopherol alone, the only form maintained in plasma. Acknowledging "great uncertainties" in these data, the FNB has called for research to identify other biomarkers for assessing vitamin E requirements.

RDAs in the table are for vitamin E are for alpha-tocopherol in both milligrams (mg) and IU of the natural form. For example, $15 \text{ mg} \times 1.49 \text{ IU/mg} = 22.4 \text{ IU}$ in the natural form. The corresponding value for synthetic alpha-tocopherol would be 33.3 IU ($15 \text{ mg} \times 2.22 \text{ IU/mg}$).

Because insufficient data are available to develop RDAs for infants, AIs were developed based on the amount of vitamin E consumed by healthy breastfed babies.

Recommended Dietary Allowances (RDAs) for Vitamin E (in milligrams) of α -TE for Children and Adults

Age	Males and Females (mg/day)	Pregnancy (mg/day)	Lactation (mg/day)
0 – 6 mos	4 mg (6 IU)*	N/A	N/A
7 – 12 mos	6 mg (7.5 IU)*	N/A	N/A
1-3 years	6 (9 IU)	N/A	N/A
4-8 years	7 (10.4 IU)	N/A	N/A
9-13 years	11 (16.4 IU)	N/A	N/A
14-18 years	15 (22.4 IU)	15 (22.4 IU)	19 (28.4 IU)
19+ years	15 (22.4 IU)	15 (22.4 IU)	19 (28.4 IU)

N/A, Not applicable.

*Adequate Intake (AI)

Vitamin E content of food is stated as milligrams of α -tocopherol, milligrams of α -tocopherol equivalents (mg α -TE), or as international units (IUs) on supplement labels. 1 unit = 0.67 α -TE in the *d* form and approximately $\frac{1}{2}$ of that in the *dl* or synthetic form. The vitamin E content of foods and dietary supplements is listed on labels in international units (IUs), a measure of biological activity rather than quantity. Naturally sourced vitamin E is called d-alpha-tocopherol; the synthetically produced form is dl-alpha-tocopherol. Conversion rules are as follows:

- To convert from mg to IU: 1 mg of alpha-tocopherol is equivalent to 1.49 IU of the natural form or 2.22 IU of the synthetic form.

- To convert from IU to mg: 1 IU of alpha-tocopherol is equivalent to 0.67 mg of the natural form or 0.45 mg of the synthetic form.

Numerous foods provide vitamin E. Nuts, seeds, and vegetable oils are among the best sources of alpha-tocopherol, and significant amounts are available in green leafy vegetables and fortified cereals. See Table. Most vitamin E in American diets is in the form of gamma-tocopherol from soybean, canola, corn, and other vegetable oils and food products.

Selected Food Sources of Vitamin E (Alpha-Tocopherol)

Food	Milligrams (mg) per Serving	Percent DV*
Wheat germ oil, 1 tablespoon	20.3	100
Sunflower seeds, dry roasted, 1 ounce	7.4	37
Almonds, dry roasted, 1 ounce	6.8	34
Sunflower oil, 1 tablespoon	5.6	28
Safflower oil, 1 tablespoon	4.6	25
Hazelnuts, dry roasted, 1 ounce	4.3	22
Peanut butter, 2 tablespoons	2.9	15
Peanuts, dry roasted, 1 ounce	2.2	11
Corn oil, 1 tablespoon	1.9	10
Spinach, boiled, ½ cup	1.9	10
Broccoli, chopped, boiled, ½ cup	1.2	6
Soybean oil, 1 tablespoon	1.1	6
Kiwifruit, 1 medium	1.1	6
Mango, sliced, ½ cup	0.7	4
Tomato, raw, 1 medium	0.7	4
Spinach, raw, 1 cup	0.6	3

*DV = Daily Value. DVs were developed by the U.S. Food and Drug Administration (FDA) to help consumers compare the nutrient content of different foods within the context of a total diet. The DV for vitamin E is 30 IU (approximately 20 mg of natural alpha-tocopherol) for adults and children age 4 and older. However, the FDA does not require food labels to list vitamin E content unless a food has been fortified with this nutrient. Foods providing 20% or more of the DV are considered to be high sources of a nutrient, but foods providing lower percentages of the DV also contribute to a healthful diet.

The U.S. Department of Agriculture's (USDA's) Nutrient Database Web site lists the nutrient content of many foods, including, in some cases, the amounts of alpha-, beta-, gamma-, and delta-tocopherol. The USDA also provides a comprehensive

list of foods containing vitamin E arranged by nutrient content and by food name.

SAMPLE MEAL PLAN

Breakfast

- ¾ cup ready-to-eat cereal, fortified with vitamin E
- ½ cup low-fat or fat-free milk
- 1 red delicious apple
- 2 Tbsp peanut butter (2.5 mg vitamin E)

Lunch

- 1 cup mixed salad greens
- 3 oz tuna steak
- 2 slices multigrain bread
- ½ cup fruit salad

Dinner

- 3 oz grilled chicken breast
- ½ cup fresh steamed spinach (1.9 mg vitamin E)
- ½ cup whole grain rice
- Side salad

Snack

- 1 oz dry roasted almonds (6.8 mg vitamin E)
- 1 Tbsp low-fat granola
- ½ cup low-fat or fat-free yogurt
- 1 tsp wheat germ oil (6.7 mg vitamin E).

Nutritional Facts on Vitamin K

Vitamin K refers to a family of compounds with a common chemical structure. These compounds include phyloquinone (vitamin K1) and a series of menaquinones known as vitamin K2. They are further designated as MK-4 through MK-13 depending on the length of their individual side chains. Vitamin K is fat soluble and is naturally present in some foods, is produced by the bacteria naturally present in the gastrointestinal tract, and is available as a dietary supplement. Vitamin K1, the main dietary form of vitamin K, is present mainly in green leafy vegetables. Menaquinones, primarily of bacterial origin, are found in some animal based foods and in fermented foods. Natto, a Japanese fermented soy food is an excellent source of vitamin K2. Menaquinones are also produced by the naturally occurring bacteria in the gut. However, MK-4 is unique in that it is produced from phyloquinone by a conversion process that does not involve bacteria.

Vitamin K functions as a coenzyme for vitamin K-dependent carboxylase, an enzyme required for the synthesis of proteins involved in hemostasis (blood clotting) and bone metabolism, and other diverse physiological functions. Prothrombin (clotting factor II) is a vitamin K-dependent protein in plasma that is directly involved in blood clotting. <https://ods.od.nih.gov/factsheets/VitaminK-HealthProfessional/>.

Matrix Gla-protein, is another vitamin K-dependent protein present in vascular smooth muscle, bone, and cartilage, is the focus of considerable scientific research because it might help reduce abnormal calcification. Osteocalcin is another vitamin K-dependent protein, and is present in bone and may be involved in bone mineralization or turnover. See Chapter 24.

Dietary Reference Intakes: Adequate Intakes (AIs) for Vitamin K for Children and Adults

Age (years)	Males and Females (mcg/day)	Pregnancy (mcg/day)	Lactation (mcg/day)
Birth to 6 mos	2	N/A	N/A
7 – 12 mos	2.5	N/A	N/A
1-3	30	N/A	N/A
4-8	55	N/A	N/A
9-13	60	N/A	N/A
14-18	75	75	75
19+	120 for men; 90 for women	90	90

N/A, Not applicable.

The Dietary Reference Intakes for vitamin K are adequate intakes and are listed in the table.

- Adequate Intake (AI): established when evidence is insufficient to develop a Recommended Dietary Allowance (RDA); intake at this level is assumed to ensure nutritional adequacy.
- Tolerable Upper Intake Level (UL): maximum daily intake unlikely to cause adverse health effects. ULs for vitamin K are listed on the inside cover of this text.

Antibiotics may interfere with this normal production. Circumstances that may lead to vitamin K deficiency include liver disease, serious burns, health problems that can prevent the absorption of vitamin K (such as gallbladder or biliary disease, which may alter the absorption of fat), cystic fibrosis, celiac disease, Crohn’s disease, and chronic antibiotic therapy. Excess vitamin E can inhibit vitamin K activity and precipitate signs of deficiency. The classic sign of a vitamin K deficiency is a prolonged prothrombin time, which increases the risk of spontaneous hemorrhage. Because vitamin K is stored in the liver, clinical deficiencies are rare.

Vitamin K is needed to make clotting factors that help the blood to clot and prevent bleeding. The amount of vitamin K in food may affect drug therapy, such as that from warfarin or other anticoagulants. Warfarin (Coumadin®) and some anticoagulants used primarily in Europe antagonize the activity of vitamin K and, in turn, prothrombin. For this reason, individuals who are taking these anticoagulants need to maintain consistent vitamin K intakes. When taking these medications, it is necessary to eat a normal, balanced diet, maintaining a consistent amount of vitamin K, and avoiding large changes in vitamin K intake.

In general, leafy green vegetables and certain legumes and vegetable oils contain high amounts of vitamin K. Foods that contain a significant amount of vitamin K include beef liver, green tea, turnip greens, broccoli, kale, spinach, cabbage, asparagus, and dark green lettuce. Chlorophyll, which is water soluble, is the substance in plants that gives them their green color and provides vitamin K; thus chlorophyll supplements need to be considered when assessing vitamin K intake. Foods that appear to contain low amounts of vitamin K include roots, bulbs, tubers, the fleshy portion of fruits, fruit juices and other beverages, and cereal grains and their milled products.

Selected Food Sources of Vitamin K (Phylloquinone, Except as Indicated)

Food	Micrograms		Food	Micrograms	
	(mcg) per Serving	Percent DV*		(mcg) per Serving	Percent DV*
Natto, 3 ounces (as MK-7)	850	1,062	Canola oil, 1 tablespoon	10	13
Collards, frozen, boiled, ½ cup	530	662	Cashews, dry roasted, 1 ounce	10	13
Turnip greens, frozen, boiled ½ cup	426	532	Carrots, raw, 1 medium	8	10
Spinach, raw, 1 cup	145	181	Olive oil, 1 tablespoon	8	10
Kale, raw, 1 cup	113	141	Ground beef, broiled, 3 ounces (as MK-4)	6	8
Broccoli, chopped, boiled, ½ cup	110	138	Figs, dried, ¾ cup	6	8
Soybeans, roasted, ½ cup	43	54	Chicken liver, braised, 3 ounces (as MK-4)	6	8
Carrot juice, ¾ cup	28	34	Ham, roasted or pan-broiled, 3 ounces (as MK-4)	4	5
Soybean oil, 1 tablespoon	25	31	Cheddar cheese, 1 ½ ounces (as MK-4)	4	5
Edamame, frozen, prepared, ½ cup	21	26	Mixed nuts, dry roasted, 1 ounce	4	5
Pumpkin, canned, ½ cup	20	25	Egg, hard boiled, 1 large (as MK-4)	4	5
Pomegranate juice, ¾ cup	19	24	Mozzarella cheese, 1 ½ ounces (as MK-4)	2	3
Okra, raw, ½ cup	16	20	Milk, 2%, 1 cup (as MK-4)	1	1
Salad dressing, Caesar, 1 tablespoon	15	19	Salmon, sockeye, cooked, 3 ounces (as MK-4)	0.3	0
Pine nuts, dried, 1 ounce	15	19	Shrimp, cooked, 3 ounces (as MK-4)	0.3	0
Blueberries, raw, ½ cup	14	18			
Iceberg lettuce, raw, 1 cup	14	18			
Chicken, breast, rotisserie, 3 ounces (as MK-4)	13	17			
Grapes, ½ cup	11	14			
Vegetable juice cocktail, ¾ cup	10	13			

*DV = Daily Value. DVs were developed by the U.S. Food and Drug Administration (FDA) to help consumers compare the nutrient contents of products within the context of a total diet. **The DV for vitamin K is 80 mcg for adults and children age 4 and older.** However, the FDA does not require food labels to list vitamin K content unless a food has been fortified with this nutrient. Foods providing 20% or more of the DV are considered to be high sources of a nutrient.

The U.S. Department of Agriculture's (USDA's) Nutrient Database website (https://ods.od.nih.gov/pubs/usdandb/MK-4_Nutrient_Content_SR27.pdf) lists the nutrient content of many foods and provides comprehensive lists of foods containing vitamin K (phylloquinone) arranged by nutrient content and by food name, and of foods containing vitamin K (MK-4) arranged by nutrient content and food name.

Nutritional Facts on Vitamin D

Vitamin D is a fat-soluble vitamin that is naturally present in very few foods, is added to some foods, is available as a nutritional supplement, and is made when ultraviolet light, specifically UVB rays from the sun, strike the skin and stimulate its synthesis. Both the vitamin D that is absorbed from food and supplements, and that is made by the skin is biologically inert. It must be hydroxylated twice in the body – first into 25(OH) vitamin D (calcidiol) by the liver, and again into 1,25(OH)² vitamin D (calcitriol.) by the kidney.

Vitamin D is needed for the absorption of calcium from the small intestine and for the functioning of calcium in the body. Vitamin D also acts like a hormone and has many functions unrelated to its co-functions with calcium absorption and bone growth and remodeling. (See Chapter 24) Besides being in bone, receptors for vitamin D have been identified in the gastrointestinal tract, brain, breast, nerve, and many other tissues. Vitamin D maintains adequate serum calcium and phosphate concentrations to prevent hypocalcemic tetany. It also modulates cell growth, neuromuscular and immune function, and reduction of inflammation. Many genes that encode for the regulation of cell proliferation, differentiation and apoptosis are modulated by vitamin D (see Chapter 5.) <https://ods.od.nih.gov/factsheets/VitaminD-HealthProfessional/>. RDAs were established for vitamin D in 2011, and are presented in Table 1.

VITAMIN D SYNTHESIZED FROM SUNLIGHT EXPOSURE

Vitamin D made in the skin lasts twice as long in the blood as vitamin D ingested from the diet. The skin not only makes vitamin D upon exposure to UVB rays, but also makes other photo-products that cannot be obtained from food or supplements. It

is unknown if any of these products have unique benefits to health, but research continues in this area.

UVB light cannot pass through glass; exposure of the skin to sunlight through glass will not result in vitamin D synthesis. Another deterrent to vitamin D synthesis by the skin is sunscreen. A sunscreen with an SPF 15 reduces skin synthesis of vitamin D by 95%, and an SPF30 reduces it by 99%.

How much sun exposure is the correct amount to maintain optimal vitamin D levels in the body? A person sunbathing in a bathing suit will have received a dose of between 10,000 and 25,000 IU of vitamin D when he or she has sunbathed long enough to be slightly pink 24 hours later (technically called a minimal erythema dose or “1 MED.”) Exposing 25% of the body (arms and legs) for ¼ to ½ the time it takes to get slightly pink will allow the body to make 2,000 to 4,000 IU of vitamin D with each exposure.

The amount of time necessary for sunlight exposure to produce adequate vitamin D depends on the person’s skin type (pale skin requires less time than dark skin with a lot of the burn protecting pigment melanin), season of the year (the lower the sun on the horizon in the winter, the greater the time needed), the latitude (within + or – 35 degrees from the equator, the most vitamin D can be produced when skin is exposed to UVB rays), and the time of day (more vitamin D is synthesized by the skin when the sun is directly overhead between 11:00 am and 3:00 pm.) A person should be exposed to sunlight 2 to 3 times per week from March through October in northern climates to accumulate enough vitamin D to get through the winter with adequate vitamin D. See Holick for tables of time of sun exposure needed to make adequate amounts of vitamin D. Several apps are also available to determine this – Vitamin D Calculator, Vitamin D Pro, and D-Minder.

VITAMIN D IN FOODS

Vitamin D is measured in international units (IUs). 1 mcg = 40 IU of vitamin D or calciferol. IUs are used on food and supplement labels and both are used in the 2011 RDAs for vitamin D. The vitamin D in foods is measured as calciferol. There are only a few food sources of vitamin calciferol. Fish such as salmon, tuna and mackerel and fish oils are one of the few natural sources of vitamin D. Beef liver, cheese and egg yolks contain small amounts of vitamin D₃, a metabolite of vitamin D which appears to be approximately five times more potent than the parent vitamin (calciferol) in raising serum 25(OH)D concentrations. At the present time, the USDA’s Nutrient Database does not include this vitamin D metabolite when reporting the vitamin D content of foods. Actual vitamin D intakes in the U.S. population may be underestimated for this reason.

TABLE 1 Recommended Dietary Allowances (RDAs) for Vitamin D

Age	Male	Female	Pregnancy	Lactation
0–12 months*	400 IU (10 mcg)	400 IU (10 mcg)	N/A	N/A
1–13 years	600 IU (15 mcg)	600 IU (15 mcg)	N/A	N/A
14–18 years	600 IU (15 mcg)	600 IU (15 mcg)	600 IU (15 mcg)	600 IU (15 mcg)
19–50 years	600 IU (15 mcg)	600 IU (15 mcg)	600 IU (15 mcg)	600 IU (15 mcg)
51–70 years	600 IU (15 mcg)	600 IU (15 mcg)	N/A	N/A
>70 years	800 IU (20 mcg)	800 IU (20 mcg)	N/A	N/A

Adequate Intake (AI)

Mushrooms are the only plant food known to contain vitamin D, and the amount varies widely depending on the type of mushroom and amount of sunlight exposure during growth. Commercially raised mushrooms are now being grown with controlled UVB exposure so that they synthesize and thus contain much more vitamin D than if grown in the wild. In fact, grown with lots of UVB exposure, 4-5 button or crimini mushrooms may contain as much as 400 IU of vitamin D.

Good sources of vitamin D are fortified foods and beverages such as milk, fortified soy, rice and nut beverages, some yogurts and margarine fortified breakfast cereals, fortified orange juice and other juices, and fortified products. (check the labels on these foods.) These fortified foods supply most of the calcium in the American diet. Cow's milk in the US is voluntarily fortified to 100 IU/cup and in Canada is fortified by law to 35-40 IU/100 ml (84 – 96 IU/cup). Yogurt, cheese, cottage cheese, quark and other milk products, unless made with vitamin D fortified milk (which is not required), or are fortified with vitamin D during production, are not good sources of vitamin D. See Table 2 for the vitamin D content of selected foods.

TABLE 2 Selected Food Sources of Vitamin D

Food	IUs per Serving*	Percent DV**
Cod liver oil, 1 tablespoon	1,360	340
Swordfish, cooked, 3 ounces	566	142
Salmon (sockeye), cooked, 3 ounces	447	112
Mushrooms, maitake, raw, 3 ounces	943	235
Mushrooms, portabella, exposed to UV light, raw, 3 ounces	375	94
Mushrooms, chanterelle, raw, 3 ounces	15	4
Mushrooms, shitake, raw, 3 ounces	178	45
Mushrooms, white, raw, 3 ounces	6	2
Tuna fish, canned in water, drained, 3 ounces	100	39
Orange juice fortified with vitamin D, 1 cup (check product labels, as amount of added vitamin D varies)	137	34
Milk, nonfat, reduced fat, and whole, vitamin D-fortified, 1 cup	115	29-31
Yogurt, fortified, with 20% of the daily value (DV) for vitamin D, 6 ounces (some yogurts are more heavily fortified – check label)	80	20
Margarine, fortified, 1 tablespoon	60	15
Sardines, canned in oil, drained, 2 sardines	46	12
Liver, beef, cooked, 3 ounces	42	11
Egg, 1 large (vitamin D is found in yolk)	41	10
Ready-to-eat cereal, fortified with 10% of the DV for vitamin D, 0.75-1 cup (more heavily fortified cereals might provide more of the DV)	40	10
Cheese, Swiss, 1 ounce	6	2

DV for vitamin D is 400 IU (10 mcg).

*IUs = International Units.

The U.S. Department of Agriculture's (USDA's) Nutrient Database Web site lists the nutrient content of many foods and provides a comprehensive list of foods containing vitamin D arranged by nutrient content and by food name.

VITAMIN D IN SUPPLEMENTS

In supplements, as well as in fortified foods, vitamin D is available in two forms, D₂ (ergocalciferol) and D₃ (cholecalciferol). Vitamin D₂ is manufactured by the UV irradiation of ergosterol in yeast, and vitamin D₃ is manufactured by the irradiation of 7-dehydrocholesterol from lanolin and the chemical conversion of cholesterol. Both forms effectively raise serum 25(OH)D levels. Firm conclusions about any different effects of these two forms of vitamin D cannot be drawn at this time. However, it appears that at nutritional doses vitamins D₂ and D₃ are equivalent, but at high doses vitamin D₂ appears to be less potent. <https://ods.od.nih.gov/factsheets/VitaminD-HealthProfessional/> It also appears that frequent smaller dosing (daily) rather than much, much larger bolus dosing (weekly or monthly) of vitamin D may be more effective in improving 25(OH) vitamin D levels.

Nutritional Facts on Calcium

Calcium, the most abundant mineral in the body, is found in some foods, is added to others, is available as a dietary supplement, and is present in some medications such as antacids. Less than 1% of total body calcium supports critical metabolic functions required for vascular contraction and vasodilation, muscle function, nerve transmission, intracellular signaling and hormonal secretion. The remaining 99% of the body's calcium supply is stored in the bones and teeth where it supports their structure and function. See Chapters 24 and 25.

Serum calcium is very tightly regulated and does not fluctuate with changes in dietary intakes; the body uses bone tissue as a reservoir for and source of calcium, in order to maintain constant concentrations of calcium in blood, muscle, and intercellular fluids. <https://ods.od.nih.gov/factsheets/Calcium-HealthProfessional> is an excellent resource for additional calcium nutrition information.

RECOMMENDED INTAKES

- Recommended Dietary Allowance (RDA): average daily level of intake sufficient to meet the nutrient requirements of nearly all (97%–98%) healthy individuals.
- Adequate Intake (AI): established when evidence is insufficient to develop an RDA; intake at this level is assumed to ensure nutritional adequacy.
- Estimated Average Requirement (EAR): average daily level of intake estimated to meet the requirements of 50% of healthy individuals. It is usually used to assess the adequacy of nutrient intakes in population groups but not individuals.
- Tolerable Upper Intake Level (UL): maximum daily intake unlikely to cause adverse health effects.

Recommended Dietary Allowances (RDAs) for Calcium

Age	Male	Female	Pregnancy	Lactating
0-6 months*	200 mg	200 mg		
7-12 months*	260 mg	260 mg		
1-3 years	700 mg	700 mg		
4-8 years	1,000 mg	1,000 mg		
9-13 years	1,300 mg	1,300 mg		
14-18 years	1,300 mg	1,300 mg	1,300 mg	1,300 mg
19-50 years	1,000 mg	1,000 mg	1,000 mg	1,000 mg
51-70 years	1,000 mg	1,200 mg		
71+ years	1,200 mg	1,200 mg		

*Adequate Intake (AI)

CALCIUM IN FOODS

There are many dietary sources of calcium, but low-fat milk or yogurt or fortified substitutes are the most efficient and readily available. The lactose in mammalian milks appears to improve the absorption of calcium from milk. Lactose-free milk and soy, nut, rice and other grain milks fortified with calcium and vitamin D are now available. They are usually fortified to 300 mg calcium per cup, equivalent to the amount of calcium in cow's or goat's milk, but the nutrition label should be checked.

In addition to milk, a variety of foods and calcium-fortified juices contain calcium and can help children, teens, and adults get sufficient levels of calcium in their diets. If it is difficult to get the recommended amounts of calcium from foods alone, a combination of food sources and supplements may be needed.

The absorption of calcium from the gut is increased when there is high body need such as during pregnancy and lactation, growth in infancy, childhood and adolescence, and when there is adequate vitamin D. Absorption is decreased by the presence of phytic acid and oxalic acid containing foods in the gut (see Chapter 35), alcohol and caffeine.

SELECTED FOOD SOURCES OF CALCIUM

See Table Selected Food Sources of Calcium. See <http://ndb.nal.usda.gov/ndb/nutrients/index> for a complete list of the calcium content of foods.

Selected Food Sources of Calcium

Food	Milligrams per Serving
Dairy Foods	
Milk, with added calcium, 1 cup	420
Milk, whole, 2%, 1% skim, 1 cup	300
Yogurt, low fat, plain, ¾ cup	300
Cheese, processed slices, 2 slices	265
Yogurt, fruit on the bottom, ¾ cup	250
Processed cheese spread, 3 Tbsp	250
Cheese, hard, 1 oz	240
Milk, evaporated, ¼ cup	165
Cottage cheese, ¾ cup	120
Frozen yogurt, soft serve, ½ cup	100
Ice cream, ½ cup	85
Macaroni and Cheese, prepared as per box instructions, ½ cup	80
Beans and Bean Products	
Soy cheese substitutes, 1 oz	0-200
Tofu, firm, made with calcium sulfate, 3½ oz	125
White beans, ½ cup	100

Continued

Selected Food Sources of Calcium—cont'd

Food	Milligrams per Serving
Navy beans, ½ cup	60
Black turtle beans, canned, ½ cup	42
Pinto beans, chickpeas, ½ cup	40
Nuts and Seeds	
Almonds, dry roasted, ¼ cup	95
Whole sesame seeds (black or white), 1 Tbsp	90
Tahini (sesame seed butter), 1 Tbsp	63
Brazil, hazelnuts, ¼ cup	55
Almond butter, 1 Tbsp	43
Meats, Fish, and Poultry	
Sardines, canned, 3½ oz (8 med)	370
Salmon, canned with bones, 3 oz	180
Oysters, canned, ½ cup	60
Shrimp, canned, ½ cup	40
Turnip greens, boiled, ½ cup	99
Okra, frozen, ½ cup	75
Chinese cabbage or bok choy, ½ cup	75
Kale, raw, chopped, ½ cup	50
Mustard greens, boiled, ½ cup	76
Chinese broccoli (gai lan), ½ cup	44
Broccoli, raw, ½ cup	21
Fruit	
Orange, 1 med	55
Dried figs, 2 med	54
Nondairy Drinks	
Calcium enriched orange juice, 1 cup	300
Fortified rice milk, 1 cup	300
Fortified almond milk, 1 cup	300
Fortified soy milk, 1 cup	300
Regular soy milk, 1 cup	20
Grains	
Amaranth, raw, ½ cup	150
Whole wheat flour, 1 cup	40
Pizza, cheese, 1 small slice (1 oz)	120
Macaroni and cheese, boxed mix, prepared as per label, 1 cup	80
Other	
Blackstrap molasses, 1 Tbsp	80
Regular molasses, 1 Tbsp	41
Asian Foods	
Sea cucumber, fresh, 3 oz	285
Shrimp, small, dried, 1 oz	167
Dried fish, smelt, 2 Tbsp	140
Seaweed, dry (hijiki), 10 g	140
Seaweed, dry (agar), 10 g	76
	70
	69
	50
Boiled bone soup, ½ cup	Negligible
Laver, nori, and wakame seaweeds are low in calcium.	
Native Foods	
Oolichan, salted, cooked, 3 oz	210
Fish head soup, 1 cup	150
Native American ice cream (whipped soapberries), ½ cup	130

CALCIUM SUPPLEMENTS

Calcium carbonate is the most common and least expensive calcium supplement. It can be difficult to digest and causes gas and constipation in some people. Calcium carbonate is 40% elemental calcium; 1000 mg will provide 400 mg of calcium. This supplement should be taken with food to aid in absorption. Taking magnesium with it can help to prevent constipation.

Calcium citrate is more easily absorbed (bioavailability is 2.5 times higher than calcium carbonate), easier to digest, and less likely to cause constipation and gas than calcium carbonate. It also has a lower risk of contributing to the formation of kidney stones. However, it is less concentrated, providing approximately 21% elemental calcium; 1000 mg will provide 210 mg of calcium. It is more expensive than calcium carbonate, and more of it must be taken to get the same amount of calcium, but it is better absorbed. It can be taken with or without food.

Calcium phosphate costs more than calcium carbonate but less than calcium citrate. It is easily absorbed and is less likely to cause constipation and gas.

Calcium lactate and calcium aspartate are both more easily digested but more expensive than calcium carbonate.

As the dose of calcium supplement increases, the percentage absorbed decreases. Because it appears that absorption is highest with dosages of <500 mg at a time, it is best to take calcium supplements in at least two dosages per day.

CALCIUM IN MEDICATIONS

Many over the counter antacids such as Tums and Roloids contain calcium carbonate because of calcium carbonate's ability to neutralize stomach acid. Depending on the product, each chewable pill or soft chew contains 200 – 300 mg of elemental calcium, which can be a significant source of calcium supplementation for the person with normal levels of stomach acid.

Nutritional Facts on Chromium

Chromium is known to enhance the action of insulin; chromium was identified as the active ingredient in the “glucose tolerance factor” many years ago. Chromium also appears to be directly involved in carbohydrate, fat, and protein metabolism; but more research is needed to determine the full range of its roles in the body.

Chromium is widely distributed in the food supply, but most foods provide only small amounts (less than 2 mcg per serving). Meat and whole-grain products, as well as some fruits, vegetables, and spices, are relatively good sources, but Brewer’s yeast is by far the most concentrated food source. Foods high in simple sugars (such as sucrose and fructose) are low in chromium. Dietary intakes of chromium cannot be reliably determined because the content of the mineral in foods is substantially affected by agricultural and manufacturing processes and food-composition databases are inadequate. Chromium values in foods are approximate and should only serve as a guide. It appears that chromium picolinate and chromium nicotinate used in supplements are more bioavailable than chromic chloride.

Dietary Reference Intakes for Chromium are Adequate Intakes (AIs). See table.

Dietary Reference Intakes (AIs) for Chromium for Children and Adults

Age (years)	Males and Females (mcg/day)	Pregnancy (mcg/day)	Lactation (mcg/day)
0-6 months	.2		
7-12 months	5.5		
1-3	11	N/A	N/A
4-8	15	N/A	N/A
9-13	25 for boys, 21 for girls	N/A	N/A
14-18	35 for men, 24 for women	29	44
19+	35 for men, 25 for women	30	45
50+	30 for men, 29 for women	N/A	N/A

N/A, Not applicable.

Selected Food Sources of Chromium

Food	Micrograms per Serving
Broccoli, ½ cup	11
Grape juice, 1 cup	8
English muffin, whole wheat, 1	4
Potatoes, mashed, 1 cup	3
Garlic, dried, 1 tsp	3
Basil, dried, 1 Tbsp	2

Selected Food Sources of Chromium—cont’d

Food	Micrograms per Serving
Beef cubes, 3 oz	2
Orange juice, 1 cup	2
Turkey breast, 3 oz	2
Whole wheat bread, 2 slices	2
Red wine, 5 oz	1-13
Apple, unpeeled, 1 med	1
Banana, 1 med	1
Green beans, ½ cup	1

DV = Daily Value. DVs were developed by the FDA to help consumers compare the nutrient contents of products within the context of a total diet. **The DV for chromium is 120 mcg.** The percentage DV listed on the label indicates the percentage of the DV provided in one serving. A food providing 5% of the DV or less is a source, whereas a food that provides 10% to 19% of the DV is a good source. A food that provides 20% or more of the DV is high in that nutrient.

Interactions Between Chromium and Medications

Medications	Nature of Interaction
Antacids Corticosteroids H ₂ blockers (e.g., cimetidine, famotidine, nizatidine, and ranitidine) Proton-pump inhibitors (e.g., omeprazole, lansoprazole, rabeprazole, pantoprazole, and esomeprazole)	These medications alter stomach acidity and may impair chromium absorption or enhance excretion.
β-blockers (such as atenolol or propranolol) Corticosteroids Insulin Nicotinic acid Nonsteroidal antiinflammatory drugs Prostaglandin inhibitors (e.g., ibuprofen, indomethacin, naproxen, piroxicam, and aspirin)	These medications may have their effects enhanced if taken together with chromium, or they may increase chromium absorption.

Nutritional Facts on Iodine

Iodine is an important mineral that is naturally found in some foods and added to others (primarily iodized salt). It is most concentrated in foods from the ocean. More than 70 countries, including the US and Canada, have salt iodization programs.

Iodine is an essential component of thyroid hormones, thyroxine (T4) and triiodothyroxine (T3), which help to regulate metabolic rate, body temperature, growth, reproduction, blood cell production, muscle function, nerve function, and even gene expression. Iodine appears to have physiological functions including a role in the immune response and possibly a beneficial effect on mammary dysplasia and fibrocystic breast disease. See Chapter 31.

The most useful clinical tool for measuring thyroid function and thus iodine sufficiency is to measure thyroid-stimulating hormone (TSH), which is released from the pituitary gland and stimulates thyroid hormone production and release. If the TSH is high, thyroid function should be evaluated further. Selenium-dependent enzymes are also required for the conversion of thyroxine (T4) to the biologically active thyroid hormone, triiodothyronine (T3); thus deficiencies of selenium, vitamin A, or iron may also affect iodine status. Another method to assess iodine status is the urinary iodine excretion test.

DEFICIENCY

Iodine deficiency is an important health problem throughout much of the world. Most of the earth's iodine is found in its oceans and soils; thus parts of the world away from the oceans exposed for millions of years longer, have iodine-deficient soils, and the food grown in these soils have low iodine content. Thus, large percentages of people eating foods from those iodine deficient soils, and not able to consume fish, can become iodine deficient unless public health measures are taken. Iodine deficiency can cause mental retardation, hypothyroidism, goiter, and varying degrees of other growth and developmental abnormalities. Iodine is now recognized as the most common cause of preventable brain damage in the world, with millions living in iodine-deficient areas.

The major source of dietary iodine in the United States is "iodized" salt, which has been fortified with iodine. In the United States assume that any salt in processed foods is iodized unless the product label shows that it is not iodized. In the United States and Canada iodized salt contains 77 mcg of iodine per gram of salt. Iodine is also added in the diet because it is used in the feed of animals and in many processed or preserved foods as a stabilizer and as a component of red food dyes.

Vegetarian and nonvegetarian diets that exclude iodized salt, fish, and seaweed have been found to contain very little iodine. Urinary iodine excretion studies suggest that iodine intakes are declining in the United States, possibly as a result of increased adherence to dietary recommendations to reduce salt intake.

GOITROGENS

Substances that interfere with iodine use or thyroid hormone production are known as goitrogens and occur in some foods. Some species of millet and cruciferous vegetables (e.g., cabbage, broccoli, cauliflower, and Brussels sprouts) contain goitrogens; and the soybean isoflavones genistein and daidzein have also been found to inhibit thyroid hormone synthesis. Most of these goitrogens are not of clinical importance unless they are consumed in large amounts or there is a coexisting iodine or selenium deficiency.

RECOMMENDED INTAKES

- Recommended Dietary Allowance (RDA): average daily level of intake sufficient to meet the nutrient requirements of nearly all (97%–98%) healthy individuals.
- Adequate Intake (AI): established when evidence is insufficient to develop an RDA; intake at this level is assumed to ensure nutritional adequacy.
- Estimated Average Requirement (EAR): average daily level of intake estimated to meet the requirements of 50% of healthy individuals. It is usually used to assess the adequacy of nutrient intakes in population groups but not individuals.
- Tolerable Upper Intake Level (UL): maximum daily intake unlikely to cause adverse health effects. ULs are listed on the inside back cover of this text.

Recommended Dietary Allowances (RDAs) for Iodine

Age	Male mcg/day	Female mcg/day	Pregnancy mcg/day	Lactation mcg/day
0-6 months	110*	110*	N/A	N/A
7-12 months	130*	130*	N/A	N/A
1-3 years	90	90	N/A	N/A
4-8 years	90	90	N/A	N/A
9-13 years	120	120	N/A	N/A
14-18 years	150	150	220	290
19+	150	150	220	290

*Adequate intake.
N/A not applicable

The World Health Organization, United Nations Children's Fund and the International Council for the Control of Iodine Deficiency Disorders recommend a slightly higher iodine intake for pregnant women of 250 mcg per day. See Chapter 15.

The iodine contents of some common foods containing iodine are given in the table. As already mentioned, the iodine content of fruits and vegetables depends on the soil in which they were grown; the iodine content of animal foods, outside of those from the ocean, depends on where they were raised and which plants they consumed. Therefore these values are average approximations.

Selected Food Sources of Iodine

Food	Serving	Micrograms (mcg) per Serving	% Daily Value*
Salt (iodized)	1 g	475	31.3%
Cod	3 oz	99	66
Shrimp	3 oz	35	23
Fish sticks	2 fish sticks (2 oz)	54	36
Tuna, canned in oil	3 oz (½ can)	17	11
Milk (cow's), reduced fat	1 cup (8 fluid oz)	56	37
Egg, boiled	1 large	24	16
Navy beans, cooked	½ cup	35	23
Potato with peel, baked	1 medium	63	42
Seaweed	1 g, dried	Variable; 16 to 2,984; may be greater than 18,000 mcg (18 mg)	11 to 1,989

National Institutes of Health: *Office of Dietary Supplements* (website). <https://ods.od.nih.gov/factsheets/Iodine-HealthProfessional/> Accessed January 27, 2016.

DV = Daily Value. DVs were developed by the Food and Drug Administration (FDA) to help consumers to compare the nutrient content of products. The DV for iodine is 150 mcg for adults and children 4 years and older. Foods containing 20% or more of the DV are considered to be excellent sources. However, the FDA does not require

Nutritional Facts on Iron

Iron is a nutrient found in trace amounts in every cell of the body. Iron is part of hemoglobin in red blood cells and myoglobin in muscles. The role of both of these molecules is to carry oxygen. Iron also makes up part of many proteins and enzymes in the body. Iron deficiency anemia is common in children, adolescent girls, and women of childbearing age. It is usually treated with an iron-rich diet as well as iron supplements. Iron exists in foods in two forms: heme iron and non-heme iron. Vitamin C containing foods (See Appendix 42) enhance the absorption of nonheme iron and should be consumed at the same time as an iron-rich food or meal. The presence of heme iron in the meal also enhances the absorption of nonheme iron. Substances that decrease the absorption of nonheme iron are:

- Oxalic acid, found in raw spinach and chocolate
- Phytic acid, found in wheat bran and beans (legumes)
- Tannins, found in commercial black or pekoe teas
- Polyphenols, found in coffee
- Calcium carbonate supplements

Heme iron found in animal foods is absorbed more efficiently than nonheme iron. The richest dietary sources of heme iron are: oysters, liver, lean red meat (especially beef), poultry (the dark red meat), tuna and salmon. Less rich sources are lamb, pork, shellfish and eggs (especially the yolks).

Non-heme iron is harder for the body to absorb. Sources of non-heme iron are: iron-fortified cereals, dried beans, whole grains (wheat, millet, oats, brown rice), legumes (lima beans, soybeans, dried beans and peas, kidney beans), nuts (almonds, brazil nuts), dried fruits (especially prunes, raisins, apricots), vegetables and greens (broccoli, spinach, kale, collards, asparagus, dandelion greens). See Table Selected Food Sources of Iron.

Breast milk contains a highly bioavailable form of iron that is well absorbed by infants, but the amount is not enough to meet the needs of the infant older than 4 to 6 months, so a food source of iron (usually as infant cereal) should be offered to the older infant.

RECOMMENDED INTAKES

- Recommended Dietary Allowance (RDA): average daily level of intake sufficient to meet the nutrient requirements of nearly all (97%–98%) healthy individuals.
- Adequate Intake (AI): established when evidence is insufficient to develop an RDA; intake at this level is assumed to ensure nutritional adequacy.
- Estimated Average Requirement (EAR): average daily level of intake estimated to meet the requirements of 50% of healthy individuals. It is usually used to assess the adequacy of nutrient intakes in population groups but not individuals.
- Tolerable Upper Intake Level (UL): maximum daily intake unlikely to cause adverse health effects. ULs are listed on the inside cover of this text.

See Table RDA for Iron.

Recommended Dietary Allowances for Iron for Children and Adults

Age	Male	Female	Pregnancy	Lactation
0-6 months	0.27 mg*	0.27 mg*		
7-12 months	11 mg	11 mg		
1-3 years	7 mg	7 mg		
4-8 years	10 mg	10 mg		
9-13 years	8 mg	8 mg		
14-18 years	11 mg	15 mg	27 mg	10 mg
19-50 years	8 mg	18 mg	27 mg	9 mg
51+ years	8 mg	8 mg		

*Adequate Intake (AI)

Selected Food Sources of Iron

Food	Milligrams Per Serving	% Daily Value*
Clams, canned, drained, 3 oz	2.28	12.67
Fortified ready-to-eat cereals (various), ≈1 oz	1.8-19.2	10-107
Oysters, eastern, wild, cooked, moist heat, 3 oz	8	44
Organ meats (liver, giblets), various, cooked, 3 oz†	5.2-9.9	29-55
Fortified instant cooked cereals (various), 1 packet	1.77-33.46	9.83-185.9

Selected Food Sources of Iron—cont'd

Food	Milligrams Per Serving	% Daily Value*
Navy beans, cooked, ½ cup	2.2	12
Refried beans, ½ cup	2.1	11.5
Beef, top sirloin, lean, 0 in fat, all grades, cooked, 3 oz	2.0	11
Tomato paste, ¼ cup	2.0	11

*High in cholesterol.

DV = Daily Value. DVs were developed by the Food and Drug Administration to help consumers compare the nutrient content of products. The %DV listed on the Nutrition Facts panel of food labels states the percentage of the DV provided in one serving.

The DV for iron is 18 mg. Foods containing 20% or more of the DV are considered to be excellent sources of the nutrient.

TIPS FOR INCREASING IRON INTAKE

The amount of iron the body absorbs varies, depending on several factors. For example, the body will absorb more iron from foods when iron stores are low and will absorb less when stores are sufficient. In addition, use these tips to enhance absorption:

- Include heme and non-heme iron at the same meal
- Include a vitamin C rich food in a meal
- Drink coffee or tea between meals rather than with a meal
- Cook acidic foods in cast iron pots; which can increase the iron content of food up to 30 times.

WHAT ABOUT TOO MUCH IRON?

It is unlikely that a person would take iron at toxic (too high) levels. However, children can sometimes develop iron toxicity by eating iron supplements, mistaking them for candy. Symptoms include the following: fatigue, anorexia, dizziness, nausea, vomiting, headache, weight loss, shortness of breath, and grayish color to the skin.

Hemochromatosis is a genetic disorder that affects the regulation of iron absorption. Treatment consists of a low-iron diet,

no iron supplements, and phlebotomy (blood removal) on a regular basis. See Chapter 32.

Excess storage of iron in the body is known as hemosiderosis. The high iron stores come from eating excessive iron supplements or from receiving frequent blood transfusions, not from increased iron intake in the diet. See Chapter 32.

To reduce the iron from dietary sources, review the list of foods and exclude or severely limit their intake until the iron overload is alleviated. Pay particular attention to sports drinks, energy bars, fortified cereals, and multivitamin mineral supplements that have significant amounts of added iron.

SAMPLE MEAL PLAN

Breakfast

Spinach and red pepper omelet with at least 1 egg yolk (1.6 mg)
 1 whole wheat English muffin with I T. molasses (3.5 mg)
 1 Tbsp almond butter
 Prune juice, ¾ c (2.3 mg)

Lunch

2 grilled steak fajitas (with mixed peppers) (2.8)
 1 oz shredded low-fat pepper jack cheese
 ½ cup black refried beans (2.1 mg)
 Side salad with low-fat dressing

Dinner

3 oz grilled turkey breast
 ½ cup mashed potatoes
 ½ cup fresh steamed green beans topped with almonds
 1 small whole wheat dinner roll
 ½ cup fresh strawberries

Snack

1 med orange
 1 oz roasted pumpkin seeds (2.3 mg)

Nutritional Facts on Magnesium

The mineral magnesium is important for every organ in the body, particularly the heart, muscles, and kidneys. It also contributes to the composition of teeth and bones. Most important, it is a cofactor in hundreds of enzyme systems, contributing to energy production and DNA synthesis, and it helps regulate calcium levels, as well as copper, zinc, potassium, vitamin D, and other important nutrients in the body.

DIETARY SOURCES

Rich sources of magnesium include tofu, legumes, whole grains, green leafy vegetables, wheat bran, Brazil nuts, soybean flour, almonds, cashews, blackstrap molasses, pumpkin and squash seeds, pine nuts, and black walnuts. Other good dietary sources of this mineral include peanuts, whole-wheat flour, oat flour, beet greens, spinach, pistachio nuts, shredded wheat, bran cereals, oatmeal, bananas, baked potatoes (with skin), chocolate, and cocoa powder. Many herbs, spices, and seaweeds supply magnesium, such as agar seaweed, coriander, dill weed, celery seed, sage, dried mustard, basil, cocoa powder, fennel seed, savory, cumin seed, tarragon, marjoram, and poppy seed. See Table - Selected Food Sources of Magnesium.

DIETARY RECOMMENDED INTAKES

- Recommended Dietary Allowance (RDA): average daily level of intake sufficient to meet the nutrient requirements of nearly all (97%–98%) healthy individuals.
- Adequate Intake (AI): established when evidence is insufficient to develop an RDA and is set at a level assumed to ensure nutritional adequacy.
- Estimated Average Requirement (EAR): average daily level of intake estimated to meet the requirements of 50% of healthy individuals. It is usually used to assess the adequacy of nutrient intakes in population groups but not individuals.
- Tolerable Upper Intake Level (UL): maximum daily intake unlikely to cause adverse health effects. The ULs for magnesium are listed on the inside back cover of this text.

See Table for RDA for Magnesium.

Recommended Dietary Allowance (RDA) for Magnesium for Children and Adults

†Calcium sulfate and magnesium chloride.

DV = Daily Value. DVs were developed by the Food and Drug Administration to help consumers compare the nutrient content of products. The %DV listed on the Nutrition Facts panel of food labels states the percentage of the DV provided in one serving.

The DV for magnesium is 400 mg. Foods containing 20% or more of the DV are considered to be excellent sources of the nutrient.

Common and Important Magnesium-Drug Interactions

Drug	Potential Interaction
Loop and thiazide diuretics (e.g., Lasix, Bumex, edecrin, and hydrochlorothiazide)	These drugs may increase the loss of magnesium in urine; thus taking these medications for long periods may contribute to magnesium depletion.
Antineoplastic drugs (e.g., cisplatin)	
Antibiotics (e.g., gentamicin and amphotericin)	
Tetracycline antibiotics	Magnesium binds tetracycline in the gut and decreases the absorption of tetracycline.
Magnesium-containing antacids and laxatives	Many antacids and laxatives contain magnesium. When frequently taken in large doses, these drugs can inadvertently lead to excessive magnesium consumption and hypermagnesemia.

SAMPLE MEAL PLAN

Breakfast

1 med oat bran muffin (45 mg magnesium)
 1 small banana
 ½ cup low-fat or fat-free milk

Lunch

½ cup penne pasta with the following:
 3 oz grilled chicken breast
 ½ cup fresh cooked spinach (78 mg magnesium)
 2 oz toasted pine nuts (142 mg magnesium)
 1 cup mixed salad greens topped with spinach leaves, tomatoes, shredded lettuce
 1 oz shredded low-fat mozzarella cheese

Dinner

2 Cajun shrimp skewers
 ½ cup fresh steamed green beans
 ½ cup brown rice (42 mg magnesium)
 ½ cup fresh pineapple

Snack

1 cup soy fruit smoothie (47 mg magnesium)
 1 oz Brazil nuts (107 mg magnesium)

Note: Take one multivitamin or multimineral supplement daily.

Nutritional Facts on Potassium

A potassium-rich diet is useful for cardiac patients who are trying to lower their blood pressure using diet. If diuretics are also used, it is important to know if potassium is retained or depleted by the diuretic, and it should be monitored. Most patients with chronic kidney disease or on renal dialysis may need to restrict potassium in their diets. See Chapter 35. Because potassium is lost in sweat, athletes need to pay attention to the potassium in their diets. See Chapter 23.

There is no RDA for potassium. Dietary Reference Intake (DRI) is a general term for a set of reference values used to plan and assess nutrient intakes of healthy people. The DRIs for potassium are stated as Adequate Intakes (AIs). For breastfed infants the AI is the mean intake; for older individuals the AI is believed to cover the needs of all individuals in the group, but there is a lack data to be more specific. AIs are given in the table.

Dietary Reference Intakes: Adequate Intakes (AIs) for Potassium for Children and Adults

Age	Males and Females (g/day)	Pregnancy (g/day)	Lactation (g/day)
0-6 months	0.4	N/A	N/A
7-12 months	0.7	N/A	N/A
1-3m years	3	N/A	N/A
4-8 years	3.8	N/A	N/A

Bananas, 1 med	422	12.1	Yogurt, plain, whole milk, 8-oz container	352	10.0
Spinach, cooked, ½ cup	419	12	Cod, Pacific, cooked, 3 oz	246	7.0
Peaches, dried, uncooked, ¼ cup	398	11.4			
Prunes, stewed, ½ cup	398	11.4			

*Daily values (DVs) are reference numbers based on the recommended dietary allowance. They were developed to help consumers determine if a food contains a lot or a little of a specific nutrient. **The DV for potassium is 3500 mg.** The %DV listed on the Nutrition Facts panel of food labels states the percentage of the DV provided in one serving. Percent DVs are based on a 2000-calorie diet.

Nutritional Facts on Selenium

Selenium is incorporated into proteins to make selenoproteins, which are important antioxidant enzymes. The antioxidant properties of selenoproteins prevent cellular damage from free radicals. Other selenoproteins help regulate thyroid function and play a role in the immune system. Selenium, as a nutrient that functions as an antioxidant, may be protective against some types of cancer. Its role in heart disease is not clear, but it may have a preventive role.

Plant foods are the major dietary sources of selenium. The content of selenium in food depends on the selenium content of the soil where plants are grown or animals are raised. Soil in Nebraska and the Dakotas has very high levels of selenium. The southeast coastal areas in the United States have very low levels; selenium deficiency is often reported in these regions. Selenium is also found in some meats and seafood. Animals that eat grains or plants that were grown in selenium-rich soil have higher levels of selenium in their muscle. In the United States meats, bread, and Brazil nuts are common sources of dietary selenium.

Most food labels do not list the selenium content of a food however, if they do, it is listed as a % Daily Value (DV). DVs were developed by the Food and Drug Administration to help

consumers compare the nutrient content of products. The % Daily Value (DV) listed on the label indicates the percentage of the DV provided in one serving. A food providing 5% of the DV or less is a source, whereas a food that provides 10% to 19% of the DV is a good source. A food that provides 20% or more of the DV is high in that nutrient. It is important to remember that foods that provide lower percentages of the DV also contribute to a healthful diet.

Dietary Reference Intakes for Selenium for Children and Adults

Age (years)	Males and Females (mcg/day)	Pregnancy (mcg/day)	Lactation (mcg/day)
1-3	20	N/A	N/A
4-8	30	N/A	N/A
9-13	40	N/A	N/A
14-18	55	60	70
19+	55	60	70

N/A, Not applicable.

Selected Food Sources of Selenium

Food	Micrograms per Serving	% DV	Food	Micrograms per Serving	% DV
Brazil nuts, dried, unblanched, 1 oz	544	777	Macaroni, elbow, enriched, boiled, 1 cup	37	53
Tuna, yellowfin, cooked, dry heat, 3 oz	92	131	Egg, whole, 1 med	15	21
Ground Beef, 25% fat, cooked, oz	18	26	Cottage cheese, 1% fat, 1 cup	20	29
Spaghetti sauce, marinara, 1 cup	4	6	Oatmeal, instant, fortified, cooked, 1 cup	13	19
Corn Flakes, 1 cup	2	3	Milk, 1%, 1 cup	8	11
Turkey, light meat, roasted, 3 oz	31	44	Lentils, boiled, 1 cup	6	9
Spinach, frozen, boiled, 1 cup	11	16	Bread, whole wheat, 1 slice	13	19
Chicken breast, meat only, roasted, 3 oz	22	31	Rice, brown, long grain, cooked, 1 cup	19	27
Noodles, enriched, boiled, ½ cup	19	27	Cashew nuts, dry roasted, 1 oz	3	4

DV = Daily Value. DVs were developed by the Food and Drug Administration to help consumers compare the nutrient content of products. The %DV listed on the Nutrition Facts panel of food labels states the percentage of the DV provided in one serving. **The DV for selenium for adults and children aged 4 and over is 70 mcg.** Foods containing 20% or more of the DV are considered to be excellent sources of the nutrient.

SAMPLE MEAL PLAN

Breakfast

½ cup oatmeal (6 mcg selenium)
1 medium scrambled egg (14 mcg selenium)
1 small banana
½ cup low-fat or fat-free milk

Lunch

1 turkey sandwich (36 mcg selenium)
½ cup carrot sticks
1 bag baked chips

Dinner

3 oz meatloaf
½ cup macaroni and cheese (20 mcg selenium)
½ cup fresh steamed green beans

Snack

½ cup cottage cheese (12 mcg selenium)
½ cup fresh sliced peaches

Nutritional Facts on Zinc

Zinc is an essential mineral that is found in almost every cell. It stimulates the activity of approximately 100 enzymes, which are substances that promote biochemical reactions in the body. Zinc supports immunity; is needed for wound healing; helps maintain the sense of taste and smell; is needed for deoxyribonucleic acid (DNA) synthesis; and supports normal growth and development during pregnancy, childhood, and adolescence.

Zinc is found in a wide variety of foods. Atlantic oysters contain more zinc per serving than any other food, but red meat and poultry provide the majority of zinc in the American diet. Other good food sources include beans, nuts, certain seafood, whole grains, fortified breakfast cereals, and dairy products.

Because zinc absorption is greater from a diet high in animal protein than a diet rich in plant proteins, vegetarians may become deficient if they are not monitored carefully. Phytates from whole-grain breads, cereals, legumes, and other products can decrease zinc absorption.

DIETARY RECOMMENDED INTAKES

- Recommended Dietary Allowance (RDA): average daily level of intake sufficient to meet the nutrient requirements of nearly all (97%–98%) healthy individuals.
- Adequate Intake (AI): established when evidence is insufficient to develop an RDA; intake at this level is assumed to ensure nutritional adequacy.
- Estimated Average Requirement (EAR): average daily level of intake estimated to meet the requirements of 50% of healthy individuals. It is usually used to assess the adequacy of nutrient intakes in population groups but not individuals.
- Tolerable Upper Intake Level (UL): maximum daily intake unlikely to cause adverse health effects. ULs are listed on the inside back cover of this text.

Recommended Dietary Allowance (RDA) for Zinc for Children and Adults

Age	Males and Females (mg/day)	Pregnancy (mg/day)	Lactation (mg/day)
0-6 months	2	N/A	N/A
7-12 months	2	N/A	N/A
1-3	3	N/A	N/A
4-8	5	N/A	N/A
9-13	8	N/A	N/A
14-18	11 for boys, 9 for girls	12	13
19+	11 for men, 8 for women	11	12

N/A, Not applicable.
DV = daily value. **The DV for zinc is 15 mg.**

Food	Milligrams (mg) per Serving	% Daily Value*
Oysters, battered and fried, 6 med	16.0	100
RTE breakfast cereal, fortified with 100% of the DV for zinc per serving, ¾ cup serving	15.0	100
Beef shank, lean only, cooked 3 oz	8.9	60
Beef chuck, arm pot roast, lean only, cooked, 3 oz	7.1	47
Beef tenderloin, lean only, cooked, 3 oz	4.8	30
Beef, eye of round, lean only, cooked, 3 oz	4.0	25
RTE breakfast cereal, fortified with 25% of the DV for zinc per serving, ¾ cup	3.8	25
RTE breakfast cereal, complete wheat bran flakes, ¾ cup serving	3.7	25
Pork shoulder, arm picnic, lean only, cooked, 3 oz	3.5	25
Baked beans, canned, plain or vegetarian, ½ cup	2.9	19
Chicken leg, meat only, roasted, 1 leg	2.7	20
Pork tenderloin, lean only, cooked, 3 oz	2.5	15
Pork loin, sirloin roast, lean only, cooked, 3 oz	2.2	15
Yogurt, plain, low fat, 1 cup	2.2	15
Baked beans, canned, with pork, ½ cup	1.8	10
Cashews, dry roasted without salt, 1 oz	1.6	10
Yogurt, fruit, low fat, 1 cup	1.6	10
Raisin bran, ¾ cup	1.5	9
Chickpeas, mature seeds, canned, ½ cup	1.5	9
Pecans, dry roasted without salt, 1 oz	1.4	10
Oatmeal, instant, low sodium, 1 packet	1.3	9
Cheese, Swiss, 1 oz	1.2	8
Mixed nuts, dry roasted with peanuts, without salt, 1 oz	1.1	8
Walnuts, black, dried, 1 oz	1.0	6
Almonds, dry roasted, without salt, 1 oz	1.0	6
Milk, fluid, any kind, 1 cup	0.9	6
Chicken breast, meat only, roasted, ½ breast with bone and skin removed	0.9	6
Cheese, cheddar, 1 oz	0.9	6

Continued

Selected Food Sources of Zinc—cont'd

Food	Milligrams (mg) per Serving	% Daily Value*
Cheese, mozzarella, part skim, low moisture, 1 oz	0.9	6
Beans, kidney, California red, cooked, ½ cup	0.9	6
Peas, green, frozen, boiled, ½ cup	0.5	4
Flounder or sole, cooked, 3 oz	0.3	2

RTE, Ready to eat.

DV = Daily Value: developed by the Food and Drug Administration to help consumers compare the nutrient content of products. Foods containing 20% or more of the DV are considered to be excellent sources.

SAMPLE MEAL PLAN

Breakfast

- ¼ cup scrambled eggs
- ¾ cup ready-to-eat breakfast cereal with 25% DV (3.8 mg zinc)
- ½ cup sliced peaches
- ½ cup low-fat or fat-free milk

Lunch

- 1 chicken salad sandwich
- ½ cup carrot sticks
- 2 Tbsp Ranch dressing
- 1 bag baked chips

Snack

- Yogurt, plain (2.2 mg zinc)

Dinner

- 3 oz grilled beef shank (8.9 mg zinc)
- ½ cup fresh steamed peas (0.95 mg zinc)

Side Salad

- 1 small sweet potato
- ½ cup fresh pineapple

Snack

- ½ cup Trail mix (raisins, pecans, cashews, dried cranberries)

Dietary Reference Intakes (DRIs): Acceptable Macronutrient Distribution Ranges

Food and Nutrition Board, Institute of Medicine, National Academies

Macronutrient	RANGE (PERCENT OF ENERGY)		
	Children, 1-3 yr	Children, 4-18 yr	Adults
Fat	30-40	25-35	20-35
<i>n</i> -6 polyunsaturated fatty acids ^a (linoleic acid)	5-10	5-10	5-10
<i>n</i> -3 polyunsaturated fatty acids ^a (α -linolenic acid)	0.6-1.2	0.6-1.2	0.6-1.2
Carbohydrate	45-65	45-65	45-65
Protein	5-20	10-30	10-35

Source: *Dietary Reference Intakes for Energy, Carbohydrate, Fiber, Fat, Fatty Acids, Cholesterol, Protein, and Amino Acids* (2002/2005). The report may be accessed via www.nap.edu.

^aApproximately 10% of the total can come from longer-chain *n*-3 or *n*-6 fatty acids.

Dietary Reference Intakes (DRIs): Acceptable Macronutrient Distribution Ranges

Food and Nutrition Board, Institute of Medicine, National Academies

Macronutrient	Recommendation
Dietary cholesterol	As low as possible while consuming a nutritionally adequate diet
Trans fatty acids	As low as possible while consuming a nutritionally adequate diet
Saturated fatty acids	As low as possible while consuming a nutritionally adequate diet
Added sugars ^a	Limit to no more than 25% of total energy

Source: *Dietary Reference Intakes for Energy, Carbohydrate, Fiber, Fat, Fatty Acids, Cholesterol, Protein, and Amino Acids* (2002/2005). The report may be accessed via www.nap.edu.

^aNot a recommended intake. A daily intake of added sugars that individuals should aim for to achieve a healthful diet was not set.

Dietary Reference Intakes (DRIs): Tolerable upper Intake Levels, Vitamins^a

NOTE: A Tolerable Upper Intake Level (UL) is the highest level of daily nutrient intake that is likely to pose no risk of adverse health effects to almost all individuals in the general population. Unless otherwise specified, the UL represents total intake from food, water, and supplements. Due to a lack of suitable data, ULs could not be established for vitamin K, thiamin, riboflavin, vitamin B₁₂, pantothenic acid, biotin, and carotenoids. In the absence of a UL, extra caution may be warranted in consuming levels above recommended intakes. Members of the general population should be advised not to routinely exceed the UL. The UL is not meant to apply to individuals who are treated with the nutrient under medical supervision or to individuals with predisposing conditions that modify their sensitivity to the nutrient.

*The tolerable upper intake levels for the following nutrients have not been determined: vitamin K, thiamin, riboflavin, vitamin B₁₂, pantothenic acid, biotin, and the carotenoids. The levels have not been determinable due to lack of data of adverse effects in this age group and concern with regard to lack of ability to handle excess amounts. Source of intake should be from food only to prevent high levels of intake.

^aAs preformed vitamin A only.

^bAs α -tocopherol; applies to any form of supplemental -tocopherol.

^cThe ULs for vitamin E, niacin, and folate apply to synthetic forms obtained from supplements, fortified foods, or a combination of the two.

^d β -Carotene supplements are advised only to serve as a provitamin A source for individuals at risk of vitamin A deficiency.

SOURCES: *Dietary Reference Intakes for Calcium, Phosphorus, Magnesium, Vitamin D, and Fluoride* (1997); *Dietary Reference Intakes for Thiamin, Riboflavin, Niacin, Vitamin B₆, Folate, Vitamin B₁₂, Pantothenic Acid, Biotin, and Choline* (1998); *Dietary Reference Intakes for Vitamin C, Vitamin E, Selenium, and Carotenoids* (2000); *Dietary Reference Intakes for Vitamin A, Vitamin K, Arsenic, Boron, Chromium, Copper, Iodine, Iron, Manganese, Molybdenum, Nickel, Silicon, Vanadium, and Zinc* (2001); and *Dietary Reference Intakes for Calcium and Vitamin D* (2011). NOTE: A Tolerable Upper Intake Level (UL) is the highest level of daily nutrient intake that is likely to pose no risk of adverse health effects to almost all individuals in the general population. Unless otherwise specified, the UL represents total intake from food, water, and supplements. Due to a lack of suitable data, ULs could not be established for vitamin K, thiamin, riboflavin, vitamin B₁₂, pantothenic acid, biotin, and carotenoids. In the absence of a UL, extra caution may be warranted in consuming levels above recommended intakes. Members of the general population should be advised not to routinely exceed the UL. The UL is not meant to apply to individuals who are treated with the nutrient under medical supervision or to individuals with predisposing conditions that modify their sensitivity to the nutrient.

^aAlthough the UL was not determined for arsenic, there is no justification for adding arsenic to food or supplements.

^bThe ULs for magnesium represent intake from a pharmacological agent only and do not include intake from food and water.

^cAlthough silicon has not been shown to cause adverse effects in humans, there is no justification for adding silicon to supplements.

^dAlthough vanadium in food has not been shown to cause adverse effects in humans, there is no justification for adding vanadium to food and vanadium supplements should be used with caution. The UL is based on adverse effects in laboratory animals and this data could be used to set a UL for adults but not children and adolescents.

^eND = Not determinable due to lack of data of adverse effects in this age group and concern with regard to lack of ability to handle excess amounts. Source of intake should be from food only to prevent high levels of intake.
